ON LOOP DELIGNE–LUSZTIG VARIETIES OF COXETER-TYPE FOR INNER FORMS OF GLₙ

CHARLOTTE CHAN AND ALEXANDER B. IVANOV

Abstract. For a reductive group $G$ over a local non-archimedean field $K$ one can mimic the construction from the classical Deligne–Lusztig theory by using the loop space functor. We study this construction in special the case that $G$ is an inner form of $GL_n$ and the loop Deligne–Lusztig variety is of Coxeter type. After simplifying the proof of its representability, our main result is that its $\ell$-adic cohomology realizes many irreducible supercuspidal representations of $G$, notably almost all among those whose $L$-parameter factors through an unramified elliptic maximal torus of $G$. This gives a purely local, purely geometric and – in a sense – quite explicit way to realize special cases of the local Langlands and Jacquet–Langlands correspondences.

1. Introduction

Let $G$ be an inner form of $GL_n$ ($n \geq 2$) over a local non-archimedean field $K$ and let $G = G(K)$ be the group of its $K$-points. Let $T \subseteq G$ be a maximal elliptic unramified torus. Then $T$ is uniquely determined up to $G$-conjugation and $T = T(K) \cong L^\times$ where $L/K$ is the unramified extension of degree $n$. In [CI18] we constructed a scheme $X$ over $\overline{\mathbb{F}}_q$ with an action by $G \times T$, which can be seen as an analog over $K$ of a Deligne–Lusztig variety attached to $T \subseteq G$. As in the classical Deligne–Lusztig theory [DL76], this allows to attach to a smooth character $\theta: T \to \overline{\mathbb{Q}}_\ell^\times$ the $\theta$-isotypic component $R^G_T(\theta)$ of the $\ell$-adic Euler characteristic of $X$, which is a smooth virtual $G$-representation. If $\theta$ is primitive (i.e., the Howe decomposition of $\theta$ has at most one member), we showed that $R^G_T(\theta)$ is irreducible supercuspidal and isomorphic to the representation attached to $(L/K, \theta)$ by Howe [How77], and hence provides a geometric and purely local realization of the local Langlands and Jacquet–Langlands correspondences.

These results indicate that $X$ and more generally, another schemes obtained by similar Deligne–Lusztig-type constructions for other reductive groups over $K$ allow a quite explicit, purely local and purely geometric way to realize the local Langlands correspondence and/or some instances of automorphic induction for at least those irreducible representations of $G$, whose $L$-parameter factors through an unramified torus. This is highly desirable, as the existing local proofs of the local Langlands correspondence are purely algebraic (e.g. via Bushnell–Kutzko types), and the existing geometric proofs tend to be very inexplicit and/or use global arguments (except for [BW16], which – similar to [CI18] – only deals with primitive $\theta$). Moreover, an exact analog of the classical Deligne–Lusztig theory over non-archimedean local fields is highly interesting in its own right.

The first goal of the present article is to give a more satisfactory definition of $X$ and simplify the proof of its representability. The second goal is to show that $R^G_T(\theta)$ is irreducible supercuspidal and realizes the local Langlands and Jacquet–Langlands correspondences for a much wider class of irreducible supercuspidal representations of $G(K)$ (almost all among those, whose $L$-parameter factors through $T \subseteq G$), thus going far beyond the corresponding results of [BW16] and [CI18]. As the methods from [CI18] for primitive $\theta$ do not apply anymore, our main concern here will be to develop new geometric methods to study the cohomology of Deligne–Lusztig constructions of Coxeter type over local fields, in particular.
Theorem A. There are natural bijections of (sub)schemes of $X$ by unipotent radicals of rational parabolic subgroups of $G$, which generalizes (in the special case for $G, T$) to the situation over $K$ particular results of [Lus76]. Some of these methods immediately work for all reductive groups, and some rely on $G$ being an inner form of $\text{GL}_n$.

To describe our result, we need more notation. First of all there is an unique integer $\kappa \in \{0, 1, \ldots, n - 1\}$, such that if $n' = \gcd(n, \kappa)$, $n = n'n_0$, $\kappa = n'k_0$, we have $G \cong \text{GL}_{n'}(D_{k_0/n_0})$, where $D_{k_0/n_0}$ denotes the central division algebra over $K$ with Hasse-invariant $k_0/n_0$.

Let $\varepsilon$ be any character of $K^\times$ with $\theta(\varepsilon) = N_{L/K}(L^\times)$, the image of the norm map of $L/K$. Denote by

- $\mathcal{X}$ the set of smooth characters of $L^\times$ with trivial stabilizer in $\text{Gal}(L/K)$,
- $\mathcal{S}_K(n)$ the set of isomorphism classes of smooth $n$-dimensional representations $\sigma$ of the Weil group $W_K$ of $K$ satisfying $\sigma \cong \sigma \otimes (\varepsilon \circ \text{rec}_K)$,
- $\mathcal{S}_K(n, \kappa)$ the set of smooth irreducible supercuspidal representations $\pi$ of $G (= G(K)$ with $G$ corresponding to $\kappa$) such that $\pi \cong \pi \otimes (\varepsilon \circ \text{rec}_G)$.

There are natural bijections

$$
\mathcal{X} / \text{Gal}(L/K) \xrightarrow{\text{LL}} \mathcal{S}_K(n) \xrightarrow{\text{JL}} \mathcal{S}_K(n, 0) \xrightarrow{\text{JL}} \mathcal{S}_K(n, \kappa)
$$

$$
\theta \quad \mapsto \quad \sigma_\theta \quad \mapsto \quad \text{LL}(\sigma_\theta) := \pi^{\text{GL}_n}_{\theta} \quad \mapsto \quad \text{JL}(\pi^{\text{GL}_n}_{\theta}) := \pi_\theta.
$$

The latter two maps are the local Langlands and the Jacquet–Langlands correspondences respectively. Here $\sigma_\theta := \text{Ind}_W^L(\theta \cdot \mu)$ is the induction to $W_K$ of the character $W_L \to W_{L, \mu}$,rectifier a similar result was shown in [Iva18], where $\mu$ is the rectifier, i.e. the unramified character of $L^\times$ defined by $\mu(\omega) = (-1)^{n-1}$ (here $\omega$ uniformizer of $L$).

Our main result is the following theorem.

**Theorem A.** Assume that $p > n$. Let $\theta : T \cong L^\times \to \mathbb{G}_m^\times$ be a smooth character such that $\theta|_{U^1_L}$ has trivial stabilizer in $\text{Gal}(L/K)$. Then $\pm R_T^G(\theta)$ is a genuine $G$-representation and

$$
\pm R_T^G(\theta) \cong \pi_\theta.
$$

In particular, $\pm R_T^G(\theta)$ is irreducible supercuspidal and $\sigma_\theta \leftrightarrow \pm R_T^G(\theta)$ is a realization of the local Langlands and Jacquet–Langlands correspondences.

For $\theta$ trivial on $U^1_L$ and with trivial $\text{Gal}(L/K)$-stabilizer, as well as for $\theta$ primitive, Theorem A is shown in [CI18] for all $p, n$. When $G$ is the group of units of a central division algebra over $K$, Theorem A gets easier and essentially follows (for all $p, n$ and all $\theta$ with trivial $\text{Gal}(L/K)$-stabilizer) from Lusztig’s original work [Lus79] along with a result of Henniart [Hen92, Théorème], see [Cha19]. The (also relatively easier) case $G = \text{GL}_2$ was first done in [Iva16].

For $G = \text{GL}_2$ and ramified elliptic tori a similar result was shown in [Iva18, Iva19].

In the rest of this introduction we explain the strategy of the proof of Theorem A and discuss the geometric methods used in it. To begin with, $G$ has a (unique up to conjugacy) smooth affine model $G_\mathcal{O}$ over the integers $\mathcal{O}_K$ of $K$, whose $\mathcal{O}_K$-points are the maximal compact subgroup $G_\mathcal{O} \cong \text{GL}_{n'}(\mathcal{O}_{D^{k_0/n_0}})$, where $\mathcal{O}_{D^{k_0/n_0}}$ is the ring of integers of $D^{k_0/n_0}$. Moreover, $G_\mathcal{O}$ can be chosen compatibly with $T$ so that $T_\mathcal{O} := T \cap G_\mathcal{O} \cong U_L$ is the maximal compact subgroup of $T$. As is shown in [CI18] (see also Proposition 2.6 below), $X$ admits a scheme-theoretically disjoint decomposition,

$$
X = \prod_{g \in G / G_\mathcal{O}} g. X_\mathcal{O}, \quad \text{where } X_\mathcal{O} = \varprojlim_{h} X_{h} \quad (1.1)
$$
is a subscheme equal to an inverse limit of affine perfect schemes $X_h$ perfectly finitely presented over $\mathbb{F}_q$. Here $X_\mathcal{O}$ carries an action of $G_\mathcal{O} \times T_\mathcal{O}$ and $X_h$ inherits an action of a certain finite (Moy–Prasad) quotient $G_h \times T_h$ of it. Then $X_1$ is (the perfection of) a classical Deligne–Lusztig variety attached to the reductive quotient of the special fiber of $G_\mathcal{O}$ (isomorphic to $\text{Res}_{\mathcal{O}/\mathcal{O}_K} \text{GL}_n$), and the deeper-level varieties $X_h$ coincide with the (perfections of) varieties considered in \[\text{Lus04}\] when $G_\mathcal{O} \otimes_{\mathcal{O}_K} \mathbb{F}_q$ is reductive (i.e., $\kappa = 0$), resp. with those in \[\text{CI19a}\] in the general case.

Let $Z$ be the center of $G$. Then $T = ZT_\mathcal{O}$. For a character $\theta$ of $T \cong L^\times$ trivial on the $h$-units $U^h_{L'}$, \[\text{(1.1)}\] plus the fact that the fibers of $X_h/\ker(T_h \to T_{h-1}) \to X_{h-1}$ are affine spaces of a fixed dimension, gives $R^G_T(\theta) = c\text{Ind}_{ZG_\mathcal{O}}^G R_{T_h}^{G_h}(\theta)$, where $R_{T_h}^{G_h}(\theta)$ is the $\theta|_{U_{L'}}$-isotypic component of the $L'$-adic Euler characteristic of $X_h$ (extended to a $ZG_\mathcal{O}$-representation by letting $z \in Z \cong K^\times$ act by $\theta(z)$).

The proof of Theorem A consists of five steps:

1. Show that $\pm R_{T_h}^{G_h}(\theta)$ is an irreducible $G_h$-representation. See Section \[\text{3}\].
2. By similar methods as in (1), show for a certain closed $G_h \times T_h$-stable perfect sub-scheme $X_{h,n'} \subseteq X_h$, that $\pm H^*_{\mathcal{O}}(X_{h,n'})_\theta$ is irreducible and $\pm R_{T_h}^{G_h}(\theta) \cong \pm H^*_{\mathcal{O}}(X_{h,n'})_\theta$. See Section \[\text{4}\].
3. Show (using (1)) that the induction $\pm R^G_T(\theta) = c\text{Ind}_{ZG_\mathcal{O}}^G (\pm R_{T_h}^{G_h}(\theta))$ is admissible (equivalently, a finite direct sum of irreducible supercuspidals). See Section \[\text{5}\].
4. Use \[\text{CI19b}\] to compute the degree $\deg H^*_{\mathcal{O}}(X_{h,n'})_\theta$ of the (finite-dimensional) representation $\pm H^*_{\mathcal{O}}(X_{h,n'})_\theta$, which is then by (2) also equal to $\deg R_{T_h}^{G_h}(\theta)$. See Section \[\text{7.1}\] and \[\text{CI19b}\].
5. Using (3) together with the traces of $R^G_T(\theta)$ \[\text{CI18}\] Theorem 11.2] and of $\pi_\theta$ on very regular elements (cf. Section \[\text{6.2}\] for a definition) in $T \subseteq G$, conclude by using an argument due to Henniart \[\text{Hen92}\] using linear independence of characters, along with matching $\deg R_{T_h}^{G_h}(\theta)$ from (4) with the explicitly known formal degree of $\pi_\theta$ \[\text{CMS90}\] See Section \[\text{7.2}\].

Let us briefly comment on steps (1)-(4) here. Step (1) relies on a precise analysis of the quotient $G_h \backslash X_h \times X_h$ (diagonal action) by methods generalizing those from \[\text{Lus04}\] in the special case that $T \subset G$ is (unramified) elliptic resp., even more specifically, in the case $G = \text{inner form of GL}_n$ and culminates in showing the following particular Mackey formula for “Deligne–Lusztig induced” $G_h$-representations.

**Theorem B** (see Theorem \[\text{3.1}\] Corollary \[\text{3.3}\]). Let $\theta, \theta'$ be two characters of $T_h$. Then

$$\left\langle R_{T_h}^{G_h}(\theta), R_{T_h}^{G_h}(\theta') \right\rangle_{G_h} = \# \left\{ w \in W^F_\mathcal{O} : \theta' = \theta \circ \text{ad}(w) \right\},$$

where $W_\mathcal{O}$ is the Weyl group of the special fiber of $G_\mathcal{O}$ and $F$ is the Frobenius of $G$ acting on it. Moreover, if the stabilizer of $\theta|_{U_{L'}}$ in $\text{Gal}(L/K)[n']$, the unique subgroup of $\text{Gal}(L/K)$ of order $n'$, is trivial, then $\pm R_{T_h}^{G_h}(\theta)$ is an irreducible $G_h$-representation and the map

$$\{ \text{characters } \theta : T_h \to \overline{\mathbb{Q}}_{\ell}^\times \text{ in general position}\} / W^F_\mathcal{O} \rightarrow \{ \text{irreducible } G_h \text{-representations}\} \theta \mapsto \pm R_{T_h}^{G_h}(\theta)$$

is injective.

The theorem looks like a special case (for given $G_h, T_h$) of the results of \[\text{Lus04}\], but the assumption “$\theta$ regular” (equivalently, primitive) which is crucial to \[\text{Lus04}\] is removed. One can hope that similar methods as used in the proof of Theorem \[\text{B}\] could lead to a general Mackey formula for all elliptic unramified tori in reductive $K$-groups.
Step (2) is a technically more elaborated version of the same idea then in step (1). It is (among other things) responsible for the assumptions that \( p > n \) and that \( \theta|_{UL} \) has trivial stabilizer in \( \text{Gal}(L/K) \). See Remark 4.3

Step (3) relies on the study of the quotient \( N_h \backslash X_h \) where \( N_h \subseteq G_h \) is a subgroup corresponding to the unipotent radical of a proper parabolic subgroup of \( G \). Once this quotient is described (Lemma 5.8), (3) is easy to show. The main technical role in this description is played by classical minor identities, dating back to 1909 results of Turnbull \([\text{Tur}09]\).

Step (4), mainly performed in \([\text{CI}19b]\), is based on the determination of the action of Frobenius (over \( \mathbb{F}_{q^n} \)) in the cohomology of \( X_{h,n'} \). This determination is strongly related to the amazing fact that \( X_{h,n'} \) is a maximal variety over \( \mathbb{F}_{q^n} \), i.e., \( \# X_{h,n'}(\mathbb{F}_{q^n}) \) attains its Weil–Deligne bound, prescribed by the Lefschetz fix point formula and the dimensions of the single \( \ell \)-adic cohomology groups.

1.1. Notation. For a non-archimedean local field \( M \) we denote by \( \mathcal{O}_M, \mathfrak{p}_M, U_M = \mathcal{O}_M^\times \) resp. \( U_M^h = 1 + \mathfrak{p}_M^h \) (with \( h \geq 1 \)) its integers, maximal ideal, units resp. \( h \)-units.

Throughout the article we fix a non-archimedean local field \( K \) with uniformizer \( \varpi \) and residue field \( \mathbb{F}_q \) of characteristic \( p \) with \( q \) elements. We denote by \( \hat{K} \) the completion of a fixed maximal unramified extension of \( K \), and by \( \mathcal{O}_{\hat{K}} \) the integers of \( \hat{K} \). The residue field \( \overline{\mathbb{F}}_q \) of \( \hat{K} \) is an algebraic closure of \( \mathbb{F}_q \), and \( \varpi \) is still a uniformizer of \( \hat{K} \). We write \( \sigma \) for the Frobenius automorphisms of \( \hat{K}/K \) and of \( \overline{\mathbb{F}}_q/\mathbb{F}_q \).

Fix an integer \( n \geq 2 \). We denote by \( K \subseteq L \subseteq \hat{K} \) the unique subextension of degree \( n \). Moreover, for any positive divisor \( r \) of \( n \) we denote by \( K \subseteq K_r \subseteq K_r = L \) the unique subextension of degree \( r \) over \( K \).

Fix another integer \( 0 \leq \kappa < n \) and write \( n = n'n_0, \kappa = n'k_0 \), where \( n' = \gcd(n, \kappa) \). Then \( n_0, k_0 \) are coprime.

Fix a prime \( \ell \neq p \) and let \( \overline{\mathbb{Q}}_\ell \) be a fixed algebraic closure of \( \mathbb{Q}_\ell \). All cohomology groups of (perfections of) quasi-projective schemes of finite type over \( \mathbb{F}_q \) will be compactly supported étale cohomology groups with coefficients in \( \overline{\mathbb{Q}}_\ell \). For such a scheme \( Y \) (and more generally, whenever the cohomology groups are defined), we write \( H^c_i(Y) := \sum_{i \in \mathbb{Z}} H^c_i(Y, \overline{\mathbb{Q}}_\ell) \) (the coefficients always will be \( \overline{\mathbb{Q}}_\ell \), so there is no ambiguity).

Unless otherwise stated, all representations of locally compact groups appearing in this article will be smooth with coefficients in \( \overline{\mathbb{Q}}_\ell \).

Acknowledgements. We want to thank Guy Henniart, Tasho Kaletha and Peter Scholze for helpful advices and Andreas Mihatsch and Johannes Anschütz for several useful discussions on the subject of this article. The first author was partially supported by the DFG via the Leibniz Prize of Peter Scholze and an NSF Postdoctoral Research Fellowship, Award No. 1802905. The second author was supported by the DFG via the Leibniz Preis of Peter Scholze.

2. Coxeter-type loop Deligne–Lusztig scheme in type \( \tilde{A}_{n-1} \)

Let \( n = n'n_0 \geq 2 \) and \( \kappa = n'k_0 \) with \( \gcd(k_0, n_0) = 1 \) be as in Section 1.1. This notation remains fixed throughout the article.

In this section we review some constructions and results concerning loop Deligne–Lusztig schemes of Coxeter type for inner forms of \( \text{GL}_n \) from \([\text{CI}18]\), and we simplify the proof of representability (Proposition 2.6).
2.1. Inner forms of \( \text{GL}_n \) and elliptic tori. Inside the group \( \text{GL}_n \) over \( K \) we fix a split maximal torus \( T_0 \) and the unipotent radicals \( U_0, U_0^- \) of two opposite \( K \)-rational Borel subgroups containing \( T_0 \). Let the roots of \( T_0 \) in \( U_0 \) be the positive roots, determining a set \( S_0 \) of simple roots. Conjugating if necessary, we may assume that \( T_0 \) is the diagonal torus and \( U_0 \) is the group of upper triangular unipotent matrices.

2.1.1. Forms of \( \text{GL}_n \). The Kottwitz map \cite{Kot85}

\[
\kappa_{\text{GL}_n} = \text{val} \circ \det: B(\text{GL}_n)_{\text{basic}} \to \mathbb{Z}
\]

for \( \text{GL}_n \) defines a bijection between the set of basic \( \sigma \)-conjugacy classes in \( \text{GL}_n(\bar{K}) \) and \( \mathbb{Z} \). Fix a basic element \( b \in \text{GL}_n(\bar{K}) \) with \( \kappa_{\text{GL}_n}(b) = \kappa \). Let \( G \) be the \( K \)-group defined by

\[
G(R) = \{ g \in \text{GL}_n(R \otimes_K \bar{K}) : g^{-1}b\sigma(g) = b \}
\]

(this is the group \( J_b \) from \cite{RZ96} 1.12). Then \( G \) is an inner form of \( \text{GL}_n \) and we may identify \( G(\bar{K}) = \text{GL}_n(\bar{K}) \). The Frobenius on \( G(\bar{K}) \) is \( F_b: g \mapsto b\sigma(g)b^{-1} \). The \( K \)-points of \( G \) are

\[
G := G(\bar{K}) \cong \text{GL}_n(D_{k_0/n_0}).
\]

We may identify the adjoint Bruhat–Tits building of \( G \) over \( \bar{K} \) with that of \( \text{GL}_n \). Denote both of them by \( \mathcal{B}_{\bar{K}} \). The adjoint Bruhat–Tits building of \( G \) over \( K \) is the subcomplex \( \mathcal{B} = \mathcal{B}_{\bar{K}} \). Let \( x_0 \in \mathcal{B}_{\bar{K}} \) be a vertex. Bruhat–Tits theory \cite{BT84} 5.2.6 attaches to \( x_0 \) a (maximal) parahoric \( O_K \)-model \( G_O \) of \( G \), whose \( O_K \)-points

\[
G_O := G_O(O_K) \cong \text{GL}_n(O_{D_{k_0/n_0}}),
\]

form a maximal compact subgroup of \( G \).

Remark 2.1. The groups \( G, G_O, G, G_O \) depend on the choice of \( b \), but if \( b' = h^{-1}b\sigma(h) \) \((h \in \text{GL}_n(\bar{K})) \) is another choice inside the same basic \( \sigma \)-conjugacy class, with corresponding groups \( G', G'O \), then conjugation with \( h \) defines an isomorphism of \( G, G \) and \( G', G'O \), and if \( x_b \) is mapped by \( h \) to \( x_{b'} \), then conjugation by \( h \) maps \( G_O, G'O \) to \( G_O, G'O \). As at the end we are interested in isomorphism classes of representations of \( G \) (or \( G_O \)), which are not affected by these isomorphisms, we leave the choice of \( b \) unspecified as long as possible. When we need concrete realizations of \( G, G_O, G, G_O \) (in Sections 3.1, 5.1 and 5.2 we will exploit the freedom of choosing different \( b \)'s inside the same basic \( \sigma \)-conjugacy class).

2.1.2. Forms of \( T_0 \). Let \( W = W(T_0, \text{GL}_n) \) be the Weyl group of \( T_0 \) in \( \text{GL}_n \), then \((W, S_0)\) form a Coxeter system. Let \( w_0 = (1_{n-1} 0) \in W \). It is a Coxeter element of \((W, S_0)\). Let \( \bar{w}_0 \in N_{\text{GL}_n}(T_0) \) be a lift of \( w_0 \). Then \( \text{Ad}(\bar{w}_0) \) induces an automorphism of the apartment \( \mathcal{A}_{T_0, \bar{K}} \subseteq \mathcal{B}_{\bar{K}} \) of \( T_0 \). It has precisely one fixed point \( x_{\bar{w}_0} \) as \( w_0 \) is Coxeter. Let \( G \) be the parahoric \( O_K \)-model of \( \text{GL}_n \) attached to this fixed point. Let \( \mathcal{T} \) be the schematic closure of \( T_0 \) in \( G \). Let \( T \) denote the (outer) form of \( T_0 \), which splits over \( \bar{K} \), and is endowed with the Frobenius \( F_{\bar{w}_0}: t \mapsto \bar{w}_0 \sigma(t)\bar{w}_0^{-1} \) (independent of the lift \( \bar{w}_0 \)), and similarly let \( T_O \) be the (outer) form of \( \mathcal{T} \), which splits over \( O_{\bar{K}} \), and is endowed with the same Frobenius. We get the group

\[
T := T(K) \cong L^x \quad \text{and its subgroup} \quad T_O := T_O(O_{\bar{K}}) \cong O_L^x,
\]

where \( L/K \) is unramified of degree \( n \). In fact, \( T = \{ \text{diag}(x, \sigma(x), \ldots, \sigma^{n-1}(x)) : x \in L^x \} \) (recall that \( T_0 \) is diagonal), and the isomorphism with \( L^x \) is determined up to composition with an element in \( \text{Gal}(L/K) \).

