Transcendental simplicial volumes

Nicolaus Heuer, Clara Löh

November 18, 2019

Abstract

We show that there exist closed manifolds with arbitrarily small transcendental simplicial volumes. Moreover, we exhibit an explicit uncountable family of (transcendental) real numbers that are not realised as the simplicial volume of a closed manifold.

1 Introduction

The simplicial volume $\|M\| \in \mathbb{R}_{\geq 0}$ is a homotopy invariant of oriented closed connected manifolds $M$ [Mun80, Gro82], namely the $\ell^1$-semi-norm of the (singular) $\mathbb{R}$-fundamental class. The set $\text{SV}(d) \subset \mathbb{R}_{\geq 0}$ of simplicial volumes of oriented closed connected $d$-manifolds is countable and can be determined explicitly in dimensions 1, 2, 3 through classification results [HL19b, Section 2.2]. In these dimensions, simplicial volume has a gap at 0.

In previous work [HL19b], we showed that those are the only dimensions with a gap and that indeed $\text{SV}(d)$ is dense in $\mathbb{R}_{\geq 0}$ for $d \in \mathbb{N} \geq 4$. We also showed that $\text{SV}(4)$ contains $\mathbb{Q}_{\geq 0}$. We now continue these investigations, with a focus on transcendental values.

Theorem A. For every $\epsilon \in \mathbb{R}_{>0}$, there exists an oriented closed connected 4-manifold $M$ such that

- $\|M\|$ is transcendental (over $\mathbb{Q}$) and
- $0 < \|M\| < \epsilon$.

In fact, we provide an explicit sequence of transcendental simplicial volumes of 4-manifolds converging to zero that are linearly independent over the algebraic numbers (Theorem C).

We also give explicit examples of real numbers that are not realised as a simplicial volume.

Theorem B. Let $d \in \mathbb{N}$ and let $A \subset \mathbb{N}$ be a subset that is not recursively enumerable. Then

$$\alpha := \sum_{n \in \mathbb{N} \setminus A} 2^{-n}$$

is transcendental (over $\mathbb{Q}$) and there is no oriented closed connected $d$-manifold $M$ with $\|M\| \in \mathbb{R}_{\geq 0}^C \cdot \alpha$, where $\mathbb{R}_{\geq 0}^C$ is the set of positive computable numbers.

MSC 2010 classification: 57N65, 57M07, 20J05, 11J86, 03D78
There are uncountably many non-recursively enumerable subsets of $\mathbb{N}$ [Cut80, Section 7] and $1 \in \mathbb{R}_{>0}$. Hence, Theorem [3] provides concrete examples of uncountably many transcendental numbers that are not realised as the simplicial volume of closed manifolds.

We previously explored connections between stable commutator length on finitely presented groups and simplicial volume [HL19a, HL19b, Theorem C/F]; see also Theorem 1.2.

There are several classes of finitely presented groups where stable commutator length is fully understood [Cal09, Chapter 5]. However, it is unknown which real non-negative numbers are generally realised as the stable commutator length of elements in finitely presented groups. For the larger class of recursively presented groups, the set of stable commutator length is known and coincides with the set of right-computable numbers [Hen19]. Thus we ask:

**Question 1.1.** Does the set of all simplicial volumes of oriented closed connected 4-manifolds coincide with the set of non-negative right-computable real numbers?

**Proof of Theorem A**

Theorem [A] will follow from the following explicit construction of simplicial volumes:

**Theorem C.** There exists a sequence $(M_n)_{n \in \mathbb{N}}$ of oriented closed connected 4-manifolds with

$$\|M_n\| = \frac{24 \cdot \arccos(1 - 2^{-n-1})}{\pi}$$

for all $n \in \mathbb{N}$. The numbers $\alpha_n := \frac{24 \cdot \arccos(1 - 2^{-n-1})}{\pi}$ have the following properties:

1. We have $\lim_{n \to \infty} \alpha_n = 0$.
2. For each $n \in \mathbb{N}_{>0}$, the number $\alpha_n$ is transcendental (over $\mathbb{Q}$).
3. The family $(\alpha_p)_{p \in \mathbb{P}}$ is linearly independent over the field of algebraic numbers; here, $\mathbb{P} \subset \mathbb{N}$ denotes the set of all prime numbers.

The simplicial volumes constructed in Theorem C will be based on our previous work [HL19b] that allows us to construct 4-manifolds with simplicial volumes prescribed in terms of the stable commutator length of certain finitely presented groups. See Calegari’s book [Cal09] for background on stable commutator length.

**Theorem 1.2** ([HL19b, Theorem F]). Let $\Gamma$ be a finitely presented group that satisfies $H_2(\Gamma; \mathbb{R}) \cong 0$ and let $g \in [\Gamma, \Gamma]$ be an element in the commutator subgroup. Then there exists an oriented closed connected 4-manifold $M_g$ with

$$\|M_g\| = 48 \cdot \text{scl}_\Gamma g.$$

As input for this theorem, we use the following groups (whose existence is established in Section 3):

**Theorem D.** There exists a central extension $E$ of $\text{SL}_2(\mathbb{Z}[1/2])$ with the following properties:
1. The group $E$ is finitely presented.

2. We have $H_2(E; \mathbb{R}) \cong 0$.

3. The image of $\text{scl}_E$ in $\mathbb{R}$ coincides with the image of $\text{scl}_{\tilde{\Gamma}}$, where $\tilde{\Gamma}$ denotes the central extension of $\text{SL}_2(\mathbb{Z}[1/2])$ corresponding to the integral Euler class of $\text{SL}_2(\mathbb{Z}[1/2])$.

