THE CAT(0) GEOMETRY OF CONVEX DOMAINS WITH THE KOBAYASHI METRICS

JINSONG LIU & HONGYU WANG

Abstract. Let $(\Omega, K_\Omega)$ be a convex domain in $\mathbb{C}^d$ with the Kobayashi metric $K_\Omega$. In this paper we prove that $m$-convexity is a necessary condition for $(\Omega, K_\Omega)$ to be CAT(0) if $d = 2$. Moreover, when $\Omega \subset \mathbb{C}^d$, $d \geq 3$, we obtain a similar result with the further smoothness assumption on its boundary.

1. Introduction

A CAT(0) space is a geodesic metric space whose geodesic triangles are slimmer than the corresponding flat triangles in the Euclidean plane $\mathbb{R}^2$. CAT(0) spaces are natural generalizations of complete simply connected manifolds with nonpositive sectional curvature. Refer to [3] for more details.

Our main result is the following.

Theorem 1.1. (1) If $\Omega \subset \mathbb{C}^2$ is a $C$-proper convex domain and $(\Omega, K_\Omega)$ is CAT(0), then $\Omega$ is locally $m$-convex for some $m \in \mathbb{N}$.

(2) Suppose that $\Omega \subset \mathbb{C}^d$ ($d \geq 2$) is a bounded convex domain with smooth boundary. If $(\Omega, K_\Omega)$ is CAT(0), then $\partial \Omega$ has finite line type.

Recall that a convex domain is called $C$-proper if $\Omega$ does not contain any entire complex affine lines. There is a well-known result on $C$-proper convex domains.

Proposition 1.2 ([2]). If $\Omega$ is a $C$-proper convex domain in $\mathbb{C}^d$, then the Kobayashi metric $K_\Omega$ is complete.

A $C$-proper convex domain is called locally $m$-convex if for any $R > 0$ there exists $C > 0$ and $m \geq 1$ such that, for all $z \in B(0, R) \cap \Omega$ and non-zero $v \in \mathbb{C}^d$,

$$\delta_\Omega(z, v) \leq C\delta_{K_\Omega}(z).$$

Note that $m$-convexity is related to finite type by the following proposition.

Proposition 1.3 ([8], Proposition 9.1). Given a bounded convex domain $\Omega$ with smooth boundary, then $\Omega$ is $m$-convex for some $m \in \mathbb{N}$ if and only if $\partial \Omega$ has finite line type in the sense of D’Angelo.

The first author is supported by NSF of China No.11671057 and No.11688101.
1.1. Motivation from Gromov Hyperbolicity.

**Definition 1.4.** Let \((X, d)\) be a metric space. Given three points \(x, y, o \in X\), the Gromov product is given by
\[
(x | y)_o = \frac{1}{2} (d(x, o) + d(o, y) - d(x, y)).
\]

A proper geodesic metric space \((X, d)\) is Gromov hyperbolic if and only if there exists \(\delta \geq 0\) such that, for all \(o, x, y, z \in X\),
\[
(x | y)_o \geq \min\{ (x | z)_o, (z | y)_o \} - \delta.
\]

Z. M. Balogh and M. Bonk [1] firstly proved those strongly pseudoconvex domains equipped with the Kobayashi metric are Gromov hyperbolic. Later A. M. Zimmer [8] proved that smooth convex domains with the Kobayashi metrics are Gromov hyperbolic if and only if they are of finite type.

Recently Zimmer proved that locally \(m\)-convexity is a necessary condition for those convex domains to be Gromov hyperbolicity.

**Theorem 1.5 ([7], Corollary 7.2).** Suppose that \(\Omega\) is a \(C\)-proper convex domain and \((\Omega, K_\Omega)\) is Gromov hyperbolicity. Then \(\Omega\) is locally \(m\)-convex.

This paper is motivated by the above Zimmer’s work, and Theorem 1.1 can be seen as an analogue of the above Theorem 1.5.