2.1.3. Case \( b = \bar{w}_0 \). In the special case \( b = \bar{w}_0 \) and \( x_0 = x_{\bar{w}_0} \), we have only one Frobenius \( F := F_b = F_{\bar{w}_0} \), \( G_O \) is a form of \( G \), and \( T \) is an elliptic maximal torus of \( G \), and \( T_O \) is a
maximal torus of $G_O$. There are unique (closed, reduced) subgroups $U, U^-$ of $G$, such that $U(\bar{K}) = U_0(\bar{K}), \ U^-(\bar{K}) = U^-_0(\bar{K})$ inside $G(\bar{K}) = GL_n(\bar{K})$. Inside $G_O$ we will need the schematic closures $U_O$ and $U^-_O$ of $U$ and $U^-$. The Frobenius $F$ acts on the roots of $T$ in $G$, so that there is a unique subgroup $F \ U \subseteq G$, satisfying $(F \ U)(\bar{K}) = F(U(\bar{K}))$, and similarly for $U^-, U_O, U^-_O$. Identifying $W$ with the Weyl group of $T$ in $G, F$ acts on $W$. Moreover, $W^F = \langle u_0 \rangle \cong \mathbb{Z}/n\mathbb{Z}$ is the subgroup generated by $u_0$. It acts on $T$ and the chosen isomorphism $T \cong L^\times$ induces an isomorphism $W^F \cong \text{Gal}(L/K)$, sending $u_0$ to the image of $\sigma$ in $\text{Gal}(L/K)$.

The maximal torus in the reductive quotient of the special fiber $T_0 \otimes_{O_K} \mathbb{F}_q \subseteq (G_O \otimes_{O_K} \mathbb{F}_q)^{\text{red}}$ is elliptic. Explicitly, these groups are isomorphic to $\text{Res}_{E^q/K} \mathbb{G}_m \subseteq \text{Res}_{E^0_q/K} \mathbb{G}_m' \otimes_{\mathbb{F}_q} \mathbb{G}_m' \otimes_{\mathbb{F}_q} \mathbb{G}_m'$. Let $W_0$ be the Weyl group of $T_0 \otimes_{O_K} \mathbb{F}_q$ in $(G_0 \otimes_{O_K} \mathbb{F}_q)^{\text{red}}$. It is naturally a subgroup of $W, F$ acts on $W_0$ and $W^F_0$, which is generated by $u_0^m$, is isomorphically mapped onto $\text{Gal}(L/K_m)$ under the above isomorphism $W^F \cong \text{Gal}(L/K)$.

2.2. Perfect schemes. Let $k$ be a perfect field of characteristic $p$ and let $X$ be a $k$-scheme. Let $\phi = \phi_X: X \to X$ be the absolute Frobenius morphism of $X$, that is $\phi$ is the identity on the underlying topological space and is given by $x \mapsto x^p$ on $O_X$. The scheme $X$ is called perfect if $\phi$ is an isomorphism. Let $\text{Alg}_k$ denote the category of all $k$-algebras, and let $\text{Perf}_k$ be the full subcategory of perfect $k$-algebras. Then the restriction functor which sends a perfect $k$-scheme, regarded as a functor on $\text{Alg}_k$, to a functor on $\text{Perf}_k$ is fully faithful [Zhu17, A.12]. Thus we equally may regard a perfect scheme as a functor on $\text{Perf}_k$, which has an open covering by representable functors in the usual sense. Every $k$-scheme $X_0$ admits a perfection, namely $X_0^{\text{perf}} := \lim_{\phi} X_0$, which is a perfect scheme. For example, the perfection of $\text{Spec } k[T]$ is $\text{Spec } k[T^{1/p^\infty}]$, where $k[T^{1/p^\infty}] = \bigcup_{r \geq 0} k[T^{p^{-r}}]$.

Except stated otherwise, throughout this article we will work with perfect schemes over $k = \mathbb{F}_q$ (or $k = \mathbb{F}_q$). So, to simplify notation we write $\mathbb{A}^m = \mathbb{A}^m_k$ resp. $\mathbb{G}_m$ resp. $\mathbb{G}_m$ for the perfection of the $m$-dimensional affine space resp. the additive resp. the multiplicative group over $k$. A morphism $f: \text{Spec } A \to \text{Spec } B$ of affine perfect schemes is perfectly finitely presented, if there is a $A = (A_0)^{\text{perf}}$ for a finitely presented $B$-algebra $A_0$ [BS17, 3.10,3.11]. For further results on perfect schemes we refer to [Zhu17, Appendix A.1] and [BS17, §3]. Here we only mention the following lemmas.

Lemma 2.2. Let $X \subseteq \mathbb{A}^m_k$ be a closed perfect subscheme of the $m$-dimensional perfect affine space. Then $X \to \text{Spec } k$ is perfectly finite presented.

Proof. Let $T = (T_1, T_2, \ldots, T_m)$ be some coordinates on $\mathbb{A}^m_k$. Let $a$ be the ideal of $X$ in the coordinate ring $k[T^{p^\infty}]$ of $\mathbb{A}^m_k$. Then it is easy to check that $X$ is the perfection of $X_0 = \text{Spec } k[T]/(a \cap k[T])$, which is (reduced and) finitely presented over $k$.

Lemma 2.3. Let $f: X \to Y$ be a morphism of perfect $k$-schemes with $X$ separated. The following are equivalent:

(i) $f$ is a monomorphism (of fpqc- or étale sheaves on $\text{Perf}_k$)
(ii) for every algebraically closed field $K/k$, $f(K): X(K) \to Y(K)$ is injective.

Proof. Assume (ii). To deduce (i) it is enough to show that for any $R \in \text{Perf}_k, f(R): X(R) \to Y(R)$ is injective. Let $x, y: \text{Spec } R \to X$ be two elements of $X(R)$, such that $fx = fy \in Y(R)$. For each point $p \in \text{Spec } R$, choose a morphism $i_p: \text{Spec } K_p \to \text{Spec } R$ with image $p$, and with $K_p$ an algebraically closed field. Then $f_xi_p = fyi_p \in Y(K_p)$ for each $p$, and from (ii) we deduce $xi_p = yi_p$. As $X$ is separated, the equalizer of $x, y$ is a closed subscheme of $\text{Spec } R$, say equal to $\text{Spec } R/I$ for some ideal $I \subseteq R$. Now, $xi_p = yi_p$ for all field valued
points of Spec $R$ implies that $I \subseteq \bigcap_{p \in \text{Spec } R} p = \text{rad}(0) = 0$, as $R$ perfect and hence reduced. The other direction is clear. □

2.3. Witt vectors and loop groups. If $K$ has positive characteristic, we denote by $\mathcal{W}$ the ring scheme over $\mathbb{F}_q$, where for any $\mathbb{F}_q$-algebra $R$, $\mathcal{W}(R) = R[\varpi]$. If $K$ has mixed characteristic, we denote by $\mathcal{W}$ the $K$-ramified Witt ring scheme over $\mathbb{F}_q$ so that $\mathcal{W}(\mathbb{F}_q) = \mathcal{O}_{\mathcal{W}}$ and $\mathcal{W}(\overline{\mathbb{F}}_q) = \mathcal{O}_{\mathcal{W}}$ (see e.g. [FF18, 1.2]). Let $\mathcal{W}_h = \mathcal{W}/V^h\mathcal{W}$ be the truncated ring scheme, where $V : \mathcal{W} \to \mathcal{W}$ is the multiplication by $\varpi$ (if char $K > 0$) resp. the Verschiebung morphism (if char $K = 0$). We regard $\mathcal{W}_h$ as a functor on $\text{Perf}_{\mathbb{F}_q}$, where it is represented by $\mathbb{A}^1_{\mathbb{F}_q}$. We denote by $\mathcal{W}^\times_h$ the perfect group scheme of invertible elements of $\mathcal{W}$ and for $1 \leq a < h$, we denote by $\mathcal{W}^\times_{a,h} = \text{ker}(\mathcal{W}^\times_h \to \mathcal{W}^\times_a)$ the kernel of the natural projection.

If $X$ is a $\tilde{K}$-scheme, the loop space $L X$ of $X$ is the functor on $\text{Perf}_{\mathbb{F}_q}$,

$$R \mapsto L X(R) = X(\mathcal{W}(R)) \quad \text{resp.} \quad R \mapsto L_+ X(R) = X(\mathcal{W}_h(R)).$$

$(h \geq 1)$. If $X$ is an affine $\mathcal{O}_K$-scheme of finite type, $L X, L_+ X$ are represented by affine perfect $\mathbb{A}^1_{\mathbb{F}_q}$-schemes, and $L_+ X$ are perfectly finitely presented (by Lemma 2.2). The same holds with $\mathcal{W}$ replaced by $\mathbb{F}_q$.

Remark 2.4. We could evaluate $\mathcal{W}, \mathcal{W}_h$ and $L X, L_+ X$ on all $R \in \text{Alg}_{\mathbb{F}_q}$, thus working with schemes $L_+ X$ of finite type over $\mathbb{F}_q$, instead of perfect schemes. When char $K > 0$, this causes absolutely no problems, so we equally good could work with schemes of finite type over $\mathbb{F}_q$ instead of their perfections. When char $K = 0$, these objects behave badly on non-perfect algebras (see e.g. [BS17] Remark 9.3, [Zhu17] end of 1.1.1). Therefore we pass to perfect schemes everywhere. Perfections are universal homeomorphisms, hence do not affect étale cohomology.

2.4. The perfect $\mathbb{F}_q$-space $X^{DL}_{\mathbb{F}_q}(b)$. By a perfect $\mathbb{F}_q$-space we mean an fpqc-sheaf on $\text{Perf}_{\mathbb{F}_q}$.

Let $b$ be any basic element with $\kappa_{\text{GL}_n}(b) = \kappa$. Let $\dot{w} \in N_{\text{GL}_n}(T_0)(\tilde{K})$ be any lift of $w$. Let $\dot{X}^{DL}_{\mathbb{F}_q}(b)$ denote the fpqc-sheafification of the presheaf on $\text{Perf}_{\mathbb{F}_q}$,

$$R \mapsto \{g \in L \text{ GL}_n(R)/L \text{ U}_0(R) : \dot{g}^{-1} b \sigma(g) \in L \text{ U}_0(R) \dot{w} L \text{ U}_0(R)\}.$$

If $G, T$ are as in Section 2.1 the group $G \times T$ acts on $\dot{X}^{DL}_{\mathbb{F}_q}(b)$ by $g, t : x \mapsto g x t$.

Lemma 2.5. Let $b$ be basic with $\kappa_{\text{GL}_n}(b) = \kappa$ and let $\dot{w}_0$ be any lift of $w$.

(i) If $b' = h^{-1} b\sigma(h)$ for some $h \in \text{GL}_n(\tilde{K})$, and if $G' = G'(K)$ is the group attached to $b'$ as in Section 2.1, then $\text{Ad}_b : G \to G'$, $g \mapsto h^{-1} g h$ is an isomorphism. Moreover, left multiplication by $h$ induces an isomorphism of $\mathbb{F}_q$-spaces $\dot{X}^{DL}_{\dot{w}_0}(b) \cong \dot{X}^{DL}_{\dot{w}_0}(b')$, which is equivariant with respect to the isomorphism $(\text{Ad}_b, \text{id}) : G \times T \to G' \times T$.

(ii) Let $\dot{w}'_0$ be a second lift of $w_0$ to $\text{GL}_n(\tilde{K})$. Assume that $\kappa_{\text{GL}_n}(\dot{w}_0) = \kappa_{\text{GL}_n}(\dot{w}'_0)$. Then there exists a $\tau \in T_0(\tilde{K})$ with $\dot{w}'_0 = \tau^{-1} \dot{w}_0 \sigma(\tau)$. Let $T' = T'(K)$ be the group attached to $\dot{w}'_0$ as in Section 2.1. Then $\text{Ad}_\tau : T \to T'$, $t \mapsto \tau^{-1} t \tau$ is an isomorphism. Moreover, right multiplication by $\tau$ induces an isomorphism of $\mathbb{F}_q$-spaces $\dot{X}^{DL}_{\dot{w}_0}(b) \cong \dot{X}^{DL}_{\dot{w}'_0}(b)$, which is equivariant with respect to the isomorphism $(\text{id}, \text{Ad}_\tau) : G \times T \to G \times T'$.

(iii) $\dot{X}^{DL}_{\dot{w}_0}(b) = \emptyset$, unless $\kappa_{\text{GL}_n}(\dot{w}_0) = \kappa$. 

Proof. (i): is an easy computation. (ii): The fiber over $w$ in $\GL_n(\tilde{K})$ is a principal homogeneous space under $T(\tilde{K})$, and it is easy to see that as $w$ is Coxeter, the map $t \mapsto \Ad(w)(t)^{-1}\sigma(t)$ from $T(\tilde{K})$ to $\{\tau \in T(\tilde{K}): \kappa_{\GL_n}(\tau) = 0\}$ is surjective. The rest is an easy computation. (iii): As $X_{w_0}^{DL}(b)$ is an inverse limit of perfectly finitely presented perfect $\FF_q$-schemes, it suffices to show that $\hat{X}_{w_0}^{DL}(b)(\FF_q) = \emptyset$. This holds as $\kappa_{\GL_n}(g^{-1}b\sigma(g)) = \kappa_{\GL_n}(b) = \kappa$ and $\kappa_{\GL_n}(L(U(\FF_q))) = 0$. □

2.5. Representability. We simplify the proof of representability of $X_{w_0}^{DL}(b)$ from \cite{CI18}.

Let $b = w_0$ be basic with $\kappa_{\GL_n}(b) = \kappa$. Then we are in the setup of Section \ref{sec:2.1.3}. Write $F: \text{LG} \to \text{LG}$ for the $\FF_q$-morphism of ind-(perfect schemes) corresponding to $F: G(\tilde{K}) \to G(\tilde{K})$, $g \mapsto b\sigma(g)b^{-1}$. Define the fqc-sheafification $X'$ of the presheaf on $\text{Perf}_{\FF_q}$, $R \mapsto \{x \in L G(R): x^{-1}F(x) \in L(FU) / L(U \cap FU)\}$. The group $G \times T$ acts on $X'$ by $g, t: x \mapsto gx.t$. Define $X_O$ as the fqc-sheafification of the presheaf on $\text{Perf}_{\FF}$,

$$X_O: R \mapsto \{x \in L^+ G_O(R): x^{-1}F(x) \in L^+(FU_0 \cap U_0)(R)\}.$$ 

Being the preimage of $L^+(FU_0 \cap U_0)$ under the Lang-morphism $\text{Lang}_F: L^+ G_O \to L^+ G_O$, $g \mapsto g^{-1}F(g)$, $X_O$ is representable by a perfect $\FF_q$-scheme. Further, the group $G_O \times T_O$ acts on $X_O$ by $(g, t): x \mapsto gx.t$. As $T$ is generated by $T_O$ and the central element $\tau \in T \subseteq G$, the obvious action of $G \times T_O$ on $\prod_{G/G_O} g.X_O$ extends to an action of $G \times T$ by letting $(1, \tau)$ act in the same way as $(\tau, 1)$.

**Proposition 2.6** (\cite{CI18}. Let $b = w_0 \in N_{\GL_n}(T_0)(\tilde{K})$ be basic with $\kappa_{\GL_n}(b) = \kappa$, and mapping to $w_0 \in W$. There are $G \times T$-equivariant isomorphisms of perfect $\FF_q$-spaces

$$X_{b}^{DL}(b) \cong X' \cong \prod_{g \in G / G_O} g.X_O. \quad (2.1)$$

In particular, $X_{b}^{DL}(b)$, $X'$ are representable by perfect $\FF_q$-schemes.

Proof. The same computation as at the end of \cite{CI18}, §3 shows that $G \times T$-equivariantly $X_{b}^{DL}(b) \cong X'$ as $\FF_q$-spaces. As the right hand side of (2.1) is representable, it suffices to show the second isomorphism in (2.1). Consider the fqc-sheafification $X''$ of the presheaf on $\text{Perf}_{\FF_q}$,

$$R \mapsto \{g \in L G(R): g^{-1}F(g) \in L(FU \cap U^{-})(R)\}.$$ 

As $w$ is Coxeter, the map $L(FU \cap U) \times L(FU \cap U^{-}) \to L(FU)$, $(h, g) \mapsto h^{-1}gF(h)$ is an isomorphism of fqc-sheaves (this follows by a concrete calculation – similar to the part of the proof of \cite{CI18} Lemma 2.12] showing equation (7.7) of loc. cit. – which can be performed on $R$-points for any $R \in \text{Perf}_{\FF_q}$. Compare also \cite{HL12}), so that $X' \cong X''$. But $X''$ is the pull-back of the closed sub-(ind-scheme) $LU$ under the Lang map $\text{Lang}_F: \text{LG} \to \text{LG}$, $g \mapsto g^{-1}F(g)$, which is a morphism of ind-schemes, hence $X''$ is representable by an ind-(perfect scheme).

For $\tau \in T(\tilde{K})$, $x \mapsto \tau^{-1}x\tau$ defines an equivariant isomorphism between $X''$ and the analog of $X''$, where $b$ is replaced by $\tau^{-1}b\tau$. Thus we may take $b = \begin{pmatrix} 1 & \tau \varepsilon \\ 0 & 1 \varepsilon \end{pmatrix}$, where $\varepsilon \in T(\mathcal{O}_K)$. Fix $R \in \text{Perf}_{\FF_q}$. Let $g \in LG(R) = G(\mathcal{W}(R)[\varepsilon^{-1}])$ with $g^{-1}F(g) =: a \in L(FU \cap U^{-})(R)$. For $1 \leq i \leq n - 1$, let $a_i \in LG(a)(R)$ denote the $(i + 1, 1)$-th entry of the matrix $a$. Then the matrix $g$ is determined by its first column, denoted $v$ (for $1 \leq i \leq n$ the $i$-th column is then equal to $(b\sigma)^{i-1}(v)$). Moreover $v$ has to satisfy $(b\sigma)^n(v) = \varepsilon^k(v + \sum_{i=1}^{n-1} a_i(b\sigma)^i(v))$,
an equation which takes place in $L G_n(R)^n$. Assume $R$ is an algebraically closed field. The valuations of the coefficients of the characteristic polynomial of a $\sigma$-linear endomorphism lie over its Newton polygon, which in our case coincide with the Newton polygon of the isocrystal attached to $b \sigma$, and is just the straight line segment connecting the origin and the point $(n, \kappa)$ in the plane (cf. [CI18, Lemma 6.1] for the precise statement). This shows $\text{val}(a_i) \geq -\frac{\kappa}{n}$ for $1 \leq i \leq n - 1$. But after explicitly determining the affine root subgroups contained in $G_0(O_K)$, this translates into the statement that $a \in L^+(F U_0 \cap U_0)(R)$. As $X''$ is a ind-(perfect scheme), this implies that $X''$ is equal to the fpqc-sheafification of
\[ R \mapsto \{ g \in L G(R) : g^{-1} F(g) \in L^+(F U_0 \cap U_0)(R) \}. \]
Consider the projection $\pi : L G \to L G / L^+ G_0$. If $g \in X''(R) \subseteq L G(R)$, then $F(g) \in gL^+(F U_0 \cap U_0)(R) \subseteq gL^+ G_0(R)$. Thus $X''$ maps under $\pi$ to the discrete subset $(L G / L^+ G_0)^F = G / G_0$. Hence $X''$ is isomorphic to the right hand side of (2.1), and we are done. □

**Corollary 2.7.** Let $b \in \text{GL}_n(\bar{K})$ be basic, $\bar{w}_0$ a lift of $w_0$ such that $\kappa_{\text{GL}_n}(b) = \kappa_{\text{GL}_n}(\bar{w}_0) = \kappa$. Then $X^{DL}_{\bar{w}_0}(b) \cong \coprod_{G / G_0} gX_0$ is representable by a perfect $\bar{F}_q$-scheme.

**Proof.** This follows from Lemma 2.5 and Proposition 2.6. □

### 2.6. Representations $R^G_{1}(\theta)$ and $R^{G_0}_{1}(\theta)$

Let a basic $b$ and a lift $\bar{w}_0$ as in Section 2.1 with $\kappa_{\text{GL}_n}(b) = \kappa_{\text{GL}_n}(\bar{w}_0) = \kappa$ be fixed. In Section 2.1 we attached to $b, \bar{w}_0$ the locally pro-finite groups $G, T$ and their maximal compact subgroups $G_0, T_0$. In [CI18] we defined families (indexed by $h \geq 1$) of perfectly finitely presented perfect group schemes over $\bar{F}_q$, with $\bar{F}_q$-points $G_h, T_h$ such that $G_0 = \lim_{\leftarrow h} G_h$ and $T_0 = \lim_{\leftarrow h} T_h$, and showed that $G \times T$-equivariantly,
\[ X^{DL}_{\bar{w}_0}(b) \cong \coprod_{G / G_0} gX_0, \quad \text{with } X_0 \cong \lim_{\leftarrow h} X_h \]
such that $X_0$ is acted on by $G_0 \times T_0$, each $X_h$ is a perfectly finitely presented perfect $\bar{F}_q$-scheme, acted on by $G_h \times T_h$, and all morphisms are compatible with all actions. Moreover, $X_h$ is the perfection of a smooth affine $\bar{F}_q$-scheme of finite type. We identify $X^{DL}_{\bar{w}_0}(b)$ with $\coprod_{G / G_0} gX_0$ via this isomorphism. The groups $G_h$ and $T_h$ are certain Moy–Prasad quotients of $G_0$ and $T_0$, and hence essentially independent of the choice of $b, x_h$ and $\bar{w}_0$. An explicit presentation of $G_h, T_h, X_h$ is reviewed in Section 3.1 below.