It is known that the image of stable commutator length of the central Euler class extension of $\text{SL}_2(\mathbb{Z}[1/2])$ contains arbitrarily small transcendental numbers [Cal09, Example 5.38]:

**Example 1.3.** Let $\Gamma := \text{SL}_2(\mathbb{Z}[1/2])$ and let $\tilde{\Gamma}$ denote the central extension of $\text{SL}_2(\mathbb{Z}[1/2])$ corresponding to the integral Euler class of $\text{SL}_2(\mathbb{Z}[1/2])$. In other words, $\tilde{\Gamma}$ is the pre-image of $\text{SL}_2(\mathbb{Z}[1/2])$ under the canonical projection $\tilde{\text{SL}}_2(\mathbb{R}) \to \text{SL}_2(\mathbb{R})$, where $\tilde{\text{SL}}_2(\mathbb{R})$ denotes the universal covering group of $\text{SL}_2(\mathbb{R})$. Then

$$\text{scl}_{\tilde{\Gamma}}(\tilde{g}) = \frac{|\text{rot}(\tilde{g})|}{2}$$

for all $\tilde{g} \in [\tilde{\Gamma}, \tilde{\Gamma}]$, where $\text{rot} : \tilde{\Gamma} \to \mathbb{R}_{\geq 0}$ denotes the rotation number [Cal09, Example 5.38].

Furthermore, for each $g \in \Gamma$ with $|\text{tr}(g)| \leq 2$, there is a lift $\tilde{g} \in \tilde{\Gamma}$ of $g$ such that [Cal09, p. 145]

$$\text{rot}(\tilde{g}) = \frac{\arccos(\text{tr}(g)/2)}{\pi}.$$

For $n \in \mathbb{N}_{>0}$, we consider

$$g_n := \begin{pmatrix} 2 & 1 + 2^{-n+1} \\ -1 & -2^n \end{pmatrix} \in \Gamma$$

and let $\tilde{g}_n \in \tilde{\Gamma}$ be the associated lift. Then $\lim_{n \to \infty} \text{rot}(\tilde{g}_n) = 0$ and

$$\text{scl}_{\tilde{\Gamma}}(\tilde{g}_n) = \frac{|\text{rot}(\tilde{g}_n)|}{2} = \frac{\arccos(\text{tr}(g_n)/2)}{2 \cdot \pi} = \frac{\arccos(1 - 2^{-n-1})}{2 \cdot \pi}.$$

With these ingredients, we can complete the proof of Theorem C (and thus of Theorem A): Let $E$ be the group from Theorem D and let $(\tilde{g}_n)_{n \in \mathbb{N}}$ be as in Example 1.3. Then, by Theorem D, for each $n \in \mathbb{N}$, there exists an element $h_n$ in the commutator subgroup of the group $E$ with

$$\text{scl}_E(h_n) = \text{scl}_{\tilde{\Gamma}}(\tilde{g}_n) = \frac{\arccos(1 - 2^{-n-1})}{2 \cdot \pi} = \frac{\alpha_n}{48}.$$

Applying Theorem 1.2 to $h_n \in [E, E]$ results in an oriented closed connected 4-manifold $M_n$ with $\|M_n\| = \alpha_n$ and hence $\lim_{n \to \infty} \|M_n\| = 24 \cdot \arccos(1)/\pi = 0$. If $n > 0$, then $\alpha_n$ is known to be transcendental (Proposition 2.2). Moreover, Baker’s theorem proves the last part of Theorem C (Proposition 2.3).
Proof of Theorem B

The proof of Theorem B relies on the following simple observation (proved in Section 4, where also the definition of right-computability is recalled):

**Theorem E.** Let $M$ be an oriented closed connected manifold. Then $\|M\|$ is a right-computable real number.

On the other hand, it is known that the numbers $\alpha$ in Theorem B are not right-computable [Spe49] (and thus, in particular, not algebraic, because every algebraic number is computable [Eis12, Section 6]) and that the product of a computable number with a number that is not right-computable is also not right-computable (Section 4.1). Therefore, applying Theorem E proves Theorem B.

Organisation of this article

In Section 2, we prove the transcendence properties of the arccos-terms. In Section 3, we solve the group-theoretic problem for the proof of Theorem D. In Section 4, we prove Theorem E.

2 Some transcendental numbers

In this section, for $n \in \mathbb{N}_{>0}$, we will investigate the transcendence of the following real numbers

$$\alpha_n := \frac{24 \cdot \arccos(1 - 2^{-n-1})}{\pi}.$$

2.1 Transcendence

As a first step, we show that the $\alpha_n$ are transcendental, using Niven’s theorem.

**Theorem 2.1 (Niven [Niv56, Corollary 3.12]).** Let $\text{trig} \in \{\sin, \cos\}$ and let $x \in \mathbb{Q}$ with $\text{trig}(\pi \cdot x) \in \mathbb{Q}$. Then $\text{trig}(\pi \cdot x) \in \{0, \pm 1/2, \pm 1\}$.

**Proposition 2.2.** Let $n \in \mathbb{N}_{>0}$. Then $\alpha_n$ is transcendental (over $\mathbb{Q}$).

**Proof.** As a consequence of the Gelfond-Schneider theorem, the number $\alpha_n$ is either rational or transcendental [Lim17, Theorem 1]. Assume for a contradiction that $\alpha_n$ were rational. Then, because $\cos(\pi \cdot \alpha_n) = 1 - 2^{-n-1}$ is also rational, by Niven’s theorem (Theorem 2.1), we obtain

$$1 - \frac{1}{2^{n+1}} = \cos(\pi \cdot \alpha_n) \in \{0, \pm 1/2, \pm 1\}.$$

However, this contradicts the hypothesis that $n > 0$. Hence, $\alpha_n$ must be transcendental.