2. Preliminaries

2.1. Notations.

1. For \(z \in \mathbb{C}^d\), let \(|z|\) be the standard Euclidean norm and let \(d_{\text{euc}}(z_1, z_2) = |z_1 - z_2|\) be the standard Euclidean distance.

2. Given an open set \(\Omega \subset \mathbb{C}^n\), \(p \in \Omega\) and \(v \in \mathbb{C}^n \setminus \{0\}\), let
\[
\delta_\Omega(p) = \inf\{ d_{\text{euc}}(p, x) : x \in \partial \Omega \}
\]
as before, and let
\[
\delta_\Omega(p, v) = \inf\{ d_{\text{euc}}(p, x) : x \in \partial \Omega \cap (p + Cv) \}.
\]

3. For any curve \(\sigma\), we denote by \(L(\sigma)\) the length of \(\sigma\).

4. For any \(z_0 \in \mathbb{C}^n\) and \(\delta > 0\), let \(B_{\text{euc}}(z_0, \delta)\) denote the open ball \(B_{\text{euc}}(z_0, \delta) = \{ z \in \mathbb{C}^n \mid |z - z_0| < \delta \}\).

5. Write \(Af(f)(\mathbb{C}^d)\) the group of complex affine automorphisms of \(\mathbb{C}^d\).

6. Let \(X_d\) denote the set of all \(C\)-proper convex domains in \(\mathbb{C}^d\) endowed with the local Hausdorff topology.

2.2. The Kobayashi metric. Given a domain \(\Omega \subset \mathbb{C}^d\), the (infinitesimal) Kobayashi metric is the pseudo-Finsler metric defined by
\[
k_\Omega(x; v) = \inf \{ |\xi| : f \in \text{Hol}(\mathbb{D}, \Omega), f(0) = x, d(f)_{\ast, 0}(\xi) = v \}.
\]

Define the length of any curve \(\sigma\) to be
\[
L(\sigma) = \int_a^b k_\Omega(\sigma(t); \sigma'(t)) \, dt.
\]
Then we can define the Kobayashi pseudo-distance to be
\[ K_Ω(x, y) = \inf \{ L(σ) | σ : [a, b] → Ω \text{ is any absolutely continuous curve} \]
with \( σ(a) = x \) and \( σ(b) = y \).

The following is a well known property on the Kobayashi metric.

**Proposition 2.1.** If \( f : Ω_1 → Ω_2 \) is holomorphic, then, for all \( z ∈ Ω_1 \) and \( v ∈ C^d \),
\[ k_{Ω_2}(f(z); df_z(v)) ≤ k_{Ω_1}(z; v). \]
Moreover,
\[ K_{Ω_2}(f(z_1), f(z_2)) ≤ K_{Ω_1}(z_1, z_2), \]
for all \( z_1, z_2 ∈ Ω_1 \).

For any product domain, the Kobayashi metric has the following product property (cf. [6], p.107),
\[ K_{Ω_1 × Ω_2}((x_1, y_1), (x_2, y_2)) = \max\{ K_{Ω_1}(x_1, x_2), K_{Ω_1}(y_1, y_2) \}, \]
which makes a product domain behave like a positively curved space.

### 2.3. CAT(0) space.

**Definition 2.2.** Let \( I ⊂ \mathbb{R} \) be an interval. A map \( σ : I → Ω \) is called a geodesic segment if, for all \( s, t ∈ I \),
\[ K_Ω(σ(s), σ(t)) = |t − s|. \]
And \((X, d)\) is called a geodesic metric space if any two points in \( X \) are joined by a geodesic segment.

**Remark 2.3.** Note that the paths which are commonly called ‘geodesics’ in differential geometry need not be geodesics in the above sense. In general they will only be local geodesics.

