Improved bounds on the size of the smallest representation of relation algebra $32_{65}$ with the aid of a SAT solver

July 2019

Abstract

In this paper, we shed new light on the spectrum of relation algebra $32_{65}$. We show that 1024 is in the spectrum, and no number smaller than 20 is in the spectrum. In addition, we derive upper and lower bounds on the smallest member of the spectra of an infinite class of algebras derived from $32_{65}$ via splitting.

1 Introduction

Relation algebra $32_{65}$ has atoms $1'$, $a$, $b$, and $c$, all symmetric, with all diversity cycles not involving $a$ forbidden. The atom $a$ is flexible, and $32_{65}$ has the mandatory cycles required to make $a$ flexible and no others.

Relation algebra $32_{65}$ was shown in [1] to be representable over a finite set, namely a set of 416,714,805,914 points. This was reduced in [4] to 63,432,274,896 points, which was later reduced to 8192 by the first and fifth authors (unpublished), and finally to 3432 in [2]. Here, we give the smallest known representation, over 1024 points.

There are few published lower bounds in the literature. Most can be found in [3], where the spectrum of every relation algebra with three or fewer atoms. Going up to four atoms increases the difficulty considerably. To the best of our knowledge, the only finitely representable symmetric integral RA on four atoms for which the spectrum is known is $25_{65}$, and Spec($25_{65}$) = $\{4\}$.

No lower bound on the size of representations of $32_{65}$ has been published. We give a non-trivial such bound for an infinite class of algebras in Section 3.

Definition 1. Let $A$ be a finite relation algebra. Then

$$\text{Spec}(A) = \{\alpha \leq \omega : A \text{ has a representation over a set of cardinality } \alpha\}.$$ 

Let $A_n$ denote the integral symmetric relation algebra with atoms $1'$, $r$, $b_1$, $\ldots$, $b_n$, where a diversity cycle is mandatory if and only if it involves the atom.
r. (So \( A_2 \) is \( 32_{65} \).) Let
\[
    f(n) = \min(\text{Spec}(A_n)).
\]
It was shown in [1] that \( f(n) \) is finite for all \( n \).

Because representing finite integral relation algebras amounts to edge-coloring complete graphs with the diversity atoms, we will use the language of graph theory. So that we can use colors to make pretty pictures, we will refer to \( a \) as \textit{red}, to \( b \) as \textit{light blue}, and to \( c \) as \textit{dark blue}.

\centering
\includegraphics[width=\textwidth]{image.png}
\caption{Depiction of “needs” and forbidden triangles for \( 32_{65} \)}
\end{figure}

2 An upper bound on \( f(n) \)

In this section, we give a representation of \( 32_{65} \) over 1024 points, and then generalize to give representations of all the \( A_n \)'s.

Consider \( G = (\mathbb{Z}/2\mathbb{Z})^{10} \), and consider the elements as bitstrings. Define
\[
    R = \{ x \in G : x \text{ has between one and six 1s} \}
\]
\[
    B = \{ x \in G : x \text{ has at least seven 1s} \}
\]
This defines a group representation of \( 67 \), which is a subalgebra of \( 32_{65} \).

There exists a way of splitting \( B \) into \( B_1 \) and \( B_2 \) so that:
\begin{itemize}
    \item \( R + B_i = G \smallsetminus \{0\}, \ i = 1, 2; \)
    \item \( B_i + B_i = R \cup \{0\}, \ i = 1, 2; \)
    \item \( B_1 + B_2 = R. \)
\end{itemize}

This yields a group representation of \( 32_{65} \) over \( 2^{10} = 1024 \) points, improving the previous smallest-known representation over \( \binom{14}{7} = 3432 \) points [2]. We note that while the representation given here is smaller, the representation over 3432 points in [2] has a nice, compact description.