2.2 Linear independence over the algebraic numbers

We will now refine Proposition 2.2 using Baker’s theorem.

**Theorem 2.3 (Baker [Bak66]).** Let $\Lambda \subset \{\ln(\alpha) \in \mathbb{C} \mid \alpha \text{ algebraic over } \mathbb{Q}\}$ be linearly independent over $\mathbb{Q}$. Then $\Lambda$ is linearly independent over the field of algebraic numbers.
Proposition 2.4. Let \( \mathbb{P} \subseteq \mathbb{N} \) be the set of prime numbers. Then the sequence \((\alpha_{p-2})_{p \in \mathbb{P}}\) is linearly independent over the algebraic numbers.

For the prime \( p = 2 \) we compute that \( \alpha_{p-2} = \frac{24 \arccos(1/2)}{\pi} = 8 \), which is rational. Hence, Proposition 2.4 includes a proof that \( \alpha_{p-2} \) is transcendental for every odd prime \( p \).

Proof. We will use Baker’s Theorem 2.3. Rewriting \( \arccos \) as
\[
\arccos(z) = -i \cdot \ln(i \cdot z + \sqrt{1 - z^2}),
\]
we see that
\[
\alpha_{p-2} = \frac{24 \arccos(1 - 2^{-p+1})}{\pi} = -\frac{24}{\pi} \cdot i \cdot \ln(\gamma_p),
\]
where
\[
\gamma_p := i \cdot \frac{2^{p-1} - 1}{2^{p-1}} + \frac{1}{2^{p-1}} \cdot \sqrt{2^p - 1}.
\]
We will show in Claim 2.8 that for every finite set \( \{p_1, \ldots, p_k\} \) of distinct primes the family \( \{\ln(\gamma_{p_j})\}_{j \in \{1, \ldots, k\}} \) is linearly independent over \( \mathbb{Q} \). As \( \alpha_{p-2} \) is a uniform rescaling of \( \ln(\gamma_p) \), this will imply by using Baker’s Theorem that this family is also linearly independent over the algebraic numbers.

We will show the linear independence of \( \{\ln(\gamma_{p_j})\}_{j \in \{1, \ldots, k\}} \) over \( \mathbb{Q} \) in several steps:

Claim 2.5. Let \((m_k)_{k \in \mathbb{N}}\) be a sequence of pairwise coprime positive integers. Then, for every \( k \in \mathbb{N} \geq 2 \), we have that
\[
\sqrt{m_k} \notin \mathbb{Q}[i, \sqrt{m_1}, \ldots, \sqrt{m_{k-1}}].
\]

Proof. This follows from a classical result of Besicovitch [Bes40]. □

Claim 2.6. Let \( \{p_1, \ldots, p_k\} \) be a finite set of distinct primes. Then
\[
\sqrt{2^{p_k} - 1} \notin \mathbb{Q}[i, \sqrt{2^{p_1} - 1}, \sqrt{2^{p_2} - 1}, \ldots, \sqrt{2^{p_{k-1}} - 1}]
\]

Proof. For all primes \( p, q \in \mathbb{N} \) with \( p \neq q \), the Mersenne numbers \( 2^p - 1 \) and \( 2^q - 1 \) are coprime. We may conclude using the previous claim. □

Claim 2.7. Let \( \{p_1, \ldots, p_k\} \) be a finite set of distinct primes and let \( n \in \mathbb{N}_{>0} \). Then
\[
\gamma_{p_k}^n \notin \mathbb{Q}[i, \sqrt{2^{p_k} - 1}, \sqrt{2^{p_{k-2}} - 1}, \ldots, \sqrt{2^{p_1} - 1}].
\]

Proof. We compute that
\[
\gamma_{p_k}^n = \left( i \cdot \frac{2^{p_k-1} - 1}{2^{p_k-1}} + \frac{1}{2^{p_k-1}} \cdot \sqrt{2^{p_k} - 1} \right)^n
= \frac{1}{2^{n(p_k-1)}} \cdot \sum_{j=0}^{\lfloor \frac{n}{2} \rfloor} \binom{n}{j} \cdot i^{n-j} \cdot (2^{p_k-1} - 1)^{n-j} \cdot (2^{p_k} - 1)^{\frac{j}{2}}.
\]
We see that the terms contributing to \( \sqrt{2^{p_k} - 1} \) are the terms where \( j \) is odd and that there exist \( q_1, q_2 \in \mathbb{Q} \) with
\[
\gamma_{p_k}^n = i^n \cdot (q_1 + q_2 \cdot i \cdot \sqrt{2^{p_k} - 1}).
\]
Assume for a contradiction that \( q_2 \) were zero. Then \( \gamma_{p_k} \in \mathbb{Q} \cup i \cdot \mathbb{Q} \) and as \( |\gamma_{p_k}| = 1 \) we obtain \( \gamma_{p_k}^n \in \{ \pm 1, \pm i \} \). In particular, \( \gamma_{p_k} \) is a root of unity. Therefore, there exists an \( x \in \mathbb{Q} \) with
\[
\gamma_{p_k} = \cos(2\pi \cdot x) + i \cdot \sin(2\pi \cdot x).
\]
According to Niven’s Theorem 2.1, by comparing with the definition of \( \gamma_{p_k} \), we see that
\[
|\gamma_{p_k}| = 2^{\frac{n}{pk} - \frac{1}{2}} \cdot \sqrt{2^{pk - 1} - 1} \]}
by Claim 2.6.

Claim 2.8. Let \( \{ p_1, \ldots, p_k \} \) be a finite set of distinct primes. Then the corresponding family \( \{ \ln(\gamma_{p_j}) \}_{j \in\{1, \ldots, k\} } \) is linearly independent over \( \mathbb{Q} \).