Let \((X, d)\) be a geodesic metric space. For any three points \( a, b, c ∈ X \), suppose that \([a, b], [b, c], [c, a]\) form a geodesic triangle \( Δ \). Let \( Δ(\bar{a}, \bar{b}, \bar{c}) ⊂ \mathbb{R}^2 \) be a triangle in the Euclidean plane with the same edge lengths as \( Δ \). Let \( p, q \) be any points on \([a, b]\) and \([a, c]\), and let \( \bar{p}, \bar{q} \) be the corresponding points on \([\bar{a}, \bar{b}]\) and \([\bar{a}, \bar{c}]\), respectively, such that
\[ \text{dist}_X(a, p) = \text{dist}_{\mathbb{R}^2}(\bar{a}, \bar{p}), \quad \text{dist}_X(a, q) = \text{dist}_{\mathbb{R}^2}(\bar{a}, \bar{q}). \]

**Definition 2.4.** We call \((X, d)\) a CAT(0) space, if for any geodesic triangle \( Δ ⊂ X \) the inequality \( \text{dist}_X(p, q) ≤ \text{dist}_{\mathbb{R}^2}(\bar{p}, \bar{q}) \) holds.

Typical examples are trees and complete simply connected manifolds with non-positive sectional curvature. Note that there is an equivalent definition about CAT(0) spaces.

**Theorem 2.5** ([3]). Let \((X, d)\) be a geodesic metric space. Then \((X, d)\) is CAT(0) if and only if for any three points \( x, y, z ∈ X \),
\[ d^2(z, m) ≤ \frac{1}{2}(d^2(z, x) + d^2(z, y)) - \frac{1}{4}d^2(x, y), \]
where \( m \) is the midpoint of the geodesic segment from \( x \) to \( y \).
2.4. Finite type. For any function $f : \mathbb{C} \to \mathbb{R}$ with $f(0) = 0$, we will denote by $\nu(f)$ the order of vanishing of $f$ at 0.

Let $\Omega = \{ z \in \mathbb{C}^d : r(z) < 0 \}$ where $r$ is a $C^\infty$ defining function with $\nabla r \neq 0$ near $\partial \Omega$. A point $x \in \partial \Omega$ is said to have finite line type $L$ if

$$\sup \{ \nu(r \circ \ell) : \ell : \mathbb{C} \to \mathbb{C}^d \text{ is a non-trivial affine map and } \ell(0) = x \} = L$$

Note that $\nu(r \circ \ell) \geq 2$ if and only if $\ell(\mathbb{C})$ is tangent to $\Omega$.

2.5. Local Hausdorff topology. Given a set $A \subset \mathbb{C}^d$, let $N_\epsilon$ denote the $\epsilon$-neighborhood of $A$ with respect to the Euclidean distance. The Hausdorff distance between any two compact sets $A, B$ is given by

$$d_H(A, B) = \inf \{ \epsilon > 0 : A \subset N_\epsilon(B) \text{ and } B \subset N_\epsilon(A) \}.$$ 

The Hausdorff distance is a complete metric on the space of compact sets in $\mathbb{C}^d$. The space of all closed convex sets in $\mathbb{C}^d$ can be given a topology from the local Hausdorff semi-norms.

For $R > 0$ and a set $A \subset \mathbb{C}^d$, let $A^{(R)} := A \cap B_R(0)$. Then we can define the local Hausdorff semi-norms by

$$d_H^{(R)}(A, B) := d_H(A^{(R)}, B^{(R)}).$$

Since an open convex set is completely determined by its closure, we say a sequence of open convex sets $\{A_n\}$ converges in the local Hausdorff topology to an open convex set $B$ if $d_H^{(R)}(A_n, B) \to 0$ for all $R > 0$.

Recently A M. Zimmer proved the following result.

**Theorem 2.6** ([8], Theorem 4.1). Suppose that $\{\Omega_n\}$ is a sequence of $C$-proper convex domains converging to a $C$-proper convex domain $\Omega$ in the local Hausdorff topology. Then, for all $x, y \in \Omega$,

$$K_\Omega(x, y) = \lim_{n \to \infty} K_{\Omega_n}(x, y),$$

uniformly on compact sets of $\Omega \times \Omega$.

3. Proof of Theorem 1.1

Our proof is based on the following simple observation.

**Observation 3.1.** If $\Omega = \Omega_1 \times \Omega_2$ is a Kobayashi hyperbolic domain, then $(\Omega, K_\Omega)$ is not a $CAT(0)$ space.