We review the definition of certain étale cohomology groups with compact support of $X^{DL}_{\bar{w}_0}(b)$ and $X_0$ (which are not perfectly finitely presented over $\bar{F}_q$). First, for $h \geq 1$ and a character $\chi : T_h \to \overline{\underline{\mathbb{Q}}_l}^\times$, the $\chi$-isotypic components $H^*_\chi(X_h)$ of the $\ell$-adic cohomology groups with compact support are defined as $H^*_\chi(X_h)$ as $X_h$ is the perfection of smooth scheme of finite type over $\bar{F}_q$. Second, for $h \geq 1$, the fibers of $X_h / \ker(T_h \to T_{h-1}) \to X_{h-1}$ are isomorphic to $A^{n-1}$. Let $\chi : T_0 \to \overline{\underline{\mathbb{Q}}_l}^\times$ be a smooth character. Then there exists an $h \geq 1$, such that $\chi$ is trivial on $\ker(T_h \to T_{h-1})$ for some $h \geq 1$. Let $h' \geq h$ and denote the characters induced by $\chi$ on $T_h$ and $T_{h'}$ again by $\chi$. Then $H^*_\chi(X_h) = H^*_\chi(X_{h'})$, where $H^*_\chi$ is the alternating sum of the cohomology. Thus we can define $H^*_\chi(X_0)$ as $H^*_\chi(X_{h'})$ for any $h' \geq h$ and this is independent of $h'$. So, if $\chi$ is a character of $T_0$ of level $h$, we have the

\[ H_0^{\dim(Y) - 1}(Y)(\dim(Y)) \] in [Lus79], which removes precisely this shift in degree.

\[ \text{Note that } T \text{ is generated by } T_0 \text{ and a central element of } G, \text{ when } G, T \text{ are both regarded as subgroups of } \text{GL}_n(\bar{K}), \text{ so that } \coprod_{G / G_0} gX_0 \text{ admits also a natural right } T\text{-action.} \]

\[ \text{Recall from Section 1.1] that we omit the constant coefficients } \underline{\mathbb{Q}}_l \text{ from the notation.} \]

\[ \text{Note that the single cohomology groups } H^*_\chi(X_0) \text{ are not defined, due to a degree shift: } H^*_\chi(X_{h'}) = H^*_{\ell^{-2d}(X_h)} \text{ for an appropriate } d \geq 0. \text{ One can remedy this by introducing homology groups } H_i(Y) := H^*_{\dim(Y) - 1}(Y)(\dim(Y)) \text{ as in } \text{[Lus79]}, \text{ which removes precisely this shift in degree.} \]
Definition 2.10. and only if \( G \) is isomorphic for the \( R\)

\[ R_{T_h}^G(\chi) := H^*_c(X_\mathcal{O})_\chi = H^*_c(X_h)_\chi. \]

and we denote the \( G \)-representation obtained by inflation via \( G \) \( G \) again by \( R_{T_h}^G(\chi) \).

Let \( Z \subseteq G \) be the center and let \( \widetilde{X}_\mathcal{O} := \bigcup_{g \in ZG} g.X_\mathcal{O} \) be the union in \( X^{DL}_{w_0}(b) \) of all \( ZG \)-translates of \( X_\mathcal{O} \). Then \( \widetilde{X}_\mathcal{O} \) is acted on by \( ZG \times T \) and is a disjoint union of copies of \( X_\mathcal{O} \). Exactly as above for \( X_\mathcal{O} \), for a smooth character \( \theta : T \to \mathbb{Q}_p^\times \) we may define the smooth \( ZG \)-representation \( H^*_c(\widetilde{X}_\mathcal{O})_\theta \).

**Lemma 2.8.** Let \( \theta : T \to \mathbb{Q}_p^\times \) be a smooth character of level \( h \). As \( G \)-representations, \( H^*_c(\widetilde{X}_\mathcal{O})_\theta \cong R_{T_h}^G(\theta) \). As a \( ZG \)-representation, \( H^*_c(\widetilde{X}_\mathcal{O})_\theta \) is just the \( G \)-representation \( R_{T_h}^G(\theta) \), with action extended to \( Z \) by letting \( \varpi \in Z \cong K^\times \) act by the scalar \( \theta(\varpi) \).

**Proof.** This is immediate (see e.g. [Iva16] Lemma 4.5)).

Justified by this lemma we write \( R_{T_h}^G(\theta) \) for the \( ZG \)-representation \( H^*_c(\widetilde{X}_\mathcal{O})_\theta \). For schemes \( Y_i \) such that \( H^*_c(Y_i) \) are defined, put \( H^*_c(\prod_{i \in I} Y_i) := \bigoplus_{i \in I} H^*_c(Y_i) \). We get our main object of study, the smooth \( G \)-representation

\[ R_{T_h}^G(\theta) := H^*_c(X^{DL}_{w_0}(b))_\theta = c\text{Ind}_{ZG}^G R_{T_h}^G(\theta) \]

(cf. [CH18] Theorem 11.2)).

**Remark 2.9.** By construction and by Lemma 2.5 the isomorphism class of the \( G \)-representation \( R_{T_h}^G(\theta) \) is independent of the choices of representatives \( b, w_0 \). A similar independence holds for the \( ZG \)-representation \( R_{T_h}^G(\theta) \).

**2.7. Norms and characters.** The following definitions do not depend on the choice of an isomorphism \( T \cong L^\times \) (as in Section 2.1.2).

**Definition 2.10.** We say that a smooth character \( \theta : T \cong L^\times \to \mathbb{Q}_p^\times \) is of level \( h \) if it is trivial on \( \ker(T_\mathcal{O} \to T_h) \cong U_h^L \), but non-trivial on \( \ker(T_\mathcal{O} \to T_{h-1}) \cong U_{h-1}^L \).

Recall the subextensions \( L \supseteq K_r \supseteq K \) (Section 1.1). Whenever \( r, s \) are positive divisors of \( n \) such that \( s \) divides \( r \), we denote by \( N_{r/s} : K^\times_r \to K^\times_s \) the norm map for the field extension \( K_r/K_s \). For any \( h \geq h^r \geq 1 \), it induces maps

\[ U_{K_h}/U_{K_h}^L \to U_{K_r}/U_{K_r}^L \quad \text{and} \quad U_{K_h}/U_{K_r} \to U_{K_s}/U_{K_r}^L \]

which are surjective (see e.g. [Ser95] Chap. V, §2]), and which we again denote by \( N_{r/s} \).

**Definition 2.11.**

(i) A character \( \theta : T \cong L^\times \to \mathbb{Q}_p^\times \) resp. \( \theta : T_\mathcal{O} \cong L_\mathcal{O} \to \mathbb{Q}_p^\times \) is in general position, if the stabilizer of \( \theta \) in \( \text{Gal}(L/K) \) is trivial. We say \( \theta|_{U_L} \) is in general position, if the stabilizer of \( \theta|_{U_L} \) in \( \text{Gal}(L/K) \) is trivial.

(ii) Let \( h \geq 1 \). A character \( \theta : T_h \cong L_h^\times \to \mathbb{Q}_p^\times \) (resp. \( \theta|_{T_h} = U_h^L/U_h^L \)) is in general position if its inflation to \( T_\mathcal{O} \) (resp. to \( \ker(T_\mathcal{O} \to T_j) \)) is in general position.

Note that \( \theta : T \cong L^\times \to \mathbb{Q}_p^\times \) is in general position if and only if \( \theta|_{T_\mathcal{O}} \) is.

**Lemma 2.12.** Let \( \theta : T \cong L^\times \to \mathbb{Q}_p^\times \) be a character. Let \( s \in \mathbb{Z} \). Then

\[ \theta \circ \sigma^s = \theta \iff \theta \text{ factors through } N_{L/K_{\text{odd}(n,s)}} \]

The analogous claim holds for \( \theta|_{U_L} \). In particular, \( \theta \) is in general position if and only if \( \theta \) does not factor through any of the maps \( N_{n/r} \) with \( r < n \), and \( \theta|_{U_L} \) is in general position if and only if \( \theta|_{U_L} \) does not factor through any of the maps \( N_{n/r} \) with \( r < n \).
Proof. $\theta \circ \sigma^s = \theta$ is equivalent to $\theta$ being trivial on the image of the map $L^x \to L^x$, $x \mapsto x^{-1}\sigma^s(x)$. By Hilbert’s Theorem 90, this image is equal to the kernel of the norm map of $L$ over the field stable by $\sigma^s$, which is $K_{\gcd(n,s)}$.

3. Mackey formulas

In this section we prove the following special case of a Mackey-type formula.

**Theorem 3.1.** Let $\theta, \theta' : T_h \to \overline{\mathbb{Q}}_l^\times$ be two characters. Then

$$\left\{ R_{T_h}^G(\theta), R_{T_h}^G(\theta') \right\}_{G_h} = \# \left\{ w \in W^F_O : \theta' = \theta \circ \text{ad}(w) \right\}$$

**Remark 3.2.** The theorem shows that in the special cases considered in [CI18] and here the assumption in [Lus04, Corollary 2.4] resp. [CI19a, Corollary 4.7] that $\theta$ is regular is obsolete.

**Corollary 3.3.** Let $\theta : T_h \to \overline{\mathbb{Q}}_l^\times$ be a character, whose stabilizer in $\text{Gal}(L/K)[n']$, the unique subgroup of $\text{Gal}(L/K)$ of order $n'$, is trivial. Then $\pm R_{T_h}^G(\theta)$ is irreducible $G_h$-representation. In particular, $\text{Fr}_{q^n}$ acts in $\pm R_{T_h}^G(\theta)$ by multiplication with a scalar. Moreover, the map

$$\left\{ \text{Characters } \theta : T_h \to \overline{\mathbb{Q}}_l^\times \text{ in general position} \right\} / W^F_O \to \{ \text{irreducible } G_h\text{-representations} \}$$

$$\theta \mapsto \pm R_{T_h}^G(\theta)$$

is injective.

**Proof.** This follows from the description of $W^F_O$ in Section 2.1.3 and Theorem 3.1.

We prove Theorem 3.1 in four steps (Sections 3.1–3.4). After general preparations in Section 3.1 we show in Section 3.2 that several of the perfect schemes $\Sigma_w$ (as in Lus04 1.9) are empty in our case; then in Sections 3.3–3.4 we generalize Lusztig’s argument from Lus04 1.9, proof of claim (b)] with the extension of action on $\Sigma'_w$ in two different ways to cover the remaining $\Sigma'_w$. The first generalization uses our concrete situation, whereas the second is quite general.

3.1. General preparations. In contrast to [CI18] where we worked with Coxeter-type and special representatives for $[b]$ (see CI18 $\S5.1$), here it is most convenient to work with a third type of representatives. We put

$$b = b_0 t_{\kappa,n} \in \text{GL}_n(\bar{K})$$

(3.1)

where

$$b_0 := \begin{pmatrix} 0 & 1 \\ 1_{n-1} & 0 \end{pmatrix}, \quad \text{and} \quad t_{\kappa,n} := \begin{cases} \text{diag}(1, \ldots, 1, \varpi, \ldots, \varpi) & \text{if } (\kappa,n) = 1, \\ \text{diag}(t_{k_0,0}, \ldots, t_{k_0,0}) & \text{otherwise.} \end{cases}$$

are as in [CI18 $\S5.2.1$]. In particular, we work in the setup of Section 2.1.3

Recall the (unique) fixed point $x_b$ of $F$ in the apartment $\mathcal{A}_{T,R}$ of $T$ in $\mathcal{B}_K$, and the corresponding maximal parahoric $\mathcal{O}_K$-model $G_{\mathcal{O}}$ of $G$. We have the stabilizer $\tilde{G}_{x_b,0} = G_{\mathcal{O}}(\mathcal{O}_K)$ of $x_b$ in $G(\bar{K}) = \text{GL}_n(\bar{K})$ and its Moy–Prasad filtration [MP94] given by subgroups $\tilde{G}_{x_b,r}$ ($r \geq 0$). Similarly as in [CI18 $\S5.3$], consider the affine perfect group scheme $\mathbb{G}$ over $\mathbb{F}_q$ defined by

$$\mathbb{G}(\mathbb{F}_q) = \tilde{G}_{x_b,0}, \quad \mathbb{G}(\mathbb{F}_q) = \tilde{G}_{x_b} = G_{\mathcal{O}}.$$
and for \( h \in \mathbb{Z}_{\geq 1} \), the affine perfectly finitely presented perfect group scheme \( \mathbb{G}_h \) over \( \mathbb{F}_q \) such that
\[
\mathbb{G}_h(\mathbb{F}_q) = \hat{G}_{x_0,0}/\hat{G}_{x_0,(h-1)+}, \quad \mathbb{G}_h := \mathbb{G}_h(\mathbb{F}_q) = \hat{G}_{x_0,0}/\hat{G}_{x_0,(h-1)+}.
\]
We denote the Frobenius on \( \mathbb{G}, \mathbb{G}_h \) again by \( F \). The groups \( \mathbb{G}, \mathbb{G}_h \) possess an explicit description in terms of matrices similar to [CI18] §5.3.

**Remark 3.4.** In [CI18] Section 7], we worked instead with the Coxeter representatives \( b' = t'^{e_{n,n}}t_{n,n} \) as in [CI18] §5.2.1]; but if \( \gamma \) is as in [CI18] §7.6, then \( b = \gamma b' \gamma^{-1} \), i.e., \( b \) is integrally \( \sigma \)-conjugate to \( b' \). In fact, the groups \( \mathbb{G}, \mathbb{G}_h \) used here are equal to \( \gamma \mathbb{G} \gamma^{-1}, \gamma \mathbb{G}_h \gamma^{-1} \) with the latter \( \mathbb{G}, \mathbb{G}_h \) as in [CI18].

As (perfect) \( \mathbb{F}_q \)-groups, \( \mathbb{G}_1 \cong \text{Res}_{\mathbb{F}_q'^{n_0}/\mathbb{F}_q} \text{GL}_{n'} \). The above-mentioned description identifies \( \mathbb{G}_1 \) with a closed \( \mathbb{F}_q \)-subgroup of \( \text{GL}_{n,\mathbb{F}_q} \). In fact, \( \mathbb{G}_1(\mathbb{F}_q) \) is the closed subgroup of \( \text{GL}_{n,\mathbb{F}_q} \), consisting of those \( n \times n \)-matrices \( g = (g_{ij})_{i,j \in \mathbb{Z}/n\mathbb{Z}} \in \text{GL}_{n,\mathbb{F}_q} \) for which \( X_{ij} = 0 \), unless \( i \equiv j \mod n_0 \); if we now equip \( \text{GL}_{n,\mathbb{F}_q} \) with the \( \mathbb{F}_q \)-structure given by the Frobenius \( \mathbb{F}_0: g \mapsto b_0 \sigma(g) b_0^{-1} \) and denote the resulting \( \mathbb{F}_q \)-group simply by \( \text{GL}_n \), then this defines an \( \mathbb{F}_q \)-embedding \( \mathbb{G}_1 \to \text{GL}_n \).

We regard the symmetric group on \( n \) letters \( S_n \) as the group of set automorphisms of \( \mathbb{Z}/n\mathbb{Z} \), and for an element \( i \in \mathbb{Z}/n\mathbb{Z} \) let \([i]\) be the unique integer between 1 and \( n \) having residue \( i \) modulo \( n_0 \). We also identify \( S_n \) with the Weyl group of the diagonal torus in \( \text{GL}_n \) (either over \( \mathbb{F}_q \) or \( \hat{K} \)) by sending a permutation \( v \in S_n \) to the permutation matrix (again denoted \( v \)) whose non-zero entries are \((v(i),i)\) for \( 1 \leq i \leq n \).

As \( \mathbb{G}_1 \) is naturally isomorphic to the reductive quotient of the special fiber of \( \mathbb{G}_O \), the group \( \text{W}_O \) is simply the Weyl group of \( \mathbb{T}_1 \) in \( \mathbb{G}_1 \). Thus, using the above identifications, \( \text{W}_O \) is the subgroup of \( S_n \), isomorphic to \( S_{n'} \times \cdots \times S_{n'} \) \((n_0 \text{ times})\), of those permutations which preserve the residue modulo \( n_0 \).

Applying \( L^+_h \) to the inclusions \( \mathbb{T}_O, \mathbb{U}_O, \mathbb{U}_O^O \subseteq \mathbb{G}_O \) gives closed subgroups \( \mathbb{T}_h, \mathbb{U}_h, \mathbb{U}_h^O \subseteq \mathbb{G}_h \), with \( \mathbb{T}_h \) defined over \( \mathbb{F}_q \) and \( \mathbb{U}_h, \mathbb{U}_h^O \) defined over \( \mathbb{F}_{q'} \) (cf. [CI19a 2.6]). For a closed subgroup \( \mathbb{H}_h \subseteq \mathbb{G}_h \) and \( 1 \leq \alpha \leq h - 1 \), we write \( \mathbb{H}_h^\alpha := \mathbb{H}_h \cap \ker(\mathbb{G}_h \to \mathbb{G}_\alpha) \). If \( \mathbb{H}_h \) is defined over \( \mathbb{F}_q \), we write \( \mathbb{H} := \mathbb{H}(\mathbb{F}_q) \) and \( \mathbb{H}_h^\alpha := \mathbb{H}_h^\alpha(\mathbb{F}_q) \).

Then we have (by a slight modification – or conjugation with \( \gamma \) from Remark [3.4] of [CI18] Section 7], in particular, Propositions 7.10,7.11) as perfect \( \mathbb{F}_q \)-spaces
\[
X_h \cong \{ g \in \mathbb{G}_h : g^{-1}F(g) \in \mathbb{U}_h^O \cap F\mathbb{U}_h \} \cong S_h/(\mathbb{U}_h \cap F\mathbb{U}_h), \tag{3.2}
\]
where
\[
S_h = \{ g \in \mathbb{G}_h : g^{-1}F(g) \in \mathbb{U}_h^O \},
\]
and the action of \( \mathbb{U}_h \cap F\mathbb{U}_h \) on \( S_h \) is by right multiplication (here and in the following: all presheaves have to be sheafified). Moreover, (3.2) is \( \mathbb{G}_h \times \mathbb{T}_h \)-equivariant with respect to the \( \mathbb{G}_h \times \mathbb{T}_h \)-action on the right hand side given by \((g',t): (g,t') \mapsto g'gt\).

The fibers of the projection \( \mathbb{S}_h \to X_h \) are isomorphic to affine spaces of fixed dimension, so that \( R_{\mathbb{S}_h}^\beta(0) = H^*_v(\mathbb{S}_h)_\beta \). As in [Lus04 1.9], if
\[
\Sigma = \{(x,x',y) \in F\mathbb{U}_h \times F\mathbb{U}_h \times \mathbb{G}_h : xF(y) = yx'\}
\]
with the \( \mathbb{T}_h \times \mathbb{T}_h \)-action given by \((t,t'): (x,x',y) \mapsto (txt^{-1},t'x't'^{-1},tyt'^{-1})\), then the map
\[
\mathbb{G}_h(\mathbb{F}_q)(X_h \times X_h) \to \Sigma, \tag{3.3}
\]
induced by \((g,g') \mapsto (g^{-1}F(g),g^{-1}F(g'),g^{-1}g')\) is an \( \mathbb{T}_h \times \mathbb{T}_h \)-equivariant isomorphism (the quotient of the left side is taken with respect to the diagonal action).
The group $G_1$ is reductive and $\ker(G_h \to G_1)$ is unipotent. Thus the Bruhat decomposition $G_1 = \coprod_{w \in W_\varnothing} U_1 T_1 w U_1$ of $G_1$ lifts to a decomposition $G_h = \coprod_{w \in W_\varnothing} G_{h,w}$, with $G_{h,w} = U_h T_h w \mathbb{P}^1 U_h$, $\mathbb{P}^1 = (\mathbb{P}^1)^1 \cap w^{-1}(\mathbb{P}^1)^1 w$ [C18, Lemma 8.6]. We then have the locally closed decomposition $\Sigma = \coprod_{w \in W_\varnothing} \Sigma_w$, where

$$\Sigma_w = \{ (x,x',y) \in F U_h \times F U_h \times G_{h,w} : x F(y) = y x' \}.$$  

is $T_h \times T_h$-stable. Further, let

$$\hat{\Sigma}_w = \{ (x,x',y_1,\tau,z,y_2) \in F U_h \times F U_h \times U_h \times T_h \times \mathbb{P}^1 \times U_h : x F(y_1 \tau \hat{w} z y_2) = y_1 \tau \hat{w} z y_2 x' \}.$$  

where $\hat{w}$ is an arbitrary but from now on fixed lift of $w$. It has a $T_h \times T_h$-action by

$$(t,t') : (x,x',y_1,\tau,z,y_2) \mapsto (tx t^{-1}, t' x' t'^{-1}, ty_1 t^{-1}, t \tau t \hat{w} t'^{-1} \hat{w}^{-1}, t' \tau t' t'^{-1}, t' y_2 t'^{-1}) \quad (3.4)$$

Then the map $\hat{\Sigma}_w \to \Sigma_w$ given by $(x,x',y_1,\tau,z,y_2) \mapsto (x,x',y_1 \tau \hat{w} y_2)$ is a $T_h \times T_h$-equivariant Zariski-locally trivial fibration. All in all, as in [Lus04], using (3.3) it is enough to show that

$$\sum \dim_{\Sigma_T} H^i(\hat{\Sigma}_w)_{\theta^{-1},\theta'} = \begin{cases} 1 & \text{if } w \in W_\varnothing^F \text{ and } \theta' = \theta \circ \text{ad}(w) \\ 0 & \text{otherwise.} \end{cases} \quad (3.5)$$

So far we were essentially following [Lus04] 1.9, but now we have to deviate.

3.2. Emptyness of certain $\hat{\Sigma}_w$. Let $w \in W_\varnothing$. As in [Lus04] 1.9, make the change of variables $x F(y_1) \mapsto x$, $x' F(y_2)^{-1} \mapsto x'$. We thus may rewrite

$$\hat{\Sigma}_w = \{ (x,y_1,\tau,z,y_2) \in F U_h \times U_h \times T_h \times \mathbb{P}^1 \times U_h : x F(\tau \hat{w} z) = y_1 \tau \hat{w} z y_2 F U_h \} \quad (3.6)$$

with the $T_h \times T_h$-action still given by (3.4).

Lemma 3.5. Assume that there exists some $2 \leq i \leq n$ such that $|w(i)| > |w(i-1) + 1| > 1$. Then $\hat{\Sigma}_w = \varnothing$.

