

Explicit Deligne pairing

Paolo Dolce

Abstract

We give an explicit formula for the Deligne pairing for a proper and flat morphisms $f : X \rightarrow S$ of schemes, in terms of the determinant of cohomology. The whole construction is justified by an analogy with the intersection theory on non-singular projective algebraic varieties.

0 Introduction

The intersection pairing between two divisors on a projective non-singular surface is the unique bilinear and symmetric pairing with values in \mathbb{Z} that satisfies some very natural properties: it counts the number of intersection points (when the divisor are normal crossing) and it is invariant if we “move” any of the two divisors in their linear class of equivalence. With the same philosophy, such a definition of intersection pairing between divisors can be extended naturally for projective non-singular varieties of any dimension: we list a number of natural properties and we find a unique multi-linear symmetric pairing satisfying them. It turns out that this unique intersection pairing on algebraic varieties can be expressed explicitly in terms of the Euler-Poincare characteristics of (invertible sheaves associated to the) divisors. For example, for a surface over a field k we have the well known formula:

$$C.D = \chi_k(\mathcal{O}_X) - \chi_k(\mathcal{O}_X(C)^{-1}) - \chi_k(\mathcal{O}_X(D)^{-1}) + \chi_k(\mathcal{O}_X(C)^{-1} \otimes \mathcal{O}_X(D)^{-1}) \quad (0.1)$$

which is involved in the proof of the Riemann-Roch theorem for surfaces (see for example [1]).

For a relative scheme $X \rightarrow S$, if we don’t appeal to any “compactification arguments” of X and S , there is in general no hope for finding a reasonable intersection pairing for divisors which is invariant up linear equivalence. Let’s see an example in the case of an arithmetic surface $X \rightarrow \text{Spec } \mathbb{Z}$. Consider a prime $p \in \text{Spec } \mathbb{Z}$, the fibre X_p is a principal vertical divisor on X . Now let D be an irreducible horizontal divisor on X , then certainly D meets X_p , which means $D.X_p > 0$ because our phantom intersection pairing should count the number of intersection points with multiplicity. Thus, for any other divisor $E \in \text{Div}(X)$ we obtain $D.E < D.(E + X_p)$ but $E \sim (E + X_p)$ since X_p is principal by construction.

The closest object to an intersection pairing on a relative scheme $X \rightarrow S$ of relative dimension n is called the Deligne pairing: it is a map

$$\langle \dots, \rangle_{X/S} : \text{Vec}_1(X)^{n+1} \rightarrow \text{Vec}_1(S),$$

where $\text{Vec}_1(\cdot)$ denotes the set of invertible sheaves, which descends to a symmetric, multi-linear map at the level of Picard groups. This pairing is of crucial importance in arithmetic geometry, since it gives “the schematic contribution” to the Arakelov intersection number.

The Deligne pairing was constructed by Deligne in [5] for arithmetic surfaces and then generalised to any dimension in [7], [21] and [8]. Its definition was not built as the unique solution of a universal problem, but it was given a list of properties satisfied by the Deligne pairing. A set of axioms that uniquely identify the Deligne pairing were found recently in the preprint [20].

For arithmetic surfaces one can show the following isomorphism of invertible sheaves which turns out to be very useful in the proof of Faltings-Riemann-Roch theorem (see for example [5] and [15] for more details):

$$\langle \mathcal{L}, \mathcal{M} \rangle_{X/S} \cong \det Rf_*(\mathcal{O}_X) \otimes (\det Rf_*(\mathcal{L}))^{-1} \otimes (\det Rf_*(\mathcal{M}))^{-1} \otimes \det Rf_*(\mathcal{L} \otimes \mathcal{M}). \quad (0.2)$$

One can notice immediately the similarities between equations (0.1) and (0.2). The only substantial difference is that for algebraic surfaces we use the Euler-Poincaré characteristic whereas for arithmetic surfaces we use the determinant of the cohomology. Such a distinction makes perfectly sense because the determinant of the cohomology is constructed to be the arithmetic analogue of the Euler-Poincaré characteristic.

At this point the natural question is the following one: is it possible to give an explicit definition of the Deligne pairing (in the most general case) in terms of the determinant of cohomology¹? In this paper we give an affirmative answer. By working in complete analogy of the theory of algebraic varieties, we write down a simple explicit formula for the Deligne pairing in terms of the determinant of cohomology. Let $f : X \rightarrow S$ be a proper, flat morphism of reduced Noetherian schemes, and assume that f has pure dimension n , then we put

$$\begin{cases} \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S} := \det Rf_*(c_1(\mathcal{L}_0^{-1})c_1(\mathcal{L}_1^{-1}) \dots c_1(\mathcal{L}_n^{-1})\mathcal{O}_X) & \text{if } n > 0 \\ \langle \mathcal{L}_0 \rangle_{X/S} := \det Rf_*(c_1(\mathcal{L}_0^{-1})\mathcal{O}_X)^{-1} = N_{X/S}(\mathcal{L}_0) & \text{if } n = 0 \end{cases} \quad (0.3)$$

where $c_1(\mathcal{L})\mathcal{F} := \mathcal{F} - \mathcal{L}^{-1} \otimes \mathcal{F} \in K_0(X)$ for any coherent sheaf \mathcal{F} and any invertible sheaf \mathcal{L} (here only the class of \mathcal{F} in the Grothendieck group matters). Moreover $N_{X/S}$ is the norm, relative to f , of an invertible sheaf. We show that definition (0.3) satisfies the axioms of [20], and this implies that our definition is exactly the Deligne pairing.

Let’s mention some other papers that previously investigated in our direction: an explicit formula for the Deligne pairing when X and S are integral schemes over \mathbb{C} was announced in [3], although a complete proof is not given. The approach of [3] is essentially different from ours, indeed the authors work on local trivializations of invertible sheaves. A more complicated expression of the Deligne pairing in terms of symmetric difference of the functor $\det Rf_*$ is proved in [6] with heavy usage of category theory. An explicit calculation of the Deligne pairing $\langle \mathcal{L}, \dots, \mathcal{L} \rangle$ (here \mathcal{L} is always the same) is given in [17].

This paper is organized in the following way: in section 1 we introduce the map $c_1(\mathcal{L}) : K_0(X) \rightarrow K_0(X)$ with all its properties. Section 2 is a review of intersection theory for algebraic varieties and it gives to the reader the philosophical guidelines for the case of relative schemes. In section 3 we give the axioms of the Deligne pairing and we show with all details that if such pairing exists it must be unique (we follow [20]). Afterwards we show that the pairing (0.3) satisfies all the axioms. appendix A is a review of the determinant of cohomology, this part is crucial in order to understand section 3. Finally appendix B is a “bonus section” where we show with all details the original construction of Deligne pairing of [5] (very often this construction is just sketched in the literature).

Acknowledgements. The author wants to express his gratitude to R.S. De Jong for his time spent in discussing the topic during summer 2019 in Nottingham and for his precious comments. A special thanks goes also to P. Corvaja, I. Fesenko, S. Urbinati and F. Zucconi.

¹This was briefly conjectured already in [7]: “ (...) Dans le cas général, c’est-à-dire en dimension quelconque, et sans hypothèse de lissité, l’intersection doit aussi s’exprimer en termes de déterminants d’images directes (...) malheureusement, pour l’instant, des problèmes de signe obscurcissent sérieusement la situation.”

1 An endomorphism of the group $K_0(X)$

Let's briefly recall the abstract construction of the Grothendieck group $K_0(\mathbf{C})$. Fix an abelian category \mathbf{C} and let $F(\mathbf{C})$ be the free abelian group over the set $\text{Ob}(\mathbf{C})/\cong$, where \cong is the isomorphism relation. If $C \in \text{Ob}(\mathbf{C})$, then (C) denotes isomorphism class in $\text{Ob}(\mathbf{C})/\cong$. To any short exact sequence in \mathbf{C} :

$$\mathcal{S}: \quad 0 \rightarrow C' \rightarrow C \rightarrow C'' \rightarrow 0$$

we associate an element $Q(\mathcal{S}) := (C) - (C') - (C'') \in F(\mathbf{C})$. Now $H(\mathbf{C})$ is the subgroup of $F(\mathbf{C})$ generated by all the elements $Q(\mathcal{S})$ for \mathcal{S} running over all short exact sequences. Then:

$$K_0(\mathbf{C}) := F(\mathbf{C})/H(\mathbf{C}),$$

and $[C] \in K_0(\mathbf{C})$ denotes the equivalence class associated to $C \in \text{Ob}(\mathbf{C})$.

Let's fix a reduced Noetherian scheme X , then $K_0(X) := K_0(\mathbf{Coh}(X))$, where $\mathbf{Coh}(X)$ is the category of coherent sheaves on X . From now on, by an abuse of notation we identify any coherent sheaf \mathcal{F} with its class in $K_0(X)$. In this paper, with the notation $\mathbf{Coh}_r(X)$ we denote the category of coherent sheaves on X whose support has dimension at most r , and we define $K_{0,r}(X) := K_0(\mathbf{Coh}_r(X))$. Clearly when $0 \leq i \leq j$, then $K_{0,i}(X) \subseteq K_{0,j}(X)$.

For any invertible sheaf \mathcal{L} on X we define a map:

$$\begin{aligned} c_1(\mathcal{L}) : K_0(X) &\rightarrow K_0(X) \\ \mathcal{F} &\mapsto c_1(\mathcal{L})\mathcal{F} := \mathcal{F} - \mathcal{L}^{-1} \otimes \mathcal{F}. \end{aligned} \tag{1.1}$$

Note that it is well defined because tensoring with an invertible sheaf is an exact functor, moreover it defines an endomorphism of the group $K_0(X)$. Since the notation for the function $c_1(\mathcal{L})$ is multiplicative, the symbol $c_1(\mathcal{L})c_1(\mathcal{L}')$ denotes the composition of functions. The properties of the operator $c_1(\mathcal{L})$ are well described in [11, Appendix B], so here we just recall them.

Proposition 1.1. *The following properties hold for the operator $c_1(\mathcal{L})$:*

- (i) $c_1(\mathcal{L})c_1(\mathcal{M}) = c_1(\mathcal{L}) + c_1(\mathcal{M}) - c_1(\mathcal{L} \otimes \mathcal{M})$, where clearly the sum is taken in $\text{End}(K_0(X))$.
- (ii) $c_1(\mathcal{M})c_1(\mathcal{L}) = c_1(\mathcal{L})c_1(\mathcal{M})$.
- (iii) If $Z \subset X$ is a closed subscheme and $\mathcal{L}|_Z = \mathcal{O}_Z(D)$ where D is an effective Cartier divisor on Z , then $c_1(\mathcal{L})\mathcal{O}_Z = \mathcal{O}_D$.

Proof. Both sides of the equality in (i) expand to:

$$\mathcal{F} - \mathcal{L}^{-1} \otimes \mathcal{F} - \mathcal{M}^{-1} \otimes \mathcal{F} + \mathcal{L}^{-1} \otimes \mathcal{M}^{-1} \otimes \mathcal{F}. \tag{1.2}$$

(ii) Follows easily by looking at equation (1.2). For (iii) Consider the short exact sequence

$$0 \rightarrow \mathcal{O}_Z(-D) \rightarrow \mathcal{O}_Z \rightarrow \mathcal{O}_D \rightarrow 0.$$

□

Proposition 1.2. *Let $\mathcal{F} \in K_{0,r}(X)$ and let Z_1, \dots, Z_s the r -dimensional irreducible components of $\text{supp}(\mathcal{F})$ whose generic points are denoted respectively by z_i . Let $n_i = \text{length } \mathcal{F}_{z_i}$. Then in $K_{0,r}(X)$ we have the equality:*

$$\mathcal{F} \equiv \sum_{i=1}^s n_i \mathcal{O}_{Z_i} \pmod{K_{0,r-1}(X)}.$$

Proof. See [11, Lemma B4].