Proof. Assume for a contradiction that this family were linearly dependent over \( \mathbb{Q} \), whence over \( \mathbb{Z} \). Thus, there are integers \( n_i \in \mathbb{Z} \), not all zero, such that
\[
\ln(\gamma_{p_1}^{n_1} \cdots \gamma_{p_k}^{n_k}) = n_1 \cdot \ln(\gamma_{p_1}) + \cdots + n_k \cdot \ln(\gamma_{p_k}) = 0.
\]
Without loss of generality we may assume that \( n_k > 0 \). Hence,
\[
\gamma_{p_1}^{n_1} \cdots \gamma_{p_k}^{n_k} \in \{ 1 + k \cdot 2\pi i \mid k \in \mathbb{Z} \}.
\]
The left-hand side is algebraic over \( \mathbb{Q} \), but the right-hand side is only algebraic if \( k = 0 \). Thus, we conclude that \( \gamma_{p_1}^{n_1} \cdots \gamma_{p_k}^{n_k} = 1 \); in other words,
\[
\gamma_{p_k}^{n_k} = \gamma_{p_1}^{-n_1} \cdots \gamma_{p_{k-1}}^{-n_{k-1}}.
\]
Moreover, by construction, \( \gamma_{p_1}^{-n_1} \cdots \gamma_{p_{k-1}}^{-n_{k-1}} \in \mathbb{Q}[i, \sqrt{2^{p_1 - 1}}, \ldots, \sqrt{2^{p_{k-1} - 1}}] \). However, this contradicts Claim 2.7. Thus, \( \ln(\gamma_{p_1}), \ldots, \ln(\gamma_{p_k}) \) are linearly independent over \( \mathbb{Q} \).

This finishes the proof of Proposition 2.4.

3 Solving the group-theoretic problem

As the basic building block for our constructions we pick \( \text{SL}_2(\mathbb{Z}[1/2]) \) because its low-degree (co)homology, its second bounded cohomology, and its quasi-morphisms are already known to basically have the right structure.

3.1 Basic properties of \( \text{SL}_2(\mathbb{Z}[1/2]) \)

We collect basic properties of \( \text{SL}_2(\mathbb{Z}[1/2]) \) needed in the sequel; further information on the (bounded) Euler class for circle actions can be found in the literature [BFH16, Ghy87].

Proposition 3.1 (low-degree (co)homology of \( \text{SL}_2(\mathbb{Z}[1/2]) \)).

1. The group \( \text{SL}_2(\mathbb{Z}[1/2]) \) is finitely presented.
2. The group \( H_1(\text{SL}_2(\mathbb{Z}[1/2]); \mathbb{Z}) \) is finite (and non-trivial).
3. The group \( \text{SL}_2(\mathbb{Z}[1/2]) \) does not admit any non-trivial quasi-morphisms.
4. We have $H^2_0(\mathrm{SL}_2(\mathbb{Z}[1/2]); \mathbb{R}) \cong \mathbb{R}$ and the bounded Euler class $\Gamma \, \mathrm{eu}^R_0$ is a generator.

5. The evaluation map $(\Gamma \, \mathrm{eu}^R, \cdot) : H_2(\mathrm{SL}_2(\mathbb{Z}[1/2]); \mathbb{Z}) \to \mathbb{Z}$ is non-trivial.

Proof. Ad 1. The group $\mathrm{SL}_2(\mathbb{Z}[1/2])$ can be written as an amalgamated free product of the form

$$\mathrm{SL}_2(\mathbb{Z}[1/2]) \cong \mathrm{SL}_2(\mathbb{Z})*_{\Gamma_0(2)} \mathrm{SL}_2(\mathbb{Z}),$$

where $\Gamma_0(2)$ is the subgroup of $\mathrm{SL}_2(\mathbb{Z})$ of those matrices whose lower left entry is divisible by 2; this leads to an explicit finite presentation [Ser03, p. 81].

Ad 2. In particular, one obtains that $H_1(\mathrm{SL}_2(\mathbb{Z}[1/2]); \mathbb{Z}) \cong \mathbb{Z}/3$ is finite [AN98, Proposition 3.1]. (Moreover, applying the Mayer-Vietoris sequence to the decomposition in the proof of the first part allows to compute the cohomology $H^*(\mathrm{SL}_2(\mathbb{Z}[1/2]); \mathbb{Z})$ [AN98].)

Ad 3. This is one of many examples of groups acting on the circle with this property [Cal09, Example 5.38].

Ad 4. This is a result of Burger and Monod: The inclusion $\mathrm{SL}_2(\mathbb{Z}[1/2]) \to \mathrm{SL}_2(\mathbb{R})$ induces an isomorphism $H^2_0(\mathrm{SL}_2(\mathbb{R}); \mathbb{R}) \to H^2_0(\mathrm{SL}_2(\mathbb{Z}[1/2]); \mathbb{R})$ [BM02a, Corollary 24] [BM17, Corollary 4]. Moreover, $H^2_0(\mathrm{SL}_2(\mathbb{R}); \mathbb{R}) \cong \mathbb{R}$, generated by the bounded Euler class [BM02b].

Ad 5. We write $\Gamma := \mathrm{SL}_2(\mathbb{Z}[1/2])$. Because the space $Q(\mathrm{SL}_2(\mathbb{Z}[1/2]))$ of quasi-morphisms (modulo trivial quasi-morphisms) is trivial, the comparison map $c_{\Gamma} : H^2_{\Gamma}(\Gamma; \mathbb{R}) \to H^2(\Gamma; \mathbb{R})$ is injective [Cal09, Theorem 2.50]. In particular, $\Gamma \, \mathrm{eu}^R = c_{\Gamma}(\Gamma \, \mathrm{eu}^R)$ is non-trivial in $H^2(\Gamma; \mathbb{R})$. Therefore, by the universal coefficient theorem, also the evaluation map $(\Gamma \, \mathrm{eu}^R, \cdot) : H_2(\Gamma; \mathbb{Z}) \to \mathbb{Z}$ associated with the integral Euler class $\Gamma \, \mathrm{eu}^R \in H^2(\Gamma; \mathbb{Z})$ is non-trivial.