Proof. We may assume $h = 1$, and hence we may ignore $z \in \mathbb{P}^1$ whose image in $G_1$ is 1. We use the identification of $G_1$ with the closed subgroup of $\text{GL}_n$ from Section 3.1. Write $y_i = y_{i,1} y_{i,2}$ with $y_{i,1}, y_{i,2} \in U_1 \cap F U_1$ and $y_{i,2,1} \in U_1 \cap F U_1^\varnothing$. Replacing $x$ by $y_{i,1}^{-1} x$ and putting $y_{i,2}$ into the $F U_1$ on the right hand side, we are reduced to show that there are no $(x,y_{i,2,1},\tau) \in F U_1 \times (U_1 \cap F U_1^\varnothing) \times (U_1 \cap F U_1^\varnothing) \times T_1$ with

$$\hat{w}^{-1} \tau y_{i,2}^{-1} x F(\tau \hat{w}) y_{i,2} \in y_{i,2,1} F(U_1).$$

Replacing everything by appropriate conjugates resp. inverses, it suffices to show that there are no $(x,y,y_{i,2,1},\tau') \in F U_1 \times (U_1 \cap F U_1^\varnothing) \times (U_1 \cap F U_1^\varnothing) \times T_1$ satisfying

$$\hat{w}^{-1} y x F(\hat{w}) \in \tau' y_{i,2,1} F(U_1).$$

For a $n \times n$-matrix $X$, let $X_{i,j}$ denote its $(i,j)$th entry. Consider the closed subset

$$M = \{ X \in G_1 : X_{i,j} \in \mathbb{G}_m \forall 2 \leq i \leq n \text{ and } X_{i,j} = 0 \forall n \geq i > j > 1 \}$$

of $G_1$. We have

$$U_1 \cap F U_1^\varnothing = \{ X \in G_1 : X_{i,j} = 1 \forall i \text{ and } X_{i,j} = 0 \forall (i,j) \text{ with } j \neq 1 \text{ or } i \neq j \}$$

One easily checks that $T_1 \cdot (U_1 \cap F U_1^\varnothing) \cdot F U_1 \subseteq M$. Thus it suffices to check that

$$\hat{w}^{-1} M F(\hat{w}) \cap M = \varnothing.$$  

For $X \in G_1$ (and even more generally for $X \in \text{GL}_n$ and $F$ replaced by $F_0$ as in Section 3.1), one has the formula

$$\hat{w}^{-1} X F(\hat{w})_{i,j} = X_{w(i),w(j-1)+1} \quad (3.7)$$
Let $2 \leq i \leq n$ be such that $[w(i)] > [w(i-1)+1] > 1$. Then for $X \in M$, the $(i,i)$th diagonal entry of $\bar{w}^{-1}XF(\bar{w})$ is

$$(\bar{w}^{-1}XF(\bar{w}))_{i,i} = X_{w(i),[w(i-1)+1]} = 0,$$

by definition of $M$. This shows that $X \not\in M$ and we are done. \hfill \Box

As mentioned in Section 2.1.3, $W_0^F = \langle w_0^{no} \rangle$. Clearly, no element from $W_0^F$ satisfies the condition in Lemma 3.6. Thus Lemma 3.5 implies (3.5) for all $w$ satisfying the condition in the lemma.

3.3. An extension of action. It remains to show (3.5) for all $w \in W_0 \subseteq S_n$ for which there is no $2 \leq i \leq n$ satisfying $[w(i)] > [w(i-1)+1] > 1$. Consider the closed subgroup $H_w = \{(t,t') \in T_h \times T_h : \bar{w}^{-1}t^{-1}F(t)\bar{w} = t'^{-1}F(t')\}$ centralizes $K_h = U_h^- \cap \bar{w}^{-1}U_h^w \bar{w}$ of $T_h \times T_h$. It contains $T_h \times T_h$. It is easy to check that the action of $T_h \times T_h$ on $\Sigma_w$ extends to an action of $H_w$ given by the formula

$$(t,t') : (x,y_1,\tau,z,y_2) \mapsto (F(t)xF(t)^{-1},F(t)y_1F(t)^{-1},t\tau\bar{w}t'^{-1}\bar{w}t^{-1},t'zt'^{-1},F(t')y_2F(t')^{-1}).$$

Lemma 3.6. Let $1 \neq w \in W_0$. Assume that there is no $2 \leq i \leq n$ with $[w(i)] > [w(i-1)+1] > 1$. Then there is a proper Levi subgroup $L$ of $G_\mathbb{K}$ containing $T_K$ such that if $\mathbb{L}_h$ denotes the corresponding subgroup of $G_h$, then $\mathbb{K}_h \subseteq \mathbb{L}_h$.

Proof. First we prove the following claim: there is an $s \in \mathbb{Z}_{>1}$ and a sequence $0 =: i_0 < 1 \leq i_1 < \cdots < i_{s-1} < i_s := n$ of integers such that for each $1 \leq j \leq s$, and for each $i_{j-1}+1 \leq i \leq i_j$ (if $j > 1$) resp. for each $1 \leq i \leq i_1$ (if $j = 1$), one has $w(i) = n - i_{j-1} - (i_j - i)$. Indeed, find the $1 \leq i_1 \leq n$ such that $w(i_1) = n$. It follows from the condition on $w$ that $w(i_1-1) = n-1$, ..., $w(1) = n - (i_1 - 1)$. The maximal value which $w$ has on $\{i_1+1,\ldots,n\}$ is $n-i_1$. Find the $i_1+1 \leq i_2 \leq n$ such that $w(i_2) = n - i_1$. It follows from the condition on $w$ that $w(i_2-1) = n-i_1-1$, ..., $w(i_1+1) = n-i_2+1$. Then, proceed inductively until $i_s = n$ is reached. The claim is proven.

Note that $i_1 < n$, as $i_1 = n$ would imply $w = 1$, whereas $w \neq 1$ is assumed in the lemma. Let $L$ be the (proper) Levi subgroup of $GL_{n,\mathbb{K}} = G_\mathbb{K}$ containing $T_K$ of type $(i_1,i_2-i_1,\ldots,i_s-i_{s-1})$. From the claim it easily follows that $\mathbb{K}_h = U_h^w \cap w^{-1}U_h^- w \subseteq \mathbb{L}_h$. \hfill \Box

For $i = 1,2$ we have the composed maps

$$\pi_i : H_w \subseteq T_h \times T_h \rightarrow T_h \rightarrow T_1,$$

where the middle map is the projection to the $i$-th component, and the last map is the natural projection. For $1 \leq i \neq j \leq n$, let $\alpha_{i,j}$ denote the root of $GL_{n,\mathbb{F}_q}$ corresponding to $(i,j)$th matrix entry. Recall from Section 3.1 that $T_1 \subseteq G_1 \subseteq GL_{n,\mathbb{F}_q}$ and that $T_1$ is the diagonal (and in fact elliptic with respect to the Frobenius $F_0$) torus of $GL_{n,\mathbb{F}_q}$. Let $\alpha_{i,j}$ be the roots of $T_1$ in $GL_{n,\mathbb{F}_q}$ corresponding to $(i,j)$th entry.

Lemma 3.7. Let $\delta : \mathbb{Z}/n\mathbb{Z} \rightarrow \{0,1\}$ be a non-zero function, and let $\chi : G_m \rightarrow T_1$ be the cocharacter $X \mapsto \text{diag}(X^{\delta(1)},\ldots,X^{\delta(n)})$. Then $S_\chi := \{t \in T_1 : t^{-1}F(t) \in \text{im}(\chi)\}$ is a one-dimensional subgroup of $T_1$. Let $1 \leq j < i \leq n$. If $\delta$ does not factor as $\mathbb{Z}/n\mathbb{Z} \rightarrow \mathbb{Z}/\gcd(n,i-j)\mathbb{Z} \rightarrow \{0,1\}$, then the connected component $S_\chi^0$ of $S_\chi$ is not contained in the subtorus $\ker(\alpha_{i,j})$ of $T_1$.

In particular, if for any divisor $d > 1$, $\delta$ does not factor as $\mathbb{Z}/n\mathbb{Z} \rightarrow \mathbb{Z}/d\mathbb{Z} \rightarrow \{0,1\}$, then $S_\chi^0$ is not contained in any of the subtorus $\ker(\alpha_{i,j})$ $(1 \leq i \neq j \leq n)$ of $T_1$.

Proof. Assume that $\delta$ does not factor through $\mathbb{Z}/n\mathbb{Z} \rightarrow \mathbb{Z}/\gcd(n,i-j)\mathbb{Z}$. As $\dim S_\chi = 1$, it suffices to show that $S_\chi \cap \ker(\alpha_{i,j})$ is finite. We write an element in $T_1$ as an $n$-tuple $(t_k)_{k=1}^n$
corresponding to the diagonal matrix with entries $t_1, \ldots, t_n$. We have $\text{im}(\chi) = \{(a^{-\delta(k)})_{k=1}^n \in T_1 : a \in \mathbb{G}_m\}$. Thus $(t_k)_{k=1}^n \in T_1$ lies in $S_\chi$ if and only if $t_1^{-1}t_2^n = a^{-\delta(1)}$, $t_2^{-1}t_3^n = a^{-\delta(2)}, \ldots, t_{n-1}^{-1}t_n^n = a^{-\delta(n)}$. Thus $S_\chi$ is isomorphic to the one-dimensional subscheme of $\mathbb{G}_m^n$,

$$\{t_1, a \in \mathbb{G}_m^n : t_1^{q^n-1} - a^{\sum_{k=2}^{n} q^{-k+1}\delta(k)}\},$$

which is embedded into $T_1$ by sending $(t_1, a)$ to the tuple $(t_k)_{k=1}^n$ with $t_k = t_1^{q^k-1}a^{\sum_{k=2}^{n} q^{-k+1}\delta(k)}$.

Thus the intersection $S_\chi \cap \ker(\alpha_{i,j})$ is the closed subscheme of (3.8) given by the equation $t_i = t_j$, i.e.,

$$t_i^{q^{i-1}-q^{j-1}} = a^{\sum_{k=2}^{i-1} q^{i-k}\delta(k) - \sum_{k=2}^{j} q^{j-k}\delta(k)}.$$

Taking this to $(q^n-1)$-th power, taking the equation in (3.8) to the power $q^{i-1} - q^{j-1}$, and equalizing the left hand sides, we deduce that on $S_\chi \cap \ker(\alpha_{i,j})$ we must have

$$a^{(q^{i-1}q^{j-1})\delta(1)+\sum_{k=2}^{n} q^{-k+1}\delta(k)} = a^{(q^n-1)\delta(1)+\sum_{k=2}^{n} q^{-k}\delta(k)}.$$

Thus it suffices to show that

$$(q^{i-1} - q^{j-1})\delta(1) + \sum_{k=2}^{n} q^{-k+1}\delta(k) \neq (q^n-1)\delta(1) + \sum_{k=2}^{n} q^{-k}\delta(k),$$

or equivalently, that

$$\sum_{k=1}^{n-1} q^k\delta(n-k+i) - \sum_{k=1}^{n-1} q^k\delta(n-k+j) \neq -\sum_{k=0}^{j-2} q^k\delta(i-k) + \sum_{k=0}^{j-2} q^k\delta(j-k),$$

or that

$$\sum_{k=0}^{n-1} q^k(\delta(i-k) - \delta(j-k)) \neq 0.$$

Assume this is wrong, and this sum is 0. All terms $\delta(i-k) - \delta(j-k)$ lie in the set \{-1,0,1\} and hence $q^{n-1}$ is bigger than the sum of the absolute values of the remaining summands. It follows that we must have $\delta(i-k) = \delta(j-k)$ for all $k \in \mathbb{Z}/n\mathbb{Z}$. Or equivalently, that $\delta(k) = \delta(k+i-j)$ for all $k \in \mathbb{Z}/n\mathbb{Z}$. This is equivalent to saying that $\delta$ factors through $\mathbb{Z}/n\mathbb{Z} \rightarrow \mathbb{Z}/\gcd(n,i-j)\mathbb{Z}$, contradicting our assumption. \(\square\)

Now let $1 \neq w \in W_Q$, such that there is no $2 \leq i \leq n$ with $|w(i)| > |w(i-1) + 1| > 1$. Let $L_h$ be as in Lemma 3.6 and let $1 \leq i_1 < n$ be the size of its first block (cf. the proof of Lemma 3.6). Let $\delta : \mathbb{Z}/n\mathbb{Z} \rightarrow \{0,1\}$, $i \mapsto 1$ if $i \leq i_1$ and $i \mapsto 0$ otherwise. Let $\chi = (\chi_{i_1},0_{n-i_1})$ be the corresponding cocharacter. We have (again, cf. the proof of Lemma 3.6, $(w\delta)(i) = \delta(i+\lambda)$ for an appropriate $\lambda \in \mathbb{Z}/n\mathbb{Z}$. It follows from Lemma 3.6 and the definition of $H_w$ that $\pi_1(H_w) \supseteq S_{w\chi}$ and $\pi_2(H_w) \supseteq S_{\chi}$. Hence also

$$\pi_1(H_w^o) \supseteq S_{w\chi}^o \quad \text{and} \quad \pi_2(H_w^o) \supseteq S_{\chi}^o.$$  

(3.9)

From this together with Lemma 3.7 it follows that for $i = 1,2$, $\pi_i(H_w^o)$ is not contained in any of the $\ker(\alpha_{i,j}: T_1 \rightarrow \mathbb{G}_m)$ ($1 \leq i \neq j \leq n$). Hence it also holds for $\pi_i(H_{w,\text{red}}^o)$, where $H_{w,\text{red}}^o$ is the reductive part of $H_w^o$ (it is a torus). As in [Lus04] we have now $H_{c}^o(\hat{S}_w)_{\theta-1,\theta'} = H_{e}^o(\hat{S}_w)_{\theta-1,\theta'}$ and because $\pi_i(H_{w,\text{red}}^o)$ is not contained in any of the $\ker(\alpha_{i,j})$, we have

$$\hat{S}_w^{H_{w,\text{red}}^o} \subseteq \{(1,1,\tau,1,1) : \tau \in \mathbb{T}_h, F(\tau w) = \tau w\},$$

and (3.5) for $\hat{S}_w$ easily follows (cf. [Lus04], 1.9, proof of claim (6)).

\footnote{The fact that we are working with perfect schemes here does not affect the argument.}
3.4. Another extension of action. It remains to deal with the case \( w = 1 \). We prove first a more general result, again generalizing Lusztig’s method. The proof does not depend on special properties of \( \text{GL}_n \) and can be carried out for any group, so we put ourselves – until the end of Section 3.4 only – in the general setup of [CI19a]. Let \( G \) be a reductive group over \( K \), which is split over \( \bar{K} \), and let \( T, T' \) be two maximal \( K \)-rational, \( \bar{K} \)-split tori in \( G \). There is a natural inclusion of the reduced Bruhat–Tits building \( \mathcal{B}_K \) of \( G \) over \( K \) into the reduced Bruhat–Tits building \( \mathcal{B}_{\bar{K}} \) of \( G \) over \( \bar{K} \). Assume there is a point \( y \) in the intersection of \( \mathcal{B}_K \) and the apartments of \( T \) and \( T' \) inside \( \mathcal{B}_{\bar{K}} \). We have then the parahoric \( \mathcal{O}_K \)-model \( P_y \) of \( G \) attached to \( y \). Its \( \mathcal{O}_{\bar{K}} \)-points \( P_{\bar{y}}(\mathcal{O}_{\bar{K}}) \) form the parahoric subgroup of \( G(\bar{K}) \) attached to \( y \), which is the stabilizer of \( y \). On \( P_{\bar{y}}(\mathcal{O}_{\bar{K}}) \) we have the descending Moy–Prasad filtration given by certain subgroups \( P_{\bar{y}}(\mathcal{O}_{\bar{K}})^h \) \((h \geq 0)\). Using the truncated loop group construction [CI19a, 2.6], for any \( h \geq 1 \) one can defined an affine perfectly finitely presented perfect \( \mathbb{F}_q \)-group \( G_h \) satisfying

\[ G_h(\mathbb{F}_q) = P_{\bar{y}}(\mathcal{O}_{\bar{K}})/P_{\bar{y}}(\mathcal{O}_{\bar{K}})^{(h-1)} \]

We denote by \( T \) the (geometric) Frobenius on \( G_h(\mathbb{F}_q) \) and its closed subgroups. To a closed subgroup \( H \subseteq G \) one can naturally attach a closed subgroup \( H_h \subseteq G_h \), first taking the schematic closure of \( H \) in \( P_y \) and then applying \( L_y^+ \). We write \( H_h = \ker(\mathbb{H}_h \rightarrow \mathbb{H}_0) \) for the kernel of the natural projection. We also write \( G_h := G_h(\mathbb{F}_q) \) and \( H_h := H_h(\mathbb{F}_q) \) (the latter only if \( H \) is defined over \( \mathbb{F}_q \)). For more details we refer to [CI19a, 2.6].

Let \( U, U^- \) resp. \( U', U'^- \) be the unipotent radicals of a pair of opposite Borel subgroups containing \( T \) resp. \( T' \) and let \( U_h, U_h^- \) resp. \( U_h', U'_h^- \) be the corresponding subgroups of \( G_h \). We have the closed perfect subscheme of \( G_h \),

\[ S_{T,U,h} = \{ g \in G_h : g^{-1}F(g) \in FU_h \} \]

with a \( G_h \times T_h \)-action by \((\gamma,t) : g \mapsto \gamma g t \). Similarly we have the perfect subscheme \( S_{T',U',h} \subseteq G_h \). As already above, Lusztig’s scheme \( \Sigma = \{(x,x',y) : x \in FU_h \times FU'_h \times G_h : xF(y) = yx'\} \) is very useful to compute the inner product between the virtual \( G_h \)-representations obtained from \( S_{T,U,h} \) and \( S_{T',U',h} \). More precisely, for \( \Xi_\ell \)-valued characters \( \theta \) resp. \( \theta' \) of \( T_h \) resp. \( T'_h \) we have

\[ \langle H_\ell^c(S_{T,U,h})\theta, H_\ell^c(S_{T',U',h})\theta' \rangle_{G_h} = \dim_{\Xi_\ell} H_\ell^c(\Sigma)\theta \circ \theta' \]

To study \( H_\ell^c(\Sigma) \) Lusztig in [Lus04] (and many authors in follow-up articles) used a locally closed decomposition \( \Sigma = \prod_{w \in W(T,T)} \Sigma_w \) where \( W_T(T',T) = \{ T_1 : v^{-1}T_1v = T_1' \} \) is the transporter from \( T_1' \) to \( T_1 \) in \( G_1 \) (= reductive quotient of the special fiber of \( P_y \)) conjugating \( T_1' \) to \( T_1 \). Now, we generalize this construction in a substantial way.

Let \( V \) resp. \( V' \) be the unipotent radical of a second Borel subgroup containing \( T \) resp. \( T' \). We have the corresponding subgroups \( \mathcal{V}_h, \mathcal{V}'_h \) of \( G_h \). For \( v \in W_T(T',T) \) we have the corresponding preimage \( \mathcal{V}_hT_v \mathcal{V}'_h \) (with \( \mathcal{K}_{V,V',\tau} := \mathcal{V}'_h \cap v^{-1} \mathcal{V}_h \)) of the Schubert cell in \( G_1 \) attached to \( v \). We consider the following generalization of \( \Sigma_w, \Sigma'_w \) from [Lus04]:

\[ \Sigma_{V,V',\tau,v} := \{(x,x',y) \in FU_h \times FU'_h : x \in \mathcal{V}_hT_v \mathcal{V}'_h : xF(y) = yx'\} \]

\[ \Sigma_{V,V',\tau,v} := \{(x,x',y,\tau,z,y') \in FU_h \times FU'_h \times \mathcal{V}_h \times T_h \times \mathcal{K}_{V,V',\tau} \times \mathcal{V}'_h : xF(y')u \mathcal{V}_h = y'\mathcal{V}'_h \}
\]

which have the same alternating sum of cohomology. The action of \( T_h \times T'_h \) on \( \Sigma_{V,V',\tau,v} \) is given by

\[ (t,t') : (x,x',y,\tau,z,y') \mapsto (txt^{-1},t'x't^{-1},ty't^{-1},t\tau \dot{t}^{-1} \dot{t}^{-1} t',t'x't^{-1},t'yl't^{-1}) \]

and by a similar formula for \( \Sigma_{V,V',\tau,v} \). There is an element \( v_0 \in v_0(V,V') \in W_T(T',T) \), such that the (generalized) Bruhat cell \( \mathcal{V}_hT_1v_0 \mathcal{V}'_h \) is generic in \( G_1 \), i.e., \( v_0^{-1} \mathcal{V}_h \mathcal{V}_h = \mathcal{V}'_h \). For this
\[ v_0 \text{ we have } K_{V,V',h} = 1. \] We can write \( y' \in \mathcal{V}_h \) and \( y'' \in \mathcal{V}_h' \) as
\[
y' = y_1y_2' \quad \text{and} \quad y'' = y_1''y_2'' \quad \text{with} \quad y'_1 \in U_h \cap V_h, \ y'_2 \in U_h \cap V_h, \ y''_1 \in U_h' \cap V_h, \ y''_2 \in U_h' \cap V_h.
\]
(the action of \((t, t') \in T_h \times T_h'\) is given by \((y'_1, y'_2, y''_1, y''_2) \mapsto (ty'_1t^{-1}, ty'_2t^{-1}, t'y''_1t^{-1}, t'y''_2t^{-1})\)).

Changing the variables \( xF(y'_1) \mapsto x, xF(y''_2) \mapsto x' \) we can rewrite
\[
\Sigma_{V,V',v_0} := \{ (x, y'_1, y'_2, \tau, y''_1, y''_2) \in F(U_h \times (U_h \cap V_h) \times (U_h' \cap V_h) \times T_h \times (U_h' \cap V_h') \times (U_h' \cap V_h) : xF(y''_2) = y'_1y''_1, xF(y'') = y''_2F(U_h) \}. 
\]

Let
\[
H'_{v_0} = \{(t, t') \in T_h \times T_h' : F(t)t^{-1} = v_0t'F(t')^{-1}v_0^{-1} \text{ centralizes } U_h' \cap V_h' \text{ and } v_0(FU_h' \cap V_h')v_0^{-1} \}. 
\]

Define an action of \( H'_{v_0} \) on \( \Sigma_{V,V',v_0} \) by
\[
(t, t') : (x, y'_1, y'_2, \tau, y''_1, y''_2) \mapsto (F(t)xF(t)^{-1}, F(t)y'_1F(t)^{-1}, ty'_2t^{-1}, t\tau t^{-1}v_0^{-1}, t'y''_1t^{-1}, t'y''_2t'^{-1}).
\]

It extends the action of \( T_h \times T_h' \). We have to show that \( (x, y'_1, y'_2, \tau, y''_1, y''_2) \in \Sigma_{V,V',v_0} \), then the same holds for \((t, t')(x, y'_1, y'_2, \tau, y''_1, y''_2)\).

This reduces to show that
\[
xF(y'_1)F(\tau)F(y''_2) = y'_1y''_1, xF(y'') = y''_2F(U_h) 
\]
Writing \( y''' = y''y_2'' \in \mathcal{V}_h' \) as \( y''_1y''_2'' \) with \( y''_2'' \in \mathcal{V}_h' \cap V_h' \) and \( y''_1 \in \mathcal{V}_h' \cap FU_h' \), it suffices to check that \( F(t)t^{-1} \) commutes with \( y'_2 \in U_h' \cap \mathcal{V}_h \) and that \( t^{-1}F(t') = v_0^{-1}F(t')v_0^{-1} \) commutes with \( \mathcal{V}_h' \cap F\mathcal{V}_h' \). This holds by definition of \( H'_{v_0} \). We thus have proven the following lemma.

**Lemma 3.8.** The action of \( T_h \times T'_h \) on \( \Sigma_{V,V',v_0} \) extends to an action of the algebraic group \( H'_{v_0} \) given by the above formula.