□

Proposition 1.3. *let \mathcal{L} an invertible sheaf on X , then $c_1(\mathcal{L})K_{0,r}(X) \subset K_{0,r-1}(X)$ for any $r \geq 0$.*

Proof. See [11, Lemma B5].

□

Remark 1.4. The operator $c_1(\mathcal{L})$ can be ‘‘extended’’ to bounded complexes of coherent sheaves on X . Let \mathcal{F}^\bullet be a bounded complex of objects in $\mathbf{Coh}(X)$ then we can define:

$$c_1(\mathcal{L})\mathcal{F}^\bullet := \sum_i (-1)^i c_1(\mathcal{L})\mathcal{F}^i \in K_0(X).$$

Such a map is clearly zero on short exact sequences.

2 Intersection theory for algebraic varieties

Definition 2.1. Let X be a n -dimensional projective, non-singular algebraic variety over a field k . An *intersection pairing* on X is a map:

$$\begin{aligned} \text{Div}(X)^n &\rightarrow \mathbb{Z} \\ (D_1, \dots, D_n) &\mapsto D_1.D_2.\dots.D_n \end{aligned} \tag{2.1}$$

satisfying the following properties:

- (1) It is symmetric and \mathbb{Z} -multilinear.
- (2) It descends to a pairing $\text{Pic}(X)^n \rightarrow \mathbb{Z}$.
- (3) Let D_i be an effective divisor for any i and let $e_{i,x} \in \mathcal{O}_{X,x}$ be a local equation of D_i at the point x . Assume that for all x in the support of all divisors D_i , the $e_{i,x}$'s form a regular sequence in $\mathcal{O}_{X,x}$ (i.e. the divisors are in general position), then:

$$D_1.D_2.\dots.D_n = \sum_{x \in \cap D_i} \text{length} \frac{\mathcal{O}_{X,x}}{(e_{1,x}, e_{2,x}, \dots, e_{n,x})}$$

Now we show that if an intersection pairing exists, it is uniquely defined by the three axioms of Definition 2.1.

Proposition 2.2. *If an intersection pairing exists, then it is unique.*

Proof. Let $\langle \rangle_1$ and $\langle \rangle_2$ two pairings satisfying the axioms (1) – (3) and fix $D_1, \dots, D_n \in \text{Div}(X)^n$; by (1) we can assume that all D_i are effective. Thanks to Chow's moving lemma we can find some divisors D'_i such that $D \sim D'_i$ and D'_1, \dots, D'_n are in general position. Therefore by using (2) and (3) we get:

$$\langle D_1, \dots, D_n \rangle_1 = \langle D'_1, \dots, D'_n \rangle_1 = \langle D'_1, \dots, D'_n \rangle_2 = \langle D_1, \dots, D_n \rangle_2 .$$

□

The remaining part of this section is devoted to give the explicit expression of the intersection pairing on X as in [18], [19] and later [4]; then we see that the axioms of definition 2.1 are satisfied. Such an intersection pairing uses the endomorphism defined in section 1 and the Euler-Poincare characteristic for coherent sheaves.

We actually give a definition of the intersection pairing in a more general setting, in fact we will assume that X is a relative scheme over a scheme S and we define a “partial” intersection number of a particular subclass of divisors: roughly speaking, if we restrict to the case of arithmetic surfaces, we define an intersection number between two divisors provided that one of them is vertical.

From now on in this section we assume that $X \rightarrow S$ is a flat and proper morphism of irreducible Noetherian schemes. Let's denote with $\mathbf{Coh}(X/S)$ the category of coherent sheaves on X whose schematic support is a proper over a 0-dimensional subscheme of S . Moreover $\mathbf{Coh}_r(X/S)$ is the subcategory of $\mathbf{Coh}(X/S)$ made of sheaves whose support has dimension at most r . The motivation behind the restriction to sheaves with this kind of support is that for any $\mathcal{F} \in \mathbf{Coh}(X/S)$ we have a well defined notion of Euler-Poincare characteristic. In fact if T is the schematic support of \mathcal{F} and $S_0 = f(T)$, we know that S_0 is Noetherian of dimension 0, so $S_0 = \text{Spec } A$ with A artinian; at this point we can put

$$\chi_S(\mathcal{F}) := \sum_{i \geq 0} (-1)^i \text{length}_A H^i(X, \mathcal{F}).$$

When $S = \text{Spec } k$, then χ_S is the usual Euler-Poincare characteristic (for coherent sheaves with proper support). Thanks to the “additivity” of χ_S with respect to short exact sequences, it is immediate to notice that we have a naturally induced group homomorphism $\chi_S : K_0(\mathbf{Coh}_r(X/S)) \rightarrow \mathbb{Z}$.

Definition 2.3. Let $X \rightarrow S$ as above and let $\mathcal{F} \in \mathbf{Coh}_r(X/S)$. Then the *intersection number of the invertible sheaves* $\mathcal{L}_1, \dots, \mathcal{L}_r$ (with respect to \mathcal{F}) is defined as:

$$(\mathcal{L}_1.\mathcal{L}_2.\dots.\mathcal{L}_r, \mathcal{F}) := \chi_S(c_1(\mathcal{L}_1)c_1(\mathcal{L}_2)\dots c_1(\mathcal{L}_r)\mathcal{F}) .$$

When $\mathcal{F} = \mathcal{O}_X$, which implies $r \geq \dim(X)$, we put for simplicity

$$\mathcal{L}_1.\mathcal{L}_2.\dots.\mathcal{L}_r := (\mathcal{L}_1.\mathcal{L}_2.\dots.\mathcal{L}_r, \mathcal{O}_X).$$

Moreover if $\mathcal{L}_i = \mathcal{O}_X(D_i)$ for a Cartier divisor D_i on X , then:

$$D_1.D_2.\dots.D_r := \mathcal{O}_X(D_1).\mathcal{O}_X(D_2).\dots.\mathcal{O}_X(D_r).$$

Example 2.4. If X is a surface over k and C, D are two divisors, then:

$$\begin{aligned} C.D &= \chi_k(c_1(\mathcal{O}_X(C))c_1(\mathcal{O}_X(D))\mathcal{O}_X) = \chi_k(c_1(\mathcal{O}_X(C))(\mathcal{O}_X - \mathcal{O}_X(D)^{-1})) = \\ &= \chi_k(\mathcal{O}_X) - \chi_k(\mathcal{O}_X(C)^{-1}) - \chi_k(\mathcal{O}_X(D)^{-1}) + \chi_k(\mathcal{O}_X(C)^{-1} \otimes \mathcal{O}_X(D)^{-1}) \end{aligned}$$

The mere definitions tell us that we can intersect a number of divisors which is greater or equal to the dimension on X . On the other hand the next lemma shows that the intersection of a number of divisor which is strictly bigger than the dimension of X is always 0.

Lemma 2.5. *If $\mathcal{F} \in \mathbf{Coh}_r(X/S)$, then $(\mathcal{L}_1.\mathcal{L}_2.\dots.\mathcal{L}_{r+1}, \mathcal{F}) = 0$.*

Proof. It follows directly from Proposition 1.3. □

Proposition 2.6. *The intersection number of $\mathcal{L}_1, \dots, \mathcal{L}_m$ with respect to \mathcal{F} is a \mathbb{Z} -multilinear map in the \mathcal{L}_j 's (the operation is the tensor product).*

Proof. Follows by Proposition 1.1(i) and Lemma 2.5. □

Proposition 2.7. *Let $g : X' \rightarrow X$ be an morphism of S -schemes and let $\mathcal{F} \in \mathbf{Coh}_r(X'/S)$, then*

$$(g^*\mathcal{L}_1.g^*\mathcal{L}_2.\dots.g^*\mathcal{L}_n, \mathcal{F}) = (\mathcal{L}_1.\mathcal{L}_2.\dots.\mathcal{L}_n, g_*\mathcal{F}).$$

Proof. See [11, Lemma B.15]. □

We can give the explicit expression of the intersection number on varieties:

Proposition 2.8. *Let X be an algebraic variety of dimension r over a field k . The pairing*

$$(D_1, \dots, D_r) \mapsto D_1.D_2.\dots.D_r$$

defines the intersection number on X .

Proof. Axiom (1) is satisfied thanks to Proposition 2.6. Axiom (2) is obvious and axiom (3) is [13, IV, Theorem 2.8]. □

Finally we state a proposition regarding the intersection along fibres:

Proposition 2.9. *Let $s \in S$ be a closed point and let X_s be the fibre over s . Assume that $\dim(X_s) = d$, then the map:*

$$s \mapsto (\mathcal{L}_1, \dots, \mathcal{L}_d; \mathcal{O}_{X_s})$$

is locally constant on S .

Proof. See [13, VI, Proposition 2.10]. □

3 The case of schemes over a general base

3.1 Multi-monoidal and symmetric functors

The Deligne pairing will be expressed as a collection of functors, so in this section we recall what is the functorial equivalent of a multi-linear homomorphism of abelian groups.

We assume that the reader is familiar with some basic notions of category theory and the concept of *Picard groupoid*. Roughly speaking a Picard groupoid is a category where morphisms are only isomorphisms and moreover there is a “group-like” operation between the object of the category. The simplest example is the *Picard category* $\mathbf{Pic}(X)$ made of all invertible sheaves over a scheme X where the morphisms are just the isomorphisms. The “operation” in $\mathbf{Pic}(X)$ is clearly the tensor product of invertible sheaves and the identity element is the structure sheaf. The morphisms we want to consider between Picard groupoids are monoidal functors, i.e. functors that preserve the monoidal structure of the categories:

For the remaining part of this subsection we fix two Picard groupoids (\mathbf{C}, \otimes) and (\mathbf{D}, \otimes) .

Definition 3.1. A monoidal functor $\mathbf{C} \rightarrow \mathbf{D}$ is a collection (F, ϵ, μ) where $\mu := \{\mu_{X,Y}\}_{X,Y \in \text{Obj}(\mathbf{C})}$, satisfying the following properties:

- $F : \mathbf{C} \rightarrow \mathbf{D}$ is a functor.
- $\epsilon : F(1_{\mathbf{C}}) \xrightarrow{\cong} 1_{\mathbf{D}}$ is an isomorphism.
- $\mu_{X,Y} : F(X) \otimes F(Y) \xrightarrow{\cong} F(X \otimes Y)$ is an isomorphism functorial in X and Y which satisfies associativity and unitality in the obvious categorical sense.

For simplicity we often omit ϵ and μ and we say that F is a monoidal functor between \mathbf{C} and \mathbf{D} . In symbols we write $F \in L^1(\mathbf{C}, \mathbf{D})$.

Definition 3.2. A *natural transformation* between monoidal functors (F, ϵ, μ) and (F', ϵ', μ') is a monoidal natural transformation $\alpha : F \rightarrow F'$ which maps ϵ to ϵ' and μ to μ' .

