Pythagorean Theorem & curvature with lower or upper bound

Xiaole Su, Hongwei Sun, Yusheng Wang

Abstract. In this paper, we give a comparison version of Pythagorean Theorem to judge the lower or upper bound of the curvature of Alexandrov spaces (including Riemannian manifolds).

Key words. Pythagorean Theorem, Alexandrov space, Toponogov’s Theorem

Mathematics Subject Classification (2000): 53-C20.

0 Introduction

Let $\mathbb{S}^n_k$ be the complete and simply connected $n$-dimensional space form with constant curvature $k$. For any minimal geodesics $[pq],[pr] \subset \mathbb{S}^n_k$ which form an angle $\angle qpr$ at $p$, the Law of Cosine says that

$$
\begin{cases}
\cos(\sqrt{k}|qr|) = \cos(\sqrt{k}|pq|) \cos(\sqrt{k}|pr|) + \sin(\sqrt{k}|pq|) \sin(\sqrt{k}|pr|) \cos \angle qpr, & k > 0 \\
|qr|^2 = |pq|^2 + |pr|^2 - 2|pq||pr| \cos \angle qpr, & k = 0, \\
\cosh(\sqrt{-k}|qr|) = \cosh(\sqrt{-k}|pq|) \cosh(\sqrt{-k}|pr|) - \sinh(\sqrt{-k}|pq|) \sinh(\sqrt{-k}|pr|) \cos \angle qpr, & k < 0
\end{cases}
$$

where $|\cdot|$ denotes the distance between two given points. In particular, if $\angle qpr = \frac{\pi}{2}$, then

$$
\begin{cases}
\cos(\sqrt{k}|qr|) = \cos(\sqrt{k}|pq|) \cos(\sqrt{k}|pr|), & k > 0 \\
|qr|^2 = |pq|^2 + |pr|^2, & k = 0, \\
\cosh(\sqrt{-k}|qr|) = \cosh(\sqrt{-k}|pq|) \cosh(\sqrt{-k}|pr|), & k < 0
\end{cases}
$$

(0.1)

which is the famous Pythagorean Theorem on $\mathbb{S}^n_k$, especially the middle one for $k = 0$ (the Gougu Theorem in China). A fascinating thing is that the Law of Cosine can be derived from Pythagorean Theorem, i.e. the Law of Cosine is equivalent to Pythagorean Theorem.

For a general Riemannian manifold $M$, it is well-known that a necessary and sufficient condition of sectional curvature $\mathrm{sec}_M \geq k$ (or $\leq k$) is a local comparison version of the Law of Cosine. Namely,

**Theorem 0.1.** Let $M$ be a complete Riemannian manifold. Then $\mathrm{sec}_M \geq k$ (or $\leq k$) if and only if for any $x \in M$ there exists a neighborhood $U_x$ of $x$ such that for any minimal geodesics $[pq],[pr] \subset U_x$

$$
\begin{cases}
\cos(\sqrt{k}|qr|) \geq (\leq) \cos(\sqrt{k}|pq|) \cos(\sqrt{k}|pr|) + \sin(\sqrt{k}|pq|) \sin(\sqrt{k}|pr|) \cos \angle qpr, & k > 0 \\
|qr|^2 \leq (\geq) |pq|^2 + |pr|^2 - 2|pq||pr| \cos \angle qpr, & k = 0, \\
\cosh(\sqrt{-k}|qr|) \leq (\geq) \cosh(\sqrt{-k}|pq|) \cosh(\sqrt{-k}|pr|) - \sinh(\sqrt{-k}|pq|) \sinh(\sqrt{-k}|pr|) \cos \angle qpr, & k < 0
\end{cases}
$$

and equality holds for all $x \in M$ and all $[pq],[pr] \subset U_x$ if and only if $\mathrm{sec}_M \equiv k$.

Inspired by the relation between Pythagorean Theorem and the Law of Cosine, a natural question is:

**Question 0.2.** Is there a comparison version of Pythagorean Theorem to judge the lower or upper bound of $\mathrm{sec}_M$?

In this paper, for three points $p, q, r$ in a metric space, we denote by $\hat{Z}_{kqpr}$ the angle between $[\tilde{p}q]$ and $[\tilde{p}r]$ in $S^2_k$ with $|\tilde{p}q| = |pq|$, $|\tilde{p}r| = |pr|$ and $|\tilde{q}r| = |qr|$. Note that a comparison version of (0.1),

$$
\begin{align*}
\cos(\sqrt{k}|qr|) & \geq (\leq) \cos(\sqrt{k}|pq|) \cos(\sqrt{k}|pr|), & k > 0 \\
|qr|^2 & \leq (\geq) |pq|^2 + |pr|^2, & k = 0, \\
\cosh(\sqrt{-k}|qr|) & \leq (\geq) \cosh(\sqrt{-k}|pq|) \cosh(\sqrt{-k}|pr|), & k < 0
\end{align*}
$$

is equivalent to

$$
\hat{Z}_{kqpr} \leq (\geq) \frac{\pi}{2}.
$$

The main goal of the paper is to give a positive answer to Question 0.2 not only for a Riemannian manifold but also for an Alexandrov space through the following result.

**Theorem A.** Let $X$ be a complete Alexandrov space. Then $X$ is of curvature $\geq (\leq) k$ if and only if for any $x \in X$ there exists a neighborhood $U_x$ of $x$ such that, for any $q \in U_x$ and $[r_1r_2] \subset U_x$, if there is $p \in [r_1r_2]^{o}$ (the interior part of $[r_1r_2]$) satisfying $|qp| = |q[r_1r_2]|$ (where $|q[r_1r_2]| \triangleq \min_{s \in [r_1r_2]} \{|qs|\}$) then

$$
\hat{Z}_{kqpr} \leq (\geq) \frac{\pi}{2}, \quad i = 1, 2.
$$

Moreover, if equality in (0.2) holds for all $x \in X$ and all $q \in U_x$, $[r_1r_2] \subset U_x$ and such $p \in [r_1r_2]$, then $X^o$ (the interior part of $X$) is a Riemannian manifold with sectional curvature equal to $k$.

In this paper, that $X$ is an Alexandrov space means that for any $x \in X$ there is a real number $k_x$ such that a neighborhood of $x$ is a so-called Alexandrov space with curvature $\geq k_x$ or $\leq k_x$; and we call $x$ a CBB-type or CBA-type point when $X$ is of curvature $\geq k_x$ or $\leq k_x$ around $x$ respectively. Of course, a Riemannian manifold is an Alexandrov space. Note that although $X$ is complete, $X$ might not be equal to $X^o$ (this differs from the Riemannian case). Refer to Section 1 for details on Alexandrov spaces.

Note that if $X$ is a complete CBB-type Alexandrov space, then $'|qp| = |q[r_1r_2]|'$ in Theorem A implies that $\angle qpr_i = \frac{\pi}{2}$ for any $|qp|$ and $|pr_i|$ (see Lemma 1.6 below). Thence, it is clear that Theorem A has the following corollary, a positive answer to Question 0.2.

**Corollary B.** Let $X$ be a complete CBB-type Alexandrov space. Then $X$ is of curvature $\geq (\leq) k$ if and only if for any $x \in X$ there exists a neighborhood $U_x$ of $x$ such that, for all $[pq], [pr] \subset U_x$ with $\angle qpr = \frac{\pi}{2}$,

$$
\hat{Z}_{kqpr} \leq (\geq) \frac{\pi}{2}.
$$

Moreover, if equality in (0.3) holds for all $x \in X$ and all such $[pq], [pr] \subset U_x$, then $X^o$ is a Riemannian manifold with sectional curvature equal to $k$.

**Remark 0.3.** For the rigidity part of Corollary B, one can consider the following simple example. Note that a geodesic triangle on $S^2_k$ separates $S^2_k$ into two parts with boundary. The smaller one is a complete Alexandrov space with curvature $\geq k$, but not a Riemannian manifold with boundary, and satisfies Pythagorean Theorem locally. (However, the larger one is an Alexandrov space with curvature $\leq k$, and does not satisfy Pythagorean Theorem around the vertices of the triangle.)

**Remark 0.4.** For a CBA-type Alexandrov space $X$, we cannot judge whether $X$ is of curvature $\geq k$ or $\leq k$ in a similar way as Corollary B. For example, the union of three rays in $\mathbb{R}^2$ starting from a common point (with the induced intrinsic metric), a CBA-type Alexandrov space, has no $\frac{\pi}{2}$-angle nor lower curvature bound.

**Remark 0.5.** If $X$ is a Riemannian manifold, one can give a proof for Theorem A via the second variation formula and the comparison results on index forms (the main tools in proving the well-known Rauch’s
Theorem), which do not work when \( X \) is a general Alexandrov space. Of course, in our proof relying on Toponogov’s Theorem, many arguments can be removed in the case where \( X \) is a Riemannian manifold (i.e. the proof can be much shorter).

As an application of Theorem A, we supply a way to judge whether a point in a CBB-type Alexandrov space is a Riemannian one (i.e. its space of directions is a unit sphere, see Section 1).

**Theorem C.** Let \( x \) be an interior point in a complete CBB-type Alexandrov space. If there is a function \( \chi(\varepsilon) \) with \( \varepsilon > 0 \) and \( \chi(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \) such that, for all \( [pq], [pr] \subset B_x(\varepsilon) \) with \( \angle qpr = \frac{\pi}{2} \),

\[
\left| \frac{|qr|^2}{|pq|^2 + |pr|^2} - 1 \right| < \chi(\varepsilon),
\]

then \( x \) is a Riemannian point.

We would like to point out that the condition for \( x \) to be a Riemannian point in Theorem C should just be sufficient, but not necessary.

As an almost immediate corollary of Theorem C, we have the following known result ([AKP]).

**Corollary D.** Let \( x \) be an interior point in a complete CBB-type Alexandrov space \( X \). If in addition \( x \) is a CBA-type point, then \( x \) is a Riemannian point (as a result, if each point in \( X^\circ \) is a CBA-type one, then \( X^\circ \) is a manifold).

In the rest, the paper is organized as follows. In Section 1, we will recall some basic conceptions on Alexandrov spaces. In Sections 2 and 3, we will give a proof of Theorem A for curvature \( \geq (\leq) k \) and \( \equiv k \) respectively. In Section 4, we shall give proofs for Theorem C and Corollary D.

## 1 On Alexandrov spaces

In this section, we will recall the definition and some basic properties of Alexandrov spaces, which will be used in the proof of Theorem A.

First of all, it is well known that Theorem [CE] has the following twin version.