**Proof.** Take $x \neq y \in \Omega_1$ and let $m$ be the midpoint of the geodesic segment from $x$ to $y$ in $(\Omega_1, K_{\Omega_1})$. Then, we can choose $z, w \in \Omega_2$ such that

$$K_{\Omega_2}(z, w) = K_{\Omega_2}(x, m) = K_{\Omega_1}(y, m) = \frac{1}{2} K_{\Omega_1}(x, y),$$

which implies that

$$\frac{1}{2} (K_{\Omega_1}^2((x, w), (m, z)) + K_{\Omega_1}^2((y, w), (m, z))) - \frac{1}{4} K_{\Omega_1}^2((x, w), (y, w)) = 0.$$ 

Since $K_{\Omega_2}(m, w), (m, z)) > 0$, it follows from Theorem 2.5 that $(\Omega, K_\Omega)$ is not $CAT(0)$. It completes the proof. □

To prove Theorem 1.1, we shall need a recent result due to A M. Zimmer.
**Theorem 3.2** (Theorem 6.1). Suppose that $\Omega$ is a $C$-proper convex domain and every domain in $Aff(\mathbb{C}^d) : \Omega \cap \mathbb{X}_d$ does not contain any affine disk in the boundary. Then $\Omega$ is locally $m$-convex for some $m \geq 1$.

The above theorem shows that: if $\Omega$ is not $m$-convex, then by scaling we can find an affine disk in the boundary. By using the above theorem, the next Lemma is obvious.

**Lemma 3.3.** Let $\Omega$ be a $C$-proper convex domain. If $\Omega$ is not locally $m$-convex for any $m \in \mathbb{N}$, then there exists $A_m \in Aff(\mathbb{C}^d)$ such that $A_m \Omega \to \hat{\Omega}$ and $\hat{\Omega} \supseteq C(\alpha, \beta) \times \Delta \times \{0\}$, where $C(\alpha, \beta) = \{z \in \mathbb{C} : \arg z \in (\alpha, \beta)\}$ is a convex cone.

**Proof.** In view of Theorem 3.2, we may assume that $\{0\} \times \Delta \times \{0\} \subset \partial \Omega$, and $\Omega \subset \{(z_1, \ldots, z_d) : \text{Im} z_1 > 0\}$.

Writing

$$A_n(z) = \begin{pmatrix} n & 0 \\ 0 & I_{d-1} \end{pmatrix},$$

we obtain

$$A_n(\Omega \cap \mathbb{C} \times \{0\}) = C(\alpha, \beta) \times \{0\},$$

where $C(\alpha, \beta) = \bigcup_{t > 0} t(\Omega \cap \mathbb{C} \times \{0\})$. 

**Lemma 3.4.** Let $\Omega \subset \mathbb{C}^d$ be a $C$-proper convex domain. Suppose that $P : \mathbb{C}^d \to \mathbb{C}$ is the projection map $P(z_1, \ldots, z_d) = z_1$. If $\Omega \cap (\mathbb{C} \times \{0\}) = U \times \{0\}$ and $P(\Omega) = U$, then the map $F : U \to \Omega$ given by $F(z) = (z, 0)$ induces an isometric embedding $(U, K_U) \to (\hat{\Omega}, K_{\hat{\Omega}})$.

**Proof.** Since both $F$ and $P$ are holomorphic maps, from the distance decreasing property of the Kobayashi metrics, it follows that

$$K_{\hat{\Omega}}(F(z_1), F(z_2)) \leq K_U(z_1, z_2).$$

Noting that $P \circ F = id$, we thus have

$$K_U(z_1, z_2) \leq K_{\hat{\Omega}}(F(z_1), F(z_2)).$$

Now we are ready to prove Theorem 3.1.

**Proof.** Part (1). We shall first prove the theorem when $\Omega \subset \mathbb{C}^2$ is a $C$-proper convex domain.

Assume, by contradiction, that $\Omega$ is not locally $m$-convex. From Lemma 3.3 it follows that there exists $A_m \in Aff(\mathbb{C}^d)$ such that $A_m \Omega \to \hat{\Omega}$ and $\hat{\Omega} \supseteq C(\alpha, \beta) \times \Delta$ and $\hat{\Omega} \cap \mathbb{C} = C(\alpha, \beta)$.