In order to give the next definition we need to introduce some notations. An object of the category \mathbf{C}^n (i.e. a n -uple of objects of \mathbf{C}) is denoted by $X = (X_1, \dots, X_n)$. Let $X, Y \in \mathbf{C}^n$ and let $i \in \{1, \dots, n\}$ such that for any $j \in \{1, \dots, n\}$ with $j \neq i$ we have $X_j = Y_j$, then we define $X \otimes_i Y \in \mathbf{C}^n$ in the following way:

$$(X \otimes_i Y)_j = \begin{cases} X_j \otimes Y_j & \text{if } i = j \\ X_j & \text{if } i \neq j \end{cases}$$

Definition 3.3. A multi-monoidal² functor $\mathbf{C}^n \rightarrow \mathbf{D}$ is the datum of

- A functor $F : \mathbf{C}^n \rightarrow \mathbf{D}$.
- For any functor $F' : \mathbf{C} \rightarrow \mathbf{D}$ obtained by fixing $n - 1$ components in \mathbf{C} , we have a collection μ' such that (F', μ') is a monoidal functor \mathbf{C} and \mathbf{D} .
- For every $i, j \in \{1, \dots, n\}$ and $X, Y, Z, W \in \mathbf{C}^n$ such that $X_k = Y_k = Z_k = W_k$ for all $k \neq i, j$, a commutative diagram:

$$\begin{array}{ccc} & F(X) \otimes F(Y) \otimes F(Z) \otimes F(W) & \\ & \swarrow & \searrow \\ (F(X) \otimes_j F(Y)) \otimes (F(Z) \otimes_j F(W)) & & (F(X) \otimes_i F(Y)) \otimes (F(Z) \otimes_i F(W)) \\ \downarrow & & \downarrow \\ F((X \otimes_j Y) \otimes_i (Z \otimes_j W)) & \xrightarrow{=} & (F(X) \otimes_i F(Y)) \otimes_j (F(Z) \otimes_i F(W)) \end{array}$$

The notion of symmetry is what one expects:

Definition 3.4. A multi-monoidal functor $\mathbf{C}^n \rightarrow \mathbf{D}$ is *symmetric* if for any $c_i \in \mathbf{C}$ and any permutation $\sigma \in \Sigma_n$ we have $F(c_1, \dots, c_n) \cong F(c_{\sigma(1)}, \dots, c_{\sigma(n)})$.

The set of symmetric multi-monoidal morphisms from \mathbf{C}^n to \mathbf{D} is denoted by $L^n(\mathbf{C}, \mathbf{D})$.

²Very often in literature one can find the term multi-additive.

Definition 3.5. A natural transformation between two multi-monoidal functors $F, F' \in L^n(\mathbf{C}, \mathbf{D})$ is a functorial isomorphism $\alpha : F \rightarrow F'$ which restricts to a natural transformation to each component in the sense of definition 3.2.

3.2 Axiomatic Deligne pairing

The Deligne pairing was introduced in [5] as a bilinear and symmetric map $\langle \cdot, \cdot \rangle : \text{Vec}_1(X) \times \text{Vec}_1(X) \rightarrow \text{Vec}_1(S)$, where $X \rightarrow S$ is an arithmetic surface. Such a definition is quite implicit, in fact requires the choice of rational sections of invertible sheaves and some operations in the étale topology on the base S . The Deligne pairing satisfies some compatibility conditions: it behaves well with respect to the base change and the pullback functor; moreover it is strictly related to the norm functor. In [7] Deligne's construction was extended straight away for proper flat morphisms of integral schemes of any dimension.

Let $f : X \rightarrow S$ a proper flat morphism between Noetherian reduced schemes, the guiding idea of this paper is that the Deligne pairing relative to f should be the generalisation the intersection pairing described in section 2. We want to work in complete analogy with the case of algebraic varieties, so in this section we give a set of “natural axioms” that uniquely define the Deligne pairing³. The explicit construction of the Deligne pairing will be carried out in section 3.3.

Let X and S be two Noetherian reduced schemes, with the symbol $\mathcal{F}^n(X, S)$ we denote the set of all proper flat morphisms $X \rightarrow S$ of pure dimension n .

Definition 3.6. A *Deligne pairing* consists of the following data for any two irreducible Noetherian schemes X, S , any $n \in \mathbb{N}$ and any $f \in \mathcal{F}^n(X, S)$: a functor

$$\langle \cdot, \dots, \cdot \rangle_f = \langle \cdot, \dots, \cdot \rangle_{X/S} \in L^{n+1}(\mathbf{Pic}(X), \mathbf{Pic}(S))$$

and a collection of natural transformations $\alpha, \beta, \gamma, \delta$ described below:

- (1) For any commutative square given by a base change $g : S' \rightarrow S$ which is proper, flat and with connected fibres

$$\begin{array}{ccc} X' = X \times_S S' & \xrightarrow{f'} & S' \\ \downarrow g' & & \downarrow g \\ X & \xrightarrow{f} & S \end{array}$$

a natural transformation between multi-monoidal functors $\alpha_{f,g} : \mathbf{Pic}(X)^{n+1} \rightarrow \mathbf{Pic}(S')$ such that

$$\alpha_{f,g} : g^* \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S} \xrightarrow{\cong} \langle g'^* \mathcal{L}_0, \dots, g'^* \mathcal{L}_n \rangle_{X'/S'} .$$

- (2) When $n > 0$ and $D \in \text{Div}(X)$ is an effective relative Cartier divisor, a natural transformation between multi-monoidal functors $\beta_{f,D} : \mathbf{Pic}(X)^n \rightarrow \mathbf{Pic}(S)$ such that

$$\beta_{f,D} : \langle \mathcal{L}_1, \dots, \mathcal{L}_n, \mathcal{O}_X(D) \rangle_{X/S} \xrightarrow{\cong} \langle \mathcal{L}_1|_D, \dots, \mathcal{L}_n|_D \rangle_{D/S} .$$

Moreover $\beta_{f,D}$ is natural with respect to base change in the following sense: for a base change diagram as in axiom (1) we have a commutative diagram:

$$\begin{array}{ccc} \langle g'^* \mathcal{L}_1, \dots, g'^* \mathcal{L}_n, g'^* \mathcal{O}_X(D) \rangle_{X'/S'} & \xrightarrow{\beta_{f',g'^*D}} & \langle g'^* \mathcal{L}_1|_{g'^*D}, \dots, g'^* \mathcal{L}_n|_{g'^*D} \rangle_{g'^*D/S'} \\ \downarrow \cong & & \downarrow \cong \\ g^* \langle \mathcal{L}_1, \dots, \mathcal{L}_n, \mathcal{O}_X(D) \rangle_{X/S} & \xleftarrow{g^* \beta_{f,D}} & g^* \langle \mathcal{L}_1|_D, \dots, \mathcal{L}_n|_D \rangle_{D/S} \end{array}$$

Where the vertical isomorphisms are given by $\alpha_{f,g}$ (remember that $g'^* \mathcal{O}_X(D) = \mathcal{O}_{X'}(g'^*D)$).

³We follow [20], but we prefer to give a self contained presentation with all details.

- (3) When $n > 0$, a natural transformation between multi-monoidal functors $\gamma_f : \mathbf{Pic}(S) \times \mathbf{Pic}(X)^n \rightarrow \mathbf{Pic}(S)$ such that

$$\gamma_f : \langle f^* \mathcal{L}, \mathcal{L}_1, \dots, \mathcal{L}_n \rangle_{X/S} \xrightarrow{\cong} \mathcal{L}(\mathcal{L}_1|_{X_s}, \mathcal{L}_2|_{X_s}, \dots, \mathcal{L}_n|_{X_s}; \mathcal{O}_{X_s})$$

where X_s is a generic fibre of f (see Proposition 2.9). Moreover γ_f is natural with respect to base change in the following sense: for a base change diagram as in axiom (1) we have a commutative diagram:

$$\begin{array}{ccc} \langle g'^* f^* \mathcal{L}, g'^* \mathcal{L}_1, \dots, g'^* \mathcal{L}_n \rangle_{X'/S'} & \xrightarrow{\gamma_{f'}} & g^* \mathcal{L}(g'^* \mathcal{L}_1|_{g'^* X_s}, g'^* \mathcal{L}_2|_{g'^* X_s}, \dots, g'^* \mathcal{L}_n|_{g'^* X_s}; \mathcal{O}_{g'^* X_s}) \\ \downarrow \cong & & \downarrow = \\ g^* \langle f^* \mathcal{L}, \mathcal{L}_1, \dots, \mathcal{L}_n \rangle_{X/S} & \xleftarrow{g^* \gamma_f} & g^* \mathcal{L}(\mathcal{L}_1|_{X_s}, \mathcal{L}_2|_{X_s}, \dots, \mathcal{L}_n|_{X_s}; \mathcal{O}_{X_s}) \end{array}$$

where the vertical isomorphism is given $\alpha_{f,g}$ and the equality follows from proposition 2.7 and the properties of g .

- (4) When $n = 0$, a natural transformation between monoidal functors $\delta_f : \mathbf{Pic}(X) \rightarrow \mathbf{Pic}(S)$ such that

$$\delta_f : \langle \mathcal{L} \rangle_{X/S} \xrightarrow{\cong} N_{X/S}(\mathcal{L})$$

where $N_{X/S}$ is the norm of f (see Definition A.7). Moreover δ_f is natural with respect to base change in the following sense: for a base change diagram as in axiom (1) we have a commutative diagram:

$$\begin{array}{ccc} \langle g'^* \mathcal{L} \rangle_{X'/S'} & \xrightarrow{\delta_{f'}} & N_{X'/S'}(g'^* \mathcal{L}) \\ \downarrow \cong & & \downarrow \cong \\ g^* \langle \mathcal{L} \rangle_{X/S} & \xleftarrow{g^* \delta_f} & g^* N_{X/S}(\mathcal{L}) \end{array}$$

where the vertical isomorphisms are given respectively by $\alpha_{f,g}$ and thanks to the properties of the norm.

We have to show that if a Deligne pairing exists, then it is unique. Roughly speaking we will show that any two pairings $(\langle \cdot, \dots, \cdot \rangle^i, \alpha^i, \beta^i, \gamma^i, \delta^i)$, with $i = 1, 2$, satisfying the axioms of definition 3.6 are related by natural transformation of functors that respects all the data. We will work by induction on the relative dimension of the morphism f . Note that we cannot use straight away property (2) to pass from relative dimension n to $n - 1$, since the whole construction will depend on the choice of the relative divisor D , but we want our constructions to be natural in a functorial way. Let's describe a general well known procedure to reduce the relative dimension of f without any particular choice of divisors. It is called *universal extension*.

Let $f \in \mathcal{F}^n(X, S)$ and let \mathcal{L} be an invertible sheaf on X . We assume that \mathcal{L} is *sufficiently ample* (with respect to f), i.e. that the following properties are satisfied: \mathcal{L} is very ample (with respect to f) and $R^i f_* \mathcal{L} = 0$ for $i > 0$.

Remark 3.7. The following properties hold for sufficient ampleness:

- It is preserved after base change.
- If $f \in \mathcal{F}^n(X, S)$ and \mathcal{L} is sufficiently ample on X , then $f_* \mathcal{L}$ is a locally free sheaf on S .
- If \mathcal{L}_0 is an invertible sheaf on X , then there exists a sufficiently ample \mathcal{L} such that $\mathcal{L}_0 \otimes \mathcal{L}$ is sufficiently ample. In particular we can always find on X a sufficiently ample invertible sheaf.