**Theorem 1.1 ([CE]).** Let \( M \) be a complete Riemannian manifold. Then \( \text{sec}_M \geq k (\leq k) \) if and only if for any \( x \in M \) there exists a neighborhood \( U_x \) of \( x \) such that

\[
(1.1) \quad \text{for any } q \in U_x, [pr] \subset U_x, \text{ and } \tilde{q} \in S^2_{k_x} \text{ and } [\tilde{p}\tilde{r}] \subset S^2_{k_x} \text{ with } |\tilde{q}\tilde{p}| = |qp|, |\tilde{q}\tilde{r}| = |qr| \text{ and } |\tilde{p}\tilde{r}| = |pr|, \text{ we have that, for any } s \in [pr] \text{ and } \tilde{s} \in [\tilde{p}\tilde{r}] \text{ with } |ps| = |\tilde{p}\tilde{s}|, \]

\[
|qs| \geq (\leq) |\tilde{q}\tilde{s}|.
\]

We now, based on Theorem [AKP], can give the definition of the Alexandrov space in Theorem A.

**Definition 1.2** (cf. [BGP], [AKP]). A locally compact length space \( X \) is called an Alexandrov space if for any \( x \in X \) there is a real number \( k_x \) and a neighborhood \( U_x \) of \( x \) such that the corresponding condition (1.1) with respect to \( S^2_{k_x} \) holds, and \( X \) is said to be of curvature \( \text{cur}_X \geq k_x \) or \( \leq k_x \) on \( U_x \) according to \( |qs| \geq |\tilde{q}\tilde{s}| \) or \( |qs| \leq |\tilde{q}\tilde{s}| \) respectively.

Given an Alexandrov space \( X \), we call \( x \in X \) a CBB-type (resp. CBA-type) point when \( \text{cur}_X \geq k_x \) (resp. \( \leq k_x \)) around \( x \); and we call \( X \) a CBB-type (resp. CBA-type) Alexandrov space if each \( x \in X \) is a CBB-type (resp. CBA-type) point.

It is obvious that Alexandrov spaces include Riemannian manifolds. To a general Alexandrov space \( X \), a significant difference from a Riemannian manifold is that a geodesic (locally shortest path) on \( X \) might not be prolonged even when \( X \) is complete (in the sense of distance topology).
In an Alexandrov space $X$, we can define an angle $\angle yxz$ between two minimal geodesics $[xy]$ and $[xz]$. Assume that $X$ is of $\text{cur}_X \geq k_x$ around $x$. Let $a \in [xy]$ and $b \in [xz]$. By condition (1.1), $\tilde{\angle} k_{a} x y z b$ is non-decreasing when $a, b$ converge to $x$ ([BGP]), i.e. $\lim_{a, b \to x} \tilde{\angle} k_{a} x y z b$ exists. And note that, for any $k \neq k_x$,

$$\lim_{a, b \to x} \tilde{\angle} k_{a} x y z b = \lim_{a, b \to x} \tilde{\angle} k_{x} x y z b.$$  

So, we can define

$$\angle y x z \triangleq \lim_{a, b \to x} \tilde{\angle} k_{a} x y z b. \quad (1.2)$$

Similarly, we can also define $\angle y x z$ if $X$ is of $\text{cur}_X \leq k_x$ around $x$ because, in such a situation, $\tilde{\angle} k_{a} x y z b$ is non-increasing when $a, b$ converge to $x$ ([AKP]).

By (1.2) and Definition 1.2, it is not hard to see that Theorem 0.1 also holds for $X$ ([BGP], cf. [Pl]).

**Theorem 1.3.** Let $X$ be a complete CBB-type Alexandrov space. Then $X$ is of $\text{cur}_X \geq (\leq) k$ if and only if for any $x \in X$ there exists a neighborhood $U_x$ of $x$ such that the inequality in Theorem 0.1 holds for any $[pq], [pr] \subset U_x$, or equivalently, for any triangle $\triangle pqr \subset U_x$ (i.e. a union of three minimal geodesics $[pq], [pr], [pr]$) we have that $\angle qpr \geq (\leq) \tilde{\angle} k_{q} p r$, $\angle p q r \geq (\leq) \tilde{\angle} k_{p} q r$ and $\angle p r q \geq (\leq) \tilde{\angle} k_{p} r q$.

**Theorem 1.3′.** Let $X$ be a complete CBA-type Alexandrov space. Then $X$ is of $\text{cur}_X \leq k$ (resp. $\geq k$) if and only if (resp. only if) the condition for $\text{cur}_X \leq k$ (resp. $\geq k$) in Theorem 1.3 holds.

In Theorem 1.3′, the “if” (i.e. the sufficiency of the condition) for $\text{cur}_X \geq k$ needs an additional condition that $\angle q s p + \angle q s r = \pi$ for all $s \in [p r]^{\circ}$ ([BGP], [AKP]).

And similar to Riemannian case, we have the first variation formula on Alexandrov spaces.

**Lemma 1.4** ([BGP], [AKP]). Let $X$ be a complete Alexandrov space. Then for any $x \in X$, there is a neighborhood $U_x$ of $x$ such that, for any $[pq], [pr] \subset U_x$ and $p_i \in [pr]$ with $p_i \to p$ as $i \to \infty$,

$$\begin{align*}
|q_p| &= |q_p| - |p'| \cdot |q_p| \cdot \cos \angle q p r + o(|p'|), \quad x \text{ is a CBA-type point;} \\
|q_p| &= |q_p| - |p'| \cdot |q_p| \cdot \cos |q_p| + o(|p'|), \quad x \text{ is a CBB-type point.} \quad (1.3)
\end{align*}$$

In this paper, for a given $[xy]$, $\uparrow_x^y$ denotes its direction at $x$ (in Riemannian case, $\uparrow_x^y$ is just the unit tangent vector of $[xy]$ from $x$ to $y$); and $\uparrow_x^{y'}$ denotes the union of directions of all minimal geodesics from $x$ to $y$. Note that by Definition 1.2 in the case where $X$ has an upper curvature bound on $U$, there is a unique minimal geodesic between any two distinct points in $U$.

**Remark 1.5.** For $\text{cur}_X \geq k$, Theorem 1.3 (and 0.1) guarantees a global version of itself ([BGP], cf. [Pl] and [Wa]), which is the well-known Toponogov’s Theorem; namely, $\text{cur}_X \geq k$ implies that (1.1) holds for any $q \in X$ and $[pr] \subset X$. However, there is no global version for $\text{cur}_X \leq k$ in general ([AKP]). As a result, (1.3) has a global version (the first variation formula) on a complete Alexandrov space $X$ with $\text{cur}_X \geq k$, but does not on $X$ with only an upper curvature bound.

Moreover, the angles on Alexandrov spaces satisfy the following property.

**Lemma 1.6** ([BGP], [AKP]). Let $X$ be a complete Alexandrov space. Then for any $x \in X$, there is a neighborhood $U_x$ of $x$ such that, for any $[qp], [r_1 r_2] \subset U_x$ with $p \in [r_1 r_2]$,

$$\begin{align*}
\angle q p r_1 + \angle q p r_2 \geq \pi, \quad x \text{ is a CBA-type point;} \\
\angle q p r_1 + \angle q p r_2 = \pi, \quad x \text{ is a CBB-type point.} \quad (1.4)
\end{align*}$$

As a result, if $x$ is a CBB-type point and if in addition $|q p| = |q r_1 r_2|$, then $\angle q p r_1 = \angle q p r_2 = \frac{\pi}{2}$. 

And it is easy to see that the angles on Alexandrov spaces have semi-continuity. Namely, given a complete Alexandrov space $X$ which has a lower (resp. upper) curvature bound on a neighborhood $U$, if $[p_i q_i] \to [pq]$ and $[p_i r_i] \to [pr]$ as $i \to \infty$ in $U$, then $\angle qpr \leq \liminf_{i \to \infty} \angle q_i p_i r_i$ (resp. $\angle qpr \geq \limsup_{i \to \infty} \angle q_i p_i r_i$).

This, together with (1.4), implies the following continuity.

**Lemma 1.7.** Let $X$ be a complete Alexandrov space, and let $U$ be a neighborhood in $X$. Suppose that $[qp], [q_i p_i], [r_i r_2] \subset U$ with $p, p_i \in [r_1 r_2]$. If $\angle q_i p_i r_i \to \angle qpr$ as $i \to \infty$. If $X$ has a lower curvature bound on $U$, or if $X$ has an upper curvature bound on $U$ and $\angle qpr_1 + \angle qpr_2 = \pi$, then

$$
\lim_{i \to \infty} \angle q_i p_i r_i = \angle qpr_1 \text{ and } \lim_{i \to \infty} \angle q_i p_i r_2 = \angle qpr_2.
$$

We now end this section with some conceptions which only apply to CBB-type Alexandrov spaces ([BGP]). A CBB-type Alexandrov space $X$ has the conception of dimension, and the space of directions $\Sigma_p X$ at any $p \in X$ is an Alexandrov space with curvature $\geq 1$ and has a dimension one less than $X$. If $\Sigma_p X$ is isometric to a unit sphere, we say that $p$ is a Riemannian point.

As a result, by induction we can define $p$ to be a boundary or interior point if $\Sigma_p X$ contains boundary or no boundary point respectively. Usually, we denote by $X^\circ$ and $\partial X$ the set of interior points and boundary points respectively. Note that $\partial X$ may be not empty even if $X$ is complete.

As another result, for any $p \in X$, we can define the tangent cone $C_p X$, which is a metric cone over $\Sigma_p X$. $C_p X$ plays an important role in studying CBB-type Alexandrov spaces because of:

**Lemma 1.8 ([BGP]).** Let $X$ be a complete CBB-type Alexandrov space. Then with base point $p \in X$, $(\lambda X, p)$ converge in the Gromov-Hausdorff sense to $C_p X$ as $\lambda \to +\infty$.

In this paper, $\lambda X$ denotes $X$ endowed with the metric $\lambda \cdot d$, where $d$ is the original metric on $X$.

### 2 Proof of Theorem A for curvature $\geq (\leq) k$

In this section, we will show the former part of Theorem A, i.e. the sufficiency and necessity of the condition for curvature $\geq k$ or $\leq k$ in Theorem A. By Theorems 1.3 and 1.3’, it suffices to verify the sufficiency, and the verification shall be proceeded according to:

- Case 1: For curvature $\geq k$ around a CBB-type point $x \in X$;
- Case 2: For curvature $\geq k$ around a CBA-type point $x \in X$;
- Case 3: For curvature $\leq k$ around a CBA-type point $x \in X$;
- Case 4: For curvature $\leq k$ around a CBB-type point $x \in X$.

