THE HERMITE-SYLVester CRITERION FOR REAL-ROOTED POLYNOMIALS

MELVYN B. NATHANSON

ABSTRACT. A polynomial is real-rooted if all of its roots are real. This note gives a simple proof of the Hermite-Sylvester theorem that a polynomial $f(x) \in \mathbb{R}[x]$ is real-rooted if and only if an associated quadratic form is positive semidefinite.

A polynomial is real-rooted if all of its roots are real. Hermite and Sylvester \cite{1} proved that a polynomial $f(x) \in \mathbb{R}[x]$ is real-rooted if and only if a certain quadratic form is positive semidefinite. Here is a short proof of the Hermite-Sylvester theorem that uses only Lagrange interpolation.

The quadratic form associated with a real $n \times n$ matrix $H = (h_{i,j})$ is

$$Q = Q(x_1, \ldots, x_n) = \sum_{i=1}^{n} \sum_{j=1}^{n} h_{i,j} x_i x_j.$$  

This form is positive semidefinite if $Q(x_1, \ldots, x_n) \geq 0$ for all vectors $\left(\begin{array}{c} x_1 \\ \vdots \\ x_n \end{array} \right) \in \mathbb{R}^n$.

Let $f(x)$ be a polynomial of degree $n$, and let $\lambda_1, \ldots, \lambda_n$ be the (not necessarily distinct) roots of $f(x)$. Define the $k$th power sum

$$m_k = m_k(\lambda_1, \ldots, \lambda_n) = \sum_{\ell=1}^{n} \lambda_{\ell}^k.$$  

Newton’s identities \cite{2} enable the efficient computation of the numbers $m_k$ from the coefficients of $f(x)$. The Hermite matrix constructed from the polynomial $f(x)$ is the $n \times n$ matrix

$$H_f = \begin{pmatrix} m_0 & m_1 & m_2 & \cdots & m_{n-1} \\ m_1 & m_2 & m_3 & \cdots & m_n \\ m_2 & m_3 & m_4 & \cdots & m_{n+1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ m_{n-1} & m_n & m_{n+1} & \cdots & m_{2n-2} \end{pmatrix} = (h_{i,j})$$  

where $h_{i,j} = m_{i+j-2}$ for all $i, j \in \{1, \ldots, n\}$.

Let $\overline{\lambda}$ denote the complex conjugate of the complex number $\lambda$.

Lemma 1. Let \( \Lambda \) be a nonempty finite set of \( r \) complex numbers that is closed under complex conjugation, that is,
\[
\Lambda = \{ \overline{\lambda} : \lambda \in \Lambda \}.
\]

Let
\[
p(t) = \sum_{j=0}^{r-1} c_j t^j \in \mathbb{C}[t]
\]
be a polynomial of degree at most \( r - 1 \). If
\[
(1) \quad p(\lambda) = \overline{p(\lambda)}
\]
for all \( \lambda \in \Lambda \), then \( p(t) \in \mathbb{R}[t] \).

Proof. We use the fact that if polynomials \( p(t) \in \mathbb{C}[t] \) and \( q(t) \in \mathbb{C}[t] \) have degrees at most \( r - 1 \), and if \( p(\lambda) = q(\lambda) \) for all \( \lambda \) in a set of size \( r \), then \( p(t) = q(t) \). Let
\[
q(t) = \sum_{j=0}^{r-1} c_j t^j.
\]
For all \( \lambda \in \mathbb{C} \), we have \( \overline{\lambda} = \lambda \). For all \( \lambda \in \Lambda \), we have \( \overline{\lambda} \in \Lambda \), and so
\[
p(\lambda) = p(\overline{\lambda}) = p(\lambda) = \sum_{j=0}^{r-1} c_j \overline{\lambda}^j = \sum_{j=0}^{r-1} c_j \lambda^j = q(\lambda).
\]
Therefore, \( p(t) = q(t) \), and so, for all \( j \in \{0, 1, \ldots, r - 1\} \), we have \( c_j = \overline{c_j} \in \mathbb{R} \) and \( p(t) \in \mathbb{R}[t] \). This completes the proof.

Lemma 2. Let \( \Lambda = \{ \lambda_1, \lambda_2, \lambda_3, \ldots, \lambda_r \} \) be a nonempty finite set of \( r \) complex numbers that is closed under complex conjugation. Suppose that \( \lambda_1 \in \Lambda \) is not real, and that \( \lambda_2 = \overline{\lambda_1} \in \Lambda \). There exists a polynomial \( p(t) \in \mathbb{R}[t] \) of degree at most \( r - 1 \) such that
\[
(2) \quad p(\lambda_1) = i, \quad p(\lambda_2) = -i
\]
and
\[
(3) \quad p(\lambda_j) = 0 \quad \text{for all } j \in \{3, 4, \ldots, r\}.
\]

Proof. By Lagrange interpolation, there exists a polynomial \( p(t) \in \mathbb{C}[t] \) of degree at most \( r - 1 \) that satisfies (2) and (3). We have
\[
p(\lambda_1) = p(\lambda_2) = -i = \overline{i} = p(\overline{\lambda_1}).
\]
and
\[
p(\lambda_2) = p(\lambda_1) = i = \overline{-i} = p(\overline{\lambda_2}).
\]
Also, \( p(\lambda_j) = 0 = p(\overline{\lambda_j}) \) for all \( j \in \{3, 4, \ldots, r\} \). It follows from Lemma 1 that \( p(t) \in \mathbb{R}[t] \). This completes the proof.