The split was found in the following way. The first author checked several million random splits. None of them worked, but some got “close”. He took one
of the close ones and tinkered with it for about three hours until it worked. The curious can view the process in the Jupyter notebook 32.65 splitting.ipynb at https://github.com/algorithmachine/RA-32-of-65. Also there can be found the happily-named 32.65-VICTORY.txt, which contains the members of $B_1$ encoded as integers between 1 and 1023.

We generalize this argument as follows:

**Theorem 2.** For all $n \geq 2$, $A_n$ is representable over $(\mathbb{Z}/2\mathbb{Z})^{3k+1}$ for sufficiently large $k \in \omega$. In particular, for $n \geq 14$, it suffices to take $k = n$.

**Proof.** We will proceed via a probabilistic argument. Consider $G = (\mathbb{Z}/2\mathbb{Z})^{3k+1}$, and for $x \in G$, let $x(i)$ denote the $i$th coordinate of $x$. Let $|x|$ denote $|\{i : x(i) = 1\}|$. The key idea is the following partition of $G \setminus \{0\}$ into two sets $R$ and $B$.

Let $R = \{x \in G : 1 \leq |x| \leq 2k\}$ and $B = \{x \in G : 2k + 1 \leq |x| \leq 3k + 1\}$

Then $R + R = G$, $R + B = G \setminus \{0\}$, and $B + B = R \cup \{0\}$. As we will see below, $B$ is a sum-free set with high additive energy.

We actually prove a stronger result, namely that we can split both the “red” and “blue” atoms of $67$ into $n$ atoms and find a representation over a finite set. So we will now split $R$ and $B$ into $n$ parts $R_1, \ldots, R_n$ and $B_1, \ldots, B_n$ uniformly at random. We need to count the “witnesses” to the “needs” of each element. We will show that each need is witnessed at least $2^k$ times.

First we count witnesses for $R \subseteq B + B$. Let $1 \leq \ell \leq k$. For $|z| = \ell$, we show that there are at least $2^k$ witnesses to $z \in B + B$. Let $I$ be the support of $z$. We construct $x, y$ randomly so that $z = x + y$. For each $i \in I$, flip a coin to choose between

$x(i) = 1$ and $y(i) = 0$
OR
$x(i) = 0$ and $y(i) = 1$

(This is $2^\ell$ flips.)

For the $k - \ell$ left-most indices $j \notin I$, flip a coin to choose between

$x(j) = 1 = y(j)$
OR
$x(j) = 0 = y(j)$

(This is $2^{k-\ell}$ flips.)

For all remaining indices, let $x(i) = 1 = y(i)$. Thus $x, y \in B$, and since there were a total of $k$ flips, there are at least $2^k$ ordered pairs $(x, y)$ such that $z = x + y$.  

Now let \( k + 1 \leq \ell \leq 2k \), let \( |z| = \ell \), and let \( I \) be the support of \( z \). For the \( k \) least indices \( i \in I \), flip a coin to choose between

\[
\begin{align*}
x(i) &= 1 \text{ and } y(i) = 0 \\
\text{OR} \\
x(i) &= 0 \text{ and } y(i) = 1
\end{align*}
\]

For the remaining \( \ell - k \) indices \( i \in I \), let \( x(i) = 1 \) and \( y(i) = 0 \), or \( x(i) = 0 \) and \( y(i) = 1 \) in such a way that ensures that both \( x \) and \( y \) have at least \( \ell - k \) 1’s in coordinates in \( I \).

Then for all indices \( j \notin I \), let \( x(j) = 1 = y(j) \). There were \( k \) flips, so there are at least \( 2^k \) witnesses.

Now let us consider witnesses to \( B \subseteq R + B \). Fix \( \ell \) with \( 2k + 1 \leq \ell \leq 3k + 1 \), and let \( |z| = \ell \). We randomly construct \( x \in B, y \in R \) so that \( z = x + y \).