3.2 Imitating the universal central extension

If $G$ is a perfect group, then its universal central extension $E$ satisfies $H_2(E; \mathbb{R}) \cong 0$. Moreover, we may compute the quasi-morphisms on $E$ from $H^1_0(G; \mathbb{R})$, which in turn allows us to compute the stable commutator length on $E$ using Bavard’s Duality Theorem [HL96, Section 5]. The group $\mathrm{SL}_2(\mathbb{Z}[1/2])$ is not perfect, thus it does not have a universal central extension. Instead, we will construct a central extension of $\mathrm{SL}_2(\mathbb{Z}[1/2])$ that is able to play the same role in our context.

**Proposition 3.2.** Let $\Gamma$ be a finitely presented group with finite $H_1(\Gamma; \mathbb{Z})$, let $H := H_2(\Gamma; \mathbb{Z})$, and let $E$ be a central extension group of $\Gamma$ that corresponds to a class $\varphi \in H^2(\Gamma; H)$ whose evaluation $(\varphi, \cdot) : H_2(\Gamma; \mathbb{Z}) \to H = H_2(\Gamma; \mathbb{Z})$ has finite kernel and finite cokernel. Then:

1. The group $E$ is finitely presented.
2. We have $H_2(E; \mathbb{R}) \cong 0$.

**Proof.** The central extension group $E$ fits into a short exact sequence of the form

$$1 \to H \to E \to \Gamma \to 1.$$

Ad 1. As $\Gamma$ is finitely presented, the group $H$ is finitely generated [Bro94, II.5]. Therefore, the central extension of $\Gamma$ by $H$ is also finitely presented.
Ad 2. Because the extension is central, we have the associated exact sequence

\[
\begin{array}{ccccccccc}
H_1(E; \mathbb{Z}) \otimes_{\mathbb{Z}} H & \longrightarrow & H_2(E; \mathbb{Z}) & \longrightarrow & H_2(\Gamma; \mathbb{Z}) & \beta & H & \longrightarrow & H_1(E; \mathbb{Z}) & \longrightarrow & H_1(\Gamma; \mathbb{Z}) & \longrightarrow & 0
\end{array}
\]

by Eckmann, Hilton, and Stammbach [EHS72 (1.4) and Theorem 2.2], where

\[
\beta: H \to H_2(\Gamma; \mathbb{Z}) \to H
\]

By Proposition 3.1, we know that indeed

\[
\begin{array}{l}
\beta: H \to H_2(\Gamma; \mathbb{Z}) \to H
\end{array}
\]

By assumption, \( \beta \) has finite cokernel and \( H_1(\Gamma; \mathbb{Z}) \) is finite. Hence, \( H_1(E; \mathbb{Z}) \) is finite and therefore also the left-most term \( H_1(E; \mathbb{Z}) \otimes_{\mathbb{Z}} H \) is finite. As \( \beta \) has finite kernel, this implies that \( H_2(E; \mathbb{Z}) \) is finite. Applying the universal coefficient theorem, shows that \( H_2(E; \mathbb{R}) \cong H_2(E; \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{R} \cong 0 \). \( \square \)

**Proposition 3.3.** Let \( \Gamma := \text{SL}_2(\mathbb{Z}[1/2]) \), let \( \text{r} \text{eu} \mathbb{Z} \in H^2(\Gamma; \mathbb{Z}) \) be the Euler class of \( \Gamma \), let \( H := H_2(\Gamma; \mathbb{Z}) \), and let \( m \in \mathbb{N}_{>0} \) be a generator of \( \text{im}(\text{r} \text{eu} \mathbb{Z}, \cdot) \subset \mathbb{Z} \). We consider the epimorphism \( \epsilon := 1/m \cdot (\text{r} \text{eu} \mathbb{Z}, \cdot): H \to \mathbb{Z} \). Then:

1. There is a class \( \varphi \in H^2(\Gamma; \mathbb{H}) \) with

\[
H^2(\text{id}_\Gamma; \epsilon)(\varphi) = \text{r} \text{eu} \mathbb{Z} \quad \text{and} \quad \langle \varphi, \cdot \rangle = m \cdot \text{id}_H.
\]

2. Let \( E \) be the central extension of \( \Gamma \) associated with \( \varphi \) and let \( \tilde{\Gamma} \) be the central extension of \( \Gamma \) associated with \( \text{r} \text{eu} \mathbb{Z} \). Then there is an epimorphism \( \psi: E \to \tilde{\Gamma} \) with \( \psi|_H = \epsilon: H \to \mathbb{Z} \) and \( \ker \psi \subset H \).

**Proof.** By Proposition 4.1, we know that indeed \( m \) is non-zero. Therefore, the epimorphism \( \epsilon: H \to \mathbb{Z} \) is well-defined.