For the convenience of readers, we first give a rough idea of our proof. For instance, in Case 1, if the curvature of $X$ is not $\geq k$ around the CBB-type point $x$, then by Theorem 1.3 there must be a triangle $\triangle pqr$ containing a ‘bad’ angle, say $\angle qpr$, i.e. $\angle qpr < \check{k} qpr$. A key observation is that such a triangle can be cut into two (smaller) triangles and at least one of them still contains a ‘bad’ angle (cf. [Wa]), which is guaranteed by the lemma right below. By repeating such a cutting operation finite times, we will get a triangle which contradicts the condition for curvature $\geq k$ in Theorem A.

In this paper, for a given $\triangle qpr$, its comparison triangle is defined to be a $\triangle \tilde{p}\tilde{q}\tilde{r} \subset S^2_k$ with $|\tilde{p}q| = |pq|$, $|\tilde{p}\tilde{r}| = |pr|$ and $|\tilde{q}\tilde{r}| = |qr|$.

**Lemma 2.1 (cf. [Wa]).** Let $x$ be a CBB-point in a complete Alexandrov space, and let $k$ be a real number. Then there is a neighborhood $U_x$ of $x$ such that, for any $\triangle q_r r_2 \subset U_x$ and its comparison triangle $\triangle \tilde{q}_r \tilde{r} \subset S^2_k$, if $|qs| - |\tilde{q}s|$ with $s \in [r_1 r_2]$, $\tilde{s} \in [\tilde{r}\tilde{r}_2]$ and $|r_i s| = |\tilde{r}\tilde{s}|$ attains a negative minimum at $s_0 \in [r_1 r_2]$, then any $|qs_0|$ satisfies

$$
\angle q s_0 r_1 < \check{k} q s_0 r_1 \text{ or } \angle q s_0 r_2 < \check{k} q s_0 r_2;
$$

(2.1)
Proof. Since $x$ is a CBB-point, by Lemmas \[1.4\] and \[1.6\] there is a neighborhood $U_x$ of $x$ such that we can apply \[1.3\] and \[1.4\] on it. For any $|qs|$, by \[1.3\], the negative minimum of $|qs| - |\tilde{qs}|$ at $s_0$ implies

\[ \angle qs_0 \tilde{r}_i, \quad i = 1, 2. \]

It then has to hold that

\[ \angle qs_0 r_i = \angle \tilde{qs}_0 \tilde{r}_i, \quad i = 1, 2 \]

because, by \[1.4\], we have that

\[ \angle qs_0 r_1 + \angle qs_0 r_2 = \pi. \]

On the other hand, since $|qs| < |\tilde{qs}|$, there is $\tilde{q} \in [\tilde{q}_s]_0$ such that $|\tilde{q}_s| = |qs|$. It is clear that at least one of $|\tilde{q}_s r_i| < |\tilde{q}_r r_i|$ holds. It follows that at least one of $\angle \tilde{q}_s \tilde{r}_i < \angle \tilde{k}_s q_0 r_i$ holds; especially, if $|r_i s_0| < |r_i q|$ for $i = 1$ or $2$, then $\angle \tilde{q}_s \tilde{r}_i < \angle \tilde{k}_s q_0 r_i$. As a result, the lemma follows. \[\square\]

Remark 2.2. (2.2.1) In Lemma \[2.1\] if $|qs| - |\tilde{qs}|$ attains a positive maximum at $s_0 \in [r_1 r_2]_0$, then similar to \[2.1\] either $\angle qs_0 r_2 > \angle \tilde{k}_s q_0 r_2$ for the $[qs]$ with $|\hat{q}_s |^{t_s}_s | = |\hat{q}_s |^{t_s}_s |$, or $\angle qs_0 r_1 > \angle \tilde{k}_s q_0 r_1$ for the $[qs]$ with $|\hat{q}_s |^{t_s}_s | = |\hat{q}_s |^{t_s}_s |$. And similar to \[2.2\], if $\angle \tilde{r}_i \tilde{q}_s < \frac{\pi}{2}$ for $i = 1$ or $2$, then $\angle \tilde{q}_s \tilde{r}_i > \angle \tilde{k}_s q_0 r_i$ and thus the corresponding $\angle \tilde{q}_s q_0 r_i > \angle \tilde{k}_s q_0 r_i$.

(2.2.2) In Lemma \[2.1\] if $x$ is a CBA-point, the lemma is not true unless $\angle qs_0 r_1 + \angle qs_0 r_2 = \pi$ (see \[2.4\]); note that it may occur that $\angle qs_0 r_1 + \angle qs_0 r_2 > \pi$ by \[1.4\]).

(2.2.3) In Lemma \[2.1\] if $x$ is a CBA-point, and if $|qs| - |\tilde{qs}|$ attains a positive maximum at $s_0 \in [r_1 r_2]_0$, then similar to \[2.1\] we have that $\angle q_0 r_i > \angle \tilde{k}_s q_0 r_i$ for $i = 1$ or $2$. (Here, there is a unique minimal geodesic between $q$ and $s_0$ because of the CBA-property.) And similar to \[2.2\], if $\angle \tilde{r}_i \tilde{q}_s < \frac{\pi}{2}$ for $i = 1$ or $2$, then $\angle \tilde{q}_s \tilde{r}_i > \angle \tilde{k}_s q_0 r_i$ and thus $\angle qs_0 r_i > \angle \tilde{k}_s q_0 r_i$.

Now, according to the four cases listed in the beginning of this section, we begin to prove the former part of Theorem A case by case.

Proof for Case 1.

In this case, around a CBB-type point $x \in X$, we will prove:

(2.5) $X$ is of curvature $\geq k$ if there is a neighborhood $U_x$ of $x$ such that,

\[ \text{for any } q \in U_x \text{ and } [r_1 r_2] \subset U_x, \text{ if } p \in [r_1 r_2], \text{ satisfies } |qp| = |q[r_1 r_2]|, \text{ then } \angle q_0 p r_i \leq \frac{\pi}{2}. \]

If $X$ is not of curvature $\geq k$ around $x$, then we claim that there is a triangle $\triangle q_0 p r \subset U_x$ such that

\[ |qs| = |q[p]| \text{ for some } s \in [p]_0, \text{ and } |qs| < |\tilde{qs}| \text{ for } \tilde{s} \in [\tilde{p}]_\tilde{p} \text{ with } |\tilde{s}| = |sp|, \]

where $[\tilde{p}]_\tilde{p}$ belongs to the comparison triangle $\triangle \tilde{q}_s \tilde{p} \subset S^2_k$ of $\triangle q_0 p r$. Nevertheless, the $\triangle q_0 p r$ contradicts \[2.6\]. In fact, note that either $\angle \tilde{q}_s \tilde{p} \geq \frac{\pi}{2}$ or $\angle \tilde{q}_s \tilde{r} \geq \frac{\pi}{2}$, say $\angle \tilde{q}_s \tilde{r} \geq \frac{\pi}{2}$. Then by applying \[2.6\] on $\triangle q_0 p r$, it has to hold that $|qs| \geq |\tilde{qs}|$, a contradiction.

We now need only to verify the claim, i.e. to show the existence of the desired triangle. By Theorem \[1.3\] if $X$ is not of curvature $\geq k$ around $x$, there exists a sufficiently small triangle $\triangle q_0 p r \subset U_x$ which contains a ‘bad’ angle, say $\triangle q_0 p r$, i.e. $\angle q_0 p r < \angle \tilde{k}_s q_0 r_i$. 
First of all, observe that the badness of $\angle qpr$ implies that there is $\tilde{s} \in [pr]\setminus \{p\}$ and $\tilde{t} \in [pq]\setminus \{p\}$ such that, for all $s \in [ps]$ and $t \in [pt]$,

$$|\tilde{s}| < |\tilde{t}|, |\tilde{s}t| < |\tilde{s}t|, |\tilde{s}\tilde{t}| = |\tilde{s}\tilde{t}|$$

and $\angle tps - \tilde{k}_{\Delta tps} = \angle qpr - \tilde{k}_{qpr}$,

where $\tilde{s}, \tilde{t}$, $\tilde{t}$ belong to the comparison triangle $\Delta \tilde{p}\tilde{q}\tilde{r} \subset S^2$ of $\Delta qpr$ and correspond to $s, t, t$ respectively with $\tilde{s} \in [\tilde{p}\tilde{r}]$ and $|\tilde{s}\tilde{p}| = |sp|$, etc. In fact, by the badness of $\angle qpr$ and Lemma 1.4 there is $s_1 \in [pr]\setminus \{p\}$ such that

$$|qs_1| = |\tilde{q}\tilde{s}_1| \quad \text{and} \quad |qs| < |\tilde{q}\tilde{s}| \tag{2.9}$$

for all $s \in [ps]$ and $\tilde{s}_1 \in [\tilde{p}\tilde{r}]$ with $|\tilde{s}_1\tilde{p}| = |s_1p|$ and $|\tilde{s}_{\tilde{p}}| = |sp|$. Note that $\Delta q\tilde{s}_1\tilde{p}$ is a comparison triangle of $\Delta qps_1$ with

$$\angle qps_1 - \tilde{k}_{qps_1} = \angle qpr - \tilde{k}_{qpr},$$

so $\angle qps_1$ is still ‘bad’ in $\Delta qps_1$. And similarly, there is $t_1 \in [pq]\setminus \{p\}$ such that

$$|s_1t_1| = |\tilde{s}_1\tilde{t}_1| \quad \text{and} \quad |s_1t| < |\tilde{s}_1\tilde{t}| \tag{2.10}$$

for all $t \in [pt]$ and $\tilde{t}_1 \in [\tilde{p}\tilde{q}]$ with $|\tilde{t}_1\tilde{p}| = |t_1p|$ and $|\tilde{t}_1\tilde{t}| = |tp|$. Furthermore, we can locate an $s_2 \in [ps_1]\setminus \{p\}$ similar to $s_1$ and a $t_2 \in [pt_1]\setminus \{p\}$ similar to $t_1$. Then we can get a sequence of $(s_j)_{j=1}^\infty$ and $(t_j)_{j=1}^\infty$ (it may occur that $s_j = s_{j_0}$ and $t_j = t_{j_0}$ for all $j \geq j_0$) such that

$$\angle s_jt_{j-1} - \tilde{k}_{k}\angle s_jt_{j-1} = \angle s_jt_j - \tilde{k}_{k}\angle s_jt_j = \angle qpr - \tilde{k}_{qpr}, \tag{2.11}$$

which, by (1.2), implies that

$$s_j \to \tilde{s} \in [pr]\setminus \{p\} \quad \text{and} \quad t_j \to \tilde{t} \in [pq]\setminus \{p\} \quad \text{as} \quad j \to \infty.$$

By the corresponding (2.6) and (2.10) for each $j$ and (2.11), we can conclude that $\tilde{s}$ and $\tilde{t}$ must satisfy the two equalities in (2.5). Then up to repeating this process on $\Delta \tilde{t}\tilde{p}\tilde{s}$, we can assume that $\tilde{s}$ and $\tilde{t}$ also satisfy the two inequalities in (2.8). Namely, we have found the desired $\tilde{s}$ and $\tilde{t}$.