Let \( I \) be the support of \( z \). For the \( 2k + 1 \) indices \( i \in I \) of least index, set \( x(i) = 1 \) and \( y(i) = 0 \). For the remaining \( n - (2k + 1) \) indices \( i \in I \), flip a coin to choose between

\[
\begin{align*}
x(i) &= 1 \text{ and } y(i) = 0 \\
\text{OR} \\
x(i) &= 0 \text{ and } y(i) = 1
\end{align*}
\]

For each index \( j \notin I \), flip a coin to choose between

\[
\begin{align*}
x(j) &= 1 = y(j) \\
\text{OR} \\
x(j) &= 0 = y(j)
\end{align*}
\]

Again, there were \( k \) flips, so we have at least \( 2^k \) witnesses.

Next, let us consider witnesses to \( B \in R + R \). Let \( z \in B \), and let \( I \) be the support of \( z \). We construct \( x, y \in R \) so that \( z \leq x + y \). For every \( j \in I \), set \( x(j) = 0 = y(j) \). For the smallest \( k \) indices \( i \in I \), flip a coin to choose between

\[
\begin{align*}
x(i) &= 1 \text{ and } y(i) = 0 \\
\text{OR} \\
x(i) &= 0 \text{ and } y(i) = 1
\end{align*}
\]

For the remaining indices \( i \in I \), choose either

\[
\begin{align*}
x(i) &= 1 \text{ and } y(i) = 0 \\
\text{OR} \\
x(i) &= 0 \text{ and } y(i) = 1
\end{align*}
\]

in such a way that ensures that neither \( x \) nor \( y \) receives more than \( 2k \) 1’s. Clearly, there are at least \( 2^k \) witnesses.
Now we consider witnesses for $R \subseteq B + R$.

Let $z \in R$, and let $I$ be the support of $z$. Suppose $|I| = \ell$. We build $x \in B$, $y \in R$ so that $z = x + y$. First, consider the case where $1 \leq \ell \leq k$. For $i = I$, set $x(i) = 1$ and $y(i) = 0$. For $j \notin I$, choose $2k + 1 - \ell$ of the $3k + 1 - \ell$ indices, and set $x(j) = 1 = y(j)$. [Set all others to $x(j) = 0 = y(j)$.] Since $(\binom{3k+1-n}{k}) \geq (\binom{2k+1}{k}) > 2^k$, we have at least $2^k$ witnesses. Now consider the case where $k + 1 \leq n \leq 2k$. For the smallest $k$ indices $i \in I$, set $x(i) = 1$ and $y(i) = 0$. For the remaining $\ell - k$ indices $i \in I$, flip a coin to choose between

$$x(i) = 1 \text{ and } y(i) = 0$$

OR

$$x(i) = 0 \text{ and } y(i) = 1.$$ Now we choose $k + 1$ of the remaining $3k + 1 - \ell$ indices $j \notin I$. There are $\binom{3k+1-\ell}{k+1}$ choices, which ranges between $\binom{k+1}{k+1}$ and $\binom{2k+1}{k+1}$. Therefore there are at least $2^{\ell-k} \cdot \binom{3k+1-\ell}{k+1}$ witnesses. It is not hard to check that for $0 \leq N \leq k$, $\binom{k+1+\ell}{k+1} > 2^N$, and therefore $2^{\ell-k} \cdot \binom{3k+1-\ell}{k+1} > 2^k \cdot 2^{2k-\ell} = 2^k$.

Finally, we consider witnesses for $R \subseteq R + R$. Let $z \in R$ with support $I$ with $|I| = \ell$. We construct $x, y \in R$ so that $z = x + y$. First, consider the case where $1 \leq \ell \leq k$. For each $i \in I$, set $x(i) = 1$ and $y(i) = 0$. Then for the smallest $2k$ indices outside of $I$, choose $k$ of them. For each such selected $j$, set $x(j) = 1 = y(j)$, and $x(j) = 0 = y(j)$ otherwise. This gives at least $\binom{2k}{k} > 2^k$ witnesses.