Theorem 1 (Hermite-Sylvester). The nonconstant polynomial \( f(x) \in \mathbb{R}[x] \) is real-rooted if and only if the quadratic form \( Q_f \) constructed from the Hermite matrix \( H_f \) is positive semidefinite.
Proof. Let \( f(x) \in \mathbb{R}[x] \) be a polynomial of degree \( n \geq 1 \), and let \( \Lambda \) be the set of distinct roots of \( f(x) \). We have \( |\Lambda| = r \leq n \). Let \( \Lambda = \{\lambda_1, \lambda_2, \ldots, \lambda_r\} \). Because \( f(x) \) has real coefficients, the set \( \Lambda \) is closed under conjugation.

Extend the sequence \( \lambda_1, \lambda_2, \ldots, \lambda_r \) of \( r \) distinct roots of \( f(x) \) to the sequence \( \lambda_1, \ldots, \lambda_r, \lambda_{r+1}, \ldots, \lambda_n \) of \( n \) roots of \( f(x) \) with multiplicity. Thus, for \( j \in \{1, \ldots, r\} \), the root \( \lambda_j \) with multiplicity \( \mu_j \) appears \( \mu_j \) times in this sequence.

Let \( H_f = (h_{i,j}) \) be the Hermite matrix constructed from the polynomial \( f(x) \), and let \( Q_f \) be the quadratic form constructed from \( H_f \). For \( \left( \begin{array}{c} x_1 \\ \vdots \\ x_n \end{array} \right) \in \mathbb{R}^n \), we have

\[
Q_f(x_1, \ldots, x_n) = \sum_{i=1}^{n} \sum_{j=1}^{n} h_{i,j} x_i x_j = \sum_{i=1}^{n} \sum_{j=1}^{n} m_{i+j-2} x_i x_j
\]

where

\[
p(t) = \sum_{j=1}^{n} x_j t^{j-1} \in \mathbb{R}[t].
\]

If \( f(x) \) is real-rooted, then \( \lambda_\ell \in \mathbb{R} \) for all \( \ell \in \{1, \ldots, n\} \), and so the sum \( p(\lambda_\ell) = \sum_{j=1}^{n} x_j \lambda_\ell^{j-1} \) is real and \( p(\lambda_\ell)^2 \geq 0 \). Thus, if \( f(x) \) is real-rooted, then \( Q_f(x_1, \ldots, x_n) \geq 0 \) and the quadratic form \( Q_f \) is positive semidefinite.

Suppose that \( f(x) \) is not real-rooted. In this case, the set \( \Lambda \) contains a complex number that is not real, and \( \Lambda \) also contains its complex conjugate. We can assume that \( \lambda_1 \in \Lambda \) is not real and that \( \lambda_2 = \overline{\lambda_1} \). Note that \( \mu_1 \geq 1 \) is the multiplicity of the root \( \lambda_1 \), and that \( \mu_1 \) is also the multiplicity of the root \( \lambda_2 \). By Lemma 2, there exists a polynomial \( p(t) \in \mathbb{R}[t] \) of degree \( d - 1 \leq r - 1 \) such that

\[
p(\lambda_1) = i, \quad p(\lambda_2) = -i
\]

and

\[
p(\lambda_\ell) = 0 \quad \text{for} \quad \ell = 3, \ldots, r.
\]

Because \( r - 1 \leq n - 1 \), we can write \( p(t) = \sum_{j=1}^{n} x_j t^{j-1} \), where \( x = \left( \begin{array}{c} x_1 \\ \vdots \\ x_n \end{array} \right) \in \mathbb{R}^n \).

Note that \( x_j = 0 \) for \( j = d + 1, \ldots, n \). We obtain

\[
Q_f(x_1, \ldots, x_n) = \sum_{\ell=1}^{n} \left( \sum_{j=1}^{n} x_j \lambda_{\ell}^{j-1} \right)^2 = \sum_{\ell=1}^{n} p(\lambda_\ell)^2
\]

\[
= \mu_1 p(\lambda_1)^2 + \mu_1 p(\lambda_2)^2 = \mu_1 i^2 + \mu_1 (-i)^2
\]

\[
= -2 \mu_1 < 0.
\]

Thus, if \( f(x) \) is not real-rooted, then the quadratic form \( Q_f \) is not positive semidefinite. This completes the proof. \( \square \)