Returning now to the proof Theorem 3.1 we apply Lemma 3.8 to our \( \mathbf{G} \) (= inner form of \( \mathbf{GL}_n \)), the point \( y = x_0 \), the diagonal (elliptic unramified) torus \( \mathbf{T} = T'_h \) of \( \mathbf{G} \), the subgroup \( U = U' \) of unipotent upper triangular matrices and to \( V = U, V' = U' \), \( v_0 = 1 \), in which case \( U_h' \cap V_h = 1 \) and \( v_0(FU_h' \cap V_h')v_0^{-1} \) is contained in \( L_h \) for some proper Levi subgroup \( L \) of \( G_K \), and hence the reductive part \( H'_{v_0,\text{red}} \) of the connected component of \( H'_{v_0} \) is big enough in the sense of Lemma 3.7. Note finally that \( \Sigma_1 = \Sigma_{U,U,1} \) is a closed subscheme of \( \Sigma_{U,U',-1} \), (in fact, on \( \Sigma_{U,U',-1}, \) \( y \) varies in \( T_hU_hU_hU_h^{-1} \) and \( \Sigma_1 \) is given by the closed condition \( y \in T_hU_hU_h^{-1} \)).

Let \( \Sigma_1 \) denote the pullback of \( \Sigma_1 \) along \( \Sigma_{U,U',-1} \rightarrow \Sigma_{U,U',-1} \). It has the same alternating sum of cohomology as \( \Sigma_1 \), and it is clearly stable under the action of \( H'_{v_0} \). Thus the argument from \( \text{Lus04 1.9} \) applies to \( \Sigma_1 \) and we obtain \( H^*_c(\Sigma_1) = H^*_c(\Sigma_1) = H^*_c(\Sigma_1) = H^*_c(\Sigma_1) \) (and the same for \( \theta^{-1} \otimes \theta'\)-isotypic parts), hence verifying (3.5) in the only remaining case \( w = 1 \). Theorem 3.1 is proven.

4. A variation of the Mackey formula

We work with exactly the same setup and notation as in Section 3 (and in particular Section 3.1). Recall the presentation (3.2) of \( X_{h,w} \). Then
\[
X_{h,w} = \{ g \in \mathcal{G}_h : g^{-1}F(g) \in U_{h'-1} \cap F \mathcal{V}_h \},
\]
is a closed perfect subscheme of \( X_h \), stable under the action of \( G_h \times T_h \). In fact, \( X_h \) has a stratification in locally-closed pieces \( \mathbf{C}19 \) indexed by divisors \( r \) of \( n' \), and \( X_{h,w} \) is precisely the closed stratum.
Theorem 4.1. Let \( \theta : T_h \to \overline{\mathbb{Q}_l}^* \) be a character. Assume that \( p > n \), and that \( \theta|_{T_h} \) has trivial stabilizer in \( W^F_{\mathbb{Q}} \). Then
\[
\left< R^G_{T_h}(\theta), H^*_c(X_{h,n})_{\theta} \right>_{G_h} = 1
\]
and
\[
\left< H^*_c(X_{h,n})_{\theta}, H^*_c(X_{h,n})_{\theta} \right>_{G_h} = 1.
\]

We prove Theorem \ref{thm:main} in Sections \ref{sec:proof-thm-main} \ref{sec:proof-thm-main-section}. From Theorems \ref{thm:main} and \ref{thm:main} we deduce:

Corollary 4.2. Under the assumptions of Theorem \ref{thm:main} \ref{thm:main}, \( H^*_c(X_{h,n})_{\theta} \) is up to sign an irreducible representation of \( G_h \), and \( H^*_c(X_{h,n})_{\theta} \cong R^G_{T_h}(\theta) \).

Remark 4.3. There are two general principles used in the proofs of Theorems \ref{thm:main} and \ref{thm:main} \ref{thm:main}: (1) If \( X \) is a reasonably nice (perfect) scheme over a field with an action of an algebraic group \( H \), then the induced action of \( H \) in \( H^*_c(X, \overline{\mathbb{Q}_l}) \) is trivial (\( \forall i \geq 0 \)), and (2) if moreover \( X \) is the perfection of a quasi-projective scheme over a finite field, \( H \) is a torus, and \( \alpha : X \to X \) is a finite order automorphism commuting with the \( H \)-action, then \( \text{tr}(\alpha, H^*_c(X, \overline{\mathbb{Q}_l})) = \text{tr}(\alpha, H^*_c(X, \overline{\mathbb{Q}_l})) \). For our purposes (2) is stronger than (1), which for example does not allow quantitative results in Section \ref{sec:quantitative-results}. Theorem \ref{thm:main} \ref{thm:main} is less general than Theorem \ref{thm:main} because in its proof we have to use both (2) and (1), whereas in the proof of Theorem \ref{thm:main} we manage to work with (2) only.

4.1. Proof of Theorem \ref{thm:main} \ref{thm:main}: multiplicative extension. Parts of the proof follows along the same lines as the proof of Theorem \ref{thm:main}, thus we will be slightly sketchy below. Similar as in \cite[Lemma 7.12]{CIT} we have an isomorphism
\[
(\mathbb{U}_1^h \cap F\mathbb{U}_1^h) \times (\mathbb{U}_h^{-1} \cap F\mathbb{U}_h^1) \to F\mathbb{U}_h^1, \quad (g, x) \mapsto g^{-1}xF(g).
\]

Thus we have \( G_h \times T_h \)-equivariantly \( X^*_{h,n} \cong S^*_{h,n}/(\mathbb{U}_1^h \cap F\mathbb{U}_h^1) \), where
\[
S^*_{h,n} = \{ g \in G_h : g^{-1}F(g) \in F\mathbb{U}_h^1 \}
\]
and \( G_h \times T_h \) acts on \( S^*_{h,n} \) by \( g, t : x \mapsto gxt \), and \( (\mathbb{U}_1^h \cap F\mathbb{U}_h^1) \) by right multiplication. Hence
\[
H^*_c(X^*_{h,n})_{\theta} \cong H^*_c(S^*_{h,n})_{\theta}.
\]

Using Lang’s theorem, we have \( T_h \times T_h \)-equivariantly
\[
G_h \setminus (S^*_{h, n} \times \Sigma_{(1,n)}) = \{(x, x', y) \in F\mathbb{U}_h^1 \times F\mathbb{U}_h^1 \times G_h : xF(y) = yx' \}
\]
where \( T_h \times T_h \) acts on \( \Sigma_{(1,n)} \) by \( (t, t') : (x, x', y) \mapsto (ttx^{-1}, t'x'^{-1}, tyy^{-1}) \). For \( w \in W_{\mathbb{Q}} \) let \( \Sigma_{(1,n), w} = \{(x, x', y) \in \Sigma_{(1,n)} : y \in G_{h,n} \} \) (it is an \( T_h \times T_h \)-stable locally closed perfect subscheme) and putting \( K_h = \mathbb{U}_h \cap \mathbb{U}_h^{-1} \mathbb{U}_h \), we let
\[
\hat{\Sigma}_{(1,n), w} = \{(x, x', y, \tau, z, y_2) \in F\mathbb{U}_h \times \mathbb{U}_h \times T_h \times K_h \times \mathbb{U}_h : xF(y_1 \tau wyz) = y_1 \tau wyz F\mathbb{U}_h^1 \}
\]
be the Zariski-locally trivial covering of \( \Sigma_{(1,n), w} \) with \( T_h \times T_h \)-action given by the same formula as in \ref{sec:zariski}. As in Section \ref{sec:proof-thm-main} we have
\[
\left< R^G_{T_h}(\theta), H^*_c(X^*_{h,n})_{\theta} \right>_{G_h} = \sum_{w \in W_{\mathbb{Q}}} \dim H^*_c(\hat{\Sigma}_{(1,n), w})_{\theta^{-1}, \theta}.
\]

We claim that
\[
\dim H^*_c(\hat{\Sigma}_{(1,n), w})_{\theta^{-1}, \theta} = \begin{cases} 1 & \text{if } w = 1 \\ 0 & \text{otherwise,} \end{cases} \tag{4.1}
\]
which implies the first formula of Theorem \ref{thm:main} \ref{thm:main}. Assume first \( w \) satisfies the condition in Lemma \ref{lem:condition-w}. Then \( \hat{\Sigma}_{(1,n), w} \subseteq \Sigma_{w} = \emptyset \) and we are done. Now assume that \( w = 1 \). Then
\[
\hat{\Sigma}_{(1,n), 1} = \{(x, x', y_1, \tau, z) \in F\mathbb{U}_h \times F\mathbb{U}_h^1 \times \mathbb{U}_h \times T_h \times \mathbb{U}_h^{-1} : xF(y_1 \tau z) = y_1 \tau x x' \}
\]
is another a Zariski-locally trivial covering of $\Sigma(1,n)_1$ (with obvious $T_h \times T_h$-action), so that $H^1_c(\Sigma(1,n)_1; \theta^{-1}, \theta) = H^1_c(\Sigma(1,n)_1; \theta^{-1}, \theta)$, and we can replace $\Sigma(1,n)_1$ by $\Sigma(1,n)_1$. We can write uniquely $z = z_1 z_2$ with $z_1 \in \mathbb{U}_h^{-1} \cap F \mathbb{U}_h^{-1}$ and $z_2 \in \mathbb{U}_h^{-1} \cap F \mathbb{U}_h^{-1}$ and make the change of variables $xF(y_1) \mapsto x$, $y_2 x' \mapsto x'$ (note that the latter indeed works, as $z_2 \in F \mathbb{U}_h$), so that $\Sigma(1,n)_1 \cong \{(x, y_1, \tau, z_1, z_2) \in F \mathbb{U}_h \times \mathbb{U}_h \times T_h \times (\mathbb{U}_h^{-1} \cap F \mathbb{U}_h^{-1}) \times (\mathbb{U}_h^{-1} \cap F \mathbb{U}_h^{-1}) : xF(\tau z_1 z_2) \in y_1 \tau z_1 F \mathbb{U}_h\}$

The $T_h \times T_h$-action on $\Sigma(1,n)_1$ is given by

$$(t, t') : (x, y_1, \tau, z_1, z_2) \mapsto (txt^{-1}, ty_1 t^{-1}, t\tau t^{-1}, t'z_1 t^{-1}, t'z_2 t^{-1}).$$

Let

$$H_1 := \{(t, t') \in T_h \times T_h : t^{-1}F(t) = t'^{-1}F(t') \text{ centralizes } \mathbb{U}_h \cap F \mathbb{U}_h^{-1}\}.$$

As is checked similar to computations in Sections 3.3 and 3.4, $H_1$ acts on $\Sigma(1,n)_1$ by

$$(t, t') : (x, y_1, \tau, z_1, z_2) \mapsto (F(t)xF(t)^{-1}, F(t)_y F(t)^{-1}, t\tau t^{-1}, t'z_1 t^{-1}, t'z_2 t^{-1}).$$

(and this action extends the action of $T_h \times T_h$). As $\mathbb{U}_h \cap F \mathbb{U}_h^{-1}$ is contained in the subgroup of $G_\mathbb{K}$ attached to a proper rational Levi subgroup $L \subseteq G_\mathbb{K}$, it follows that the connected component $H^1_{1, \text{red}}$ of the reductive part of $H$ is big enough (in the sense of Lemma 3.7) so that we deduce dim $H^1_c(\Sigma(1,n)_1; \theta^{-1}, \theta) = 1$, and hence (4.1) for $w = 1$ (this is the same argument as at the end of Section 3.4).

4.2. Proof Theorem 4.1[4.1]: additive extension. It remains to show (4.1) for $1 \neq w \in W_\mathbb{K}$ not satisfying the condition from Lemma 3.5. Assume $w$ is such an element. Let

$$H^1_{w, \text{red}} := \{(t, t') \in T_h \times T_h : w^{-1}t^{-1}F(t)w = t'^{-1}F(t') \text{ centralizes } \mathbb{K}_h\}$$

In $\Sigma(1,n)_w$ make the change of variables $xF(y_1) \mapsto x$, so that

$$\Sigma(1,n)_w = \{(x, y_1, \tau, z, y_2) \in F \mathbb{U}_h \times \mathbb{U}_h \times T_h \times \mathbb{K}_h \times \mathbb{U}_h : xF(\tau w z) \in y_1 \tau w z y_2 F(\mathbb{U}_h^{-1}y_2^{-1})\}$$

with $T_h \times T_h$-action given by the same formula as in (4.4). Now

$$(t, t') : (x, y_1, \tau, z, y_2) \mapsto (F(t)xF(t)^{-1}, F(t)_y F(t)^{-1}, t\tau t^{-1}w t^{-1} \in \mathbb{K}_h, t'z_1 t^{-1}, F(t')_y F(t')^{-1})$$

defines an action of $H^1_{w, \text{red}}$ on $\Sigma(1,n)_w$. In order to check this we have to show that if $(t, t') \in H^1_{w, \text{red}}$ and $(x, y_1, \tau, z, y_2) \in \Sigma(1,n)_w$, then also $(t, t'). (x, y_1, \tau, z, y_2) \in \Sigma(1,n)_w$. After elementary cancellations this reduces to show that

$$xF(\tau w z t^{-1}) \in y_1 F(t)^{-1} t\tau w z t^{-1} F(t')_y F(t')^{-1} F(\mathbb{U}_h^{-1}y_2^{-1}) F(t')^{-1}$$

But as $t' \in T_h$, we have $U^1_h F(\mathbb{U}_h^{-1}y_2^{-1}) = U^1_h y_2^{-1}$, so this reduces to show that

$$xF(\tau w z) \in y_1 F(t)^{-1} t\tau w z t^{-1} F(t')_y F(t')^{-1} U^1_h y_2^{-1} t'.$$

Again, using $t' \in T_h$, we deduce that $t'^{-1}U^1_h y_2^{-1} t' = U^1_h y_2^{-1}$, and hence that $(t, t'). (x, y_1, \tau, z, y_2) \in H^1_{w, \text{red}}$.

Via the isomorphism $T_h \cong U_L / U^1_L$ mapping a diagonal matrix $t = (t_i)_{i=1}^n$ to its upper left entry $t_1$, we identify $T_h$ with $U_L / U^1_L$ and $T^1_h$ with $U^1_L / U^2_L$. By Lemma 2.12 (and the discussion in Section 2.1.3), the condition that $\theta^1_{T^1_h}$ has trivial stabilizer in $W_\mathbb{K} = \langle u_0^- \rangle$ translates into the condition that the restriction of $\theta$ to $U^1_L / U^2_L$ does not factor through any of the norm maps $N_{n'/n} : U^1_L / U^2_L \rightarrow U^1_{n'/n} / U^2_{n'/n}$, where $1 \leq s < n'$ goes through all divisors of $n'$. Let $H^1_{w, \text{red}}$ be the connected component of $H^1_{w, \text{red}}$.

Lemma 4.4. If $(t, t')$ varies through $(T^1_h \times T^1_h) \cap H^1_{w, \text{red}}$, then $t^{-1} t'$ varies (at least) through all elements of $\ker(N_{n'/n} \mathbb{K})$ for some divisor $1 \leq s < n'$ of $n'$ (s depends on $w$).
Before proving this lemma, we use it to finish the proof of Theorem 4.1(a). Indeed, by assumption on \( \theta \) for each divisor \( s < n' \) of \( n' \) there is an element \( x = x_s \in \ker N_{m/n s} \subseteq U^1_{L}/U^h_{L} \) such that \( \theta(x_s) \neq 1 \). By Lemma 4.4 we can find a divisor \( s < n' \) of \( n' \) and an element \((t, t') \in (T^1_{h} \times T^1_{h}) \cap H^1_{w,0} \) such that \( l_i^{-1}l'_i = x_s \), and hence \( \theta(l_i^{-1}l'_i) \neq 1 \). Seeing \( \theta \) as a character of \( T^1_{h} \) again, this simply means that \( \theta(t) \neq \theta(t') \), and it follows that the \( T^1_{h} \times T^1_{h} \)-character \( \theta^{-1} \otimes \theta \) is non-trivial on \( (T^1_{h} \times T^1_{h}) \cap H^1_{w,0} \). But the induced action of a connected algebraic group in the cohomology of a separated scheme of finite type over \( \mathbb{F}_q \) is trivial [DL76, Corollary 6.5] and the same holds after perfection, hence for each \( i \geq 0 \) we have \( H^1_{\mathbb{F}_q}(S_{(1,n),w}) \theta^{-1} \otimes \theta = 0 \), which shows claim (4.1) for all remaining elements \( w \), and hence also Theorem 4.1(a).

Remark 4.5. The basic idea in the above arguments is the same as in [DL76, Lemma 6.7]. This gives hope to generalize them to a far more general setup (e.g. all unramified maximal tori in all reductive groups).

Towards the proof of Lemma 4.4, for positive integers \( s, r \) such that \( s \) divides \( r \), we define morphisms of perfect \( \mathbb{F}_q \)-schemes

\[
Nm_{r/s} : \mathbb{W}^x_{h} \to \mathbb{W}^x_{h}, \quad x \mapsto Nm_{r/s}(x) := \prod_{i=0}^{r-1} \sigma^i(x).
\]

**Proof of Lemma 4.4** By assumption, \( w \) does not satisfy the condition of Lemma 3.6. Thus by Lemma 3.6 there is a proper Levi subgroup \( L \subseteq G_{K} \) containing \( T_{R} \), such that if \( L_{h} \) is the corresponding subgroup of \( G_{h} \), we have \( \mathbb{K}_{h} \subseteq L_{h} \). We may assume \( L \) is maximal, so that there is an \( 1 \leq m \leq n-1 \), such that \( L = \text{GL}_{m,K} \times \text{GL}_{n-m,K} \) (upper left and lower right diagonal blocks). More precisely, we may (and do) choose that \( m \) to be the \( t_1 \) from the proof of Lemma 3.6. In fact, by our explicit description of \( W_{\mathbb{Q}} \cong \prod_{i=1}^{n_0} S_{n_i} \) in Section 3.1 we see that as \( w \in W_{\mathbb{Q}} \), our choice \( m = w^{-1}(n) \) must be an integer dividing \( n_0 \). Let \( \chi = (1_m, 0_{n-m}) \) be a cocharacter of \( T_{K} \). From the explicit form of \( w \) determined in Lemma 3.6 we see that \( w\chi = (0_{n-m}, 1_m) \). Let \( Y_{h,\chi} \subseteq T_{h} \) denote the subgroup of \( T_{h} \) corresponding to the subgroup \( \text{im}(\chi) \) of \( T_{K} \) (thus \( Y_{h,\chi} \cong \mathbb{W}^x_{h} \)). As \( \text{im}(\chi) \) centralizes \( L \), \( Y_{h,\chi} \) centralizes \( L_{h} \) and hence also \( \mathbb{K}_{h} \). Thus \( H^1_{\mathbb{F}_q} \geq H^1_{w,\chi} := \{(t, t') \in T_{h} \times T_{h}^1 : \hat{w} t^{-1} F(t) \hat{w} = t'^{-1} F(t') \in \mathbb{W}^1_{h,\chi} \} \), and the same inclusion holds if we take connected components on both sides. Thus we may replace \( H^1_{w} \) by \( H^1_{w,\chi} \). Let \( (t, t') \in T_{h} \times T_{h}^1 \). Write \( t = \text{diag}(t_i)^{n} \) and \( t' = \text{diag}(t_i')^{n} \) with \( t_i, t'_i \in \mathbb{W}^x_{h,1} \). Let \( x \) be a \( \mathbb{W}^x_{h,1} \)-coordinate on \( \mathbb{W}^1_{h,\chi} \) (it is an \((h-1)\)-tuple of \( A^1 \)-coordinates). We can eliminate all “coordinates” \( t_i (i \neq n) \) and \( t'_i (i \neq m) \) by expressing them through \( x \) and \( t_m, t'_m \). More precisely,

\[
H^1_{w,\chi} \cong \{(x, t_m, t'_m) \in \mathbb{W}^x_{h,1} \times \mathbb{W}^x_{h,1} \times \mathbb{W}^x_{h,1} : \sigma^n(t_m)n^{-1} = Nm_{m/1}(x) = \sigma^n(t'_m)n^{-1} \}.
\]

We see that on \( H^1_{w,\chi} \), the equation \( \sigma(t_m^{-1}t'_m) = t_m^{-1}t'_m \) holds, so that \( t_m^{-1}t'_m \) can take only finitely many values. On \( H^1_{w,\chi} \) we must in particular have \( t_n = t'_m \), or equivalently (using the expression of \( t_1, t'_1 \) through \( t_m, t'_m \)) we have

\[
\sigma^{n-m}(t_1) = t'_1
\]

on \( H^1_{w,\chi} \). Furthermore, \( H^1_{w,\chi} \) is contained in the perfect scheme (isomorphic to)

\[
\{(x, t_n) \in \mathbb{W}^x_{h} \times \mathbb{W}^x_{h} : \sigma^n(t_n)n^{-1} = Nm_{m/1}(x)\}
\]

Now let \( 1 \leq g = \text{gcd}(m, n) < n \). As \( \sigma^n(t_n) = Nm_{n/g}(\sigma(t_n)n^{-1}) = Nm_{n/g}(Nm_{n/g}(\sigma(t_n)n^{-1})), \) and \( Nm_{n/g}(x) = Nm_{n/g}(Nm_{n/g}(x)^{-1}) \) on
this scheme, and hence $Nm_{n/g}(\sigma(t_n)_{n}^{-1})Nm_{m/g}(x)^{-1}$ is discrete on it. Hence $H^1_{w,\chi}$ is contained in the perfect scheme (isomorphic to)
\[ \{(x, t_n) \in \mathbb{W}^{x,1}_h \times \mathbb{W}^{x,1}_h ; \text{Nm}_{n/g}(\sigma(t_n)_{n}^{-1}) = \text{Nm}_{m/g}(x)\} \]
After replacing $\sigma$ by $\sigma^g$, Lemma 4.7 shows that this last perfect $\mathbb{F}_q$-scheme is connected, so that it is equal to $H^1_{w,\chi}$. On $H^1_{w,\chi}$, $t_1 = \sigma(t_n)$, so that (after replacing $\sigma(x)$ by $x$ which is harmless here), we have
\[ H^1_{w,\chi} \cong \{(x, t_1) \in \mathbb{W}^{x,1}_h \times \mathbb{W}^{x,1}_h ; \text{Nm}_{n/g}(\sigma(t_1)_{t_1}^{-1}) = \text{Nm}_{m/g}(x)\} \]
Now $H^1_{w,\chi} \cap (T^1_h \times T^1_h)$ is the locus in $H^1_{w,\chi}$ defined by $x = 1$. Thus we deduce
\[ H^1_{w,\chi} \cap (T^1_h \times T^1_h) = \{(t, t') \in T^1_h \times T^1_h ; t' = \sigma^{-m}(t_1) \text{ and } \text{Nm}_{n/g}(\sigma(t_1)_{t_1}^{-1}) = 1\} \]
(recall that in $T^1_h$, $t$ is determined by its first entry $t_1$). Note that $\text{Nm}_{n/g}(\sigma(t_1)_{t_1}^{-1}) = 1$ simply means that $\text{Nm}_{n/g}(t_1)$ is $\sigma$-stable. As $m$ is divisible by $n_0$, $T^1_h = \mathbb{W}^{x,1}_W(\mathbb{F}_q) = U^1_h/U^1_h$ and the restriction of $\text{Nm}_{n/g}$ to $T^1_h \cong U^1_h/U^1_h$ is $N_{n/g}$, the lemma now follows from Lemma 4.6.

\[ \text{Lemma 4.6. Suppose } (n, p) = 1. \text{ Let } 1 \leq m \leq n - 1 \text{ and put } g = \text{gcd}(n, m). \text{ Let}
\]
\[ \alpha : \{y \in U^1_h/U^1_h ; N_{n/g}(y) \in U^1_K/U^1_K \rightarrow U^1_h/U^1_h, \ y \mapsto \sigma^{-m}(y)\} \]
\[ \text{Then } \text{im}(\alpha) = \ker(N_{n/g} : U^1_h/U^1_h \rightarrow U^1_{K,g}/U^1_{K,g}). \]

\[ \text{Proof. For arbitrary } a \in \mathbb{Z} \text{ we have}
\]
\[ N_{n/g}(y) \in U^1_K/U^1_K \Rightarrow N_{n/g}(\sigma^a(y)y^{-1}) = \sigma^a(N_{n/g}(y))N_{n/g}(y)^{-1} = 1 \Rightarrow \sigma^a(y)y^{-1} \in \ker(N_{n/g}). \]

Hence $\text{im}(\alpha) \subseteq \ker(N_{n/g})$. Let $y \in \ker(\alpha)$. Then $N_{n/g}(y)$ is rational and $\sigma^{-m}(y) = y$ and $\sigma^n(y) = y$. The last two equalities together are equivalent to $\sigma^a(y) = y$. Hence $N_{n/g}(y) = \frac{n}{g}y$, and hence $y$ is rational (as $N_{n/g}(y)$ is, and $(n, p) = 1$). Conversely, if $y$ is rational, then surely $y \in \ker(\alpha)$. Thus $\ker(\alpha) = U^1_K/U^1_K$. Now the source of $\alpha$ is the preimage under the (surjective) map $N_{n/g} : U^1_h/U^1_h \rightarrow U^1_{K,g}/U^1_{K,g}$ of $U^1_K/U^1_K$, hence the size of the source of $\alpha$ is $\# \ker(N_{n/g}) \cdot \#(U^1_K/U^1_K)$. Thus $\#(\text{im}(\alpha)) = \#(\text{source of } \alpha)/\#(\text{ker}(\alpha)) = \#(\ker(N_{n/g}))$. As we already know that $\text{im}(\alpha) \subseteq \ker(N_{n/g})$ and both sets are finite, we are done.