Note that (2.8) implies that

$$\tilde{k}_{k}\angle t\tilde{s}p \geq |t\tilde{s}_\parallel t\parallel| \quad \text{and} \quad \tilde{k}_{k}\tilde{t}s \geq |\tilde{t}\parallel \tilde{t}\parallel|.$$

(12.12)

On the other hand, note that $\Delta pqr$ is sufficiently small, so is any $\Delta \tilde{t}\tilde{p}\tilde{s}$; and thus at least one of $\tilde{k}_{k}\angle t\tilde{s}p$ and $\tilde{k}_{k}\tilde{t}sp$ is an acute angle. This together with (2.12) implies that there is a triangle $\Delta \tilde{t}\tilde{p}\tilde{s}$ such that

$$\angle \tilde{t}\tilde{s}p \geq 1 \quad \text{and} \quad \angle \tilde{t}\tilde{p}\tilde{s} \geq 1.$$ 

At least one of $\angle t\tilde{s}p$ and $\angle \tilde{t}\tilde{p}\tilde{s}$ is acute, say $\angle \tilde{t}\tilde{p}\tilde{s}$.

(12.13)

In addition, if $\angle qpr < \frac{\pi}{2}$, then by Lemma 1.4 there is $s \in [ps]$ such that $|\tilde{s}| = |\tilde{t}|[ps]|$, i.e. $\Delta \tilde{t}\tilde{p}s$ is our desired triangle.

Hence, we need only to show that it can be assumed that $\angle qpr < \frac{\pi}{2}$. Since $\angle qpr$ is a ‘bad’ angle, for $s \in [pr]$ close to $p$ and $\tilde{s} \in [\tilde{p}\tilde{r}]$ with $|\tilde{s}\tilde{p}| = |sp|$ we have that $|qs| < |\tilde{q}\tilde{s}|$ (by Lemma 1.4). Then there is $r' \in [pr]$ and $\tilde{r}' \in [\tilde{p}\tilde{r}]$ with $|pr'| = |\tilde{p}\tilde{r}'|$ such that

$$|qr'| - |\tilde{q}\tilde{r}'| = \min_{s \in [pr], \tilde{s} \in [\tilde{p}\tilde{r}], |ps| = |\tilde{p}\tilde{s}|} \{|qs| - |\tilde{q}\tilde{s}|\} < 0,$$

(12.14)

so via Lemma 2.1 we can conclude that

$$\angle qr'p \text{ is a ‘bad’ angle in } \Delta qr'p, \quad \text{or} \quad qr'r \text{ is a ‘bad’ angle in } \Delta qr'r.$$ 

(12.15)

And in this situation, (2.16) means that

$$\angle qr'p = \angle \tilde{q}\tilde{r}'p \quad \text{and} \quad qr'r = \angle \tilde{q}\tilde{r}'r.$$ 

(12.16)
Note that if \( \angle qpr \geq \frac{\pi}{2} \), then it follows from the badness of \( \angle qpr \) that \( \angle \tilde{p} \tilde{q} \tilde{r} = \tilde{\angle}_k qpr \) \( \geq \frac{\pi}{2} \). And note that \( \triangle \tilde{p} \tilde{q} \tilde{r} \) is sufficiently small in \( S_k^2 \), so it is easy to see that

\[
\angle \tilde{q} \tilde{r} \tilde{p} < \frac{\pi}{2} \quad \text{and} \quad \angle \tilde{q} \tilde{r} \tilde{p} > \frac{\pi}{2}.
\]  

By (2.16)-(2.17), \( \triangle qpr \) contains an acute ‘bad’ angle if the angle \( \angle qpr \) is ‘bad’; otherwise, we can repeat such a cutting operation on \( \triangle qpr \). For convenience, we also let \( \triangle qpr \) denote the \( \triangle qpr \). Note that up to repeating such a cutting operation finite times, we can assume that \( |pr| \ll |pq| \), so plus (2.2) we can conclude that \( \angle qpr \) is an acute ‘bad’ angle in \( \triangle qpr \). This means that we can assume that \( \angle qpr < \frac{\pi}{2} \).

**Proof for Case 2.**

In this case, we shall prove (2.5) around a CBA-type point \( x \in X \). Compared with the proof for Case 1, the only difference and difficulty here is why (2.15) holds. Note that Lemma 2.1 fails to work here (see (2.2.2) in Remark 2.2). Namely, the proof for Case 2 will be done if one can show that: for a CBA-type point \( x \), if the \( U_x \) in Lemma 2.1 satisfies (2.6) additionally, then the conclusion of Lemma 2.1 still holds. By (2.2.2), it suffices to show that \( \angle qs_0 r_1 + \angle qs_0 r_2 = \pi \), i.e., the possible case \( \angle qs_0 r_1 + \angle qs_0 r_2 > \pi \) does not occur at all here.

Let \( q' \in [qs_0] \) be sufficiently close to \( s_0 \), and let \( s' \in [r_1 r_2] \) such that \( |q's'| = |q'[r_1 r_2]| \) (for \( [qs_0] \) and \( [r_1 r_2] \) refer to the proof of Lemma 2.1). Note that \( s' \) is close to \( s_0 \), so we can assume that \( s' \) lies in \( [r_1 r_2] \). Then for \( s' \in [\tilde{r}_1 \tilde{r}_2] \) (\( \triangle \tilde{q} \tilde{r}_1 \tilde{r}_2 \subset S_k^2 \)) with \( |\tilde{r}_1 s'| = |r_1 s'| \), there is \( \tilde{q}' \in S_k^2 \) such that

\[
|\tilde{r}_1 \tilde{q}'| + |\tilde{q}' \tilde{r}_2| = |r_1 q'| + |\tilde{q} \tilde{r}_2|
\]  

and

\[
\angle \tilde{q}' \tilde{s}' \tilde{r}_1 = \angle \tilde{q} \tilde{s} \tilde{r}_2 = \frac{\pi}{2}.
\]

By Lemma 1.4 it is easy to see that

\[
|r_1 q'| + |q' \tilde{r}_2| = |r_1 r_2| - |q' s_0| \cdot (\cos \angle qs_0 r_1 + \cos \angle qs_0 r_2) + o(|q' s_0|),
\]

and that

\[
|\tilde{r}_1 \tilde{q}'| + |\tilde{q}' \tilde{r}_2| = |\tilde{r}_1 \tilde{r}_2| - |\tilde{q}' s'| \cdot (\cos \angle \tilde{q} \tilde{s} \tilde{r}_1 + \cos \angle \tilde{q} \tilde{s} \tilde{r}_2) + o(|\tilde{q}' s'|) = |r_1 r_2| + o(|\tilde{q}' s'|).
\]

Hence, if \( \angle qs_0 r_1 + \angle qs_0 r_2 > \pi \), then from (2.15), (2.20) and (2.21) we can see that

\[
|q' s'| \leq |q' s_0| < |\tilde{q}' s'|.
\]

However, putting \( |q' s'| = |q'[r_1 r_2]| \), \( |\tilde{r}_1 s'| = |r_1 s'| \), (2.19) and (2.22) together, we can apply (2.6) to conclude that \( |r_1 q'| + |q' \tilde{r}_2| < |\tilde{r}_1 \tilde{q}'| + |\tilde{q}' \tilde{r}_2| \), which contradicts (2.18).

**Proof for Case 3.**

In this case, around a CBA-type point \( x \in X \), we will prove:

(2.23) \( X \) is of curvature \( \leq k \) if there is a neighborhood \( U_x \) of \( x \) such that, for any \( q \in U_x \) and \( [r_1 r_2] \subset U_x \), if \( |r_1 r_2| \leq \frac{|q r_1 r_2|}{\angle q r_1 r_2} \) satisfies \( |q| = |q r_1 r_2| \), then \( \tilde{\angle}_k q p r \leq \frac{\pi}{2} \).

The proof is almost a copy of that for Case 1 with reversing the directions of the corresponding inequalities. (Hint: “\( \angle qpr \) is a ‘bad’ angle” here means that \( \angle qpr \geq \tilde{\angle}_k q p r \). Then by Lemma 1.4 there is \( r' \in [pr] \) and \( \tilde{r}' \in [\tilde{p} r] \), which correspond to \( r' \) and \( \tilde{r}' \) satisfying (2.14), such that

\[
|q' r'| - |\tilde{q}' \tilde{r}'| = \max_{s \in [pr], \tilde{s} \in [\tilde{p} r], |s| \leq |\tilde{s}|} \{|qs| - |\tilde{q} \tilde{s}|\} > 0.
\]
Furthermore, we can apply (2.2.3) to see (2.15). So, we only point out the main two differences here.

One is how to see (2.13). In Case 1, (2.12) is a key, but here the corresponding (2.12) has inverse directions. However, the CBA-property of \(x\) here implies (2.12) directly when \(U_x\) is small enough.

The other is how to see the acuteness of \(\angle qpr\) as in the end of the proof for Case 1. In Case 1, a key is (2.10) which is due to \(\frac{\pi}{2} \leq \angle qpr < \angle \tilde{qpr}\); but here the ‘bad’ of \(\angle qpr\) means that \(\angle qpr > \angle \tilde{qpr}\). However, the CBA-property of \(x\) here with \(\frac{\pi}{2} \leq \angle qpr\) implies the acuteness of \(\angle qpr\) directly as long as \(U_x\) is small enough.

**Proof for Case 4.**

In this case, we should prove (2.23) around a CBB-type point \(x \in X\). If it is not true, then similarly, under the assumption that \(X\) is not of curvature \(\leq k\) around \(x\), in \(U_x\) (in (2.23)) we just need to locate a triangle contradicting (2.24), i.e. a triangle satisfying the lemma right below.

**Lemma 2.3.** Let \(x \in X\) be a CBB-type point. If \(X\) is not of curvature \(\leq k\) around \(x\), and if a sufficiently small neighborhood \(U_x\) of \(x\) satisfies (2.24), then there is a triangle \(\triangle qpr \subset U_x\) such that \(|qs| = |qpr|\) and \(|qs| > |q\tilde{s}|\) for some \(s \in [pr]\) and \(\tilde{s} \in [p\tilde{r}]\) with \(|\tilde{s}p| = |sp|\), where \([\tilde{p}\tilde{r}]\) belongs to the comparison triangle \(\Delta \tilde{q}\tilde{p}\tilde{r} \subset S^2_k\) of \(\Delta qpr\).

