Abstract. About 60 ADASS participants discussed the evolving roles of users, developers, and managers of astronomical data reduction software. Special emphasis was placed on the role of the user in the era of Big Data. Is it really inevitable that the increasingly ignorant user will just have to be satisfied with the standard products from data processing centres?

1. Introduction

The idea of this BoF started as compassion. Over the last 40 years, the quality of radio-astronomical observations has improved by up to 4 orders of magnitude. But for historical reasons, the data-reduction software for producing these impressive results is scattered over several different packages, each with its own user interface and user support, and its own issues with installation and maintenance. All this makes the software increasingly difficult to use. What's worse, while exciting new algorithms are toppling the old show-stoppers, they are slow to reach the user.

The present move towards pipeline processing addresses some of these problems. Well-designed pipelines are the backbone of LOFAR programmes like the LOTSS survey, or the detection of the Epoch of Reionization. However, therein looms a totalitarian hazard: pipelines tend to be black boxes that will be even less responsive to user comments than the pioneering packages, which have profited so much from their active involvement. Without the caring feed-back of the only people that can judge the end-result, pipelines too will turn into White Elephants, and stop evolving.

During preparation, the subject of this BoF evolved from compassion with the long-suffering users of our data reduction software, to the role of the scientific user in the era of Big Data. The new generation of giant radio telescopes (LOFAR, SKA) will need even more sophisticated processing to fully exploit their dazzling but expensive capabilities. But the consensus seems to be that data volumes will be too large to be moved, while self-propelled users will not have access to the necessary computing resources. So the question is whether it is really inevitable that (increasingly ignorant) users will just have to be satisfied with the standard products from data processing centers, or whether ways can be found to involve them somehow?

2. About the Discussion

About 60 people attended this BoF, despite the fact that it clashed with drinkies at the end of a long day. Because we only had an hour to deal with a rather large subject, we limited ourselves to three "sociological" Discussion Points about the roles of users and developers. We stayed away from technical issues.

These three points were discussed with gusto. However, since there tend to be few hard-core users at ADASS, and developers are thinkers rather than talkers, the debate was somewhat dominated by software managers and other generalists. Perhaps next year we should add a fourth Discussion Point about their role.

Unfortunately, our audio recording failed us, so we have endeavoured to reconstruct the essence from our poor short-term memories.

2.1. Discussion Point 1: A new eco-system for users?

It is clear that it will be harder for users to be involved in data processing in the era of Big Data. But that should not mean that they should be cut out of the loop.

For instance, users could still develop their own pipelines on their laptops, and exercise them on a succession of increasingly large subsets of their huge data volumes stored in a Processing Centre. The well-proved pipeline could then be run on the large computers of the Centre.

In this way, scientific users can still be actively involved in the development of data-processing software.

Several times in the discussion it became apparent that we are not using our resources wisely (or read: we are suffering from a lack of resources). We are also not using our outreach (e.g. documentation) effectively.

2.2. Discussion Point 2: A new eco-system for developers?

There is a perceived disconnect between algorithm development and implementation and the involvement of computer science professionals/students.

Software packages used to be under the sole control of a single developer. Subsequent groups of more than one developer required the added complication of Management, which changed the dynamic rather fundamentally. Should we now develop a system in which the work of (many) external developers can be included, and offered to users in an accessible way? The associated reward system (money?) could have interesting effects on competition and maintenance.

2.3. Discussion Point 3: user-developer Interaction?

Accidental "Golden Teams" of one opinionated developer and one active scientific user have been very important in the process that has improved the quality of radio-astronomical observations by four(!) orders of magnitude over the last 40 years or so.

This concept resonated strongly in the BoF discussions. It was suggested that, in addition to user-developer teams, there should also be Golden Teams of Mathematicians and Implementers. The problem then becomes one of creating the right conditions, in which compatible(!) users and developers can find each other, and get the opportunity (freedom) to do their thing.

3. Conclusion

A tentative conclusion could be that scientific users do have an important role to play, even in a time of Big Data, and that it would be a mistake to give up on them.

A. Technical Solutions

This BoF was explicitly limited to "sociological" issues, like the need for making our data reduction software more accessible, and the desirability of user control, even in the era of pipelines and Big Data. However, the discussion of such issues will be taken more seriously if there is a perception that viable technical solutions exist to implement such requirements.

It may also help to know that such discussions are not new within ADASS. During the 1990's, the last afternoon of the conference used to be devoted to a free-ranging exchange on the Future of Astronomical Data analysis Systems (FADS; Noordam 1997). After a brief introduction, the floor would be opened up, after which the only problem of the moderator was to gently curtail some speakers in order to give others a chance.

One of the ideas raised at the FADS was a triangular "Gaming Table", a system in which Software Agents would link a given data structure(1) with selected data operations(2), as specified by means of a user interface(3) of choice. The highly competent Agents would hide all the detail that a user should never have to see, thereby addressing the two sociological issues mentioned above.

A quarter century later, these issues are still with us, as the (unfortunately unrecorded) discussions at this BoF have demonstrated so clearly. Fortunately, there are many ways forward. At the simplest level, existing legacy software that is terribly useful can still have a golden future if interfaces to modern scripting languages are available. An example of this has been implemented in the AMUSE software (Portegies Zwart 2018).

Another more recent idea is the introduction of a layer of "Proxy" interface objects between users and software modules. Such Proxies would take care of input arguments and output results, and all the access incantations that a user should never have to see. Because of their uniform structure, the Proxies can talk to each other, and be handled by a single GUI. It turns out that such an extra layer has many advantages, not only in offering users access to software and involving more developers, but also in providing structure to distributed collaborations.

But the good news is that we now have the technology to implement solutions like the Gaming Table. As Ronald Reagan said: "You ain't seen nothing yet".