For positive integer $s$ define the $\mathbb{F}_q$-morphism
\[ \text{tr}_{s/1} : \mathbb{G}_a \rightarrow \mathbb{G}_a, \ x \mapsto \text{tr}_{s/1}(x) := \sum_{i=0}^{s-1} x^q. \]

\[ \text{Lemma 4.7. Let } r > s \geq 1 \text{ be coprime integers. Suppose } p > s. \text{ The closed perfect subscheme}
\]
\[ R_h = \{(y, x) \in \mathbb{W}^{x,1}_h \times \mathbb{W}^{x,1}_h ; \text{Nm}_{r/1}(\sigma(y)y^{-1}) = \text{Nm}_{s/1}(x)\} \]
\[ \text{of } \mathbb{W}^{x,1}_h \times \mathbb{W}^{x,1}_h \text{ is connected. More precisely, for } h \geq 2 \text{ the fibers of } R_h \rightarrow R_{h-1} \text{ are isomorphic to } \mathbb{A}^1 \text{ (note that } R_1 \text{ is a point).}
\]

\[ \text{Proof. It suffices to prove that the fibers of } R_h \rightarrow R_{h-1} \text{ are isomorphic to } \mathbb{A}^1. \text{ The fibers of } R_h \rightarrow R_{h-1} \text{ are isomorphic to closed sub-}(\text{perfect schemes}) \text{ of } \mathbb{G}_a^2 \text{ (with coordinates } X, Y) \text{ given by the equation}
\]
\[ C : \text{tr}_{r/1}(Y^q - Y) = \text{tr}_{s/1}(X) + \text{const}, \]
\[ \text{where } \text{const} \text{ is a constant term depending on the point in } R_{h-1}. \text{ As } \text{tr}_{r/1}(Y^q - Y) = Y^{q^s} - Y, \text{ one can eliminate this constant term by changing the variable } Y + c \rightarrow Y \text{ (for an appropriate } c \in \mathbb{F}_q). \text{ So we assume } \text{const} = 0. \text{ We may assume } s > 1, \text{ as otherwise we obviously have } C \cong \]
$\mathbb{A}^1$. Put $r_0 := r$, $r_1 := s$ and define $r_i \in \mathbb{Z}_{\geq 0}$ ($i \geq 2$), $\gamma_i \in \mathbb{Z}_{>0}$ ($i \geq 1$) by $r_i = \gamma_i + r_{i+1} + r_{i+2}$ and $r_{i+2} < r_{i+1}$ for $i \geq 0$. Say this stops at $i = \alpha$, that is $r_{\alpha+1} = \text{gcd}(r, s) = 1$, $r_{\alpha+2} = 0$.

Via the change of variables $X + Y^{q^{r-\alpha+1}} \mapsto X$, $C$ is isomorphic to the curve $C_1: \text{tr}_{r_1/1}(X) = \text{tr}_{r_2/1}(Y^q - Y)$.

Now $\text{tr}_{r_2/1}(Y^q - Y) = Y^{q^2} - Y$, so that we can successively make a series of changes of variables of the form $Y + X^{q^2} \mapsto Y$ for appropriate $\beta \in \mathbb{Z}_{\geq 0}$, to eliminate all powers of $X$ with exponent greater than $q^2$. This shows that $C_1$ is isomorphic to the curve $C_2: \text{tr}_{r_3/1}(X) + \gamma_2 \text{tr}_{r_2/1}(X) = \text{tr}_{r_2/1}(Y^q - Y)$.

Now we successively apply the perfection of Lemma 4.8 to $C_2$ and the initial tuple of integers $(a_1, b_1, c_1, d_1) = (1, \gamma_2, r_3, r_2)$. Consider the operation $(a, b, c, d) \mapsto (b, a + b\gamma, r, c)$ on quadruples of integers (satisfying $0 < c < d$) where $0 \leq r < d$ and $\gamma > 0$ are defined by $d = \gamma c + r$. First of all, if $a, b > 0$, then also $b, a + b\gamma > 0$. Moreover, the operation leaves invariant the sum of products of 1st and 3rd and of 2nd and 4th entries: $ac + bd = br + (a + b\gamma)c$. Thus if $(a_i, b_i, c_i, d_i)$ is the tuple after $(i - 1)$th iteration step, we have $a_i c_i + b_i d_i = r_3 + \gamma_2 r_2 = r_1 = s < p$. Also we have $c_i = r_{i+2}$, $d_i = r_{i+1}$, and hence $0 < c_i < d_i$ as long as $i \leq \alpha - 1$. All this implies that $0 < a_i, b_i, c_i, d_i < p$ and $0 < c_i < d_i$ for each $i = 1, 2, \ldots, \alpha - 1$, so that Lemma 4.8 indeed applies in each step, as long as $i < \alpha$. The last application (for $i = \alpha - 1$) produces a quadruple $(a_{\alpha}, b_{\alpha}, c_{\alpha}, d_{\alpha}) = (b_{\alpha-1}, a_{\alpha-1} + b_{\alpha-1} d_{\alpha-1}, 0, 1)$ and $C_2$ is thus isomorphic to the curve $b_{\alpha} X = Y^q - Y$.

and by the same preservation property of the sum $ac + bd$ we have that still $0 < b_{\alpha} < p$ holds. Thus this curve is isomorphic to $A^1_{\mathbb{F}_p}$, and we are done.

The following lemma works for schemes of finite type over $\mathbb{F}_p$, so we denote (in this lemma only) by $A_{\mathbb{F}_p}$ the usual affine space over $\mathbb{F}_p$.

Lemma 4.8. Let $a, b, c, d$ be positive integers with $a, b < p$ and $c < d$. Write $d = \gamma c + r$ with $0 \leq r < c$. Then the curve in $A^2_{\mathbb{F}_p}$ given by the equation

$C_1: a \text{tr}_{c/1}(x) + b \text{tr}_{d/1}(x) = \text{tr}_{d/1}(y^q - y)$

is $\mathbb{F}_p$-isomorphic to the curve in $A^2_{\mathbb{F}_p}$ given by the equation

$C_2: b \text{tr}_{r/1}(x) + (a + b\gamma) \text{tr}_{c/1}(x) = \text{tr}_{c/1}(y^q - y)$.

Proof. Make the change of variables $x + b^{-1}(y^q - y) \mapsto x$ (by assumption $b < p$, as $0 < c < d$). Thus $C_1$ is isomorphic to the curve $C'_1: a \text{tr}_{c/1}(x) + ab^{-1} \text{tr}_{c/1}(y^q - y) + b \text{tr}_{d/1}(x) = 0$.

Via the change of variables $-a^{-1}by \mapsto y$, $C'_1$ gets isomorphic to $C''_1: a \text{tr}_{c/1}(x) + b \text{tr}_{d/1}(x) = \text{tr}_{c/1}(y^q - y)$.

We have $\text{tr}_{d/1}(y^q - y) = y^{q^d} - y$. Thus we may successively make the changes of variables of the form $y + x^{q^d}$ (for appropriate $\alpha \in \mathbb{Z}_{\geq 0}$), to eliminate all powers of $x$ with exponent greater than $q^d$. This does not affect the first summand $a \text{tr}_{c/1}(x)$ and after all these changes $C''_1$ gets isomorphic to the curve $C'''_1: a \text{tr}_{c/1}(x) + b(\gamma \text{tr}_{c/1}(x) + \text{tr}_{r/1}(x)) = \text{tr}_{c/1}(y^q - y)$, which is the same as $C_2$. \qed
4.3. Proof Theorem 4.1. Again, we work in the setup of Section 3.1. For $w \in W_\mathcal{O}$ put
\[ \hat{\Sigma}_{(n,n),w} := \{(x, y_1, \tau, z, y_2) \in F U_h^{1} \times F U_h^{1} \times U_h \times T_h \times K_h : xF(y_1 \tau \omega z) \in y_1 \tau \omega z y_2 F(U_h^{1} y_2^{-1})\}, \]
and
\[ \hat{\Sigma}_{(n,n),1} := \{(x, x', y_1, \tau, z) \in F U_h^{1} \times F U_h^{1} \times U_h \times T_h \times U_h^{-1} : xF(y_1 \tau z) = y_1 \tau z x'\} \]
with natural $T_h \times T_h$-actions (like in Section 4.1). Similar as in the beginning of Section 4.1 it suffices to check that
\[ H^*_c(\hat{\Sigma}_{(n,n),w})_{\theta-1, \theta} = 0 \quad \text{for} \quad 1 \neq w \in W_\mathcal{O}, \]
and
\[ \dim H^*_c(\hat{\Sigma}_{(n,n),1})_{\theta-1, \theta} = 1. \]
Consider first the case $w \neq 1$. As $x \in F U_h^{1}$ and $y_1$ varies in $U_h$, we can not make the change of variables $xF(y_1) \mapsto x$ as in the proof of Theorem 4.1(a). However we can define an action of $H^*_c$ on $\hat{\Sigma}_{(n,n),w}$ by
\[ (t, t') : (x, y_1, \tau, z, y_2) \mapsto (F(t) x F(y_1) F(t)^{-1} F(F(t) y_1^{-1} F(t)^{-1}), F(t) y_1 F(t)^{-1}, t \tau \omega t^{-1} \omega^{-1}, t' z t'^{-1}, F(t') y_2 F(t')^{-1}) \]
Note that $F(t) x F(y_1) F(t)^{-1} F(F(t) y_1^{-1} F(t)^{-1}) \in F U_h^{1}$ (on the one side it is contained in $F U_h$ as $x, F(y_1) \in F U_h$; on the other side it must lie in $G_h^{1}$ as $t, x \in G_h^{1}$). The proof that this indeed is an action goes exactly the same way as in Section 4.1. The rest of the argument for $\hat{\Sigma}_{(1,n),w}$ goes then through exactly as for $\hat{\Sigma}_{(1,n),1}$ in Section 4.1.

5. CUSPIDALITY

We go back to the setup of Section 2.6. Let $\theta$ be a smooth character of $T = L^\times$ of level $h \geq 1$ in general position. Recall that the induced character of $T_h$ is again denoted by $\theta$, and that it is also in general position. By Corollary 3.3, $R^G_{T_h}(\theta)$ is up to sign an irreducible $G_\mathcal{O}$-representation, hence in particular $R^G_{T}(\theta)$ is up to sign a genuine representation. We write $|R^G_{T_h}(\theta)|$ resp. $|R^G_{T}(\theta)|$ for the genuine representation among $\pm R^G_{T_h}(\theta)$ resp. $\pm R^G_{T}(\theta)$.

Theorem 5.1. Let $\theta$ be a smooth character of $T = L^\times$ in general position. Then $|R^G_{T}(\theta)|$ is a finite direct sum of irreducible supercuspidal representations of $G$.

Proof. There are many (essentially equivalent) ways to deduce this theorem from Proposition 5.2. By [Bus90, Theorem 1] it suffices to prove that $\Xi_\theta := \text{Ind}_{Z G_\mathcal{O}}^{G_\mathcal{O}} |R^G_{T_h}(\theta)|$ is admissible. Let $K \subseteq G$ be a compact open subgroup. We have to show that $(\Xi_\theta)^K$ is finite-dimensional. Conjugating $K$ into $G_\mathcal{O}$ and making it smaller if necessary, we may assume that $K = \ker(G_\mathcal{O} \to G_r)$ for some $r > 0$. Frobenius reciprocity gives
\[ (\Xi_\theta)^K = \bigoplus_{g \in G_\mathcal{O}} |R^G_{T_h}(\theta)|^{Z G_\mathcal{O} \cap g K g^{-1}}. \]
Thus we have to show that there are only finitely many non-vanishing summands on the right. If $S$ denotes a maximal split torus of $G$ whose apartment in $B_K(G) = B_K^S$ contains the vertex stabilized by $G_\mathcal{O}$, then by the rational Iwahori-Bruhat decomposition, $Z G_\mathcal{O} \backslash G / G_\mathcal{O} \cong X_r(S) / \text{dom.}$ Hence any element of $Z G_\mathcal{O} \backslash G / K$ has a representative of the form $g = \varpi^\mu x$ with $x \in G_\mathcal{O}, \mu \in X_r(S) / \text{dom.}$ Now $K$ is normal in $G_\mathcal{O}$, so $gKg^{-1} = \varpi^\mu K \varpi^{-\mu}$ only depends on $\mu.$
Moreover, any coset $ZG_0 \pi^\mu G_0$ contains only finitely many cosets from $ZG_0 \setminus G/K$. Thus it suffices to show that for all but finitely many $\mu \in X_*(T_h/\mathbb{Z})_{\text{dom}}, [R_{T_h}^{G_0}(\theta)]^{|ZG_0 \cap \pi^\mu K - \pi^\mu|} = 0$.

It is easy to see that for all but finitely many such $\mu$, there is a proper $K$-rational parabolic subgroup $G$ with unipotent radical $N$, such that if $N = N(K)$, then $N \cap G_0 \subseteq \pi^\mu K \pi^{-\mu}$. Thus it is enough to show that for each such $N$ we have $[R_{T_h}^{G_0}(\theta)]^{N \cap G_0} = 0$. As by Corollary 3.3 $[R_{T_h}^{G_0}(\theta)] = \pm R_{T_h}^{G_0}(\theta)$ is a genuine representation, it suffices to show that $R_{T_h}^{G_0}(\theta)^{N \cap G_0} = 0$ (we have the natural map of Grothendieck groups of smooth representations with $\mathbb{Q}L$-coefficients $r$: $K_0(G_0) \to K_0(N \cap G_0)$ induced by restriction, and $R_{T_h}^{G_0}(\theta)^{N \cap G_0} = 0$ means $(1, r(R_{T_h}^{G_0}(\theta))) = 0$, where 1 is the trivial representation). This follows from Proposition 5.2.

**Proposition 5.2.** Let $N$ be the unipotent radical of a proper $K$-rational parabolic subgroup of $G$. Then

$$R_{T_h}^{G_0}(\theta)^{N \cap G_0} = 0.$$ 

We prove Proposition 5.2 in Section 5.1 in the case $\kappa = 0$, and in Section 5.2 in general. The proof in the general case is more technical, but follows exactly the same idea as in the special case $\kappa = 0$. For reasons of clarity we explain the special case first.

The explicit description in Lemma 5.6 used in the proof of Proposition 5.2 is – to the author’s knowledge – already new for classical Deligne–Lusztig varieties, i.e., when $h = 1$ (and $\kappa = 0$). In particular, for the Coxeter-type variety for $GL_m, \mathbb{F}_q$ it gives an alternative and much more direct proof of the cuspidal result for Coxeter-type varieties [DL76, Theorem 8.3], which is the last statement of the following corollary to Proposition 5.2.

**Corollary 5.3.** Let $n \geq 1$, and let $X$ be a Deligne–Lusztig variety of Coxeter type attached to $GL_n, \mathbb{F}_q$. Let $\theta$ be an arbitrary character of $T_1 \cong \mathbb{F}_q^\times$, the corresponding $GL_n(\mathbb{F}_q)$-representation $R(\theta)$ realized in the cohomology of $X$, satisfies $R(\theta)^{N(\mathbb{F}_q)} = 0$, for any unipotent radical $N$ of a proper rational parabolic subgroup of $GL_n$. In particular, if $\theta$ is in general position, the genuine $GL_n(\mathbb{F}_q)$-representation $|R(\theta)|$ is irreducible cuspidal.

**Remark 5.4.** The proof of Proposition 5.2 is based on the key lemmas 5.6 5.8 where the quotient $N_h \backslash X_h$ is determined. If $\overline{X}_h$ denotes the quotient of $X_h$ by the $T_h$-action, then (the cohomology of) $N_h \backslash \overline{X}_h$ can probably be computed in big generality by same methods as in [Lus76, (2.10)] (where Coxeter-type Deligne–Lusztig varieties in the flag manifold for a reductive group $G$ over $\mathbb{F}_q$ are studied, in particular $h = 1$). Proofs of Lemmas 5.6 5.8 suggest that the quotients $N_h \backslash X_h$ are harder to understand than $N_h \backslash \overline{X}_h$.

For $h = 1$ and $G$ arbitrary reductive group over $\mathbb{F}_q$, a quotient similar to $N_h \backslash X_h$ appears in [BR06, Section 3.2], [Dud13] and a couple of related articles. The methods used in [BR06] are indirect in the sense that the structure of the tame fundamental group of the multiplicative group $\mathbb{G}_m, \mathbb{F}_q$ is used. In our situation these methods would only apply in the case $h = 1$, because for $h > 1$ the natural covering $X_h \to \overline{X}_h$ is wildly ramified.

**5.1. Proof of Proposition 5.2 for $\kappa = 0$.** For $N$ to have a convenient form, we take $b = 1$. We also take $\tilde{w}_0$ to be the element $b_0$ as in (3.1). Then literally $G = \text{GL}_n(K)$, $G_0 = \text{GL}_n(\mathcal{O}_K)$ and $G_h = \text{GL}_n(\mathcal{O}_K/(\pi^b))$. Let $N_h$ denote the image of $N \cap G_0$ in $G_h$. We can assume that $N$ is the unipotent radical of a maximal proper parabolic subgroup. Moreover, conjugating $N$ if necessary, we may assume that there is an $1 \leq i_0 \leq n - 1$, such that $N$ consists of matrices $u = (u_{ij})_{1 \leq i, j \leq n}$, with $u_{ii} = 1$ for $1 \leq i \leq n$, and $u_{ij} = 0$ unless $i = j$ or $(1 \leq i \leq i_0$ and $n - i_0 < j \leq n)$. As the actions of $G_h$ and $T_h$ on $X_h$ commute, we have

$$R_{T_h}^{G_0}(\theta)^{N_h} = H^*_c(X_h)^{N_h} = H^*_c(N_h \backslash X_h)_{\theta}.$$
We introduce some convenient notation. For \( r \geq 1 \), and an \( r \times r \)-matrix \( g \), let \( |g| := \det g \). For \( x = (x_i)_{i=1}^r \in \mathbb{W}_h(R)^r \), write \( g_r(x) \) for the \( r \times r \)-matrix whose \( i \)-th column is \( \sigma^{i-1}(x) \).

Also we put
\[
Y_{r,h} := \{ x \in \mathbb{W}_h^r : |g_r(x)| \in \mathbb{W}_h \}.
\]

This is a functor on \( \text{Perf}_{\mathbb{F}_q} \), which is represented by an affine perfectly finitely presented perfect \( \mathbb{F}_q \)-scheme. The description of \( X_h \) in [CI18, 7.2] says precisely that \( X_h \subseteq Y_{n,h} \) is a closed subset defined by the condition \( |g_n(x)| \in \mathbb{W}_h^r(\mathbb{F}_q) \).

**Lemma 5.5.** The quotient \( N_h \setminus X_h \) exists as a perfect scheme, and \( X_h \to N_h \setminus X_h \) is finite étale.

**Proof.** \( X_h \) is affine and \( N_h \) finite, so the quotient exists. As the action has no fixed points the last claim also follows. \( \square \)

**Lemma 5.6.** There is an isomorphism of perfect schemes
\[
\alpha : N_h \setminus X_h \to \left\{ (m, x') \in Y_{i_0,h} \times Y_{n-i_0,h} : \frac{|g_{i_0}(m)|}{|g_{n-i_0}(x')|^\sum_{j=1}^{n-i_0} \sigma^j} \in \mathbb{W}_h^r(\mathbb{F}_q) \right\},
\]

induced by \( x = (x_i)_{i=1}^n \mapsto ((m_i(x))_{i=1}^{i_0}, (x_i)_{i=i_0+1}^n) \), where \( m_i(x) \) is the \((n-i_0+1) \times (n-i_0+1)\)-minor of \( g_n(x) \) given by

\[
m_i(x) := \begin{vmatrix}
x_i & \sigma(x_i) & \ldots & \sigma^{n-i_0}(x_i) \\
x_{i_0+1} & \sigma(x_{i_0+1}) & \ldots & \sigma^{n-i_0}(x_{i_0+1}) \\
x_{i_0+2} & \sigma(x_{i_0+2}) & \ldots & \sigma^{n-i_0}(x_{i_0+2}) \\
\vdots & \ldots & \ldots & \ldots \\
x_n & \sigma(x_n) & \ldots & \sigma^{n-i_0}(x_n)
\end{vmatrix}
\]

**Proof.** It is clear that the assignment in the lemma defines an \( N_h \)-equivariant morphism \( X_h \to (\mathbb{W}_h)^i_0 \times (\mathbb{W}_h)^{n-i_0} \) (with trivial \( N_h \)-action on the right). Thus it induces a map \( N_h \setminus X_h \to (\mathbb{W}_h)^i_0 \times (\mathbb{W}_h)^{n-i_0} \).

A standard argument shows that for \( x = (x_i)_{i=1}^n \in X_h(R) \) with corresponding \( x' = (x_i')_{i=i_0+1}^n \) and \( m = (m_i(x))_{i=1}^{i_0} \), one has that \( g_{n-i_0}(x') \in \mathbb{W}_h^r(R) \) (see e.g. [CI18, Lemma 6.13]). This combined with Lemma 5.7 below, shows that we also have \( |g_{i_0}(m)| \in \mathbb{W}_h^r(R) \). Thus (using Lemma 5.7 again), we see that \( \alpha \) is well-defined.