Actually, the proofs for Cases 1-3 mainly show a corresponding Lemma 2.3. Compared with them, a main difficulty here is that we can not conclude (2.13) because we have no inequalities in (2.12) as in Cases 1-2 nor the CBA-property in Case 3. Another main difficulty here appears in looking for a triangle with an acute ‘bad’ angle. In Cases 1-3, a ‘bad’ angle leads to a situation where we can apply Lemma 2.5 or (2.2.3) to locate a smaller triangle with a ‘bad’ angle. And step by step, we can locate the desired triangle. However, in Case 4, such a method fails when we try to apply (2.2.1) unless there is a unique minimal geodesic between any two points in \(U_x\).

To overcome the second difficulty right above, we have the following key observation from (2.24).

**Lemma 2.4.** Let \(x \in X\) be a CBB-type point, and let \(U_x\) be a sufficiently small neighborhood of \(x\) satisfying (2.24). Then there is a unique minimal geodesic between any two distinct points in \(U_x\).

In the proof of Lemma 2.4, we need the following property of CBB-type Alexandrov spaces.

**Lemma 2.5 ([BGP], [LR]).** Let \(x \in X\) be a CBB-type point. Then there is a sufficiently small neighborhood \(U\) of \(x\) such that if there are two minimal geodesics between two points \(r_1\) and \(r_2\) in \(U\), then they form an angle less than \(\pi\) at \(r_1\) or \(r_2\).

**Proof of Lemma 2.4.**

We argue by contradiction. Let \(r_1\) and \(r_2\) be two points in \(U_x\), and assume that there are two minimal geodesics between them, denoted by \([r_1,r_2]_1\) and \([r_1,r_2]_2\). By Lemma 2.5, \([r_1,r_2]_1\) and \([r_1,r_2]_2\) form an angle less than \(\pi\) at \(r_1\) or \(r_2\), say \(r_1\), i.e. \(|\angle r_1^{\tilde{r}_1}_1| = \angle r_1^{\tilde{r}_1}_2| < \pi\). Then, by considering \(\Sigma_{r_1} X\) (for it refer to Section 1), it is easy to see that there is a minimal geodesic \([r_1,q]\) such that

\[
|\angle r_1^{\tilde{r}_1}(\angle r_1^{\tilde{r}_1})_1| < |\angle r_1^{\tilde{r}_1}(\angle r_1^{\tilde{r}_1})_2| < \frac{\pi}{2}
\]  

(in particular, if \(|\angle r_1^{\tilde{r}_1}(\angle r_1^{\tilde{r}_1})_2| < \frac{\pi}{2}\), we can let \([r_1,q] = [r_1,r_2]_1\)). We select \(q_j \in [r_1]\) \(\setminus \{r_1\}\) such that \(q_j \to r_1\) as \(j \to \infty\). Note that, without loss of generality, we can assume that \(|\angle r_1^{\tilde{r}_1}(\angle r_1^{\tilde{r}_1})_1| = |\angle r_1^{\tilde{r}_1}(\angle r_1^{\tilde{r}_1})_2|\).

By Lemma 2.4 it follows that, as \(j \to \infty\),

\[
|r_2q_j| = |r_1r_2| - |r_1q_j| \cos |\angle r_1^{\tilde{r}_1}(\angle r_1^{\tilde{r}_1})_1| + o(|r_1q_j|).
\]
On the other hand, by Lemma 1.14, \(|\tilde{q}_j\| < \frac{\pi}{2}\) implies that there is \(q_j \in [r_1 r_2]^2\) such that \(|q_j \tilde{q}_j| = |q_j [r_1 r_2]|\). And by Lemma 1.8, we have that, as \(j \to \infty\),

\[
|q_j \tilde{q}_j| = |r_1 r_2| - |r_1 \tilde{q}_j| = |r_1 r_2| - |r_1 q_j| \cos \| r_1 q_j \| + o(|r_1 q_j|).
\] (2.28)

It follows from (2.28) that \(|q_j \tilde{v}_j| < |r_2 \tilde{v}_j|\) for sufficiently large \(j\). Since \(U_x\) can be sufficiently small, \(|q_j \tilde{v}_j| < |r_2 \tilde{v}_j|\) implies that \(\tilde{Z} q_j \tilde{q}_j r_2 < \frac{\pi}{2}\), which contradicts (2.21).

In order to solve the first difficulty mentioned above, we will use the following technical property of CBB-type Alexandrov spaces, especially (2.6.2), in Step 4 of the proof of Lemma 2.3 below.

**Lemma 2.6.** Let \(X\) be a complete Alexandrov space with curvature \(\geq \kappa\), and let \(p, q_i, r_i \in X\) with \(q_i \to p\) and \(r_i \to p\) as \(i \to \infty\). Then the following holds:

1. (BGP) As \(i \to \infty\), for any triangle \(\triangle p q_i r_i\), we have that

\[
\angle p q_i r_i - \tilde{Z}_\kappa p q_i r_i \to 0, \quad \angle p q_i r_i - \tilde{Z}_\kappa p q_i r_i \to 0, \quad \angle p q_i r_i - \tilde{Z}_\kappa p q_i r_i \to 0.
\]

2. Additionally, given \([p q_i] \ni r_i\) and \([q_i r_i] \ni s_i\), if there is \(c_1 \in (0, 1)\) and \(c_2 > 0\) such that

\[
|q_i s_i| < c_1 |q_i r_i| \quad \text{and} \quad \min \{\tilde{Z}_\kappa p q_i s_i, \tilde{Z}_\kappa p q_i s_i, \tilde{Z}_\kappa p q_i s_i\} > c_2
\] (2.29)

for all \(i\), then as \(i \to \infty\), for any triangle \(\triangle p q_i s_i\), we have that

\[
\angle p q_i s_i - \tilde{Z}_\kappa p q_i s_i \to 0, \quad \angle p q_i s_i - \tilde{Z}_\kappa p q_i s_i \to 0, \quad \angle p q_i s_i - \tilde{Z}_\kappa p q_i s_i \to 0.
\]

**Proof.** We just need to prove (2.6.2).

First of all, by the reason for (1.2), we know that \(0 \leq \angle p q_i s_i - \tilde{Z}_\kappa p q_i s_i \leq \angle p q_i r_i - \tilde{Z}_\kappa p q_i r_i\), so it follows from (2.6.1) that

\[
\angle p q_i s_i - \tilde{Z}_\kappa p q_i s_i \to 0 \quad \text{as} \quad i \to \infty.
\] (2.30)

Next, we show that \(\angle q_i s_i q_i - \tilde{Z}_\kappa q_i s_i q_i \to 0\) as \(i \to \infty\). Consider the point \(u_i \in [q_i r_i] \) with \(|u_i-q_i| = 2|s_i-q_i|\) or \(u_i = r_i\) if \(|q_i s_i| < \frac{1}{2} |q_i r_i|\) or \(|q_i s_i| \geq \frac{1}{2} |q_i r_i|\) respectively. Let \(\triangle \tilde{q}_i \tilde{u}_i \tilde{u}_i \subset S^2\) be a comparison triangle of \(\triangle q_i u_i u_i\) and let \(\tilde{s}_i \in [\tilde{q}_i \tilde{u}_i]\) such that \(|\tilde{q}_i \tilde{u}_i| = |q_i u_i|\). By Definition 1.12, we know that \(|p_i s_i| = |\tilde{p}_i \tilde{s}_i|\). On the other hand, by the same reason for (2.20), we have that \(\angle p_i q_i u_i - \tilde{Z}_\kappa p_i q_i u_i \to 0\) as \(i \to \infty\). Plus (2.29) and by Theorem 1.3 we get that \(|p_i s_i|\) is almost equal to \(|\tilde{p}_i \tilde{s}_i|\); precisely,

\[
\lim_{i \to \infty} \frac{|p_i s_i| - |\tilde{p}_i \tilde{s}_i|}{|p_i s_i|} = 0.
\] (2.31)

Together with (2.29), this implies that

\[
\tilde{Z}_\kappa q_i s_i p_i - \tilde{Z}_\kappa \tilde{q}_i \tilde{s}_i \tilde{p}_i \to 0 \quad \text{and} \quad \tilde{Z}_\kappa u_i s_i p_i - \tilde{Z}_\kappa \tilde{u}_i \tilde{s}_i \tilde{p}_i \to 0 \quad \text{as} \quad i \to \infty.
\] (2.32)

Since \(\angle q_i s_i p_i \geq \tilde{Z}_\kappa q_i s_i p_i\) and \(\angle u_i s_i p_i \geq \tilde{Z}_\kappa u_i s_i p_i\) (by Theorem 1.3), and \(\angle q_i s_i p_i + \angle u_i s_i p_i = \pi\) and \(\tilde{Z}_\kappa \tilde{q}_i \tilde{s}_i \tilde{p}_i + \tilde{Z}_\kappa \tilde{u}_i \tilde{s}_i \tilde{p}_i = \pi\), it follows from (2.32) that

\[
\angle q_i s_i p_i - \tilde{Z}_\kappa q_i s_i p_i \to 0 \quad \text{and} \quad \angle u_i s_i p_i - \tilde{Z}_\kappa u_i s_i p_i \to 0 \quad \text{as} \quad i \to \infty.
\]

At last, we show that \(\angle q_i s_i p_i - \tilde{Z}_\kappa q_i s_i p_i \to 0\) as \(i \to \infty\). Similarly, we consider \(v_i \in [q_i p]\) with \(|v_i q_i| = 2|p_i q_i|\) or \(v_i = p\) when \(|p_i q_i| < \frac{1}{2} |q_i p|\) or \(|p_i q_i| \geq \frac{1}{2} |q_i p|\) respectively, and a comparison triangle \(\triangle \tilde{q}_i \tilde{v}_i \tilde{v}_i \subset S^2\) of \(\triangle q_i s_i v_i\) and \(\tilde{v}_i \in [\tilde{q}_i \tilde{v}_i]\) with \(|\tilde{q}_i \tilde{v}_i| = |q_i v_i|\). It is easy to see that (2.31) still holds in the situation here. And if we can show

\[
\tilde{Z}_\kappa s_i p_i q_i - \tilde{Z}_\kappa s_i p_i q_i \to 0 \quad \text{and} \quad \tilde{Z}_\kappa s_i p_i u_i - \tilde{Z}_\kappa s_i p_i u_i \to 0 \quad \text{as} \quad i \to \infty.
\] (2.33)
(similar to \(2.32\)), then we can conclude that \(\angle q_i p_i s_i - \tilde{\angle} s_i q_i p_i s_i \to 0\) as \(i \to \infty\). Indeed, we can similarly show \(2.33\) except possibly when \(|q_i p_i| > \frac{1}{2} |q_i p|\). Note that \(p_i\), unlike \(s_i\) satisfying \(|q_i s_i| < c_1 |q_i r_i|\), may be sufficiently close to \(p\) and even equal to \(p\). When \(\frac{1}{2} |q_i p| < |q_i p_i| (\leq |q_i p|)\), by the latter part of \(2.29\) there is \(c_3 > 0\) such that \(\tilde{\angle} s_i q_i p > c_3\) and \(\tilde{\angle} s_i q_i p s_i > c_4\) for all \(i\). Then plus ‘\(\angle q_i p s_i - \tilde{\angle} s_i q_i p s_i \to 0\) as \(i \to \infty\) (by (2.6.1))’ and \(2.31\), we can apply the Law of Sine to conclude \(2.33\).