Put $\mathcal{M} = (f_* \mathcal{L})^\vee$ and let $\mathbb{P} := \mathbb{P}_S(\mathcal{M})$ be the projective vector bundle associated to \mathcal{M} , over S . Then we obtain the following base change diagram:

$$\begin{array}{ccc} \mathbb{X} := \mathbb{P} \times_S X & \xrightarrow{p_2} & X \\ \downarrow p_1 & & \downarrow f \\ \mathbb{P} & \xrightarrow{\pi} & S \end{array} \tag{3.1}$$

Consider now the invertible sheaf $\mathcal{L}_f := p_1^* \mathcal{O}_{\mathbb{P}}(1) \otimes p_2^* \mathcal{L}$ on \mathbb{X} . We want to construct a *canonical global section* σ of \mathcal{L}_f . It is enough to find a canonical non-zero element in \mathcal{L}_f^{-1} , because if $\phi \in \text{Hom}(\mathcal{O}_X, \mathcal{L}_f) = \mathcal{L}_f^{-1}$ then we put $\sigma := \phi_X(1)$. First of all we construct a surjective canonical morphism

$$\Psi : f^* \mathcal{M} \rightarrow \mathcal{L}.$$

Thanks to the properties of the pullback we have a canonical isomorphism $f^* \mathcal{M} \cong (f^* f_* \mathcal{L})^\vee$. Since \mathcal{L} is sufficiently ample, we have a canonical isomorphism $(f^* f_* \mathcal{L})^\vee \cong \mathcal{L}^\vee$. Moreover there is a surjective canonical map $\mathcal{L}^\vee \rightarrow \mathcal{L}$ given in the following way:

$$\begin{aligned} \text{Hom}(\mathcal{O}_X(U), \mathcal{L}(U)) &\rightarrow \mathcal{L}(U) \\ \varphi_U &\mapsto \varphi_U(1). \end{aligned}$$

By taking all compositions, we finally get our surjective Ψ . We have to prove that Ψ induces a canonical element in \mathcal{L}_f^{-1} (in order to get σ). Note that \mathcal{L}_f^{-1} is canonically isomorphic to $\text{Hom}(\mathcal{L}^{-1}, p_{2*} p_1^* \mathcal{O}_{\mathbb{P}}(1))$, but

$$p_{2*} p_1^* \mathcal{O}_{\mathbb{P}}(1) = f^* \pi_* \mathcal{O}_{\mathbb{P}}(1) = f^*(\mathcal{M}^\vee) = (f^* \mathcal{M})^\vee.$$

We conclude that the dual map of Ψ induces the non-zero element of \mathcal{L}_f^{-1} that we were searching for.

From now on we will say that the section σ constructed above is the universal section relative to \mathcal{L} . The following remark explains why we can use the universal section for our inductive step in the proof of uniqueness:

Remark 3.8. In [8, 2.2] it is shown that σ is a regular section, which is equivalent to say that the zero locus of σ (considered with its reduced scheme structure):

$$Z(\sigma) := \{x \in \mathbb{X} : 0 = \sigma(x) \in \mathcal{L}_f / \mathfrak{m}_x \mathcal{L}_f\}$$

is a relative Cartier divisor on \mathbb{X} . In this case we also have that \mathcal{L}_f is canonically isomorphic to $\mathcal{O}_{\mathbb{X}}(Z(\sigma))$. Now consider the restriction

$$p := (p_1)|_{Z(\sigma)} : Z(\sigma) \rightarrow \mathbb{P};$$

Let U be the flat locus of p and put $V := p(U)$. Then V is open in \mathbb{P} , and we denote its closed complement with W , then we conclude that

$$p : Z(\sigma) - p^{-1}(W) \rightarrow V \tag{3.2}$$

is flat of relative dimension $n - 1$.

The following theorem ensures the unicity of the Deligne pairing:

Theorem 3.9. *The Deligne pairing is unique: given two sets of data $(\langle \ , \dots, \ \rangle^i, \alpha^i, \beta^i, \gamma^i, \delta^i)$, with $i = 1, 2$, satisfying the conditions of Definition 3.6, there is a unique multi-additive morphism $\langle \ , \dots, \ \rangle^1 \rightarrow \langle \ , \dots, \ \rangle^2$ that transforms $\alpha^i, \beta^i, \gamma^i, \delta^i$ accordingly.*

Proof. We proceed by induction on n . When $n = 0$, the claim follows directly from axiom (4). Let's work now with $n > 0$; first of all we want a functorial isomorphism:

$$\Psi(\mathcal{L}_0, \dots, \mathcal{L}_n) : \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S}^1 \xrightarrow{\cong} \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S}^2. \tag{3.3}$$

Let's first construct it by assuming that one invertible sheaf $\mathcal{L} = \mathcal{L}_0$, is chosen sufficiently ample; we will denote it as $\Psi'(\mathcal{L}_0, \dots, \mathcal{L}_n)$. Let's construct for \mathcal{L} the base change diagram (3.1), with the same notations. Then σ is the universal section of \mathcal{L}_f and we also have the map p described in equation (3.2). Thanks to [9, Lemme 21.13.2], in order to give isomorphism (3.3), it is enough to give a functorial isomorphism:

$$(\pi|_V)^* \langle \mathcal{L}, \mathcal{L}_1, \dots, \mathcal{L}_n \rangle_{(\mathbb{X}-p_1^{-1}(W))/V}^1 \xrightarrow{\cong} (\pi|_V)^* \langle \mathcal{L}, \mathcal{L}_1, \dots, \mathcal{L}_n \rangle_{(\mathbb{X}-p_1^{-1}(W))/V}^2. \tag{3.4}$$

where $V \subset \mathbb{P}$ is the image of the flat locus of p (remember that V is open) and $W = \mathbb{P} - V$. Let's now put $q := p_2|_{\mathbb{X}-p_1^{-1}(W)}$. By applying axiom (1), it is enough to get a functorial isomorphism:

$$\langle q^* \mathcal{L}, q^* \mathcal{L}_1, \dots, q^* \mathcal{L}_n \rangle_{(\mathbb{X}-p_1^{-1}(W))/V}^1 \xrightarrow{\cong} \langle q^* \mathcal{L}, \mathcal{L}_1, \dots, q^* \mathcal{L}_n \rangle_{(\mathbb{X}-p_1^{-1}(W))/V}^2. \tag{3.5}$$

Now remember that by definition of \mathcal{L}_f we have:

$$q^* \mathcal{L} = \mathcal{L}_f|_{(\mathbb{X}-p_1^{-1}(W))} \otimes (p_1^* \mathcal{O}_{\mathbb{P}}(1))^{-1}$$

Let's put for simplicity of notations $\mathcal{M} := \mathcal{L}_f|_{(\mathbb{X}-p_1^{-1}(W))}$; by multi-additivity and axiom (3) we only need to find a functorial isomorphism

$$\langle \mathcal{M}, q^* \mathcal{L}_1, \dots, q^* \mathcal{L}_n \rangle_{(\mathbb{X}-p_1^{-1}(W))/V}^1 \xrightarrow{\cong} \langle \mathcal{M}, q^* \mathcal{L}_1, \dots, q^* \mathcal{L}_n \rangle_{(\mathbb{X}-p_1^{-1}(W))/V}^2. \quad (3.6)$$

At this point put $Z'(\sigma) := Z(\sigma) - p_1^{-1}(W)$; thanks to axiom (2), it is enough to find a functorial isomorphism:

$$\langle (q^* \mathcal{L}_1)|_{Z'(\sigma)}, \dots, (q^* \mathcal{L}_n)|_{Z'(\sigma)} \rangle_{Z'(\sigma)/V}^1 \xrightarrow{\cong} \langle (q^* \mathcal{L}_1)|_{Z'(\sigma)}, \dots, (q^* \mathcal{L}_n)|_{Z'(\sigma)} \rangle_{Z'(\sigma)/V}^2. \quad (3.7)$$

The relative dimension of the map $p : Z'(\sigma) \rightarrow V$ is now $n-1$ and we can apply the inductive hypothesis.

We still have to prove the existence of $\Psi(\mathcal{L}_0, \dots, \mathcal{L}_n)$ for a general \mathcal{L}_0 . For any invertible sheaf \mathcal{L}_0 there exists a sufficiently ample one \mathcal{M} such that $\mathcal{L}_0 \otimes \mathcal{M}$ is again sufficiently ample. So we can put:

$$\Psi(\mathcal{L}_0, \dots, \mathcal{L}_n) := \Psi'(\mathcal{L}_0 \otimes \mathcal{M}, \dots, \mathcal{L}_n) \otimes \Psi'(\mathcal{M}, \dots, \mathcal{L}_n)^{-1}$$

provided that the construction doesn't depend on the choice of \mathcal{M} . Such a claim is equivalent to show that $\Psi'(\cdot, \mathcal{L}_1, \dots, \mathcal{L}_n)$ is additive with respect to sufficiently ample invertible sheaves.

Now we consider two sufficiently ample invertible sheaves $\mathcal{L}^{(i)}$ for $i = 1, 2$ and the associated diagrams:

$$\begin{array}{ccc} \mathbb{X}^{(i)} := \mathbb{P}^{(i)} \times_S X & \xrightarrow{p_2^{(i)}} & X \\ \downarrow p_1^{(i)} & & \downarrow f \\ \mathbb{P}^{(i)} & \xrightarrow{\pi^{(i)}} & S \end{array} \quad (3.8)$$

where clearly $\mathbb{P}^{(i)} := \mathbb{P}_S(\mathcal{M}^{(i)})$ for $\mathcal{M}^{(i)} := (f_* (\mathcal{L}^{(i)}))^\vee$. On the other hand if we put $\mathcal{L} := \mathcal{L}^{(1)} \otimes \mathcal{L}^{(2)}$ and $\mathbb{P} := \mathbb{P}_S((f_* \mathcal{L}^{(1)})^\vee \otimes (f_* \mathcal{L}^{(2)})^\vee)$ we end up with the diagram (3.8). There is a natural map

$$\iota : \mathbb{X}^{(1)} \times_X \mathbb{X}^{(2)} \rightarrow \mathbb{X}$$

Let q_i the projections of $\mathbb{X}^{(1)} \times_X \mathbb{X}^{(2)}$ on the factors $\mathbb{X}^{(i)}$, then one can show that:

$$\begin{aligned} \iota^* \mathcal{L}_f &= q_1^* \mathcal{L}_f^{(1)} \otimes q_2^* \mathcal{L}_f^{(2)}, \\ \iota^* \sigma &= q_1^* \sigma^{(1)} \otimes q_2^* \sigma^{(2)}. \end{aligned}$$

From the properties of the universal extension discussed in [7, I.2] the claim follows.

It remains to show that Ψ transforms $\alpha^1, \beta^1, \gamma^1, \delta^1$ to $\alpha^2, \beta^2, \gamma^2, \delta^2$. Let's do it for α^i , the other cases are similar. In particular we have to prove that, given a base change diagram as in axiom (1), we get a commutative diagram:

$$\begin{array}{ccc} g^* \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S}^1 & \xrightarrow{\cong} & \langle g'^* \mathcal{L}_0, \dots, g'^* \mathcal{L}_n \rangle_{X'/S'}^1 \\ \downarrow \cong & & \downarrow \cong \\ g^* \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S}^2 & \xrightarrow{\cong} & \langle g'^* \mathcal{L}_0, \dots, g'^* \mathcal{L}_n \rangle_{X'/S'}^2 \end{array} \quad (3.9)$$

In order to construct (3.9) it is enough to proceed similarly as we did above: we work by induction on n . If $n = 0$ the claim follows from the property of δ^i with respect to base change. For the generic n we can use the universal extension procedure described above and the properties of β^i with respect to base change to reduce to $n-1$. \square

3.3 Deligne pairing in terms of determinant of cohomology

In this section we heavily use the proprieties of the determinant functor presented in appendix A in order to give an explicit expression of the Deligne pairing in terms of the determinant of cohomology.