To prove the lemma, it now suffices to check that \( \alpha \) is an isomorphism of étale sheaves on \( \text{Perf}_{\mathbb{F}_q} \). First we check that as a map of étale sheaves, \( \alpha \) is surjective. Let \( R \in \text{Perf}_{\mathbb{F}_q} \). Let \( Z \) denote the target of \( \alpha \), and let \( m = (m_i)_{i=1}^{i_0}, x' = (x_i')_{i=i_0+1}^n \) be a element of \( \mathbb{Z}(R) \). We construct a preimage \( x = (x_i)_{i=1}^n \in X_h(R') \) for some étale \( R \)-algebra \( R' \). Take \( x_i = x_i' \) for \( i_0 + 1 \leq i \leq n \). Now, we can find an (finite) étale \( R \)-algebra \( R' \), and for each \( 1 \leq i \leq i_0 \), an \( x_i = \sum_{j=0}^{h-1} |x_{i,j}| \cdot \omega^j \in \mathbb{W}_h(R') \) such that

\[
m_i = m_i(x) = \sum_{k=0}^{n-i_0} (-1)^{k+1} \sigma^k(x_i) \cdot |g_{n-i_0,k}(x')|,
\]

holds in \( \mathbb{W}_h(R') \), where \( g_{n-i_0,k}(x') \) denotes the \((n-i_0) \times (n-i_0)\)-matrix whose columns are \( x', \sigma(x'), \ldots, \sigma^k(x'), \ldots, \sigma^{n-i_0}(x') \) (here \( \cdot \) means that the vector \( \cdot \) is omitted). Indeed, note that for \( k = n-i_0 \) and for \( k = 0 \), we have

\[
|g_{n-i_0,n-i_0}(x')| = |g_{n-i_0,0}(x')| = |g_{n-i_0}(x')| \in \mathbb{W}_h^r(\mathbb{F}_q)
\]

(5.2)
Thus, fixing an $i$, and proceeding successively for $j = 0, 1, \ldots, h-1$, we can take (5.1) modulo $\varpi^{j+1}$ and resolve it for $x_{i,j}$, noting that each time to find a solution we need a (finite) étale extension of $R$. Thus $\alpha$ is an epimorphism of étale sheaves.

By Lemma 2.3 it remains to show that if $R$ is an algebraically closed field, $\alpha(R) : (N_h \setminus X_h)(R) \to Z(R)$ is injective. With notation as above, for a fixed $1 \leq i \leq i_0$ and $x_{i,0}, x_{i,1}, \ldots, x_{i,j-1}$, Equation (5.1) gives an equation for $x_{i,j}$ of degree precisely $q^{n-i_0}$ (by (5.2)), which is separable (by (5.2) again). Doing this for each $1 \leq i \leq i_0$ and $0 \leq j < h$, we obtain precisely $q^{i_0(n-i_0)h}$ possible values for $x = (x_i)_{i=1}^n \in \mathcal{W}_h(R)^n$ which map to the given point $(m, x') \in Z(R)$.

By Lemma 5.7 all those $x$ automatically lie in $X_h(R)$. This shows that each fiber of the composition of $X_h(R) \to (N_h \setminus X_h)(R)$ with $\alpha(R)$ has precisely $q^{i_0(n-i_0)h} = \#N_h$ points, i.e., that $\alpha(R)$ is injective. The lemma is proven. \hfill $\Box$

**Lemma 5.7.** Let $n \geq 2$, $1 \leq i_0 \leq n-1$. For an $\mathbb{F}_q$-algebra $R$ and $x = (x_i)_{i=1}^n \in Y_{n,h}(R)$, let $m = (m_i(x))_{i=1}^{i_0} \in Y_{i_0,h}(R)$, $x' = (x_i)_{i=i_0+1}^n \in Y_{n-i_0,h}(R)$. Then

$$|g_{i_0}(m)| = |g_n(x)| \cdot |g_{n-i_0}(x')|^{\sum_{j=1}^{i_0-1} \sigma^j}$$

(5.3)

**Proof.** For $v = (v_j)_{j=1}^r \in Y_{r,h}(R)$, and $1 \leq i \leq r$, let $v^{(i)} = (v_j)_{j=1, j \neq i}^r \in Y_{r-1,h}(R)$ denote the vector $v$ with $i$-th coordinate omitted. The claim is tautological for $i_0 = 1$ (in particular, we may assume $n > 2$). We use induction on $i_0$. Expanding along the first column and using the induction hypothesis (for $n-1$, $i_0 - 1$), we get

$$|g_{i_0}(m)| = \sum_{i=1}^{i_0} (-1)^{i+1} m_i \sigma \left( |g_{i_0-1}(m^{(i)})| \right) = \sum_{i=1}^{i_0} (-1)^{i+1} m_i \sigma \left( |g_{n-1}(x^{(i)})| \cdot \prod_{j=1}^{i_0-2} \sigma^j \left( |g_{n-i_0}(x')| \right) \right)$$

To show that this equals the right hand side of (5.3) it suffices to show that

$$\sum_{i=1}^{i_0} (-1)^{i+1} m_i \sigma \left( |g_{n-1}(x^{(i)})| \right) = |g_n(x)| \cdot \sigma \left( |g_{n-i_0}(x')| \right).$$

(5.4)

This follows from a classical minor identity of Turnbull [Tur97]. We use the more modern source [Lec93]. Let us first recall some notation from [Lec93]. Let $S$ be a ring (commutative, with 1). For $1 \leq i \leq n$, let $a_i, b_i \in S^n$. Then the $2 \times n$-tableau

$$T = \begin{bmatrix} a_1 & a_2 & \ldots & a_n \\ b_1 & b_2 & \ldots & b_n \end{bmatrix} \in S$$

is the product of the determinants of the two $n \times n$-matrices $A$ and $B$, where the $i$-th column of $A$ resp. $B$ is $a_i$ resp. $b_i$. Similarly one defines an $s \times n$-tableau for each positive integer $s$. The entries of the tableau are the elements $a_i$, $b_i$. More generally we need tableaux with boxes containing some of the entries. Let $T$ be a $s \times n$-tableau, let $A$ be a subset of elements of $T$. For a permutation $\sigma$ of elements of $A$, let $\sigma(T)$ denote the tableau obtained from $T$, where the elements of $A$ were permuted by $\sigma$. Then the tableau $\tau = (T$ with boxes around entries in $A$) is defined as the alternating sum $\sum_{\sigma} \text{sgn}(\sigma)\sigma(T)$, where the sum is taken over the cosets of the symmetric group on $A$, modulo the subgroup, which leaves unchanged the rows of $T$. We give an example for $n = 4$, $s = 2$:

$$\begin{bmatrix} a_1 & a_2 & a_3 & a_4 \\ b_1 & b_2 & b_3 & b_4 \end{bmatrix} = \begin{bmatrix} a_1 & a_2 & a_3 & a_4 \\ b_1 & b_2 & b_3 & b_4 \end{bmatrix} - \begin{bmatrix} b_3 & a_2 & a_3 & a_4 \\ b_1 & b_2 & a_1 & b_4 \end{bmatrix} - \begin{bmatrix} b_4 & a_2 & a_3 & a_4 \\ b_1 & b_2 & b_3 & a_1 \end{bmatrix}$$
To continue with our proof, we take \( S = \mathbb{W}_h(R) \). For \( 1 \leq i \leq n \), let \( i = (i_0, -1, 1, 0_{n-i}) \in \mathbb{W}_h(R)^n \) denote the \( i \)-th coordinate vector. An easy computation shows that

\[
|g_n(x)| \cdot \sigma\left(|g_{n-i_0}(x')|\right) - \sum_{i=1}^{i_0} (-1)^{i+1} m_i \sigma\left(|g_{n-1}(x^{(i)})|\right) = \pm \begin{pmatrix} 1 & 2 & \cdots & t_{i_0} \sigma(x) & \cdots & \sigma^{n-i_0}(x) \\ \sigma(x) & \cdots & \sigma^{n-1}(x) \end{pmatrix}
\]

With other words, to show (5.4) it suffices to show that the tableau on the right side vanishes. Towards this we have

\[
\begin{pmatrix} 1 & 2 & \cdots & t_{i_0} \sigma(x) & \cdots & \sigma^{n-i_0}(x) \\ \sigma(x) & \cdots & \sigma^{n-1}(x) \end{pmatrix} = 0
\]

Here the first equality is immediate from the definition of a tableau with boxes and the fact that the entries \( \sigma(x), \ldots, \sigma^{n-i_0}(x) \) appear in the second row, and the second equality is an application of Turnbull’s identity [Tur09] (see [Lec93, Proposition 1.2.2(i)]), which claims that if the number \( k \) of boxed entries satisfies \( k > n \), then the tableau vanishes. Indeed, viewed as a function on the boxed entries the tableau is a linear alternating (not only skew-symmetric as stated in the proof of [Lec93, Proposition 1.2.2(i)]) form on \( S^n \) in \( k \) variables, which must therefore vanish, as \( \Lambda^k \mathcal{M} = 0 \) for any finitely generated \( S \)-module \( M \) which can be generated by \( n \) elements (in loc. cit. the proof is only formulated when \( S \) is a field, but it generalizes to all rings).

We continue with the proof of Proposition 5.2 for \( \kappa = 0 \). The group \( G_{m,\mathbb{F}_q}^2 \) acts on \( Y_{\mathbb{F}_q, \kappa} \times Y_{n-\mathbb{F}_q, \kappa} \) by

\[
(\tau_1, \tau_2): (y, z) \mapsto (\tau_1 y, \tau_2 z).
\]

(5.5)

(here \( \tau_1 y \) := \( (\tau_1 y_i)_{i=1}^{n_0} \) means entry-wise multiplication, and similarly for \( z \)). This action restricts to an action of the closed subgroup

\[
H_0 := \left\{ (\tau_1, \tau_2) \in G_{m,\mathbb{F}_q}^2 : \sum_{j=0}^{i_0-1} \sigma^j \left( \prod_{i=0}^{n-i_0-1} \sigma^i(\tau_2) \right) = 1 \right\}
\]

on \( \alpha_0(N_h \setminus X_h) \), where \( \alpha_0 \) is as in Lemma 5.6. By Lemma 5.6 \( \alpha_0 \) induces an isomorphism on étale cohomology. Now \( H \) is 1-dimensional, hence its connected component \( H^0 \) is a 1-dimensional torus. Therefore the projection of \( H^0 \) to at least one of the \( G_{m,\mathbb{F}_q} \)-factors of the ambient group \( G_{m,\mathbb{F}_q}^2 \) is non-constant, hence surjective. Hence \( \alpha_0(N_h \setminus X_h)^{H^0} = \emptyset \).

The action of \( T_h \cong W_k^0(\mathbb{F}_q) \) on \( X_h \) induces an action on \( N_h \setminus X_h \), which under \( \alpha_0 \) is compatible with the \( T_h \)-action on \( \alpha_0(N_h \setminus X_h) \) given by \( t: (m, x') \mapsto (m \cdot \prod_{j=0}^{n_0-1} \sigma^j(t), x' \cdot t) \) (both products mean scalar multiplication). This action of \( T_h \) commutes with the above action of \( H_0 \) on \( \alpha_0(N_h \setminus X_h) \). The explicit description in Lemma 5.6 also shows that \( \alpha_0(N_h \setminus X_h) \) is affine. Thus the \( T_h \)-equivariant version of the well-known result [DM91, 10.15 Proposition] gives

\[
\dim_{\mathbb{Q}_l} H^*_{\alpha_0}(N_h \setminus X_h) = \dim_{\mathbb{Q}_l} H^*_{\alpha_0}(\alpha_0(N_h \setminus X_h)^{H^0}) = 0.
\]

This finishes the proof of Proposition 5.2 in the case \( \kappa = 0 \).

5.2. Proof of Proposition 5.2 for arbitrary \( \kappa \). Let \( \kappa \) be arbitrary. Let \( c := \left( \begin{smallmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 \end{smallmatrix} \right)^{k_0} \), and for \( r \geq 1 \) let \( b_r := \bigoplus_{r=1}^{c} \) be the block-diagonal \( n_0 r \times n_0 r \)-matrix with blocks equal to \( c \). Let \( b = b_{n_0} \) (it is the special representative corresponding to \( \kappa, n \) as in [C118, §5.2.2]). Let \( \tilde{w} = b_{b_{n_0}} \) be as in (3.1). We have then the corresponding groups \( G, G_{\rho}, T, G_{h_1}, \ldots \) as in Section 2.1. A maximal rational parabolic subgroup of \( G \) is determined by an integer
1 \leq i_0 \leq n' - 1$. Its unipotent radical $N_1$ consists of matrices $(A_{ij})_{1 \leq i,j \leq n'}$ where each $A_{ij}$ is a $n_0 \times n_0$-matrix, and $A_{ii} = 1_{n_0}$, $A_{ij} = 0$, unless $i = j$ or $1 \leq i \leq i_0$ and $n' - i_0 + 1 \leq j \leq n$. Let $t$ denote an integer which modulo $n_0$ is the multiplicative inverse of $k_0$. Moreover, for $a \in Z$ define $[a]_{n_0} \in Z$ by the requirement that $1 \leq [a]_{n_0} \leq n_0$ and $[a]_{n_0} \equiv a \mod n_0$. The subgroup $N_h$ of $G_h$ corresponding to $N_1$ (see Section 3.1) consists of $n \times n$-matrices of the same shape, where now each of the $n_0 \times n_0$-blocks $A_{ij}$ with $1 \leq i \leq i_0$ and $n' - i_0 + 1 \leq j \leq n$ is of the form

$$
\sum_{\lambda=0}^{n_0-1} \varpi^{-1} \left[ \frac{n_0}{n_0} \right] \sum_{\sigma} \text{diag}(a_\lambda, \sigma([a_\lambda]_{n_0}), \sigma([a_\lambda]_{n_0}), \ldots, \sigma([n_0 - 1]_{n_0})(a_\lambda)) \text{ with } a_\lambda \in \mathbb{W}_h(F_{q^{n_0}}) \text{ and } a_\lambda \in \mathbb{W}_{h-1}(F_{q^{n_0}}) \text{ for } \lambda > 0.
$$

In particular, $\#N_h = q^{n_0(n_0-1)(h-1)}_{n_0} = n_0(n_0 - 1)$.

Let $r \geq 1$ and let $Z_{n_0,r,h} = \{(x_1)_{i=1}^{n_0} : x_i \in \mathbb{W}_h \text{ if } i \equiv 1 \mod n_0 \text{ and } x_i \in \mathbb{W}_{h-1} \text{ otherwise}\}$. This is a affine, perfectly finitely presented perfect $\mathbb{F}_q$-scheme. For a perfect $\mathbb{F}_q$-algebra $R$ and $x \in Z_{n_0,r,h}(R)$ let $g_{n_0,r}(x)$ denote the $n_0 \times n_0$-matrix whose $i$-th column is $\varpi^{-1} \left[ \frac{n_0}{n_0} \right] (b_r, \sigma)^{-1}(x)$ (the entries of $g_{n_0,r}(x)$ are either in $\mathbb{W}_h(R)$ or in $\mathbb{W}_{h-1}(R)$ or in $\mathbb{W}_{h-1}(R) \subseteq \mathbb{W}_h(R)$). The determinant $|g_{n_0,r}(x)|$ of $g_{n_0,r}(x)$ is a well-defined element of $\mathbb{W}_h(R)$. Let

$$
Y_{n_0,r,h} = \{x \in Z_{n_0,r,h} : |g_{n_0,r}(x)| \in \mathbb{W}_h^X\}
$$

The description of $X_h$ in [CI18, 7.2] says precisely that $X_h \subseteq Y_{n_0,n',h}$ is the subset defined by the closed condition that $|g_{n_0,n'}(x)| \in \mathbb{W}_h^X(\mathbb{F}_q)$.

To simplify notation we write $s := n_0i_0$ from now on. For $x \in X_h$ and $1 \leq i \leq s$, let $m_i(x)$ denote the $(n-s+1) \times (n-s+1)$-minor obtained from $g_{n_0,n'}(x)$ by removing all rows except for the $i$-th and $s+1, s+2, \ldots, n$-th and all but the first $n-s+1$ columns. Then $m_i(x)$ makes sense as an element of $\mathbb{W}_h$ resp. of $\mathbb{W}_{h-1}$ if $i \equiv 1 \mod n_0$ resp. if $i \not\equiv 1 \mod n_0$. Thus $(m_i(x))_{i=1}^{n_0} \in Z_{n_0,i_0,h}$. The analog of Lemma 5.5 for $N_h \setminus X_h$ holds with the same proof.

We have the following generalization of Lemma 5.6.

**Lemma 5.8.** The assignment $x = (x_i)_{i=1}^{n_0} \in X_h \mapsto m = (m_i(x))_{i=1}^{s} = (x_i)_{i=s+1}^{n_0}$ induces an isomorphism of perfect schemes,

$$
\alpha_h : N_h \setminus X_h \to \left\{ (m, x') \in Y_{n_0,i_0,h} \times Y_{n_0,n'-i_0,h} : \frac{|g_{n_0,i_0}(m)|}{|g_{n_0,n'-i_0}(x')|} \sum_{j=1}^{s-1} \sigma^j \in \mathbb{W}_h^X(\mathbb{F}_q) \right\}.
$$

**Proof.** Using the description of $N_h$ given above, one checks that $m_i(x)$ is stable under the $N_h$-action on $X_h$. Now the proof goes completely analogous to the proof of Lemma 5.6 (with Lemma 5.7 replaced by its generalization Lemma 5.9). \qed

**Lemma 5.9.** Let $n \geq 2$, $1 \leq i_0 \leq n - 1$. For a perfect $\mathbb{F}_q$-algebra $R$ and $x = (x_i)_{i=1}^{n_0} \in Y_{n_0,n',h}(R)$, we have $m = (m_i(x))_{i=1}^{s} \in Y_{n_0,i_0,h}(R)$, $x' = (x_i)_{i=s+1}^{n_0} \in Y_{n_0,n'-i_0,h}(R)$ and

$$
|g_{n_0,i_0}(m)| = |g_{n_0,n'}(x')| \cdot |g_{n_0,n'-i_0}(x')| \sum_{j=1}^{s-1} \sigma^j.
$$

**Proof.** It is known that for $x \in Y_{n_0,n',h}(R)$, we have $x' \in Y_{n_0,n'-i_0,h}(R)$ (see [CI18, Lemma 6.13]). Thus the similar claim for $m$ follows, once (5.6) is shown. To show (5.6) we first notice that all entries of $g_{n_0,i_0}(m)$ (and not only those in the first column) are in fact $(n-s+1) \times (n-s+1)$-minors of $g_{n_0,n'}(x)$. More precisely, for $1 \leq i, j \leq s$ the $(i, j)$-th entry of $g_{n_0,i_0}(m)$ is the minor of $g_{n_0,n'}(x)$ obtained by removing all columns except those with numbers $j, j+1, \ldots, j+n-s$, and all rows except those with numbers $i, s, s+1, \ldots, n$. Let $X_i$ denote the $i$-th row of $g_{n_0,n'}(x)$. Let also $a$ denote the $a$-th standard basis vector of a free rank $n$ module (over an arbitrary ring). Using the formalism of tableaux with boxes (as in the proof of Lemma 5.7), − but now for the rows of $g_{n_0,n'}(x)$, we can express $|g_{n_0,i_0}(m)|$ as
the \( s \times n \)-tableau with boxes:

\[
\begin{array}{cccccccc}
X_1 & X_{s+1} & X_{s+2} & \ldots & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
1 & X_2 & X_{s+1} & X_{s+2} & \ldots & X_{n-1} & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
1 & 2 & X_3 & X_{s+1} & \ldots & X_{n-1} & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
& & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
1 & 2 & \ldots & s - 2 & X_{s-1} & X_{s+1} & X_{s+2} & \ldots & X_{n-1} & X_n & n \\
1 & 2 & \ldots & s - 1 & X_2 & X_{s+1} & \ldots & X_{n-1} & X_n \\
1 & 2 & \ldots & s - 1 & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
\end{array}
\]

As each of the entries \( X_{s+1}, X_{s+2}, \ldots, X_n \) appears in each row of this tableau, it is equal to

\[
\begin{array}{cccccccc}
X_1 & X_{s+1} & X_{s+2} & \ldots & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
1 & X_2 & X_{s+1} & X_{s+2} & \ldots & X_{n-1} & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
1 & 2 & X_3 & X_{s+1} & \ldots & X_{n-1} & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
& & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
1 & 2 & \ldots & s - 2 & X_{s-1} & X_{s+1} & X_{s+2} & \ldots & X_{n-1} & X_n & n \\
1 & 2 & \ldots & s - 1 & X_2 & X_{s+1} & \ldots & X_{n-1} & X_n \\
1 & 2 & \ldots & s - 1 & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
\end{array}
\]

Apply (second) Turnbull’s identity [Lec93 Proposition 1.2.2(ii)] to the last row of this tableau, deducing that it is equal to

\[
\begin{array}{cccccccc}
1 & X_{s+1} & X_{s+2} & \ldots & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
1 & 2 & X_{s+1} & X_{s+2} & \ldots & X_{n-1} & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
1 & 2 & 3 & X_{s+1} & \ldots & X_{n-1} & X_n & n - s + 2 & n - s + 3 & \ldots & n \\
& & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
1 & 2 & \ldots & s - 2 & s - 1 & X_{s+1} & X_{s+2} & \ldots & X_{n-1} & X_n & n \\
1 & 2 & \ldots & s - 1 & X_2 & X_{s+1} & \ldots & X_{n-1} & X_n \\
1 & 2 & \ldots & s - 1 & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
\end{array}
\]

Here all boxes can be removed without changing the value of the tableau, as any non-trivial permutation produces a zero \( s \times n \)-tableau (as at least one row will contain two equal entries and hence be equal to 0). The resulting tableau (without boxes) is precisely the right hand side of \( (5.6) \).

\[ \square \]

**Remark 5.10.** In the proof of Lemma \( 5.8 \), the fact that the entries of \( g_{n_0, n_0}(m) \) are certain minors of \( g_{n_0, n_0'}(x) \) can be shown by a somewhat tedious but straightforward calculation, which we omit here. To illustrate the principle, we give an example. Let \( n = 9, \kappa = 6 \), so that \( n' = 3, n_0 = 3, k_0 = 2 \). Let \( i_0 = 2 \). We have the two minors of \( g_{n_0, n_0'}(x) \),

\[
m_2 = \begin{vmatrix} x_2 \omega(x_3) & \sigma^2(x_1) & \sigma^3(x_1) \\ x_7 \omega(x_8) & \omega^2(x_9) & \sigma^3(x_9) \\ x_9 \sigma(x_7) & \sigma^2(x_9) & \sigma^3(x_9) \end{vmatrix} \quad \text{and} \quad M := \begin{vmatrix} \omega \sigma(x_2) & \omega \sigma^2(x_3) & \sigma^3(x_1) & \omega \sigma^4(x_2) \\ \omega \sigma(x_3) & \omega^2(x_9) & \sigma^3(x_9) & \omega^4(x_8) \\ \omega \sigma(x_9) & \sigma^2(x_7) & \sigma^3(x_9) & \omega^4(x_8) \\ \sigma(x_7) & \sigma^2(x_9) & \sigma^3(x_9) & \sigma^4(x_7) \end{vmatrix}
\]

the first corresponding to rows 2, 7, 8, 9 and columns 1, 2, 3, 4, and the second corresponding to rows 1, 7, 8, 9 and 2, 3, 4, 5. The first of these minors is by definition the \( (2, 1) \)-entry of \( g_{n_0, n_0}(m) \), and the fact mentioned above claims that the second minor is equal to the \( (1, 2) \)-entry of \( g_{n_0, n_0}(m) \), that is, to \( \omega \sigma(m_2) \in \mathcal{W}_{h_1} \subseteq \mathcal{W}_h \). First, \( M \) makes sense as an element of \( \mathcal{W}_{h_1} \). To compute it, we may lift its entries to elements in \( \mathcal{W} \), where we can multiply rows and columns by powers of \( \omega \), to see that

\[
M = \omega^{-2} \begin{vmatrix} \omega(x_2) & \omega^2(x_3) & \omega^3(x_1) & \omega^4(x_2) \\ \omega(x_3) & \omega^2(x_9) & \omega^3(x_7) & \omega^4(x_8) \\ \omega(x_9) & \omega^2(x_7) & \omega^3(x_9) & \omega^4(x_8) \\ \sigma(x_7) & \omega^2(x_9) & \omega^3(x_9) & \sigma^4(x_7) \end{vmatrix} = \omega \sigma(m_2)
\]
(after reducing modulo \( \mathbb{Z}^h \mathfrak{W} \)), as claimed.