We will end this section with proving Lemma \(2.3\) (and so the proof for Case 4 is completed).

**Proof of Lemma \(2.3\)**

First of all, in this proof, we can assume that there is a **UNIQUE** minimal geodesic between any two distinct points in \(U_x\) (see Lemma \(2.4\)).

Since it is assumed that \(X\) is not of curvature \(\leq k\) around \(x\), by Theorem \(1.3\) there is a triangle \(\triangle pqr \subset U_x\) containing a ‘bad’ angle, say \(\angle pqr\) (i.e. \(\angle pqr > \tilde{\angle} qpr\)). Then similar to the existence of \(\tilde{s}\) and \(\tilde{t}\) in the proof for Case 1, there is \(\tilde{s} \in \{p\} \setminus \{q\}\) and \(\tilde{t} \in \{p\} \setminus \{q\}\) such that, for all \(s \in \{p\} \setminus \{q\}\) and \(t \in \{p\} \setminus \{q\}\),

\[
|\tilde{s}| > |\tilde{t}|, |\tilde{s}| > |\tilde{t}|, |\tilde{s}| = |\tilde{t}| = |\tilde{t}| = |\tilde{t}|, \quad \text{and} \quad \tilde{\angle} p\tilde{s} - \tilde{\angle} q\tilde{p} = \angle pqr - \angle qpr,
\]

(2.34)

where \(\tilde{s}, \tilde{t}, \tilde{t}, \tilde{t}\) belong to the comparison triangle \(\tilde{\triangle} p\tilde{q}\tilde{p} \subset S^2_k\) of \(\triangle pqr\) and correspond to \(s, t, \tilde{t}, \tilde{t}\) respectively with \(\tilde{s} \in \{p\}, |\tilde{s}| = |\tilde{t}| = |\tilde{t}|, \text{etc.}

Our strategy is also to look for a \(\triangle pqr\) with a ‘bad’ angle \(\angle pqr\) such that the corresponding \(\tilde{\triangle} p\tilde{s}\tilde{t}\) is the desired triangle. We will fulfill the task through the following four steps based on a general \(\triangle pqr\) in which \(\angle pqr\) is a ‘bad’ angle.

(In Cases 1-3, for any \(\triangle pqr\) with ‘bad’ angle \(\angle pqr\), we can conclude that at least one of \(\angle p\tilde{s}\) and \(\angle p\tilde{t}\) is less than \(\frac{\pi}{2}\), so it suffices to find a triangle with an acute ‘bad’ angle. Unfortunately, as mentioned above, in the situation here we cannot conclude such a property for a general triangle with a ‘bad’ angle.)

**Step 1.** To show that \(\angle pqr\) can be chosen to satisfy that there is at most one point \(t \in \{p\} \setminus \{q\}\) such that \(|qt|\) is perpendicular to \(|pr|\).

Note that it suffices to consider the case where there are two distinct points \(t_1, t_2 \in \{p\} \setminus \{q\}\) such that \(\angle q t_2 = \angle q t_1 = \frac{\pi}{2}\). Claim: up to a new choice, \(t_i\) satisfies that either \(\angle q t_1 = \angle q t_2 = \frac{\pi}{2}\) for all \(t \in \{t_1 t_2\}\), or one of \(\angle q t_i\) \((i = 1, 2)\) is less than \(\frac{\pi}{2}\) for all \(t \in \{t_1 t_2\}\). In fact, if there is \(t \in \{t_1 t_2\}\) such that \(\angle q t_1 < \frac{\pi}{2}\), then \(\angle q t_1 < \frac{\pi}{2}\) for \(t\) sufficiently close to \(t\) (by Lemma \(1.4\)), which implies the claim.

If \(\angle q t_1 = \angle q t_2 = \frac{\pi}{2}\) for all \(t \in \{t_1 t_2\}\), then it has to hold that \(|qt| = |qt_1| = |qt_2|\) by Lemma \(1.4\).

Since \(U_x\) can be sufficiently small, it follows that \(\angle q t_1 < \frac{\pi}{2}\), which contradicts \(\angle q t_1 = \angle q t_2 = \frac{\pi}{2}\).

If \(\angle q t_1 < \frac{\pi}{2}\) or \(\angle q t_2 < \frac{\pi}{2}\) for all \(t \in \{t_1 t_2\}\), \(\angle pqr\) can be chosen to be \(\angle q t_1 t_2\). Note that \(\angle q t_1 t_2 = \angle q t_2 t_1 = \frac{\pi}{2}\), and at least one of \(\angle q t_1 t_2\) and \(\angle q t_2 t_1\) is less than \(\frac{\pi}{2}\) as long as \(U_x\) is small enough; i.e., \(\angle q t_1 t_2\) has a ‘bad’ angle.

**Step 2.** To show that there is \(\{p\} \setminus \{q\}\) such that \(\angle pqr\) is acute and ‘bad’ in \(\triangle pqr\).

Since \(\angle pqr > \tilde{\angle} qpr\), by Lemma \(1.4\) there is corresponding \(r' \in \{p\} \setminus \{q\}\) and \(\tilde{r} \in \{p\} \setminus \{q\}\) which satisfy \(2.25\) (cf. \(2.14\)). Then similarly we can apply \(2.21\) to conclude that \(\triangle q r' q r'\) or \(\triangle q r' q r'\) contains a ‘bad’ angle \(\angle q r' q r'\) or \(\angle q r' q r'\) respectively (cf. \(2.15\)). Moreover, as in Case 1 (see the end of the proof for Case 1), up to repeating such a cutting operation finite times we can assume that \(|pq| \ll |pq|\) which implies that \(\angle k p q r < \frac{\pi}{2}\), and thus by \(2.21\) again we can conclude that

\[
\angle q r' p\quad \text{and} \quad \angle q r' r\quad \text{are ‘bad’ angles in } \triangle q r' p\quad \text{and} \quad \triangle q r' r\quad \text{respectively.}
\]

(2.35)

Since there is at most one point \(t \in \{p\} \setminus \{q\}\) such that \(\angle q t p = \frac{\pi}{2}\) (by Step 1), we can assume that \(\{p\} \setminus \{q\}\) or \(\{t\} \setminus \{p\}\), say \(\{r\} \setminus \{p\}\), there is no point \(t\) such that \(\angle q t r = \frac{\pi}{2}\). Meantime, note that \(\angle q t r + \angle q t r = \pi\) for
all \( t \in [r']^\circ \) (by Lemma 1.4). Then by repeating the cutting operation on \( \Delta qr'r \) two more times, we can locate \([\hat{p}r] \subset [r'] \setminus \{r\} \subset [pr]^\circ \) such that \( \angle q\hat{p}r \) is acute and ‘bad’ in \( \Delta q\hat{p}r \).

**Step 3.** To show that there is \( \hat{r} \in [\hat{p}r] \) and \( p_i \in [\hat{p}r]^\circ \) with \( p_i \to \hat{r} \) as \( i \to \infty \) such that \( \angle q\hat{p}i \hat{r} \) is acute and ‘bad’ in \( \Delta q\hat{p}i \hat{r} \).

Let \( \Delta \hat{q}\hat{p}i \subset \mathbb{S}^2_k \) be a comparison triangle of \( \Delta q\hat{p}i \). Since \( \angle q\hat{p}i \) is ‘bad’ (i.e. \( \angle q\hat{p}i > \Delta \hat{q}\hat{p}i \)), by Lemma 1.4 ([there is \( t_1 \in [\hat{p}r] \setminus \{\hat{p}\} \) such that \( |qt_1| = |\hat{q}t_1| \) and \( |qt| > |\hat{q}t| \) for all \( t \in [\hat{p}r]^\circ \), where \( t_1, t \in [\hat{p}r] \) with \( |t_1\hat{p}| = |t_1\hat{p}| \) and \( |t\hat{p}| = |t\hat{p}| \)). As a result, by (2.24), it is not hard to see that

\[
|qt| \neq |q\hat{p}t_1| \quad \text{for any} \quad t \in [\hat{p}t_1]^\circ. 
\] (2.36)

And due to ‘\( \angle q\hat{p}r < \frac{\pi}{2} \)’ (see Step 2), (2.36) has a more precise version

\[
|qt| > |qt_1| \quad \text{for any} \quad t \in [\hat{p}t_1]^\circ, 
\] (2.37)

which, by Lemma 1.4, implies that

\[
\angle qt_1\hat{p} \geq \frac{\pi}{2}. 
\] (2.38)

Note that \( \Delta \hat{q}\hat{p}t_1 \) is a comparison triangle of \( \Delta q\hat{p}t_1 \), so \( \angle q\hat{p}t_1 \) is also ‘bad’ in \( \Delta q\hat{p}t_1 \). Together with ‘\( \hat{p} \in [pr]^\circ \)’ (see Step 2) and by Lemma 1.7 this implies that \( \angle q\hat{p}t_1 \) is ‘bad’ in \( \Delta q\hat{p}t_1 \) for \( t \in [\hat{p}t_1]^\circ \) sufficiently close to \( \hat{p} \). Hence, one of the following two cases must happen:

- for all \( t \in [\hat{p}t_1]^\circ \), \( \angle qt_1 \) is ‘bad’ in \( \Delta q\hat{p}t_1 \);
- there is \( t_* \in [\hat{p}t_1]^\circ \) such that \( \angle qt_1 \) is ‘bad’ in \( \Delta q\hat{p}t_1 \) for all \( t \in [\hat{p}t_*] \) except \( t_* \).

In the former case, we can put \( \hat{r} = t_1 \); otherwise, \( \angle qt_1 \geq \frac{\pi}{2} \) for all \( t \in [\hat{p}t_1]^\circ \) sufficiently close to \( t_1 \), and thus \( |qt| \leq |qt_1| \) by Lemma 1.4 which contradicts (2.37).