Ad 1. By the naturality of the short exact sequence in the universal coefficient theorem, we have the following commutative diagram with exact rows:

\[
\begin{array}{cccccc}
0 & \longrightarrow & \text{Ext}^1_\mathbb{Z}(\Gamma_1; \mathbb{Z}, H) & \longrightarrow & H^2(\Gamma; H) & \longrightarrow & \text{Hom}_\mathbb{Z}(H, H) & \longrightarrow & 0 \\
\downarrow\text{Ext}^1(\text{id}_\Gamma; \epsilon) & & \downarrow\text{Ext}^1(\text{id}_\Gamma; \epsilon) & & \downarrow f = m \cdot \epsilon & & \\
0 & \longrightarrow & \text{Ext}^1_\mathbb{Z}(\Gamma_1; \mathbb{Z}, Z) & \longrightarrow & H^2(\Gamma; Z) & \longrightarrow & \text{Hom}_\mathbb{Z}(H, Z) & \longrightarrow & 0
\end{array}
\]

The left vertical arrow is an epimorphism because \( \epsilon \) is an epimorphism and the exactness properties of \( \text{Ext} \) over the principal ideal domain \( \mathbb{Z} \). Moreover, the right vertical arrow maps \( m \cdot \text{id}_H \) to \( m \cdot \epsilon = \langle \text{r} \text{eu} \mathbb{Z}, \cdot \rangle \). A short diagram chase therefore proves the existence of the desired class \( \varphi \in H^2(\Gamma; H) \) (e.g., using the four lemma [ML95, Lemma 1.3.2]).

Ad 2. Because the extension classes are related via \( H^2(\text{id}_\Gamma; \epsilon)(\varphi) = \text{r} \text{eu} \mathbb{Z} \), there exists a group homomorphism \( \psi: E \to \tilde{\Gamma} \) with \( \psi|_H = \epsilon \) that induces the identity on \( \Gamma \):

\[
\begin{array}{cccccc}
1 & \longrightarrow & \mathbb{Z} & \longrightarrow & \tilde{\Gamma} & \longrightarrow & \Gamma & \longrightarrow & 1 \\
\downarrow \epsilon & & & & & & \downarrow \psi |_H & & \\
1 & \longrightarrow & H & \longrightarrow & E & \longrightarrow & \Gamma & \longrightarrow & 1
\end{array}
\]

As \( \epsilon: H \to \mathbb{Z} \) is an epimorphism also \( \psi: E \to \tilde{\Gamma} \) is an epimorphism. By construction, \( \ker \psi \subset H \). \( \square \)
3.3 Proof of Theorem D

With these preparations, we can now give a proof of Theorem D. To this end, we prove the following, more explicit, version of it:

**Theorem 3.4.** Let 
\[ \Gamma := \text{SL}_2(\mathbb{Z}[1/2]) \], let

\[
1 \longrightarrow \mathbb{Z} \xrightarrow{i} \tilde{\Gamma} \xrightarrow{\pi} \Gamma \longrightarrow 1
\]

be the central extension associated with the Euler class \( \Gamma \text{eu} \in H^2(\Gamma; \mathbb{Z}) \) of \( \Gamma \). Moreover, let \( H := H_2(\Gamma; \mathbb{Z}) \) and let \( E \) be the central extension group of \( \Gamma \) associated with the class \( \varphi \in H^2(\Gamma; H) \) of Proposition 3.3. Then:

1. The group \( E \) is finitely presented and \( H^2(E; \mathbb{R}) \cong 0 \).
2. The epimorphism \( \psi : E \rightarrow \tilde{\Gamma} \) of Proposition 3.3 induces an isomorphism
   \[
   Q(\psi) : Q(\tilde{\Gamma}) \rightarrow Q(E)
   \]
   \[ [f] \mapsto [f \circ \psi] \]
   and both spaces are one-dimensional. Here, \( Q \) denotes the space of quasi-morphisms modulo trivial quasi-morphisms.
3. In particular, \( \text{scl}_E([E,E]) = \text{scl}_{\tilde{\Gamma}}([\tilde{\Gamma},\tilde{\Gamma}]) \) as subsets of \( \mathbb{R} \).

**Proof.** Ad 1. This follows directly from Proposition 3.2 and Proposition 3.1.

Ad 2. We will use bounded cohomology in degree 2 to derive the statement on quasi-morphisms; we consider the commutative diagram

\[
\begin{array}{ccc}
0 & \longrightarrow & Q(\tilde{\Gamma}) \xrightarrow{\delta} H^2_\text{b}(\tilde{\Gamma}; \mathbb{R}) \\
Q(\psi) \downarrow & & H^2_\text{b}(\psi; \mathbb{R}) \downarrow & & H^2(\psi; \mathbb{R}) \\
0 & \longrightarrow & Q(E) \xrightarrow{s} H^2_\text{b}(E; \mathbb{R}) \longrightarrow H^2(E; \mathbb{R})
\end{array}
\]

with exact rows.

By construction, the kernel of the epimorphism \( \psi : E \rightarrow \tilde{\Gamma} \) lies in the Abelian group \( H \) and thus is amenable. By the mapping theorem in bounded cohomology [Gro82, p. 40][Iva85, Theorem 4.3], the induced map \( H^2_\text{b}(\psi; \mathbb{R}) : H^2_\text{b}(\tilde{\Gamma}; \mathbb{R}) \rightarrow H^2_\text{b}(E; \mathbb{R}) \) is an isomorphism.

Because \( H_2(E; \mathbb{R}) \cong 0 \), we also have \( H^2(E; \mathbb{R}) \cong 0 \). Therefore, \( \delta : Q(E) \rightarrow H^2_\text{b}(E; \mathbb{R}) \) is an isomorphism.