For the case where $k + 1 \leq \ell \leq 2k$, for each $i \in I$, flip a coin to choose between

$$x(i) = 1 \text{ and } y(i) = 0$$

OR

$$x(i) = 0 \text{ and } y(i) = 1.$$ This gives $2^\ell > 2^k$ witnesses.

Now we are ready to compute the probability that our random partition $R_1, \ldots, R_n$ and $B_1, \ldots, B_n$ fails to be a representation. Let $z \in (\mathbb{Z}/2\mathbb{Z})^n \setminus \{0\}$. If $z \in R_i$, then $z$ has $3n^2$ “needs”:

- $\forall i, j \ z \in R_i + R_j$
- $\forall i, j \ z \in R_i + B_j$
- $\forall i, j \ z \in B_i + B_j$.

If $z \in B_j$, then $z$ has $2n^2$ “needs”:

- $\forall i, j \ z \in R_i + R_j$
- $\forall i, j \ z \in R_i + B_j$. 5
So $3n^2$ is a bound on the number of "needs". Given fixed $z$, the probability that some need is not satisfied is

$$Pr[z \text{ has an unsatisfied need}] \leq 3n^2 (1 - \frac{1}{n^2})^{2^k},$$

and

$$Pr[\exists z \text{ with an unsatisfied need}] \leq \sum_z 3n^2 (1 - \frac{1}{n^2})^{2^k} \quad (1)$$

$$= 2^{3k+1} \cdot 3n^2 (1 - \frac{1}{n^2})^{2^k} \quad (2)$$

$$\leq 2^{3(k+1)} \cdot n^2 (1 - \frac{1}{n^2})^{2^k}. \quad (3)$$

We want (3) to be less than 1, which is equivalent to its logarithm being less than zero:

$$\log \left(2^{3(k+1)} \cdot n^2 \cdot \left(1 - \frac{1}{n^2}\right)^{2^k}\right) < 0 \iff 3(k + 1) \log 2 + 2 \log n + 2^k \log \left(\frac{n^2 - 1}{n^2}\right) < 0$$

$$\iff 3(k + 1) \log 2 + 2 \log n < 2k \log \left(\frac{n^2}{n^2 - 1}\right)$$

Now

$$3(k + 1) \log 2 + 2 \log n < 3(k + 1) + k$$

$$\leq 5k$$

so long as $k \geq n \geq 3$, and

$$2^k \cdot \log \left(\frac{n^2}{n^2 - 1}\right) = 2^k \left[\log(n^2) - \log(n^2 - 1)\right]$$

$$> 2^k \cdot \frac{1}{n^2}$$

So we need $5k < \frac{2^k}{n^2}$. Setting $k = n$, we have $5n^3 < 2^n$, which holds for all $n \geq 14$. Hence taking $k = n$ gives a non-zero probability that a random partition yields a representation.

\[\square\]

### 3 A lower bound

In this section, we consider representations of $32_{65}$ as edge-colorings of $K_n$ with all mandatory triangles present and no all-blue triangles. To be more precise, let $\rho : 32_{65} \to \text{Powerset}(U \times U)$, where $U = \{x_0, \ldots, x_{n-1}\}$, be a representation. Then label the vertices of $K_n$ with $\{x_0, \ldots, x_{n-1}\}$, and let the color of edge $x_i x_j$ be the atom $z$ such that $(x_i, x_j) \in \rho(z)$.
Lemma 3. \( \text{Spec}(32_{65}) \subseteq \{11, \ldots \} \cup \{ \omega \} \).  

Proof. There must be some red edge \( x_0x_1 \). Any red edge has nine “needs”. There must be nine points that witness these needs, which together with \( x_0 \) and \( x_1 \) make a total of 11 points.

We can easily obtain a slight improvement using the classical Ramsey number \( R(m,n) \).