We claim that $P(\hat{\Omega}) = C(\alpha, \beta)$, where $P(z_1, z_2) = z_1$ is the projection map. Suppose that it is not the case. Take $p = (z, \omega) \in \hat{\Omega}$, where $z$ is not contained in $C(\alpha, \beta)$ and $\omega = |\omega| e^{i\theta}$. And take $q = (\xi, -e^{i\theta})$ where $\text{Im} \xi = \text{Im} z$ and $\xi$ lies in the boundary of $C(\alpha, \beta)$ such that $\text{Re} \xi \cdot \text{Re} z > 0$. Since $\hat{\Omega}$ is also convex, it implies that

$$\{tp + (1 - t)q : t \in (0, 1)\} \subset \hat{\Omega}.$$

By taking $t = \frac{1}{|\omega| + 1}$, we obtain that $tz + (1 - t)\xi \in \hat{\Omega}$, which contradicts with the fact that $\hat{\Omega} \cap \mathbb{C} = C(\alpha, \beta)$.
Then, by using Lemma \[3.3\] it follows that the map \( f : C(\alpha, \beta) \to \hat{\Omega} \) given by \( f(z) = (z, 0) \) induces an isometric embedding

\[
(C(\alpha, \beta), K_{C(\alpha, \beta)}) \to (\hat{\Omega}, \hat{K})
\]

Now we choose \( x, y \in C(\alpha, \beta) \) and let \( m \) be the midpoint of the geodesic segment from \( x \) to \( y \) in the metric space \((C(\alpha, \beta), K_{C(\alpha, \beta)})\). Since \( f \) is isometric, \( m \) is also the midpoint of the geodesic segment from \( x \) to \( y \) in metric space \((\hat{\Omega}, \hat{K})\). Therefore, we can take \( z \in \Delta \) such that

\[
K_{\Delta}(0, z) = K_{C(\alpha, \beta)}(x, m) = K_{C(\alpha, \beta)}(m, y) = \frac{1}{2}K_{C(\alpha, \beta)}(x, y).
\]

Denote \( C = C(\alpha, \beta) \times \Delta, \hat{x} = (x, 0), \hat{y} = (y, 0), \hat{m} = (m, 0) \) and \( \hat{z} = (0, z) \).

Since \( \hat{\Omega} \supset C \), it follows that

\[
K_{\hat{C}}(\hat{x}, \hat{m}) \geq K_{\hat{\Omega}}(\hat{x}, \hat{m}),
\]

and

\[
K_{\hat{C}}(\hat{y}, \hat{m}) \geq K_{\hat{\Omega}}(\hat{y}, \hat{m}).
\]

Therefore,

\[
\frac{1}{2}(K_{\hat{\Omega}}^{2}(\hat{x}, \hat{m}) + K_{\hat{\Omega}}^{2}(\hat{y}, \hat{m})) - \frac{1}{4}K_{\hat{\Omega}}^{2}(\hat{x}, \hat{y})
\]

\[
\leq \frac{1}{2}(K_{\hat{C}}^{2}(\hat{x}, \hat{z}) + K_{\hat{C}}^{2}(\hat{y}, \hat{z})) - \frac{1}{4}K_{\hat{C}}^{2}(\hat{x}, \hat{y})
\]

\[
= 0.
\]

Choose \( x_n, y_n, z_n \in \hat{\Omega} \) such that \( A_n x_n \to \hat{x}, A_n y_n \to \hat{y} \) and \( A_n z_n \to \hat{z} \). Now Theorem \[2.6\] gives

\[
K_{\hat{\Omega}}(\hat{x}, \hat{y}) = \lim_{n \to \infty} K_{\hat{\Omega}_n}(A_n x_n, A_n y_n),
\]

and

\[
K_{\hat{\Omega}}(\hat{x}, \hat{z}) = \lim_{n \to \infty} K_{\hat{\Omega}_n}(A_n x_n, A_n z_n),
\]

and

\[
K_{\hat{\Omega}}(\hat{y}, \hat{z}) = \lim_{n \to \infty} K_{\hat{\Omega}_n}(A_n y_n, A_n z_n).
\]