We now show that also \( \delta : Q(\tilde{\Gamma}) \rightarrow H^2_\text{b}(\tilde{\Gamma}; \mathbb{R}) \) is an isomorphism: By the mapping theorem in bounded cohomology, \( H^2_\text{b}(\tilde{\pi}; \mathbb{R}) : H^2_\text{b}(\Gamma; \mathbb{R}) \rightarrow H^2_\text{b}(\tilde{\Gamma}; \mathbb{R}) \) is an isomorphism. As \( H^2_\text{b}(\Gamma; \mathbb{R}) \) is generated by the bounded Euler class (Proposition 3.1) also \( H^2_\text{b}(\tilde{\Gamma}; \mathbb{R}) \) is one-dimensional and generated by

\[
\overline{\text{eu}} := H^2_\text{b}(\tilde{\pi}; \mathbb{R})(\Gamma \text{eu}_E^\mathbb{R}).
\]

By naturality of the comparison map, we obtain that

\[
e^2_\tilde{\Gamma}(\overline{\text{eu}}) = H^2(\tilde{\pi}; \mathbb{R})(\Gamma \text{eu}_E^\mathbb{R}).
\]
By construction of the central Euler class extension $\tilde{\Gamma}$, we have $H^2(\tilde{\pi}; \mathbb{Z})(\Gamma_{eu}) = 0 \in H^2(\tilde{\Gamma}; \mathbb{Z})$. Therefore, $H^2(\tilde{\pi}; \mathbb{R})(\Gamma_{eu}) = 0$ and so $c^2_\tilde{\Gamma}(\tilde{\alpha}) = 0$. This shows that $\delta: Q(\tilde{\Gamma}) \to H^2_\mathbb{R}(\tilde{\Gamma}; \mathbb{R})$ is an isomorphism.

Now commutativity of the left square in the diagram above shows that $Q(\psi): Q(\tilde{\Gamma}) \to Q(E)$ is an isomorphism.

Ad 3. Let $[f] \in Q(\tilde{\Gamma}) \cong \mathbb{R}$ be a homogeneous generator, which exists by the second part; then $[f \circ \psi]$ is a homogeneous generator of $Q(E)$. Bavard duality $[\text{Bav91}]$ $[\text{Cal09}, \text{Theorem 2.70}]$ implies that for all $g \in [E, E]$, we have

$$\text{scl}_E(g) = \frac{|f \circ \psi(g)|}{2 \cdot D_E(f \circ \psi)} = \frac{|f(\psi(g))|}{2 \cdot D_\tilde{\Gamma}(f)} = \text{scl}_{\tilde{\Gamma}}(\psi(g));$$

the defects in the denominators are equal because $\psi$ is an epimorphism. Again, because $\psi$ is an epimorphism, we conclude that $\text{scl}_E$ and $\text{scl}_{\tilde{\Gamma}}$ have the same image in $\mathbb{R}$.

This finishes the proof of Theorem [D].

4 Right-computability of simplicial volumes

We now turn to right-computability of the numbers occurring as simplicial volumes. After recalling basic terminology in Section 4.1, we will prove Theorem [E] in Section 4.2.

4.1 Right-computability

We use the following version of (right-)computability of real numbers, which is formulated in terms of Dedekind cuts. For basic notions of (recursive) enumerability, we refer to the book of Cutland $[\text{Cut80}]$.

**Definition 4.1** (right-computable). A real number $\alpha$ is **right-computable** if the set $\{x \in \mathbb{Q} \mid \alpha < x\}$ is recursively enumerable. We say that $\alpha$ is **computable** if both $\{x \in \mathbb{Q} \mid \alpha < x\}$ and $\{x \in \mathbb{Q} \mid \alpha > x\}$ are recursively enumerable.

Further information on different notions of one-sided computability of real numbers can be found in the work of Zheng and Rettinger $[\text{ZR04}]$.

There are only countably many recursively enumerable subsets of $\mathbb{Q}$ and thus the set of right computable and computable numbers is countable. We collect some easy properties:

**Lemma 4.2.**

1. If $\alpha, \beta \in \mathbb{R}_{\geq 0}$ are right-computable and non-negative, then so is $\alpha \cdot \beta \in \mathbb{R}$.

2. If $\alpha \in \mathbb{R}_{\geq 0}$ is a real number and $c \in \mathbb{R}_{>0}$ a computable number such that $c \cdot \alpha$ is right-computable, then $\alpha$ is right-computable.

**Proof.** For the first part we observe that if $\alpha, \beta \geq 0$, then $\{x \in \mathbb{Q} \mid \alpha < x\} \cdot \{y \in \mathbb{Q} \mid \beta < y\} = \{z \in \mathbb{Q} \mid \alpha \cdot \beta < z\}$.

For the second part, let $\alpha \in \mathbb{R}_{\geq 0}$ be such that $c \cdot \alpha$ is right-computable, where $c$ is computable. Since $c$ is computable and positive, so is $c^{-1}$, thus $c^{-1}$ is in particular right-computable. Hence $\alpha = c^{-1} \cdot (c \cdot \alpha)$ is the product of non-negative right-computable numbers and thus right-computable. \qed
Lemma 4.3. Let \( f : \mathbb{N} \to \mathbb{N} \) be a function with the following property: The set \( \{(m, n) \in \mathbb{N} \times \mathbb{N} \mid f(m) \leq n\} \subset \mathbb{N} \times \mathbb{N} \) is recursively enumerable. Then
\[
\inf_{m \in \mathbb{N}_{>0}} \frac{f(m)}{m}
\]
is right-computable.