In the latter case, we shall put \( \hat{r} = t_* \) by showing that there is \( p_i \in [\hat{p}t_*]^\circ \) with \( p_i \to t_* \) as \( i \to \infty \) such that \( \angle q\hat{p}t_* \) is acute and ‘bad’ in \( \Delta q\hat{p}t_* \).

We first observe that, for any \( t \in [\hat{p}t_*]^\circ \setminus \{t_*\} \), at least one of \( \angle qt_* \) and \( \angle qt_* \) is a ‘bad’ angle of \( \Delta qt_* \). Otherwise, \( \angle qt_* \leq \hat{z} \angle qt_* \) and \( \angle qt_* \leq \hat{z} \angle qt_* \). Consider \( \Delta \hat{q}\hat{t}t_* \subset \mathbb{S}^2_k \), a comparison triangle of \( \Delta qt_* \), and let \( [\hat{t}_*] \subset [\hat{z}] \subset \mathbb{S}^2_k \) with \( |\hat{z}| = |t_*| \). Since \( \angle qt_* \geq \hat{z} \angle qt_* \) (by the badness of \( \angle qt_* \)), ‘\( \angle qt_* \leq \hat{z} \angle qt_* \)’ implies that \( |qt_*| < |\hat{z}| \). Plus ‘\( \angle qt_* < \hat{z} \angle qt_* \)’ (note that \( \angle qt_* \) is not ‘bad’ in \( \Delta q\hat{p}t_* \)), we conclude that \( \angle qt_* < \hat{z} \angle qt_* \), and thus by Lemma 1.4 we have that \( \angle qt_* > \hat{z} \angle qt_* \), a contradiction.

Based on the observation right above, for \( t \to t_* \), we can conduct a cutting operation on \( \Delta qt_* \) as in Step 2 to locate a \( \hat{t} \in [\hat{t}_*]^\circ \) such that \( \angle q\hat{p}t_* \) is ‘bad’ in \( \Delta q\hat{p}t_* \) (cf. (2.33)). Namely, we can locate \( p_i \in [\hat{p}t_*]^\circ \) with \( p_i \to t_* \) as \( i \to \infty \) such that \( \angle q\hat{p}t_* \) is ‘bad’ in \( \Delta q\hat{p}t_* \). On the other hand, we claim that \( \angle qt_* < \hat{z} \), which implies that \( \angle q\hat{p}t_* < \hat{z} \) (by Lemma 1.7). In fact, the claim follows from that \( \angle qt_* \leq \hat{z} \angle qt_* \) (note that \( \angle qt_* \) is not ‘bad’ in \( \Delta q\hat{p}t_* \)) and \( \hat{z} \angle qt_* < \frac{\pi}{2} \) (note that \( |qt_*| > |qt_1| \) by (2.37) and \( U_x \) is sufficiently small).

As shown in the beginning of the proof, for each \( \Delta q\hat{p}r \), there is \( \hat{s}_i \in [p_ri] \setminus \{p_i\} \) and \( \hat{t}_i \in [p_ri] \setminus \{p_i\} \) such that the corresponding (2.34) holds for all \( s \in [p_ri]^\circ \) and \( t \in [p_ri] \).

**Step 4.** To show that \( \Delta p_i \hat{s}_i \) is our desired triangle for large \( i \) (and thus the proof is done).

Note that if \( |\hat{s}_i\hat{t}_i| \geq |\hat{s}_i\hat{p}_i| \) or \( |\hat{s}_i\hat{t}_i| \geq |\hat{t}_i\hat{p}_i| \), say \( |\hat{s}_i\hat{t}_i| \geq |\hat{t}_i\hat{p}_i| \), then by Lemma 1.4 the acuteness of \( \angle \hat{t}_i p_i \hat{s}_i \) (\( \angle q\hat{p}r \)) implies that \( |\hat{t}_i| = |\hat{t}_i| |p_i| |\hat{s}_i| \) for some \( s \in [p_ri]^\circ \). Then, by the inequalities in the corresponding (2.34) for \( \hat{s}_i \) and \( \hat{t}_i \), we can conclude that \( \Delta p_i \hat{s}_i \) is our desired triangle.

Hence, in the rest of the proof, we only need to consider the case where

\[
|\hat{s}_i\hat{t}_i| < |\hat{s}_i\hat{p}_i| \quad \text{and} \quad |\hat{s}_i\hat{t}_i| < |\hat{t}_i\hat{p}_i|. 
\] (2.39)

In this case, it suffices to show that one of \( \Delta \hat{s}_i \hat{t}_i p_i \) and \( \Delta \hat{t}_i \hat{s}_i p_i \) is less than \( \frac{\pi}{2} \) for large \( i \), which together with the acuteness of \( \Delta \hat{t}_i p_i \hat{s}_i \) also implies that \( \Delta \hat{s}_i \hat{t}_i \hat{s}_i \) is our desired triangle by Lemma 1.4.
The main tool here is \((2.6.2)\). In order to apply it, we need to verify its conditions in the situation here. We first note that \((2.39)\) with \(|p_i t_i| \leq |p_i \bar r| \to 0\) as \(i \to \infty\) implies that \(|p_i t_i| \to 0\) as \(i \to \infty\), and thus there is \(r_i \in [p_i q]\) such that

\[
|p_i t_i| = \frac{1}{2} |p_i r_i|.
\]

On the other hand, note that \(|p_i \bar s_i| \leq |p_i \bar r| \in [p_\bar r]^\circ\), so by Lemma 1.7

\[
\angle \bar t_i p_i \bar s_i = \angle q p_i \bar r \quad \text{as} \quad i \to \infty.
\]

Moreover, we can assume that \(X\) is of curvature \(\geq k_x\) around \(x\), so we have that \(\lim_{i \to \infty} (\angle \bar t_i p_i \bar s_i - \hat Z_{k_x} \bar t_i p_i \bar s_i) = 0\) by \((2.6.1)\), which together with \((2.39)\) and \((2.41)\) implies that there is a \(c > 0\) such that

\[
\min \{\hat Z_{k_x} \bar s_i p_i \bar t_i, \hat Z_{k_x} p_i \bar s_i \bar t_i, \hat Z_{k_x} p_i \bar t_i \bar s_i\} > c.
\]

Note that \((2.40)\) and \((2.42)\) enable us to apply \((2.6.2)\) on \(\triangle \bar t_i p_i \bar s_i\) to conclude that

\[
|\angle \bar s_i \bar t_i p_i - \hat Z_{k_x} \bar s_i \bar t_i p_i| + |\angle \bar t_i p_i \bar s_i - \hat Z_{k_x} \bar t_i p_i \bar s_i| + |\angle \bar s_i p_i - \hat Z_{k_x} \bar s_i p_i| \to 0\quad \text{as} \quad i \to \infty.
\]

Note that

\[
\hat Z_{k_x} \bar s_i \bar t_i p_i + \hat Z_{k_x} \bar t_i p_i \bar s_i + \hat Z_{k_x} \bar s_i p_i \to \pi\quad \text{as} \quad i \to \infty.
\]

Then plus \((2.41)\) we can conclude that at least one of \(\angle \bar s_i \bar t_i p_i\) and \(\angle \bar t_i \bar s_i p_i\) is less than \(\frac{\pi}{2}\) for large \(i\). \(\Box\)

### 3 Proof of Theorem A for curvature \(\equiv k\) on \(X^\circ\)

In this section, we will show the rigidity part of Theorem A, i.e., we will prove that \(X^\circ\), the interior part of \(X\), is a Riemannian manifold with sectional curvature equal to \(k\) if each \(x \in X\) satisfies that

for any \(q \in U_x\) and \([r_1 r_2] \subset U_x\), if there is \(p \in [r_1 r_2]^\circ\) such that \(|qp| = |q[r_1 r_2]|\), then \(\hat Z_k q p r_s = \frac{\pi}{2}\). \((3.1)\)

Note that, by the conclusion in Theorem A for curvature \(\geq k\), \((3.1)\) implies clearly that \(X\) is of curvature \(\geq k\) around each \(x \in X\) (i.e. \(X\) is an Alexandrov space with curvature \(\geq k\)). Hence, at each \(z \in X\), we can consider the space of directions and the tangent cone, \(\Sigma_z X \) and \(C_z X\), which are still Alexandrov spaces of curvature \(\geq 1\) and \(\geq 0\) respectively. (Refer to Section 1 for \(\Sigma_z X\) and \(C_z X\).) An easy observation from \((5.1)\) is that \(\Sigma_z X\) and \(C_z X\) also satisfy a corresponding property of \((3.1)\), i.e. Lemma \((3.1)\) below. This makes it possible to apply the inductive assumption on \(\Sigma_z X\) which is of dimension one less than \(X\) and has an empty boundary if \(z \in X^\circ\).

**Lemma 3.1.** Let \(X\) be a complete Alexandrov space, and let \(U_x\) be a neighborhood of \(x \in X\) satisfying \((3.1)\), and let \(z \in U_x\). Then for all \(\bar q \in C_z X\) (resp. \(\in \Sigma_z X\)) and \([\bar r_1 \bar r_2] \subset C_z X\) (resp. \(\subset \Sigma_z X\)),

\[
\text{if there is } \bar p \in [\bar r_1 \bar r_2]^\circ \text{ such that } |\bar q \bar p| = |\bar q[\bar r_1 \bar r_2]|, \text{ then } \hat Z_0 (\text{resp. } 1) \bar q \bar p \bar r_s = \frac{\pi}{2}.
\]

*Proof.* By definition, \(C_z X\) is the cone over \(\Sigma_z X\) (\[(BGP)\]) \(^3\). So, it is not hard to see that the property of \((4.2)\) for \(C_z X\) implies that for \(\Sigma_z X\). In order to see \((3.2)\) for \(C_z X\), one just needs to notice that \(C_z X\) is the limit space of \((\lambda X, z)\) as \(\lambda \to +\infty\) by Lemma 1.8 \(\Box\)

Note that \((3.1)\) is contained in \((2.24)\). Then, since \(X\) is of curvature \(\geq k\) around \(x\), by Lemma 2.4 we have another easy observation:

\(^3\)The metric on \(C_z X\) is defined from the Law of Cosine on \(\mathbb{R}^2\) by viewing distances on \(\Sigma_z X\) as angles (\[(BGP)\]).
Lemma 3.2. Let $X$ be a cone over a circle with perimeter less than $2\pi$ (an Alexandrov space of curvature $\geq 0$). Then around its vertex there is no neighborhood such that $\delta 0$ holds with respect to $k = 0$.

Proof. The lemma is an easy corollary of Lemma 2.4 because we can find two points sufficiently close to the vertex of $X$ between which there are two minimal geodesics.