Lemma 4. \( 11 \not\in \text{Spec}(32_{65}) \).

Proof. We know that at least 11 points are required. Since \( R(4,3) = 9 \), and there are no all-blue triangles, there must be a red \( K_4 \). Let \( x_0x_1 \) be an edge in this red \( K_4 \). Then \( x_0x_1 \) must have its red-red need met twice, hence there must be ten points besides \( x_0 \) and \( x_1 \).

Lemma 5. In any representation of \( 32_{65} \), for every red edge there is a red \( K_4 \) that is vertex-disjoint from it. In particular, off of every red edge \( x_0x_1 \) one can find the configuration depicted in Figure 4.

Proof. Let \( x_0x_1 \) be red, with witnesses to all needs as in Figure 3. Then \( \{x_2,x_3,x_4,x_5\} \) induce a red \( K_4 \), since any blue edge among them would create an all-blue triangle with \( x_0 \) (and also with \( x_1 \)). Furthermore, any edge running from any of \( x_2,x_3,x_4,x_5 \) to any of \( x_6,x_7,x_8,x_9 \) must be red, since any
such blue edge would create an all-blue triangle with either $x_0$ (for $x_7$ and $x_9$) or $x_1$ (for $x_6$ and $x_8$). Thus we have the configuration depicted in Figure 4. 

**Lemma 6.** 12, 13, 14, 15, 16 $\notin \text{Spec}(32_{65})$.

*Proof.* Consider the configuration depicted in Figure 4. The edge $x_2x_5$ is red. Then $x_0$ and $x_1$ both witness the light-blue-dark-blue need for $x_9$, and let $x_3, x_4, x_6, x_7, x_8$ and $x_9$ all witness the red-red need. There are seven needs yet unsatisfied. The remaining vertex $x_{10}$ could witness some need, but vertices $x_{11}$ through $x_{16}$ will have to be added. Thus there are at least 17 points. See Figure 5. 

Lemma 6 generalizes nicely as follows.

**Theorem 7.** For all $n$, $f(n) \geq n^2 + 4n + 1$.

Note that the trivial bound is $n^2 + 2n + 3$, roughly half the bound in Theorem 7.

*Proof.* Call the shades of blue $b_1$ through $b_n$. Fix a red edge $x_0x_1$. Let $BB$ denote the set of vertices that witness a blue-blue need for $x_0x_1$, and let RB denote the set of vertices that witness either a red-blue need or a blue-red need for $x_0x_1$. $BB$ induces a red clique, and all edges from $BB$ to $RB$ are red. Note that $|BB| = n^2$ and $|RB| = 2n$. This gives the trivial lower bound of $n^2 + 2n + 3$.

Let $u \in BB$ witness $b_1b_1$ for $x_0x_1$ and let $v \in BB$ witness $b_2b_2$ for $x_0x_1$. The edge $uv$ is red, hence has $(n+1)^2$ needs. Both $x_0$ and $x_1$ witness the same blue $b_1$, and all points in $BB$ and $RB$ (besides $u$ and $v$) witness the red-red need. Hence there must be at least $4n + (n + 1)^2 - 2 = 2n^2 + 4n + 1$ points.

**Corollary 8.** In any representation of $A_n$, the clique number of the red subgraph of the underlying graph of the representation is at least $n^2$.

4 SAT solver results

In this section, we improve the lower bound on $f(2)$ using a SAT solver.