Let \( m_n \) be the midpoint of the geodesic segment from \( A_n x_n \) to \( A_n y_n \) in \((\Omega_n, K_{\Omega_n})\). Then, by choosing a subsequence (still denoted by \( m_n \)), we may suppose that \( m_n \to \hat{m} \in \hat{\Omega} \cup \{\infty\} \). Then either \( \hat{m} \neq \hat{z} \) or \( \hat{m} \neq \hat{\hat{z}} \), where \( \hat{\hat{z}} = (m, iz) \).

Since \( K_{\Delta}(0, z) = K_{\Delta}(0, iz) \), the equalities \( K_{\hat{C}}(\hat{x}, \hat{z}) = K(\hat{x}, \hat{z}) \) and \( K_{\hat{C}}(\hat{y}, \hat{z}) = K_{\hat{\Omega}}(\hat{y}, \hat{z}) \) follow. We have thus proved that

\[
\frac{1}{2}(K_{\hat{\Omega}_n}^{2}(\hat{x}, \hat{z}) + K_{\hat{\Omega}_n}^{2}(\hat{y}, \hat{z})) - \frac{1}{4}K_{\hat{\Omega}_n}^{2}(\hat{x}, \hat{y})
\]

\[
\leq \frac{1}{2}(K_{\hat{C}}^{2}(\hat{x}, \hat{z}) + K_{\hat{C}}^{2}(\hat{y}, \hat{z})) - \frac{1}{4}K_{\hat{C}}^{2}(\hat{x}, \hat{y})
\]

\[
= 0.
\]

Therefore, we deduce that: \( \forall \epsilon > 0 \), there exists \( N \in \mathbb{N} \) such that \( \forall n > N \)

\[
\frac{1}{2}(K_{\hat{\Omega}_n}^{2}(\hat{x}, \hat{z}) + K_{\hat{\Omega}_n}^{2}(\hat{y}, \hat{z})) - \frac{1}{4}K_{\hat{\Omega}_n}^{2}(\hat{x}, \hat{y}) \leq \epsilon,
\]

and

\[
\frac{1}{2}(K_{\hat{\Omega}_n}^{2}(\hat{x}, \hat{z}) + K_{\hat{\Omega}_n}^{2}(\hat{y}, \hat{z})) - \frac{1}{4}K_{\hat{\Omega}_n}^{2}(\hat{x}, \hat{y}) \leq \epsilon.
\]
Combining with the fact that \( \hat{m} \neq \hat{\beta} \) or \( \hat{m} \neq \hat{z} \), we have thus proved that there exists \( \delta > 0 \) such that one of \( K_{\Omega_n}(m_n, \hat{z}) \) and \( K_{\Omega_n}(m_n, \hat{\beta}) \) is strictly bigger than \( \delta \). Therefore, in terms of the definition of \( \text{CAT}(0) \) spaces, by choosing \( \epsilon \) small enough, we complete the proof.

Part (2). Next we prove the result for the general case that \( \Omega \subset \mathbb{C}^d \), \( d \geq 3 \), is a bounded convex domain with smooth boundary. The difference is that when \( d \geq 3 \), the claim \( \hat{P}(\hat{\Omega}) = C(\alpha, \beta) \) may be not correct without the further smoothness assumption on the boundary.

We will use the proof of Proposition 6.1 in [8]. For the sake of completeness, we present its proof here.