To $q,p,[r_1 r_2]$ in (3.1), we associate $\tilde{q} \in S_k^2$ and $\tilde{p} \in [\tilde{r}_1 \tilde{r}_2] \subset S_k^2$ with $|\tilde{r}_1 \tilde{r}_2| = |r_1 r_2|$, $|\tilde{q} r_i| = |q r_i|$ and $|\tilde{r}_1 \tilde{p}| = |r_1 p|$. Since $X$ is of curvature $\geq k$ on $U_x$, we know that $|q p| \geq |\tilde{q} \tilde{p}|$ (by Definition 1.2) and any $|q p|$ is perpendicular to $|r_1 r_2|$ at $p$ (by Lemma 1.9). Then we have the third easy observation from (3.1):

$$|q p| = |\tilde{q} \tilde{p}| \text{ (and } |\tilde{q} \tilde{p}| \text{ has to be perpendicular to } |\tilde{r}_1 \tilde{r}_2|).$$ (3.3)

Thereby, the following rigidity version of Theorem 1.3 can be applied.

Theorem 3.3 (GM). Let $X$ be a complete Alexandrov space with curvature $\geq k$, and let $q \in X$ and $[pr] \subset X$. If there is $s \in [pr]^{\circ}$ such that $|qs| = |\tilde{q} \tilde{s}|$, where $\tilde{q} \in S_k^2$ and $\tilde{s} \in [\tilde{p} \tilde{r}] \subset S_k^2$ with $|\tilde{q} \tilde{p}| = |q p|$, $|\tilde{r} s| = |pr|$, $|\tilde{q} r| = |qr|$ and $|ps| = |\tilde{p} \tilde{s}|$, then there is $[pq]$ and $[qr]$ such that $[pr]$ together with them bounds a convex surface which can be embedded isometrically into $S_k^2$.

Based on the three observations above, we can prove the rigidity part of Theorem A.

Proof for the rigidity part of Theorem A.

Note that our assumption is that (3.1) holds for each $x \in X$. So, as mentioned above, $X$ is an Alexandrov space with curvature $\geq k$ and dim($X$), the dimension of $X$, can be defined. We will give a proof by induction on dim($X$).

We first consider the case where dim($X$) = 2. It suffices to show that, for any $p \in X^\circ$, there is a convex surface $S$ (\subseteq $X$) which can be embedded isometrically into $S_k^2$ such that $p \in S^2$.

Since $p \in X^\circ$, $\Sigma_p X$ is a circle with perimeter $\leq 2\pi$ (BGP). Since $C_p X$ is the cone over $\Sigma_p X$, by Lemma 3.2 the perimeter of $\Sigma_p X$ must be equal to $2\pi$, and thus $C_p X$ is a plane. Let $\xi_i \in \Sigma_p X$, $i = 1, 2, 3$, be $\frac{2\pi}{3}$-separated (i.e. $|\xi_i \xi_j| = \frac{2\pi}{3}$ for $i \neq j$). We know that there are $\{q_{il}\}_{i=1}^3 \subset X$ with $|q_{i1} p| = |q_{i2} p| = |q_{i3} p| \to 0$ and the directions $q_{i1}^p \to \xi_i$ as $l \to \infty$ (BGP). On the other hand, we know that $C_p X$ is the limit space of $\left(\frac{1}{|pq_{il}|} X, p\right)$ as $l \to \infty$ by Lemma 1.8. It follows that $q_{i1} \to q_i$ as $\left(\frac{1}{|pq_{i1}|} X, p\right) \to C_p X$ with $|pq_{il}| = 1$ and $\gamma_i^p = \xi_i$ in $C_p X$. Note that as $\left(\frac{1}{|pq_{il}|} X, p\right) \to C_p X$ any triangle $\Delta q_{i1} q_{i2} q_{i3} \to \Delta q_i q_{i2} q_{i3}$, an equilateral triangle. It then is easy to see that, for sufficiently large $l$, $|q_{i3} q_{i1} q_{i2}| = |q_{i3} q_{i1} q_{i2}|$ for some $q \in [q_{i1} q_{i2}]^{\circ}$. Then by (3.3) and Theorem 3.3 $\Delta q_{i1} q_{i2} q_{i3}$ bounds a convex surface $S_i$ which can be embedded isometrically into $S_k^2$ (note that there is a unique minimal geodesic between any two points around $p$ by Lemma 2.4).

We claim that $S_l$ for large $l$ is just our desired surface. In fact, $S_l$ converges to the domain bounded by $\Delta q_{i1} q_{i2} q_{i3}$ in the plane $C_p X$ as $\left(\frac{1}{|pq_{i1}|} X, p\right) \to C_p X$. It follows that, for large $l$, there is $\tilde{p} \in S_i^2$ such that $|p \tilde{p}| = |p S_i|$. Since $S_l$ is a convex surface in $X$ and dim($X$) = 2, it must hold that $p = \tilde{p}$, i.e. $p \in S_i^2$.

We now assume that dim($X$) = $n \geq 3$. Similarly, for any $p \in X^\circ$, it suffices to show that $p$ lies in the interior part of a convex domain (in $X$) which can be embedded isometrically into $S_k^n$.

We first show that $C_p X$, the cone over $\Sigma_p X$, is isometric to the Euclidean space $R^n$, i.e. $\Sigma_p X$ is isometric to the unit sphere $S_k^{n-1}$. Note that $\Sigma_p X$ is a complete Alexandrov space with curvature $\geq 1$, and $(\Sigma_p X)^o = \Sigma_p X$ with dimension equal to $n - 1$ because $p \in X^\circ$. By Lemma 3.2 we can apply the inductive assumption on $\Sigma_p X$ to conclude that it is a complete Riemannian manifold with sectional curvature equal to 1. Then we need only to show that $\Sigma_p X$ is simply connected. If it is not true, then by classical results in Riemannian geometry there is a closed geodesic, a circle $S^1 \subset \Sigma_p X$, with perimeter less than $2\pi$. Note that the cone over the $S^1$ is convex in $C_p X$, which is impossible by Lemma 3.2.
Similarly, since $\Sigma_pX$ is isometric to $S_1^{n-1}$, we can select an $(\arccos \frac{1}{2})$-separated subset $\{\xi_i \in \Sigma_pX | i = 1, 2, \ldots, n + 1\}$, and $\{q_{il}\}_{l=1}^{\infty} \subset X$ with $|q_{il}| = |q_{il+1}| = \cdots = |q_{in+1}| = |q_{il}| \rightarrow 0$ and the directions $\uparrow p_i \rightarrow \xi_i$ as $l \rightarrow \infty$ and it follows that $q_{il} \rightarrow q_i$ as $(\frac{1}{|pq_{il}|}X, p) \rightarrow C_pX$ with $|pq_{il}| = 1$ and $\uparrow p_i = \xi_i$. By Theorem C, we can conclude that $x \in S$.

Claim: For sufficiently large $l$, there is a convex simplex $\Delta_l$ with vertices $q_{1l}, \ldots, q_{(n+1)l}$ which can be embedded isometrically into $S^n_0$. By the claim, we need only to show that $p \in \Delta_0^l$ for large $l$. Note that as $(\frac{1}{|pq_{il}|}X, p) \rightarrow C_pX$, $\Delta_l$ converge to the simplex with vertices $q_1, \ldots, q_{n+1}$ in $C_pX \cong \mathbb{R}^n$. It follows that, for large $l$, there is $\bar{p} \in \Delta^0_l$ such that $|p\bar{p}| = |p\Delta_l|$. Since $\Delta_l$ is a convex in $X$ and dim($\Delta_l$) = dim($X$), it must hold that $p = \bar{p}$, i.e. $p \in \Delta^0_l$.

To complete the proof, it suffices to verify the claim right above. Note that there is a unique minimal geodesic between any two points around $p$ by (4.1) and Lemma 2.4. And as in the proof for dim($X$) = 2, for large $l$, $|q_{il}| = \epsilon$ for some $q \in [q_{il}q_{il+1}]$. So, the triangle $\Delta q_{il}q_{il+1}$ bounds a convex surface $S_l$ which can be embedded isometrically into $S^n_0$ (by (4.3) and Theorem 3.3). Furthermore, there is $\bar{q}_{il} \in S^0_l$ (around the center of $S_l$) such that $|q_{il}\bar{q}_{il}| = |q_{il}S_l|$. Let $\bar{q}_{il}, i = 1, 2, 3, 4$, be the vertices of a simplex of dimension 3 with $|\bar{q}_{il}\bar{q}_{ij}| = |\bar{q}_{il}\bar{q}_{ij}|$. By applying (4.3) and Theorem 3.3 iteratively, it is not hard to see that $\bigcup_{\epsilon \in S_l} [q_{il}S]$ is convex and isometric to the simplex in $S^3_k$ with vertices $\bar{q}_{il}, \bar{q}_{il+1}, \bar{q}_{il+2}, \bar{q}_{il+3}$. And step by step, we can eventually get the desired $\Delta_l$ in the claim.

4 Proofs of Theorem C and Corollary D

Proof of Theorem C.

Let $x$ be an interior point in a complete Alexandrov space $X$ with curvature $\geq k$. As mentioned in Section 3, we can consider the space of directions and the tangent cone at $x$, $\Sigma_xX$ and $C_xX$. And by Lemma 1.8 we know that $C_xX$ is the limit space of $(\lambda X, x)$ as $\lambda \rightarrow +\infty$. It is not hard to see that if we substitute the condition $\frac{1}{|pq|^2} - 1 < \chi(\varepsilon)$ for all $[pq], [pr] \subset B_x(\varepsilon)$ with $\angle qpr = \frac{\pi}{2}$ and $\chi(\varepsilon) \rightarrow 0$ as $\varepsilon \rightarrow 0^+$ of Theorem C for the condition of Lemma 3.1, the conclusion of Lemma 3.1 for $\Sigma_xX$ and $C_xX$ still holds. Then from the proof for the rigidity part of Theorem A (in Section 3), we can conclude that $\Sigma_xX$ is isometric to the unit sphere, i.e. $x$ is Riemannian point.

$\Box$

Proof of Corollary D.

Let $x$ be an interior point in a complete CBB-type Alexandrov space $X$. If $x$ is also a CBA-type point, then by Theorems 1.3 and 1.3’ it is easy to see that there is a function $\chi(\varepsilon)$ with $\chi(\varepsilon) \rightarrow 0$ as $\varepsilon \rightarrow 0$ such that for all $[pq], [pr] \subset B_x(\varepsilon)$ with $\angle qpr = \frac{\pi}{2}$

$$\left|\frac{|qr|^2}{|pq|^2 + |pr|^2} - 1\right| < \chi(\varepsilon).$$

So, by Theorem C, $x$ is Riemannian point.