Let $f : X \rightarrow S$ be a flat morphism between Noetherian irreducible schemes. If $\mathbf{Vec}(X)$ is the category of locally free sheaves of finite rank on X , the first think to notice is that $\det Rf_*$ descends to a map on $K_0(\mathbf{Vec}(X))$. Now we put:

$$\begin{cases} \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S} := \det Rf_* (c_1(\mathcal{L}_0^{-1})c_1(\mathcal{L}_1^{-1}) \dots c_1(\mathcal{L}_n^{-1})\mathcal{O}_X) & \text{if } n > 0 \\ \langle \mathcal{L}_0 \rangle_{X/S} := \det Rf_* (c_1(\mathcal{L}_0^{-1})\mathcal{O}_X)^{-1} = N_{X/S}(\mathcal{L}_0) & \text{if } n = 0 \end{cases}$$

We want to show that this defines the Deligne pairing i.e. that there are some ‘‘canonical’’ natural transformations associated to $\langle \dots \rangle_{X/S}$ satisfying all axioms of definition 3.6.

Remark 3.10. When $n = 1$, after some simple algebraic manipulations we obtain the expected result:

$$\begin{aligned} \langle \mathcal{L}, \mathcal{M} \rangle &= \det Rf_* (c_1(\mathcal{L}^{-1})c_1(\mathcal{M}^{-1})\mathcal{O}_X) = \det Rf_* (c_1(\mathcal{L}^{-1})(\mathcal{O}_X - \mathcal{M})) = \\ &= \det Rf_* (\mathcal{O}_X) \otimes \det Rf_* (\mathcal{L})^{-1} \otimes \det Rf_* (\mathcal{M})^{-1} \otimes \det Rf_* (\mathcal{L} \otimes \mathcal{M}) \end{aligned}$$

Like in the case of algebraic varieties, Proposition 1.1 ensures that $\langle \dots \rangle_{X/S}$ is multi-monoidal and symmetric. Moreover axiom (4) of Definition 3.6 is trivially satisfied by definition (see Definition A.7). So it remains to show that axioms (1)-(3) are satisfied.

Proposition 3.11 (Axiom (1) holds). *For any commutative square given by a base change $g : S' \rightarrow S$ which is proper, flat and with connected fibres*

$$\begin{array}{ccc} X' = X \times_S S' & \xrightarrow{f'} & S' \\ \downarrow g' & & \downarrow g \\ X & \xrightarrow{f} & S \end{array}$$

there is a natural transformation between multi-additive morphisms $\alpha_{f,g} : \mathbf{Pic}(X)^{n+1} \rightarrow \mathbf{Pic}(S')$ such that

$$\alpha_{f,g} : g^* \langle \mathcal{L}_0, \dots, \mathcal{L}_n \rangle_{X/S} \xrightarrow{\cong} \langle g'^* \mathcal{L}_0, \dots, g'^* \mathcal{L}_n \rangle_{X'/S'} .$$

Proof. First of all we have that for any invertible sheaf \mathcal{L} on X and any coherent sheaf \mathcal{F}' on X' :

$$c_1(\mathcal{L})Rg'_* \mathcal{F}' = Rg'_*(c_1(g'^* \mathcal{L})\mathcal{F}')$$

(see for example the proof of [11, Lemma B.15] for a detailed explanation of the above equality). Therefore

$$\begin{aligned} c_1(\mathcal{L}_0) \dots c_1(\mathcal{L}_n)Rg'_*(\mathcal{O}_{X'}) &= c_1(\mathcal{L}_0) \dots c_1(\mathcal{L}_{n-1})Rg'_*(c_1(g'^* \mathcal{L}_n)\mathcal{O}_{X'}) = \dots \\ &= Rg'_*(c_1(g'^* \mathcal{L}_0) \dots c_1(g'^* \mathcal{L}_n)\mathcal{O}_{X'}) . \end{aligned}$$

It means that:

$$g^* \det Rf_* (c_1(\mathcal{L}_0) \dots c_1(\mathcal{L}_n)Rg'_*(\mathcal{O}_{X'})) = g^* \det Rf_* (Rg'_*(c_1(g'^* \mathcal{L}_0) \dots c_1(g'^* \mathcal{L}_n)\mathcal{O}_{X'})) . \quad (3.10)$$

But thanks to the properties of the morphism $g : S' \rightarrow S$ we have that $g'_* \mathcal{O}_{X'} = \mathcal{O}_S$ (see for example [13, Exercise 3.11]), so it follows that the left hand side of equation (3.10) is

$$g^* \det Rf_* (c_1(\mathcal{L}_0) \dots c_1(\mathcal{L}_n)\mathcal{O}_S) .$$

On the right hand side of equation (3.10) note that we have the composition of the following functors:

$$g^* \circ \det_{S'} \circ Rf'_* \circ Rg'_* . \quad (3.11)$$

By the properties of the determinant functor equation (3.11) is naturally isomorphic to

$$\det_{S'} \circ Lg^* \circ Rf'_* \circ Rg'_* \cong \det'_S \circ Rf'_* = \det Rf'_* .$$

In other words we obtained that the right hand side of equation (3.10) is naturally isomorphic to

$$\det Rf'_* (c_1(g'^* \mathcal{L}_0) \dots c_1(g'^* \mathcal{L}_n)\mathcal{O}_{X'}) .$$

□

Remark 3.12. For axioms (2) and (3), we only have to show that the natural transformations exist, since their “good behaviour” with respect to base change is ensured by the properties of the determinant of cohomology with respect to base change i.e. equation (A.2).

Proposition 3.13 (Axiom (2) holds). *When $n > 0$ and $D \in \text{Div}(X)$ is an effective relative Cartier divisor, there is a natural transformation between multi-additive morphisms $\beta_{f,D} : \mathbf{Pic}(X)^n \rightarrow \mathbf{Pic}(S)$ such that*

$$\beta_{f,D} : \langle \mathcal{O}_X(D), \dots, \mathcal{L}_n \rangle_{X/S} \xrightarrow{\cong} \langle \mathcal{L}_1|_D, \dots, \mathcal{L}_n|_D \rangle_{D/S}.$$

Moreover such a transformation is natural with respect to base change.

Proof. This follows by the simple fact that $c_1(\mathcal{O}_X(D))\mathcal{O}_X = \mathcal{O}_D$ (see Proposition 1.1(iii)). \square

Proposition 3.14 (Axiom (3) holds). *When $n > 0$ there is a natural transformation between multi-additive morphisms $\gamma_f : \mathbf{Pic}(S) \times \mathbf{Pic}(X)^n \rightarrow \mathbf{Pic}(S)$ such that*

$$\gamma_f : \langle f^*\mathcal{L}, \mathcal{L}_1, \dots, \mathcal{L}_n \rangle_{X/S} \xrightarrow{\cong} \mathcal{L}(\mathcal{L}_1|_{X_s} \cdot \mathcal{L}_2|_{X_s} \cdots \mathcal{L}_n|_{X_s}; \mathcal{O}_{X_s})$$

where X_s is a generic fibre of f . Moreover such a transformation is natural with respect to base change.

Proof. Let's put $\mathcal{E} := c_1(\mathcal{L}_1) \dots c_1(\mathcal{L}_n)\mathcal{O}_X$, then:

$$\begin{aligned} \det Rf_*(c_1(f^*\mathcal{L})c_1(\mathcal{L}_1) \dots c_1(\mathcal{L}_n)\mathcal{O}_X) &= \det Rf_*(c_1(f^*\mathcal{L})\mathcal{E}) = \det Rf_*(\mathcal{E} - (f^*\mathcal{L})^{-1} \otimes \mathcal{E}) = \\ &= \det Rf_*(\mathcal{E}) \otimes \det Rf_*((f^*\mathcal{L})^{-1} \otimes \mathcal{E})^{-1} = (*) \end{aligned}$$

Now, thanks to Proposition A.6 the above chain of equalities can be continued in the following way through a canonical isomorphism:

$$(*) \cong \det Rf_*(\mathcal{E}) \otimes \det Rf_*(\mathcal{E})^{-1} \otimes \mathcal{L}^{\chi_S(\mathcal{E}|_{X_s})} = \mathcal{L}^{\chi_S(\mathcal{E}|_{X_s})}$$

where X_s is a generic fibre. In order to conclude, it is enough to notice that $\mathcal{E}|_{X_s} = c_1(\mathcal{L}_1|_{X_s}) \dots c_1(\mathcal{L}_n|_{X_s})\mathcal{O}_{X_s}$. \square

Appendices

A Determinant functor and determinant of cohomology

In this section we briefly discuss, without proofs, the determinant functor by following [12]. First we define the determinant for locally free sheaves, then we extend it to complexes of locally free sheaves and then we extend it further for perfect complexes. We will use some basic notions from the theory of derived category (see [10] for a concise introduction.)

We fix a Noetherian irreducible scheme X . A *graded invertible sheaf* on X is a couple (\mathcal{L}, α) where \mathcal{L} is an invertible sheaf on X and $\alpha : X \rightarrow \mathbb{Z}$ is a continuous function. A morphism of graded invertible sheaves $\phi : (\mathcal{L}, \alpha) \rightarrow (\mathcal{M}, \beta)$ is a morphism of invertible sheaves such that the following condition hold: for any $x \in X$, if $\alpha(x) \neq \beta(x)$, then $\phi_x = 0$. We denote with $\mathbf{Gr}(X)$ the category of graded invertible sheaves, and $\mathbf{isGr}(X)$ is the category whose objects are graded invertible sheaves and the morphisms are just the isomorphisms; note that $\mathbf{isGr}(X)$ is a Picard groupoid. The tensor product (i.e. the group operation) between graded invertible sheaves is defined as $(\mathcal{L}, \alpha) \otimes (\mathcal{M}, \beta) = (\mathcal{L} \otimes \mathcal{M}, \alpha + \beta)$. The unit graded invertible sheaf is $(\mathcal{O}_X, 0)$. Furthermore we can define the isomorphism $\tau : \mathcal{L} \otimes \mathcal{M} \rightarrow \mathcal{M} \otimes \mathcal{L}$ such that locally and on pure tensors is given by:

$$\tau(l \otimes m) = (-1)^{\alpha\beta} m \otimes l.$$

Let $\mathbf{Vec}(X)$ be the category of locally free sheaves on X (of finite rank) and let $\mathbf{isVec}(X)$ its subcategory where the morphisms are only the isomorphisms.

For a locally free sheaf \mathcal{E} of rank r , we denote with the symbol $\bigwedge^r \mathcal{E}$ the sheafification of the following presheaf:

$$U \mapsto \bigwedge^r \mathcal{E}(U).$$

Then we can construct graded invertible sheaf $\det^* \mathcal{E}$ in the following way:

$$\det^* \mathcal{E} := \left(\bigwedge^r \mathcal{E}, r \right).$$

Then we have a functor:

$$\det_X^* : \mathbf{isVec}(X) \rightarrow \mathbf{isGr}(X).$$

For any short exact sequence of locally free sheaves:

$$0 \longrightarrow \mathcal{H} \xrightarrow{\alpha} \mathcal{F} \xrightarrow{\beta} \mathcal{G} \longrightarrow 0$$

there is an isomorphism of graded invertible sheaves

$$i_X^*(\alpha, \beta) : \det_X^*(\mathcal{H}) \otimes \det_X^*(\mathcal{G}) \xrightarrow{\cong} \det_X^*(\mathcal{F})$$

that locally is given in the following way: assume that \mathcal{H} has rank r and \mathcal{G} has rank s , then for any local sections $h_i \in \mathcal{H}(U)$ and $\beta(f_i) \in \mathcal{G}(U)$, for $f_i \in \mathcal{F}(U)$ we have:

$$i_X^*(\alpha, \beta)((h_1 \wedge \dots \wedge h_r) \otimes (\beta(f_1) \wedge \dots \wedge \beta(f_s))) = \alpha(h_1) \wedge \dots \wedge \alpha(h_r) \wedge f_1 \wedge \dots \wedge f_n.$$

We are ready to give the definition of determinant for bounded complexes of locally free sheaves.