Suppose \( \vec{0} \in \partial \Omega \) and \( \Omega \cap \mathcal{O} = \{ \vec{z} \in \mathcal{O} : \text{Im} (z_1) > f (\text{Re} (z_1), z_2, \ldots, z_d) \} \), where \( \mathcal{O} \) is a neighborhood of the origin and \( f : \mathbb{R} \times \mathbb{C}^{d-1} \rightarrow \mathbb{R} \) is a smooth convex non-negative function. Assuming that \( \vec{0} \) has infinite line type, by changing the coordinates if necessary, we have

\[
\lim_{z \to 0} \frac{f(0, z, 0, \ldots, 0)}{|z|^n} = 0.
\]

Then there are two cases (a) (b):

(a). If \( \partial \Omega \) contains an affine disk at \( \vec{0} \), without losing of generality we assume that \( \vec{0} \times \Delta \times \{ \vec{0} \} \subset \partial \Omega \). By taking

\[
A_n(z) = \begin{pmatrix} n & 0 \\ 0 & I_{d-1} \end{pmatrix},
\]

we deduce that \( A_n(\Omega) \to \hat{\Omega} \), and

\[
\mathbb{H} \times \Delta \times \{ \vec{0} \} \subset \hat{\Omega},
\]

where \( \mathbb{H} \) is the upper half plane.

Since \( \hat{\Omega} \subset \{ z \in \mathbb{C}^d : \text{Im} z_1 > 0 \} \), by considering the projection \( P : \mathbb{C}^d \to \mathbb{C}^1 \),

\[
P(z_1, \ldots, z_d) = z_1,
\]

we obtain

\[
P(\hat{\Omega}) = \mathbb{H}.
\]

Therefore, the map \( f : \mathbb{H} \to \hat{\Omega} \) given by \( f(z) = (z, \vec{0}) \) induces an isometric embedding \( (\mathbb{H}, K_{\mathbb{H}}) \to (\hat{\Omega}, K_{\hat{\Omega}}) \).

Then by repeated use of the proof of Part (1), we deduce that \( \Omega \) is not \( \text{CAT}(0) \). (b). Assume that \( \partial \Omega \) does not contain any affine disks at \( \{ \vec{0} \} \). Similarly we only need to check that \( \mathbb{H} \times \Delta \times \{ \vec{0} \} \subset \hat{\Omega} \).

The proof of the theorem could be simplified if we use the following lemma.

**Lemma 3.5** ([5], Theorem 9.3). Suppose \( \Omega \subset \mathbb{C}^d \) is a \( \mathbb{C} \)-proper convex open set. Suppose that \( V \subset \mathbb{C}^d \) is a complex affine subspace intersecting \( \Omega \) and \( \{ A_n \in \text{Aff}(V) \} \) is a sequence of affine maps such that \( A_n(\Omega \cap V) \) converges in the local Hausdorff topology to a \( \mathbb{C} \)-proper convex open set \( \hat{\Omega}_V \subset V \). Then there exists affine maps \( B_n \in \text{Aff}(\mathbb{C}^d) \) such that \( B_n \Omega \) converges in the local Hausdorff topology to a \( \mathbb{C} \)-proper convex open set \( \hat{\Omega} \) with \( \hat{\Omega} \cap V = \hat{\Omega}_V \).
Now suppose $V = \mathbb{C}^2 \times \{0\}$ and $\Omega_V = \Omega \cap V$. Let $G, W \subset \mathbb{R}$ and $U \subset \mathbb{C}$ be neighborhoods of 0 such that $f : G \times U \to W$ and

$$\Omega_V \cap \mathcal{O} = \{(x + iy, z) : x \in G, z \in U, y > f(x, z)\},$$

where $\mathcal{O} = (G + iW) \times U$. By rescaling we may assume that $B_1(0) \subset U$. We can find $a_n \to 0$ and $z_n \in B_1(0)$ such that $f(0, z_n) = a_n |z_n|^n$ and $f(0, w) \leq a_n |w|^n$ for all $w \in \mathbb{C}$ with $|w| \leq |z_n|$.