We continue with the proof of Proposition \ref{proposition:6.1}. The group \( \mathbb{G}\) acts on \( Y_{n_0,n-i_0,h} \times Y_{n_0,n-i_0,h} \) by the same formula as in \( \ref{equation:5.5} \). This action restricts to an action of the closed subgroup

\[
H_k := \left\{ (\tau_1, \tau_2) \in \mathbb{G}^2_m : \tau_1 \sum_{j=0}^{s-1} \sigma^j \prod_{i=0}^{n-1} \sigma^i (\tau_2) = 1 \right\}
\]

on \( N_h \setminus X_h \cong \alpha_e(N_h \setminus X_h) \), where \( \alpha_e \) is as Lemma \ref{lemma:5.8}. Now \( H \) is 1-dimensional, hence its connected component \( H^0 \) is a 1-dimensional torus. The rest of the argument is exactly as at the end of Section \ref{section:5.1} Proposition \ref{proposition:5.2} is now proven.

6. Review of some representation theory

We fix an isomorphism \( \overline{\mathbb{Q}}_\ell \cong \mathbb{C} \) and use it to identify the isomorphism classes of smooth complex with smooth \( \overline{\mathbb{Q}}_\ell \)-representations of all involved groups. For a finite dimensional (complex or \( \overline{\mathbb{Q}}_\ell \)) representation \( \rho \) of a group, we denote by \( \deg(\rho) \) the degree of \( \rho \).

6.1. Square-integrable representations. We recall some well-known results about square-integrable representations of \( p \)-adic reductive groups due to Harish-Chandra. For a detailed treatment we refer to [HC70] (see also [Car79]).

In this section let \( G \) be an arbitrary reductive group over \( K \) and \( G = G(K) \). Let \( Z \) be the (\( K \)-valued points of) the maximal split torus contained in the center of \( G \). Let \( \psi : Z \rightarrow \overline{\mathbb{Q}}_\ell^\times \) be a unitary character of \( Z \). We fix now an invariant Haar measure on \( G/Z \) (recall that \( G \) is unimodular). We work with complex-valued representations of \( G \). Let \( \mathcal{E}_2(G, \psi) \) denote the set of equivalence classes of irreducible unitary representations \( (\pi, V) \) of \( G \), which have central character \( \psi \) and satisfy

\[
\int_{G/Z} |(u, \pi(g)v)|^2 d\bar{g} < +\infty
\]

where \((\cdot, \cdot)\) denotes the scalar product in the Hilbert space \( V \) (the integral makes sense as \( \psi \) is unitary). These are the square-integrable representations with central character \( \chi \). All irreducible supercuspidal representations with unitary central character are square-integrable [HC70, §3].

For a given \( \pi \in \mathcal{E}_2(G, \psi) \), the integral \( \ref{equation:6.1} \) is equal to \( d(\pi, d\bar{g})|u|^2|v|^2 \), where the constant \( d(\pi, d\bar{g}) > 0 \) is independent of \( u, v \) (and thus only depends on \( \pi \) and the chosen measure \( d\bar{g} \)). The constant \( d(\pi, d\bar{g}) \) is called the formal degree of \( \pi \) (with respect to \( d\bar{g} \)). Let \( H \) be a compact open subgroup of \( G \). If \( \bar{d}g, \bar{d}g' \) are two invariant Haar measures on \( G \), then \( d(\pi, \bar{d}g) \text{vol}(HZ/Z, \bar{d}g) = d(\pi, \bar{d}g') \text{vol}(HZ/Z, \bar{d}g') \). Moreover, if \( \pi \in \mathcal{E}_2(G, \psi) \) is of the form \( \pi = c\text{Ind}_{ZH}^G \tau \) for an (automatically finite-dimensional) representation \( \tau \) on which \( Z \) acts by the character \( \psi \), then \( d(\pi, \bar{d}g) \text{vol}(HZ/Z, \bar{d}g) = \deg \tau \) (cf. [Car79, 1.6]).

For any \( \pi \in \mathcal{E}_2(G, \psi) \) and a smooth irreducible representation \( \rho \) of \( H \), let \( (\pi : \rho) \) denote the multiplicity of \( \rho \) in the restriction of \( \pi \) to \( H \). We need the following estimate due to Harish-Chandra.

**Theorem 6.1** (see [HC70, p.6]). Given \( H, \rho \) as above, let \( \pi \in \mathcal{E}_2(G, \psi) \). Then

\[
\sum_{\pi \in \mathcal{E}_2(G, \psi)} d(\pi, d\bar{g}) \text{vol}(HZ/Z, d\bar{g})(\pi : \rho) \leq \deg \rho.
\]

6.2. Traces on elliptic elements. For the moment keep the assumptions of Section \ref{section:6.1} (in particular, \( G \) is arbitrary reductive). Let \( \mathcal{H}(G) \) denote the convolution algebra of locally
constant compactly supported functions on $G$. Fix a Haar measure $dg$ on $G$. For any smooth $G$-representation $(\pi, V)$, $\mathcal{H}(G)$ acts in $V$ by $\pi(f)v = \int_G f(g)\pi(g)v \, dg$ for all $v \in V$, $f \in \mathcal{H}(G)$. If $\pi$ is admissible, then $\pi(f)$ has finite dimensional range, and hence a trace. Let $G^{\text{reg,ss}}$ denote the set of regular semi-simple elements of $G$. It is open dense in $G$.

Theorem 6.2 (see [Hen06, Theorem 1]). Let $\pi$ be a finite length (hence admissible) smooth representation of $G$. Then there is a unique (hence invariant under conjugation) locally constant function $\text{tr}(\pi, \cdot)$ on $G^{\text{reg,ss}}$ of $G$, locally integrable on $G$, such that for all $f \in \mathcal{H}(G)$, one has $\text{tr} \pi(f) = \int_G \text{tr}(\pi, g)f(g) \, dg$.

Now assume again, that $G = G(K)$ for an inner form $G$ of $GL_n$. For $g \in G$, let $P(g)$ denote the reduced characteristic polynomial of $g$. Two elements of $g_1, g_2 \in G^{\text{reg,ss}}$ are conjugate in $G$ if and only if $P(g_1) = P(g_2)$. All said above applies to $GL_n(K)$ as a special case. Moreover, for an elements $g \in G^{\text{reg,ss}}$ there is a unique up to conjugation element $g' \in GL_n(K)^{\text{reg,ss}}$ such that $P(g_1) = P(g_2)$. This has a partial converse. Let $G^{\text{ell}} \subseteq G^{\text{reg,ss}}$ denote the (open) subset of elliptic elements. For any $g' \in GL_n(K)^{\text{ell}}$ there is a unique up to conjugation $g \in G^{\text{ell}}$ with the same (reduced) characteristic polynomial. The local Jacquet–Langlands correspondence is then the following result, which in its most general form is due to Deligne–Kazhdan–Vigneras [DKV84] and Badulescu [Bad02].

Theorem 6.3 (see [Hen06, Theorem 2]). There is a unique bijection $\pi' \leftrightarrow \pi = JL(\pi')$ between the sets of $\mathcal{A}^2(G)$ and $\mathcal{A}^2(GL_n(K))$ of smooth irreducible square-integrable representations of $GL_n(K)$ and $G$, such that $\text{tr}(\pi, g) = (-1)^{n-n'}\text{tr}(\pi', g')$ whenever $g \in G^{\text{ell}}$, $g' \in GL_n(K)^{\text{ell}}$ with $P(g) = P(g')$.

Now we recall a result from [CI18]. An (elliptic) element $x \in T \cong L^\times$ is called very regular, if $x \in \mathcal{O}_L^\times$ and the image of $x$ in the residue field $\mathcal{O}_L/\mathfrak{p}_L \cong \mathbb{F}_q^n$ has trivial stabilizer in $Gal(L/K)$. This definition does not depend on the choice of the isomorphism $T \cong L^\times$ as in Section 2.1.2. Write $\gamma^\dagger := \gamma \circ \gamma$ for $\gamma \in Gal(L/K)$, $\theta : L^\times \rightarrow \overline{\mathbb{Q}}_L^\times$.

Proposition 6.4 (Theorem 11.2 of [CI18]). Let $\theta : T \rightarrow \overline{\mathbb{Q}}_L^\times$ be smooth and $x \in T$ very regular. Then $\text{tr}(R^\ell_\theta(\gamma), x) = \pm \sum_{\gamma' \in Gal(L/K)} \gamma'\theta(x)$. }

6.3. Special cases of local Langlands and Jacquet–Langlands correspondences.

As in the introduction, to a character $\theta : L^\times \rightarrow \overline{\mathbb{Q}}_L^\times$, one can attach the $n$-dimensional representation $\sigma_\theta = \text{Ind}_{W_L}^{L^\times}(\theta \cdot \mu)$ of the Weil group of $K$, where we recall that $\mu$ is the rectifying character of $L^\times$, given by $\mu|_{U_L} = 1$ and $\mu(\varpi) = (-1)^{n-1}$. The representation $\sigma_\theta$ is irreducible if and only if $\theta$ is in general position. In this case, the local Langlands correspondence attaches to $\sigma_\theta$ the irreducible supercuspidal $GL_n(K)$-representation $\pi^{GL_n}_{\theta} := LL(\sigma_\theta)$. Moreover, the local Jacquet–Langlands correspondence attaches to $\pi^{GL_n}_{\theta}$ the irreducible supercuspidal $G$-representation $\pi^G_{\theta} := JL(\pi^{GL_n}_{\theta})$.

Moreover, $\theta$ is in general position if and only if it is admissible in the sense of [How77], and the construction of Howe [How77] attaches to it an irreducible supercuspidal $GL_n(K)$-representation, which is (equivalent to) $\pi^{GL_n}_{\theta}$. With other words, with notation as in the introduction, the diagram

\[
\begin{array}{ccc}
\mathcal{A}^2 / Gal_{L/K} & \xrightarrow{\theta \mapsto \sigma_\theta} & \mathcal{A}^2_K(n) \\
\text{Howe} & \xrightarrow{\text{LL}} & \mathcal{A}^2_K(n, 0) \\
\downarrow \pi^G_{\theta} & \xrightarrow{\text{JL}} & \mathcal{A}^2_K(n, \kappa)
\end{array}
\]
commutes.

7. Realization of LL and JL in the cohomology of $X^{DL}_w(b)$ in some cases

We now will prove Theorem A from the introduction. Let $\theta: T \cong L^X \to \mathbb{Q}_l^X$ be a smooth character in general position. Let $\pi_\theta = JL(\text{LL}(\sigma_\theta)) \in \mathcal{A}_K(n, \kappa)$ be as in Section 6.3.

7.1. Degree of $R_{T_h}^{G_h}(\theta)$ and formal degree of $\pi_\theta$. First we check that the degree of $R_{T_h}^{G_h}(\theta)$ matches with the formal degree of $\pi_\theta$ (see Section 6.1). Here we use results from [CI19b].

Fix a Howe decomposition for $\theta$: there is a unique tower of fields $L = L_t \supset L_{t-1} \supset \cdots \supset L_1 \supset L_0 = K$ and characters $\chi, \phi_1, \ldots, \phi_t$ of $K^X$, $L_1^X, \ldots, L_t^X$ respectively, such that $\theta = (\chi \circ N_{L/K})(\phi_1 \circ N_{L_1/L_1}) \cdots (\phi_t)$. Denote by $h_1, \ldots, h_t$ the levels of $\phi_1, \ldots, \phi_t$ respectively and put $d_k = [L : L_k]$, in particular, $d_0 = n$, $d_t = 1$. Also, $\theta|_{U_L^1}$ is in general position if and only if $h_t > 1$.

**Lemma 7.1.** Assume $p > n$. Assume $\theta|_{U_L^1}$ is in general position. Then

$$\text{deg } |R_{T_h}^{G_h}(\theta)| = q^{\frac{1}{2}n(n(h_1-1)-(h_t-1)-\sum_{k=1}^{t-1} d_k(h_k-h_{k+1}))} n'! \prod_{i=1}^{n'-1} (q^{n_0(n'-i)} - 1). \quad (7.1)$$

**Proof.** As $R_{T_h}^{G_h}(\theta \cdot (\psi \circ N_{L/K})) \cong R_{T_h}^{G_h}(\theta) \otimes (\psi \circ \text{det})$ [CI18, Lemma 8.4], we may assume $\chi = 1$, i.e., $h = h_1$. The assumptions along with Theorem 4.1 imply that $R_{T_h}^{G_h}(\theta) \cong H^*_c(X_{h,n'})$. We may assume that $b$ is a Coxeter-type representative (as in [CI18, 5.2.1]). For $t \in T_h$ put $S_{1,t} = \{ x \in X_{h,n'} : F^m(x) = xt \}$. As in [CI18] Lemma 9.3 we see that $S_{1,t} = \varnothing$, unless $t = 1$ (in loc. cit. we worked with the special representative for $b$ and this explains the sign $(-1)^{n'-1}$ appearing there). Further, one has $S_{1,1} = G_h$ [CI19b], and so

$$\# S_{1,1} = \left( \prod_{i=1}^{h_1-1} \# G_{h_1+1} \right) \cdot \# G_1 = q^{n^2(h_1-1)} \prod_{i=0}^{n'-1} (q^{n_0n'-q^{n_0i}}) = q^{n^2(h_1-1) + \frac{1}{2}n(n'-1)} \prod_{i=0}^{n'-1} (q^{n_0(n'-i)} - 1),$$

as $G_1 \cong (\text{Res}_{\mathbb{F}_q / \mathbb{F}_q}, GL_{n'}(\mathbb{F}_{q^n}))$ and as $\# G_{h+1} = q^{n^2}$ for each $i \geq 1$. Boyarchenko’s trace formula [Boy12, Lemma 2.12] and the determination [CI19b] of the scalar by which $F^m$ acts in the non-vanishing cohomology group $H^*_c(X_{h,n'})$ gives

$$\text{dim } |R_{T_h}^{G_h}(\theta)| = \text{dim } |H^*_c(X_{h,n'})| = \frac{(-1)^{r_\theta}}{(-1)^{n^2} q^{n^2} \# T_h} \cdot \# S_{1,1},$$

The lemma follows now by an easy calculation, as $\# T_h = (q^n - 1)q^{n(h-1)}$, and as $r_\theta = (n' - n) + h_t + (n-2)h + \sum_{k=1}^{t-1} d_k(t_k - t_{k+1})$ by [CI19b].

On the other side we use the computation of the formal degree of $\pi_\theta^{GL_n}$ from [CMS90].

**Lemma 7.2.** Assume that $\theta|_{U_L^1}$ is in general position. For any left invariant Haar measure $dg$ on $G/Z$, $d(\pi_\theta, dg)\text{vol}(ZH/Z, dg)$ is equal to the right hand side of (7.1). In particular, we have

$$d(\pi_\theta, dg)\text{vol}(G_\partial Z/Z, dg) = \text{deg } |R_{T_h}^{G_h}(\theta)|. \quad (7.1)$$

**Proof.** The product on the left hand side in the lemma is independent of $dg$, so it is enough to show the lemma for a fixed (left invariant) Haar measure. Let $dx$ be the Haar measure on $G/Z$, normalised such that the Steinberg representation $St_G$ of $G$ satisfies $d(St_G, dx) = 1$. Then by Macdonald’s formula [SZ96, §3.7] (see also [Kar13, Proposition 5.4]), we have

$$\text{vol}(G_\partial Z/Z, dx) = \frac{1}{n} \prod_{i=1}^{n'-1} (q^{n_0i} - 1). \quad (7.2)$$
The normalized formal degree $d(\pi, d\bar{\gamma})$ is stable under the Jacquet–Langlands correspondence [DKV84, BHL10], so we deduce by using (7.2),

$$d(\pi, d\bar{x}) \text{vol}(ZH/Z, d\bar{x}) = d(\pi^\otimes_{GL_n}, d\bar{x}^\otimes_{GL_n}) \cdot \frac{1}{n} \prod_{i=1}^{n'-1} (q^n q^i - 1),$$

where $d\bar{x}^\otimes_{GL_n}$ is the measure $d\bar{x}$ in the special case $n' = n$. Now the normalized formal degree of $\pi^\otimes_{GL_n}$ is determined in [CMS90] Theorem 2.2.8 and coincides with the right hand side of (7.1). \hfill \Box

### 7.2. Comparison

We now prove Theorem A. Assume $p > n$ and assume that $\theta|_{U^1_L}$ is in general position. Let $Z = K^\times$ be the center of $G$. For a smooth character $\phi$ of $K^\times$ we have $R(T)(\phi \circ N_{L/K})(\phi \circ \det)$ $\cong$ $R(T)(\theta \circ N_{L/K})(\phi \circ \det)$ [CI18, Lemma 8.4]. An analogous formula holds for $\pi_\theta$. Hence we may twist both sides of the equality claimed in the theorem by a smooth character $\phi$ of $K^\times$. Thus we are reduced to the case that $\theta|_Z$ is unitary. Fix an invariant Haar measure $d\bar{\gamma}$ on $G/Z$.

By Theorem 5.1, there exists a finite set $I$ and an irreducible supercuspidal representation $\pi_i$ of $G$ for each $i \in I$ such that $|R(T)| \cong \bigoplus_{i=1}^I \pi_i$. It is easy to see (e.g. using [Boy12, Lemma 2.12]) that the central character of $R(T)$ is $\theta|_Z$. From this and the fact that all supercuspidal representations are square-integrable it follows that $\pi_i \in \mathfrak{S}_2(G, \theta|_Z)$ for all $i$. As by assumption $(p, n) = 1$, each $\pi_i$ is attached to a pair $(E_i, \chi_i)$ with $E_i / K$ a separable degree $n$ extension and $\chi_i$ is an admissible character of $E_i^\times$ in the sense of [How77] (indeed, Howe’s construction also works for inner forms of $GL_n$, so that there is no need to pass to the more general constructions of Yu [Yu01] and Kaletha [Kal19]). Let $I_{nr} \subseteq I$ denote the subset of those $i \in I$, for which $E_i / K$ is unramified, i.e., $E_i \cong K$. For each $i \in I$, $\pi_i$ has a well-defined trace on regular elliptic elements of $G$, and in particular on the very regular elements of $T \cong L^\times$. If $i \in I \smallsetminus I_{nr}$, then $\pi_i \cong \text{clnd}_{H_{E_i}}(\theta|_{H_{E_i}})$, where $H \subseteq G_\sigma$ is certain (explicitly determined) compact open subgroup, which is not maximal compact, and $E_i^\times$ is appropriately embedded as a subgroup of $G(K)$ normalizing $H$. In particular, for $i \in I \smallsetminus I_{nr}$, no conjugate of a very regular element $x \in T$ lies in $HE_i^\times$ (in fact, $x$ has precisely one fixed point on $B_K$, which has to be a vertex, so it is contained in no stabilizer of a facet of $B_K$ of dimension $\geq 1$). By [BH99] (A.14 Theorem), $\text{tr}(\pi_i, x) = 0$ for $i \notin I_{nr}$, and hence for any very regular element $x \in T \cong L^\times$, we have

$$\pm \sum_{\gamma \in \text{Gal}(L/K)} \theta^\gamma(x) = \text{tr}(R(T)(\theta|_{T_h})), x = \sum_{i \in I_{nr}} \text{tr}(\pi_i, x) = \sum_{i \in I_{nr}} c_i \sum_{\gamma \in \text{Gal}(L/K)} \chi_i^\gamma(x),$$

where $c_i \in \{\pm 1\}$, the first equality is Proposition 6.4 and the last follows from [Hen92, Théorème 3.1 Théorème] (in fact, it shows the claim only for $GL_n$, but this along with trace relations defining the Jacquet–Langlands correspondence give also the other cases). We use now the argument from [Hen92, 2.8]: if $x \in U_L$ is very regular and $y \in U^1_L$, then $xy \in U_L$ is again very regular. Thus letting $x$ be a fixed very regular element of $U_L$ and varying $y \in U^1_L$ we obtain an equality of finite linear combinations of smooth characters of the group $U^1_L$. We may find an integer $h'$ such that $\theta$ and all $\chi_i$’s are trivial on $U^h_L$, and replace $U^1_L$ by its finite quotient $U^1_L / U^h_L$. As $\theta|_{U^1_L}$ is in general position, the coefficient of $\theta|_{U^1_L}$ on the left hand side is $\theta(x) \neq 0$. By linear independence of characters of a finite group there is at least one $i_0 \in I_{nr}$ with $\chi_i|_{U^1_L} = \theta|_{U^1_L}$.

Frobenius reciprocity for the compact induction shows that

$$\left(\pi_i : |R(T_h)(\theta)|\right) \geq 1 \quad \text{for } i \in I.$$

(7.3)
with notation as in Section 6.1. Fix a Haar measure $d\bar{g}$ on $G/Z$. By Lemma 7.2 we have
\[ d(\pi_{i_0}, d\bar{g})\text{vol}(G_O/Z, d\bar{g}) = \deg |R^G_{T_h}(\theta)|, \]
so that Theorem 6.1 implies $(\pi_{i_0}: |R^G_{T_h}(\theta)|) = 1$ and $(\pi: |R^G_{T_h}(\theta)|) = 0$ for all $\pi \in \mathcal{O}_2(G, \theta|_{K^\times})$, $\pi \neq \pi_{i_0}$. Combining this with (7.3) we see that $I = \{i_0\}$. It remains to show that $\chi_{i_0} = \theta$. Either one can apply [CI18, Theorem 11.3] (as we now know that $R^G_{T_h}(\theta) \cong \pi_{i_0}$ is irreducible), or alternatively use that we already know $\chi_{i_0} = \theta$ on $K^\times U^1_L$, and then apply the same argument as in [Hen93, 5.3]. Theorem A is proven.