**Lemma 9.** 17 $\notin \text{Spec}(32_{65})$.

*Proof.* We build an unsatisfiable boolean formula $\Phi$ whose satisfiability is a necessary condition for $32_{65}$ to be representable over 17 points. For all $0 \leq i < j < 17$ and $k = 0, 1, 2$, define a boolean $\phi_{i,j,k}$. We interpret $\phi_{i,j,0}$ being TRUE to mean that $x_i x_j$ is red, $\phi_{i,j,1}$ being TRUE to mean that $x_i x_j$ is light blue, and $\phi_{i,j,0}$ being TRUE to mean that $x_i x_j$ is dark blue. Then define

$$
\Phi_0 = \bigwedge_{i < j} [(\phi_{i,j,0} \lor \phi_{i,j,1} \lor \phi_{i,j,2}) \land (\neg \phi_{i,j,0} \lor \neg \phi_{i,j,1} \lor \neg \phi_{i,j,2})]
$$

Then $\Phi_0$ asserts that for each $i < j$, exactly one of $\phi_{i,j,0}$, $\phi_{i,j,1}$, and $\phi_{i,j,2}$ is TRUE.

Consider the subgraph depicted in Figure 4. Let
• \( R = \{(i, j) : i < j, \ x_i x_j \text{ is red}\} \)
• \( Bl = \{(i, j) : i < j, \ x_i x_j \text{ is light blue}\} \)
• \( Bd = \{(i, j) : i < j, \ x_i x_j \text{ is dark blue}\} \)

Define
\[
\Phi_1 = \left( \bigwedge_{(i, j) \in R} \phi_{i,j,0} \right) \land \left( \bigwedge_{(i, j) \in Bl} \phi_{i,j,1} \right) \land \left( \bigwedge_{(i, j) \in Bd} \phi_{i,j,2} \right)
\]

Then \( \Phi_1 \) asserts that any edges colored in Figure 4 are colored correctly.

Finally, define
\[
\Phi_2 = \bigwedge_{(i, j) \in R} \left[ \bigwedge_{c_1, c_2 \in \{0, 1, 2\}} \left( \bigvee_{i \neq k \neq j} \phi_{i,k,c_1} \land \phi_{k,j,c_2} \right) \right]
\]

Then \( \Phi_2 \) asserts that every red edge in Figure 4 has its needs satisfied.

Let \( \Phi = \Phi_0 \land \Phi_1 \land \Phi_2 \).

\( \Phi \) has been verified by SAT solver to be unsatisfiable when there are 17 points.

\[\Phi_3 = \bigwedge_{i < j < k} (\phi_{i,j,0} \lor \phi_{i,k,0} \lor \phi_{j,k,0})\]

Lemma 11. Let \( \Phi = \Phi_0 \land \Phi_1 \land \Phi_2 \land \Phi_3 \). Then on 18 and on 19 points, \( \Phi \) is unsatisfiable. Hence \( 18, 19 \notin \text{Spec}(32_{65}) \).

Proof. We have verified the unsatisfiability of \( \Phi \) via SAT solver.

\[\Phi_3 = \bigwedge_{i < j < k} (\phi_{i,j,0} \lor \phi_{i,k,0} \lor \phi_{j,k,0})\]

\[\Phi_3 = \bigwedge_{i < j < k} (\phi_{i,j,0} \lor \phi_{i,k,0} \lor \phi_{j,k,0})\]

5 Summary and open problems

We summarize our work as follows.
Theorem 12. We have $20 \leq f(2) \leq 1024$, and
\[ 2n^2 + 4n + 1 \leq f(n) \leq 2^{3n+1} \]
for all $n \geq 14$.

Problem 1. Is $f(2) < 1000$?

Problem 2. Is $f(n) = O(n^k)$ for some $k$, or are exponentially many points required?

Problem 3. Can some modification of the technique used in [2] give a smaller representation of $32_{65}$? The most obvious thing to try – replacing $\binom{14}{7}$ by $\binom{11}{6}$ – doesn’t work.

Problem 4. Which has the smaller minimal representation, $31_{37}$ or $32_{65}$? While $32_{65}$ has atoms $r, b_1, b_2$, all symmetric, with all-blue triangles forbidden, $31_{37}$ has atoms $r, b, b'$, with all-blue triangles forbidden. The atom $r$ is flexible in both cases. The lower bound proven in Theorem 7 applies to representations of $31_{37}$ as well.