By the hypothesis that $\partial \Omega_V$ has no non-trivial complex affine disks, we obtain that $z_n \to 0$ and hence $f(0, z_n) \to 0$. Passing to a subsequence we may assume that $|f(0, z_n)| < 1$. Consider the sequence of linear transformations

$$A_n = \begin{pmatrix} \frac{1}{f(0, z_n)} & 0 \\ 0 & z_n^{-1} \end{pmatrix}, \quad n = 1, 2, \ldots,$$

and $\Omega_{V_n} = A_n \Omega_V \to \hat{\Omega}_V$. Therefore,

$$\Omega_{V_n} \cap \mathcal{O}_n = \{(x + iy, z) : x \in G_n, z \in U_n, y > f_n(x, z)\},$$

where $G_n = f(0, z_n)^{-1} G$, $U_n = z_n^{-1} U$, and $\mathcal{O}_n = A_n \mathcal{O}$, and

$$f_n(x, z) = \frac{1}{f(0, z_n)} f \left( f(0, z_n) x, z_n z \right).$$

For $|w| < 1$, we then have

$$f_n(0, w) = \frac{f(0, z_n w)}{f(0, z_n)} \leq \frac{a_n |z_n|^n |w|^n}{f(0, z_n)} = |w|^n,$$

which implies that

$$\{0\} \times \Delta \subset \partial \hat{\Omega}_V.$$

By using

$$\Omega_{V_n} \cap (\mathbb{C} \times \{0\}) = \frac{1}{f(0, z_n)} (\Omega_V \cap (\mathbb{C} \times \{0\})),$$

and $f(0, z_n) \to 0$, we have $\mathbb{H} \times \{0\} \subset \hat{\Omega}_V$. Since $\hat{\Omega}_V$ is convex, $\mathbb{H} \times \Delta \subset \hat{\Omega}_V$ is valid. It follows immediately from Lemma [33] that there exists $B_n \in Aff(\mathbb{C}^d)$ such that $B_n \Omega \to \hat{\Omega}$ and $\mathbb{H} \times \Delta \times \{0\} \subset \hat{\Omega}$, which completes the proof. \qed

It’s natural to ask whether the $m$-convexity is a sufficient condition for bounded convex domains being CAT(0). However, the following example shows that $m$-convexity does not imply CAT(0) in general.

**Example 3.6 (\cite{7}, Example 7.3).** Let $\Omega_1, \Omega_2$ be bounded strongly convex domains in $\mathbb{C}^2$ with $C^\infty$ boundary. Furthermore, we assume $0 \in \partial \Omega_j$, and the real hyperplane

$$\{(z_1, z_2) \in \mathbb{C}^2 : \text{Re}(z_j) = 0\}$$

is tangent to $\Omega_j$ at 0, and

$$\Omega_j \subset \{(z_1, z_2) \in \mathbb{C}^2 : \text{Re}(z_j) > 0\}.$$

Define $\Omega = \Omega_1 \cap \Omega_2$. 

Since each $\Omega_j$ has smooth boundary, we see that $(\epsilon, \epsilon) \in \Omega$ for $\epsilon > 0$ sufficiently small. So $\Omega$ is non-empty. Furthermore, since each $\Omega_j$ is strongly convex, it follows that with a constant $C > 0$

$$\delta_{\Omega_j}(z; v) \leq C\delta_{\Omega_j}(z)^{1/2}$$

for all $1 \leq j \leq 2$, $z \in \Omega_j$, and non-zero $v \in \mathbb{C}^2$. Then, for $z \in \Omega$ and non-zero $v \in \mathbb{C}^2$, we have

$$\delta_{\Omega}(z; v) = \min_{1 \leq j \leq 2} \delta_{\Omega_j}(z; v) \leq \min_{1 \leq j \leq 2} C\delta_{\Omega_j}(z)^{1/2} = C\delta_{\Omega}(z)^{1/2},$$

from which we deduce that $\Omega$ is $2$-convex. However the set of domains $\{n \cdot \Omega\}$ converges in the local Hausdorff topology to the domain

$$D = \{(z_1, z_2) \in \mathbb{C}^2 : \text{Re}(z_1) > 0, \text{Re}(z_2) > 0\}.$$ 

Thus $\partial D$ contains an affine disk.

Then, by repeated use of the proof of Theorem 1.1, we obtain that $(\Omega, K_\Omega)$ is not CAT(0).