Proof. Set \( S := \{(m, n) \in \mathbb{N} \times \mathbb{N} \mid f(m) \leq n\} \) and observe that
\[
\inf_{m \in \mathbb{N}_{>0}} \frac{f(m)}{m} = \inf_{(m, n) \in S} \frac{n}{m}.
\]
There is a Turing machine that, as input, takes a rational number and then enumerates all rational numbers above it. We may diagonally use this Turing machine and the enumeration of \( S \) to enumerate the set
\[
\left\{ x \in \mathbb{Q} \mid \exists_{(m, n) \in S} n/m < x \right\} = \left\{ x \in \mathbb{Q} \mid \inf_{m \in \mathbb{N}_{>0}} \frac{f(m)}{m} < x \right\}.
\]
Thus indeed \( \inf_{m \in \mathbb{N}_{>0}} \frac{f(m)}{m} \) is right-computable. \( \square \)

4.2 Proof of Theorem \([E]\)

Let \( M \) be an oriented closed connected manifold and \( d := \dim M \). Then \( M \) is homotopy equivalent to a finite (simplicial) complex \( T \) \([Sie68, KS69]\); let \( f : M \to |T| \) be such a homotopy equivalence and for a commutative ring \( \mathbb{R} \) with unit let
\[
[T]_R := H_d(f; R)([M]_R) \in H_d(|T|; R).
\]
If \( R \) is a normed ring, then we write \( \| \cdot \|_{1,R} \) for the associated \( \ell^1 \)-semi-norm on \( H_d(|T|; R) \). Because \( f \) is a homotopy equivalence, we have
\[
\|M\| = \|[M]_R\|_{1,R} = \|[T]_R\|_{1,R}.
\]
Moreover, the \( \ell^1 \)-semi-norm with \( \mathbb{R} \)-coefficients can be computed via rational coefficients \([Sch05, Lemma 2.9]\):
\[
\|M\| = \|[T]_\mathbb{R}\|_1 = \|[T]_\mathbb{Q}\|_1 = \inf_{m \in \mathbb{N}_{>0}} \frac{\|m \cdot [T]_\mathbb{R}\|_{1,\mathbb{Q}}}{m}.
\]
The function \( m \mapsto \|m \cdot [T]_\mathbb{Z}\|_{1,\mathbb{Q}} \) satisfies the hypothesis of Lemma \([4,3]\) (see Lemma \([4,4]\) below). Applying Lemma \([4,3]\) therefore shows that the number \( \|M\| \) is right-computable.

Lemma 4.4. In this situation, the subset
\[
\{(m, n) \in \mathbb{N} \times \mathbb{N} \mid \|m \cdot [T]_\mathbb{Z}\|_{1,\mathbb{Z}} \leq n\} \subset \mathbb{N} \times \mathbb{N}
\]
is recursively enumerable.

Proof. We can use a straightforward enumeration of combinatorial models of cycles \([Gol18, proof of Corollary 5.1]\):

First, \( H_d(|T|; \mathbb{Z}) \) is isomorphic to the simplicial homology \( H_d(T; \mathbb{Z}) \) of \( T \). Therefore, we can (algorithmically) determine a simplicial cycle \( z \) on \( T \) that represents the class \( [T]_\mathbb{Z} \); this cycle can also be viewed as a singular cycle on \( |T| \).

Simplicial approximation shows that for every singular cycle \( c \in C_d(|T|; \mathbb{Z}) \), there exists a singular cycle \( c' \in C_d(|T|; \mathbb{Z}) \) with the following properties:
The cycles $c$ and $c'$ represent the same homology class in $H_d(|T|; \mathbb{Z})$.

The chain $c'$ is a **combinatorial singular chain**, i.e., all singular simplices in $c'$ are simplicial maps from an iterated barycentric subdivision of $\Delta^d$ to an iterated barycentric subdivision of $T$.

We have $|c'|_1 \leq |c|_1$.

This allows us to restrict attention to such combinatorial singular chains. Moreover, the following operations can be performed by Turing machines:

- Enumerate all iterated barycentric subdivisions of $T$ and $\Delta^d$.
- Enumerate all simplicial maps between two finite simplicial complexes.
- Hence: Enumerate all combinatorial singular $\mathbb{Z}$-chains of $T$.
- Check, for given $m \in \mathbb{N}$, whether a combinatorial singular $\mathbb{Z}$-chain on $T$ is a cycle and represents the class $m \cdot [T]_Z$ in $H_d(|T|; \mathbb{Z})$ (through comparison with the corresponding iterated barycentric subdivision of $z$ in simplicial homology).
- Compute the 1-norm of a combinatorial singular $\mathbb{Z}$-chain.

In summary, we can enumerate the set $\{ (m, c) \mid m \in \mathbb{N}, c \in C(m) \}$, where $C(m)$ is the set of all combinatorial $\mathbb{Z}$-cycles of $T$ that represent $m \cdot [T]_Z$ in $H_d(|T|; \mathbb{Z})$.

We now consider the following algorithm: Given $m, n \in \mathbb{N}$, we search for elements of 1-norm at most $n$ in $C(m)$.

- If such an element is found (in finitely many steps), then the algorithm terminates and declares that $\| m \cdot [T]_Z \|_{1,Z} \leq n$.
- Otherwise the algorithm does not terminate.

From the previous discussion, it is clear that this algorithm witnesses that the set $\{ (m, n) \in \mathbb{N} \times \mathbb{N} \mid \| m \cdot [T]_Z \|_{1,Z} \leq n \}$ is recursively enumerable.

This completes the proof of Theorem E.

**Remark 4.5.** It should be noted that the argument above is constructive enough to also give a slightly stronger statement (similar to the case of integral simplicial volume [Loh18, Remark 5.2]): The function from the set of (finite) simplicial complexes (with vertices in $\mathbb{N}$) that triangulate oriented closed connected manifolds to the set of subsets of $\mathbb{Q}$ given by

$$ T \mapsto \| |T| \| $$

is semi-computable (and not only the resulting individual real numbers) in the following sense: There is a Turing machine that given such a triangulation $T$ and $x \in \mathbb{Q}$ as input

- halts if $\| |T| \| < x$ and declares that $\| |T| \| < x$,
- and does not terminate if $\| |T| \| \geq x$.

But it is known that this function is not computable [Wei05, Theorem 2, p. 88].