Definition A.1. Let $\mathbf{isVec}_b^\bullet(X)$ be the category of bounded complexes in $\mathbf{Vec}(X)$ where the morphism are just the quasi-isomorphisms between complexes. Then a *determinant functor on X* consists of the following data:

- (1) A functor $f_X : \mathbf{isVec}_b^\bullet(X) \rightarrow \mathbf{isGr}(X)$
- (2) For any short exact sequence in $\mathbf{isVec}_b^\bullet(X)$:

$$0 \longrightarrow \mathcal{H}^\bullet \xrightarrow{\alpha} \mathcal{F}^\bullet \xrightarrow{\beta} \mathcal{G}^\bullet \longrightarrow 0$$

an isomorphism:

$$i_X(\alpha, \beta) : f_X(\mathcal{H}^\bullet) \otimes f_X(\mathcal{G}^\bullet) \xrightarrow{\cong} f_X(\mathcal{F}^\bullet)$$

Moreover (f_X, i_X) satisfies the following conditions:

- (i) Given a commutative diagram in $\mathbf{isVec}_b^\bullet(X)$:

$$\begin{array}{ccccccc} 0 & \longrightarrow & \mathcal{H}^\bullet & \xrightarrow{\alpha} & \mathcal{F}^\bullet & \xrightarrow{\beta} & \mathcal{G}^\bullet \longrightarrow 0 \\ & & \downarrow \lambda' & & \downarrow \lambda & & \downarrow \lambda'' \\ 0 & \longrightarrow & \mathcal{H}_1^\bullet & \xrightarrow{\alpha_1} & \mathcal{F}_1^\bullet & \xrightarrow{\beta_1} & \mathcal{G}_1^\bullet \longrightarrow 0 \end{array}$$

such that the rows are short exact sequences, then the following diagram commutes

$$\begin{array}{ccc} f_X(\mathcal{H}^\bullet) \otimes f_X(\mathcal{G}^\bullet) & \xrightarrow{i_X(\alpha, \beta)} & f_X(\mathcal{F}^\bullet) \\ \downarrow f_X(\lambda') \otimes f_X(\lambda'') & & \downarrow f_X(\lambda) \\ f_X(\mathcal{H}_1^\bullet) \otimes f_X(\mathcal{G}_1^\bullet) & \xrightarrow{i_X(\alpha_1, \beta_1)} & f_X(\mathcal{F}_1^\bullet) \end{array}$$

- (ii) Given a commutative diagram in $\mathbf{isVec}_b^\bullet(X)$:

$$\begin{array}{ccccccc} & & 0 & & 0 & & 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathcal{H}_1^\bullet & \xrightarrow{\alpha_1} & \mathcal{F}_1^\bullet & \xrightarrow{\beta_1} & \mathcal{G}_1^\bullet \longrightarrow 0 \\ & & \downarrow \gamma_1 & & \downarrow \gamma & & \downarrow \gamma_2 \\ 0 & \longrightarrow & \mathcal{H}^\bullet & \xrightarrow{\alpha} & \mathcal{F}^\bullet & \xrightarrow{\beta} & \mathcal{G}^\bullet \longrightarrow 0 \\ & & \downarrow \delta_1 & & \downarrow \delta & & \downarrow \delta_2 \\ 0 & \longrightarrow & \mathcal{H}_2^\bullet & \xrightarrow{\alpha_2} & \mathcal{F}_2^\bullet & \xrightarrow{\beta_2} & \mathcal{G}_2^\bullet \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ & & 0 & & 0 & & 0 \end{array}$$

such that rows and columns are a short exact sequence, then the following diagram commutes

$$\begin{array}{ccc}
f_X(\mathcal{H}_1^\bullet) \otimes f_X(\mathcal{H}_2^\bullet) \otimes f_X(\mathcal{G}_1^\bullet) \otimes f_X(\mathcal{G}_2^\bullet) & \xrightarrow{i_X(\gamma_1, \gamma_2) \otimes i_X(\delta_1, \delta_2)} & f_X(\mathcal{H}^\bullet) \otimes f_X(\mathcal{G}^\bullet) \\
\downarrow i_X(\alpha_1, \beta_1) \otimes i_X(\alpha_2, \beta_2) & & \downarrow i_X(\alpha, \beta) \\
f_X(\mathcal{F}_1^\bullet) \otimes f_X(\mathcal{F}_2^\bullet) & \xrightarrow{i_X(\gamma, \delta)} & f_X(\mathcal{F}^\bullet)
\end{array}$$

(iii) f_X and $i_X(\cdot, \cdot)$ both commute with the base change of X . The explicit expression of such a property is the following: fix a morphism of schemes $\psi : Y \rightarrow X$ and let $L\psi^* : \mathbf{D}_-(\mathbf{QCoh}(X)) \rightarrow \mathbf{D}_-(\mathbf{QCoh}(Y))$ be the left derived functor of to the pullback ψ^* ; then the following properties hold:

- There is a natural transformation between functors: $\eta(\psi) : f_Y \circ L\psi^* \xrightarrow{\cong} \psi^* \circ f_X$.
- For any short exact sequence in $\mathbf{isVec}_b^\bullet(Y)$:

$$0 \longrightarrow \mathcal{H}^\bullet \xrightarrow{\alpha} \mathcal{F}^\bullet \xrightarrow{\beta} \mathcal{G}^\bullet \longrightarrow 0$$

then the following diagram commutes

$$\begin{array}{ccc}
f_Y(L\psi^* \mathcal{H}^\bullet) \otimes f_Y(L\psi^* \mathcal{G}^\bullet) & \xrightarrow{i_Y(L\psi^*(\alpha, \beta))} & f_Y(L\psi^* \mathcal{F}^\bullet) \\
\downarrow \eta(\psi)(\mathcal{H}^\bullet) \otimes \eta(\psi)(\mathcal{G}^\bullet) & & \downarrow \eta(\psi)(\mathcal{F}^\bullet) \\
\psi^* f_X(\mathcal{H}^\bullet) \otimes \psi^* f_X(\mathcal{G}^\bullet) & \xrightarrow{\psi^* i_X(\alpha, \beta)} & \psi^* f_X(\mathcal{F}^\bullet)
\end{array}$$

(iv) $f_X(0) = (\mathcal{O}_X, 0)$. Moreover for the short exact sequence:

$$0 \longrightarrow \mathcal{F}^\bullet \xrightarrow{\text{id}} \mathcal{F}^\bullet \xrightarrow{0} 0 \longrightarrow 0$$

we have that $i_X(\text{id}, 0) : f_X(\mathcal{F}^\bullet) \otimes (\mathcal{O}_X, 0) \rightarrow f_X(\mathcal{F}^\bullet)$ is the canonical map (i.e. the ‘‘projection on the first component’’).

(v) If we canonically identify $\mathbf{isVec}(X)$ as a subcategory of $\mathbf{isVec}_b^\bullet(X)$, then f_X restricts to \det_X^* and $i_X(\cdot, \cdot)$ restricts to $i_X^*(\cdot, \cdot)$.

Theorem A.2. *Up to natural transformation of functors there exists a unique determinant (f_X, i_X) on X . It will be denoted as (\det_X, i_X) .*

Proof. See [12, Theorem 1] for a complete proof. Here we write down just the explicit expressions for \det_X :

$$\det_X(\mathcal{F}^\bullet) = \bigotimes_i \det_X^*(\mathcal{F}^i)^{(-1)^i}. \quad (\text{A.1})$$

□

The category $\mathbf{isVec}_b^\bullet(\cdot)$ is quite restrictive, for example it doesn’t behave well with respect to the pushforward functor. Therefore, we would like to have a determinant functor for a more general category.

Definition A.3. A complex \mathcal{F}^\bullet of \mathcal{O}_X -modules is said *perfect* if for any $x \in X$ there exist an open neighbourhood $U \ni x$, a complex \mathcal{G}^\bullet in $\mathbf{Vec}_b^\bullet(U)$ and a quasi isomorphism of complexes of \mathcal{O}_U -modules $\mathcal{G}^\bullet \rightarrow \mathcal{F}|_U$. The category of perfect complexes on X is denoted by $\mathbf{Perf}(X)$, whereas $\mathbf{isPerf}(X)$ denotes the category of perfect complexes where the morphisms are just the quasi-isomorphisms.

Theorem A.4. *The determinant (\det_X, i_X) can be extended uniquely, up to natural transformation, to a determinant on $\mathbf{isPerf}(X)$. We will denote this extension again with the symbol (\det_X, i_X) and formally it is the datum of:*

- (1) A functor $\det_X : \mathbf{isPerf}(X) \rightarrow \mathbf{isGr}(X)$

(2) For any short exact sequence in $\mathbf{isPerf}(X)$:

$$0 \longrightarrow \mathcal{H}^\bullet \xrightarrow{\alpha} \mathcal{F}^\bullet \xrightarrow{\beta} \mathcal{G}^\bullet \longrightarrow 0$$

an isomorphism:

$$i_X(\alpha, \beta) : \det_X(\mathcal{H}^\bullet) \otimes \det_X(\mathcal{G}^\bullet) \xrightarrow{\cong} \det_X(\mathcal{F}^\bullet)$$

Moreover the properties (i) – (v) listed in definition A.1 are satisfied in $\mathbf{isPerf}(X)$.

Proof. See [12, Theorem 2]. □

One of the most important applications of the determinant functor appears in arithmetic geometry if we consider its interaction with the usual pushforward functor.

Definition A.5. Let $f : X \rightarrow S$ be a flat morphism between irreducible Noetherian schemes and let \mathcal{E} be a locally free sheaf of finite rank on X . It is well known ([2, Exp. 3, Proposition 4.8]) that the complex $Rf_*\mathcal{E}$ induced by the right derived functor of f_* is a perfect complex on S . Then, just by composing Rf_* with \det_S it is possible to define the functor:

$$\det Rf_* := \det_S \circ Rf_* : \mathbf{isVec}(X) \rightarrow \mathbf{isGr}(S)$$

which is called the *determinant of cohomology (relative to f)*. Very often, for simplicity we want to forget about the graduation on the target of the determinant of cohomology, so it becomes a functor $\mathbf{isVec}(X) \rightarrow \mathbf{Pic}(S)$.

Since the right derived functor Rf_* is exact in the derived sense (see [10]) it is not hard to show that for any short exact sequence of locally free sheaves on X

$$0 \longrightarrow \mathcal{H} \xrightarrow{\alpha} \mathcal{F} \xrightarrow{\beta} \mathcal{G} \longrightarrow 0$$

there is an isomorphism of graded invertible sheaves

$$i_f(\alpha, \beta) : \det Rf_*\mathcal{H} \otimes \det Rf_*\mathcal{G} \xrightarrow{\cong} \det Rf_*\mathcal{F}$$

Moreover the whole construction behaves well with respect to flat base change in the following sense: assume that the following commutative square is given by a flat base change from S to S'

$$\begin{array}{ccc} X' = X \times_S S' & \xrightarrow{f'} & S' \\ \downarrow g' & & \downarrow g \\ X & \xrightarrow{f} & S \end{array}$$

then for any locally free sheaf \mathcal{E} on X we have

$$g^*(\det Rf_*\mathcal{E}) \cong \det Rf'_*(g'^*\mathcal{E}). \tag{A.2}$$

We will also need an important property of the determinant of cohomology:

Proposition A.6. Let $f : X \rightarrow S$ be a flat morphism between irreducible Noetherian schemes and let \mathcal{E} be a locally free sheaf of finite rank on X . Moreover let \mathcal{L} be an invertible sheaf on S . Then there is a canonical isomorphism between invertible sheaves on S :

$$\det Rf_*(f^*\mathcal{L} \otimes \mathcal{E}) \xrightarrow{\cong} \mathcal{L}^{\otimes \chi_S(\mathcal{E}|_{X_s})} \otimes \det Rf_*(\mathcal{E})$$

where X_s is a generic fibre of f .

Proof. See [12]. □

Definition A.7. Let $\varphi : X \rightarrow S$ be a finite morphism between irreducible Noetherian schemes, then the *norm* of φ is defined as the functor:

$$\begin{aligned} N_\varphi = N_{X/S} : \mathbf{Pic}(X) &\rightarrow \mathbf{Pic}(S) \\ \mathcal{L} &\mapsto \det R\varphi_*\mathcal{L} \otimes (\det R\varphi_*\mathcal{O}_X)^{-1}. \end{aligned}$$

B Original construction of Deligne pairing

In this section we give all details of the construction of the Deligne pairing described in [5].

S is an irreducible Dedekind scheme and we put $K := K(S)$. $\varphi : X \rightarrow S$ is a S -scheme satisfying the following properties:

- X is two dimensional, integral, and regular. The generic point of X is η and the function field of X is denoted by $K(X)$.
- φ is proper and flat.
- The generic fibre, denoted by X_K , is a geometrically integral, smooth, projective curve over K .

We say that X is an *arithmetic surface over S* .

In this section we will also need recall the norm operator \mathcal{N} in dimension 1 and 2 (it is formally different from the norm of an invertible sheaf defined above).

Definition B.1. let C be a projective, non-singular curve over a field k , then for a closed point $x \in C$ and any non-zero rational function $f \in K(C)^\times$ we put

$$\mathcal{N}_x(f) := N_{k(x)|k}(f(x)) , \quad (\text{B.1})$$

where $f(x)$ is the obvious element of $k(x)$ associated to f . So if $D = \sum_{x \in X} v_x(D)[x] \in \text{Div}(X)$ and $f \in k(X)^\times$ is a non-zero rational function such that (f) and D have no common components, then it is well defined the following element:

$$\mathcal{N}_D(f) := \prod_{x \in X} \mathcal{N}_x(f)^{v_x(D)} \in k^\times$$

The well known Weil reciprocity law says that:

$$\mathcal{N}_{(g)}(f) = \mathcal{N}_{(f)}(g).$$

Coming back to our arithmetic surface $\varphi : X \rightarrow S$, consider

$$\Upsilon := \{ (D, E) \in \text{Div}(X) \times \text{Div}(X) : D \text{ and } E \text{ have no common components} \},$$

and note that if $(D_j, E_j) \in \Upsilon$ with $j = 1, 2$, then $(D_1 + D_2, E_1 + E_2) \in \Upsilon$.

Definition B.2. Let $(D, E) \in \Upsilon$ such that D and E are both effective, then for any closed point $x \in X$ we put:

$$i_x(D, E) := \text{length}_{\mathcal{O}_{X,x}} \mathcal{O}_{X,x} / (\mathcal{O}_X(-D)_x + \mathcal{O}_X(-E)_x) .$$

This is called the *local intersection number* of D and E at x .

The local intersection number assigns the multiplicity of the intersection at each point of X , and the following basic result summarizes its naive properties.

Proposition B.3. Let $(E, D) \in \Upsilon$ and $(E_j, D_j) \in \Upsilon$ with $j = 1, 2$ such that all the divisors are effective, then

- (1) $i_x(D, E) = i_x(E, D)$.
- (2) $i_x(D_1 + D_2, E_1 + E_2) = \sum_{j,k=1}^2 i_x(D_j, E_k)$.
- (3) $i_x(D, E) \neq 0$ if and only if $x \in \text{supp}(D) \cap \text{supp}(E)$.
- (4) If $x \in E$, $i_x(D, E) = \text{mult}_x(D|_E)$.

Proof. (1) and (3) are obvious. For (2) and (4) see [14, lemma 9.1.4]. □

Any divisor $D \in \text{Div}(X)$ can be written in a unique way as $D = D_+ - D_-$ where both D_+ and D_- are effective and if $(D, E) \in \Upsilon$, then $(D_\pm, E_\pm) \in \Upsilon$. We can use definition B.2 in order to have the local intersection at x of D and E when (D, E) is any element of Υ (so not necessarily effective):

$$i_x(D, E) := i_x(D_+, E_+) - i_x(D_+, E_-) - i_x(D_-, E_+) + i_x(D_-, E_-) .$$

Definition B.4. Let (D, E) be an element of Υ , then we define the 0-cycle on X given by:

$$i(D, E) := \sum_{x \in X^{(0)}} i_x(D, E)[x],$$

where here $[x]$ is a shorthand of $[\overline{\{x\}}]$.

Remark B.5. The sum in definition B.4 is finite because if D and E are effective without common components, then $i_x(D, E) = \text{mult}_x(D|_E)$ (proposition B.3(4)) and there is only a finite number of points on E at which the divisor $D|_E$ has non-zero multiplicity.

Proposition B.6. *If $(D, E), (D_j, E_j) \in \Upsilon$ with $j = 1, 2$, then the following properties hold for $i(D, E)$:*

- $i(D, E) = i(E, D)$ (symmetry).
- $i(D_1 + D_2, E_1 + E_2) = \sum_{j,k=1}^2 i(D_j, E_k)$ (bilinearity).

Proof. It follows immediately from proposition B.3. □

Definition B.7. We have the symmetric and bilinear pairing on Υ :

$$\begin{aligned} \Upsilon &\rightarrow \text{Div}(S) \\ (D, E) &\mapsto \langle D, E \rangle \end{aligned}$$

where

$$\langle D, E \rangle := \varphi_* i(D, E) = \sum_{x \in X} [k(x) : k(\varphi(x))] i_x(D, E) [\varphi(x)].$$

Let Γ be a prime divisor of X with generic point γ and consider a non-zero rational function $f \in K(X)^\times$ such that (f) and Γ have no common components, then define $\mathcal{N}_\Gamma(f) \in K^\times$ in the following way:

$$\mathcal{N}_\Gamma(f) := \begin{cases} N_{K(\Gamma)|K}(f|_\Gamma) & \text{if } \Gamma \text{ is horizontal} \\ 1 & \text{if } \Gamma \text{ is vertical} \end{cases}$$

where $N_{K(\Gamma)|K}$ is the usual field norm and $f|_\Gamma$ is defined as follows: since (f) and Γ have no common components it follows that $v_\gamma(f) = 0$, that is $f \in \mathcal{O}_{X,\gamma}^\times$. So $f|_\Gamma$ is the natural image of f in $k(\gamma) = K(\Gamma)$. At this point for any $D = \sum_i n_i \Gamma_i \in \text{Div}(X)$ such that D and (f) have no common components we have:

$$\mathcal{N}_D(f) := \prod_i \mathcal{N}_{\Gamma_i}(f)^{n_i} \in K^\times$$

Since $K(X)$ is the function field of any open subscheme $U \subseteq X$ and of X_K we can restrict the operator $\mathcal{N}_*(\cdot)$ to U and to X_K .

Proposition B.8. *Let $f \in K(X)^\times$ and let $D \in \text{Div}(X)$ such that (f) and D have no common components, then the following claims hold:*

- (1) *Let $U \subseteq X$ be an open subscheme, then $\mathcal{N}_{D|_U}(f) = \mathcal{N}_D(f)$.*
- (2) *$\mathcal{N}_{D|_{X_K}}(f) = \mathcal{N}_D(f)$, where the left hand side is the one-dimensional operator defined in equation (B.1).*

Proof. In both items we can restrict to the case when $D = \Gamma$ is an irreducible horizontal divisor.

- (1) The function fields and the generic points of Γ and $\Gamma|_U$ coincide, so the claim follows trivially.
- (2) Let $\gamma \in X_K$ be the generic point of Γ , it is a closed point of X_K such that $k(\gamma) = K(\Gamma)$. By the bare definitions we can check the required equality. □

Proposition B.9. *Let $f \in K(X)^\times$ and let $D \in \text{Div}(X)$ a divisor such that D and (f) have no common components, then*

$$\langle D, (f) \rangle = (\mathcal{N}_D(f)) \in \text{Princ}(S).$$

Proof. See [16, Proposition 4.3]. □

Now we will construct the Deligne pairing and see the relation with the pairing $\langle D, E \rangle$ for divisors. We divide the construction in two steps:

Step 1. Definition of the K -vector space $\langle \mathcal{L}, \mathcal{M} \rangle_K$.

Consider the sets:

$$\Upsilon_K := \left\{ (D, E) \in \text{Div}(X) \times \text{Div}(X) : \begin{array}{l} D|_{X_K} \text{ and } E|_{X_K} \text{ have no} \\ \text{common components (as divisors)} \\ \text{on } X_K \end{array} \right\},$$

$$\Sigma_K := \left\{ (l, m) : \begin{array}{l} l \text{ and } m \text{ are non-zero meromorphic sections of } \mathcal{L} \text{ and } \mathcal{M} \\ \text{such that } (\text{div}(l), \text{div}(m)) \in \Upsilon_K \end{array} \right\}.$$

Note that Υ_K is just the set of couple of divisors with no common horizontal components. Now we define some vector spaces over K .

$$V := K^{(\Sigma_K)},$$

namely V is the free K -vector space over Σ_K .

$$W' := \left\{ (fl, m) - \mathcal{N}_{\text{div}(m)|_{X_K}}(f) \cdot (l, m) : f \in K(X)^\times, (l, m), (fl, m) \in \Sigma_K \right\}, \quad (\text{B.2})$$

$$T' := \left\{ (l, gm) - \mathcal{N}_{\text{div}(l)|_{X_K}}(g) \cdot (l, m) : g \in K(X)^\times, (l, m), (l, gm) \in \Sigma_K \right\}. \quad (\text{B.3})$$

Note that the above “ $\mathcal{N}_*(\cdot)$ ” is the one-dimensional operator of definition B.1 considered on the curve X_K .

Remark B.10. $\mathcal{N}_{\text{div}(m)|_{X_K}}(f)$ and $\mathcal{N}_{\text{div}(l)|_{X_K}}(g)$ are well defined since $(l, m), (fl, m), (l, gm) \in \Sigma_K$, so $\text{div}(m)|_{X_K}$ and (f) have no common components. The same holds for $\text{div}(l)|_{X_K}$ and (g) .

Define the free vector spaces $W := K^{(W')}$ and $T := K^{(T')}$; moreover put

$$\langle \mathcal{L}, \mathcal{M} \rangle_K := V/(W + T),$$

which is considered as a constant sheaf (of K -vector spaces) over X . The natural image of any element $(l, m) \in \Sigma_K \subset V$ in $\langle \mathcal{L}, \mathcal{M} \rangle_K$ is denoted as $\langle l, m \rangle_K$.

Proposition B.11. $\langle \mathcal{L}, \mathcal{M} \rangle_K$ is a one-dimensional vector space over K .

Proof. Fix $(l_0, m_0) \in \Sigma_K$, then for any $(l, m) \in \Sigma_K$ there are two elements $f_0, g_0 \in K(X)^\times$ such that $l = f_0 l_0$, $m = g_0 m_0$ and moreover:

$$((f_0), (g_0)), ((f_0), \text{div}(m_0)), ((g_0), \text{div}(l_0)) \in \Upsilon_K.$$

By equations (B.2) and (B.3), in $\langle \mathcal{L}, \mathcal{M} \rangle_K$ we can write:

$$\langle l, m \rangle_K = \langle f_0 l_0, g_0 m_0 \rangle_K = [f_0, g_0] \mathcal{N}_{\text{div}(m_0)|_{X_K}}(f_0) \mathcal{N}_{\text{div}(l_0)|_{X_K}}(g_0) \langle l_0, m_0 \rangle_K. \quad (\text{B.4})$$

where, in order to simplify the notations, we put $[f_0, g_0] := \mathcal{N}_{(f_0)}(g_0)$ intended as operation on the curve X_K . This shows that $\langle \mathcal{L}, \mathcal{M} \rangle_K$ has dimension at most 1 over K . Define the homomorphism of K -vector spaces:

$$\theta : V \rightarrow K$$

such that

$$\theta(l, m) := [f_0, g_0] \mathcal{N}_{\text{div}(m_0)|_{X_K}}(f_0) \mathcal{N}_{\text{div}(l_0)|_{X_K}}(g_0).$$

Note that θ is non-trivial, so surjective, since $\theta(l_0, m_0) = 1$. Now by using the Weil reciprocity law we prove that θ descends to a non-trivial morphism $\bar{\theta} : \langle \mathcal{L}, \mathcal{M} \rangle_K \rightarrow K$, indeed for $f, g \in K(X)^\times$:

$$\begin{aligned} \theta(fl, m) &= [ff_0, g_0] \mathcal{N}_{\text{div}(m_0)|_{X_K}}(ff_0) \mathcal{N}_{\text{div}(l_0)|_{X_K}}(g_0) = \\ &= [f, g_0] [f_0, g_0] \mathcal{N}_{\text{div}(m_0)|_{X_K}}(f) \mathcal{N}_{\text{div}(m_0)|_{X_K}}(f_0) \mathcal{N}_{\text{div}(l_0)|_{X_K}}(g_0) = \\ &= [g_0, f] \mathcal{N}_{\text{div}(m_0)|_{X_K}}(f) \theta(l, m) = \\ &= \mathcal{N}_{\text{div}(m)|_{X_K}}(f) \theta(l, m). \end{aligned}$$

Similarly it holds that

$$\theta(l, gm) = \mathcal{N}_{\text{div}(l)|_{X_K}}(g) \theta(l, m).$$

In other words equation B.4 can be written as:

$$\langle l, m \rangle_K = \bar{\theta}(\langle l, m \rangle_K) \langle l_0, m_0 \rangle_K$$

hence, by the non triviality of $\bar{\theta}$ we conclude that $\langle \mathcal{L}, \mathcal{M} \rangle_K$ has dimension 1. \square

Step 2. Definition of $\langle \mathcal{L}, \mathcal{M} \rangle$.

Let $U \subseteq S$ be a non-empty open subset and denote with X_U the schematic inverse image of U with respect to φ . We clearly have a flat map $X_U \rightarrow U$, so we define:

$$\Upsilon_U := \left\{ (D, E) \in \text{Div}(X) \times \text{Div}(X) : \begin{array}{l} D|_{X_U} \text{ and } E|_{X_U} \text{ have no} \\ \text{common components (as divisors)} \\ \text{on } X_U \end{array} \right\},$$

$$\Sigma_U := \left\{ (l, m) : \begin{array}{l} l \text{ and } m \text{ are non-zero meromorphic sections of } \mathcal{L} \\ \text{and } \mathcal{M} \text{ such that } (\text{div}(l), \text{div}(m)) \in \Upsilon_U \text{ and} \\ \langle \text{div}(l)|_{X_U}, \text{div}(m)|_{X_U} \rangle \text{ is effective on } U \end{array} \right\}.$$

Moreover notice that $\Sigma_U \subset \Sigma_K$. We define a sheaf of \mathcal{O}_S -modules \mathcal{A} on X given by:

$$\mathcal{A}|_U := \mathcal{O}_S|_U^{(\Sigma_U)}.$$

Finally consider the morphism of sheaves: $\Phi : \mathcal{A} \rightarrow \langle \mathcal{L}, \mathcal{M} \rangle_K$ which sends $(l, m) \in \Sigma_U$ to $\langle l, m \rangle_K$ and define

$$\langle \mathcal{L}, \mathcal{M} \rangle := \mathcal{A} / \ker(\Phi).$$

The canonical image of $(l, m) \in \Sigma_U$ in $\mathcal{A}(U)$ is denoted as $\langle l, m \rangle_U$.

Proposition B.12. *Let $(l, m) \in \Sigma_U$ such that $\langle \text{div}(l)|_{X_U}, \text{div}(m)|_{X_U} \rangle = 0 \in \text{Div}(U)$. Then for any $(l', m') \in \Sigma_U$ there exists an element $a \in \mathcal{O}_S(U)$ such that $\langle l', m' \rangle_U = a \langle l, m \rangle_U$.*

Proof. There are two elements $f, g \in K(X)^\times$ such that $l' = fl$, $m' = gm$ and moreover:

$$((f), (g)), ((f), \text{div}(m)), ((g), \text{div}(l)) \in \Upsilon_K.$$

Hence by using proposition B.9:

$$\begin{aligned} \langle \text{div}(l')|_{X_U}, \text{div}(m')|_{X_U} \rangle &= \langle (f)|_{X_U} \text{div}(l)|_{X_U}, (g)|_{X_U} \text{div}(m)|_{X_U} \rangle = \\ &= \langle (f)|_{X_U}, (g)|_{X_U} \rangle + \langle (f)|_{X_U}, \text{div}(m)|_{X_U} \rangle + \langle \text{div}(l)|_{X_U}, (g)|_{X_U} \rangle + 0 = \\ &= \left(\mathcal{N}_{(f)|_{X_U}}(g) \right) + \left(\mathcal{N}_{\text{div}(m)|_{X_U}}(f) \right) + \left(\mathcal{N}_{\text{div}(l)|_{X_U}}(g) \right) = \\ &= \left(\mathcal{N}_{(f)|_{X_U}}(g) \mathcal{N}_{\text{div}(m)|_{X_U}}(f) \mathcal{N}_{\text{div}(l)|_{X_U}}(g) \right). \end{aligned}$$

Since $\langle \text{div}(l')|_{X_U}, \text{div}(m')|_{X_U} \rangle$ is effective, then

$$a := \mathcal{N}_{(f)|_{X_U}}(g) \mathcal{N}_{\text{div}(m)|_{X_U}}(f) \mathcal{N}_{\text{div}(l)|_{X_U}}(g) \in \mathcal{O}_S(U).$$

On the other hand

$$\langle l', m' \rangle_K = [f, g] \mathcal{N}_{\text{div}(m)|_{X_K}}(f) \mathcal{N}_{\text{div}(l)|_{X_K}}(g) \langle l, m \rangle_K$$

therefore by proposition B.8 we can conclude that:

$$\langle l', m' \rangle_U = \mathcal{N}_{(f)|_{X_U}}(g) \mathcal{N}_{\text{div}(m)|_{X_U}}(f) \mathcal{N}_{\text{div}(l)|_{X_U}}(g) \langle l, m \rangle_U = a \langle l, m \rangle_U.$$

\square

We are ready to show that $\langle \mathcal{L}, \mathcal{M} \rangle$ is an invertible sheaf on S . By proposition B.11 $\langle \mathcal{L}, \mathcal{M} \rangle$ is non-zero; now assume $\mathcal{L} = \mathcal{O}_X(D)$, $\mathcal{M} = \mathcal{O}_X(E)$ and fix a point $s_0 \in S$. By the moving lemma we can find a divisor D' such that $D' \sim D$ and D' doesn't have components in X_{s_0} . Suppose that x_1, \dots, x_m are the intersection points of D' and X_{s_0} , by applying again the moving lemma we can find a divisor E' such that: $E' \sim E$, E' and $D' + X_{s_0}$ have no common components, and E doesn't pass by x_1, \dots, x_m . Consider the finite subset of S

$$C := \{s \in S' : D' \cap E' \cap X_s \neq \emptyset\}$$

and note that its complement $U := S \setminus C$ has the following properties: $s_0 \in U$ and $\langle D'|_U, E'|_U \rangle = 0$. At this point any two meromorphic sections of \mathcal{L} and \mathcal{M} corresponding respectively to the divisors D' and E' will satisfy the hypothesis of proposition B.12 on U . This implies that $\langle \mathcal{L}, \mathcal{M} \rangle$ is an invertible sheaf.

One can show that the pairing constructed above satisfies the axioms (1)-(4) of definition 3.6 for $n = 1$, moreover we have the following additional properties:

Theorem B.13. *The Deligne pairing $\langle \mathcal{L}, \mathcal{M} \rangle \rightarrow \langle \mathcal{L}, \mathcal{M} \rangle$ satisfies the properties listed below. We assume that \mathcal{L} and \mathcal{M} are two invertible sheaves on X .*

- (1) *The induced map $\text{Pic}(X) \times \text{Pic}(X) \rightarrow \text{Pic}(S)$ is bilinear and symmetric.*
- (2) *Let l and m be two non-zero meromorphic sections of \mathcal{L} and \mathcal{M} , respectively, such that $\text{div}(l)$ and $\text{div}(m)$ have no common components. Then, there exists a non-zero meromorphic section $\langle l, m \rangle$ with the following properties:*

(i) *If $f, g \in K(X)^\times$ such that $(\text{div}(fl), \text{div}(m)), (\text{div}(l), \text{div}(gm)) \in \Upsilon$, then:*

$$\langle fl, m \rangle = \mathcal{N}_{\text{div}(m)}(f) \langle l, m \rangle$$

$$\langle l, gm \rangle = \mathcal{N}_{\text{div}(l)}(g) \langle l, m \rangle$$

(ii) *There is an isomorphism of invertible sheaves*

$$\langle \mathcal{L}, \mathcal{M} \rangle \cong \mathcal{O}_S(\langle \text{div}(l), \text{div}(m) \rangle)$$

Moreover, under the above isomorphism $\langle l, m \rangle$ corresponds to $1_{\langle \text{div}(l), \text{div}(m) \rangle}$. In particular:

$$\text{div}(\langle l, m \rangle) = \langle \text{div}(l), \text{div}(m) \rangle .$$

Proof. See [16, Theorem 4.7]. □

Remark B.14. Note that when $S = \text{Spec } k$ for any field k (in other words X is an algebraic curve), then $\langle \mathcal{L}, \mathcal{M} \rangle$ is just a one dimensional k -vector space.

Remark B.15. If S is a non-singular projective curve over a field k , and $\varphi : X \rightarrow S$ is a morphism over $\text{Spec } k$ (i.e. X is a fibred surface over S), then it is evident that $(D, E) \mapsto \deg \langle \mathcal{O}_X(D), \mathcal{O}_X(E) \rangle$ satisfies all the axioms of definition 2.1, so it is the intersection pairing on X . The same argument holds also when X has generic dimension n .
