November 18, 2019

Abstract

This paper considers the change-point problem for finite sequences of networks. To avoid the difficulty of computing the normalization coefficient, such as in Exponential random graphical models (ERGMs) and Markov networks, we construct a finite measure space with measure ratio statistics. A new performance measure of detection delay is proposed to detect the changes in distribution of the network. And an optimal sequential test is proposed under the performance measure. The good performance of the optimal sequential test is illustrated numerically on ERGMs and Erdos-Rényi network sequences.

Keywords: ERGMs; Optimal sequential test; finite measure space; change-point detection; finite sequences of networks

\(\text{MSC 2010 subject classification. Primary 62L10; Secondary 62L15}\)
One of the basic problems of quickest change-point detection is the design of an optimal sequential test. If an alarm is too quickly, there is a high risk that the detection is false. And at the same time, if an alarm is too slowly, the detection delay would be too large. So an optimal sequential test is important, which is expected to have the smallest detection delay among all tests without exceeding a certain false alarm rate.

Moreover, an optimal sequential test is useful in earthquake monitoring, traffic monitoring, etc. And these data are often in the form of network data. There are many network data in our daily life, such as social networks, the representations are Facebook, wechat, etc. Hence, it is useful to analyze network data, such as the change detection of network data, which is in Amini A A , Nguyen X L.(2013), Keshavarz H, Michailidis G, Atchade Y. (2018) and Wei, C. , Wiesel, A. , and Blum, R. S. . (2012). These papers discuss the change detection problem of the Gaussian graphic model. For Gaussian graphic model, we can get accurate distribution conveniently, which makes the change point problem easy to deal with. The Gaussian graphic model is a very special case.

However there are many challenges and difficulties in dealing with general large network data. When the network is large, it is difficult to obtain the distribution of network data, because that the normalization coefficient is not easy to be calculated, since it needs exponential computation complexity. For example, the distribution of exponential family of random graph models(ERGMs), also known as $p^*$ models, which is introduced by Frank and Strauss(1986), Frank(1991) and Wasserman and Pattison(1996), is $P(X = x) = \frac{\exp(\theta^T h(x))}{Z(\theta)}$, $X$ represents for a network, $h(X)$ are the features of the network, the normalization coefficient $Z(\theta)$ is difficult to obtain espe-
cially for large network. And this phenomenon also exists for the Markov networks in probabilistic graphical model which is introduced by Koller D, Friedman N(2009). It is common in network data, which urges us to find a method to overcome this difficulty.

At the same time, in the literature, there are mainly four kinds of optimal sequential tests in infinite independent observation sequence: Shiryaev test $T_S$, SLR (sum of the log likelihood ratio) test $T_{SLR}$, the conventional CUSUM test $T_C$ introduced by Page (1954) and Shiryaev-Roberts test $T_{SR}^R$ for an infinite independent observation sequence. The tests $T_S, T_{SLR}, T_{SLR}, T_C, T_{SR}^R$ and $T_{SR}^R$ were proven by Shiryaev (1963, 1978), Chow, Robbins and Siegmund (1971, P.108), Frisén (2003), Moustakides (1986) and Polunchenko and Tartakovsky (2010), to be optimal, and the control line are all constants. All of the optimal tests are based on likelihood ratio statistics, and the analyzed observation sequences are one-dimensional. Moreover, to obtain infinite sequence of networks is not realistic. So it is necessary to deal with the change-point problem for finite sequences of networks about how to give the corresponding optimal sequential tests.

In this paper, in order to overcome the above difficulties, we give a finite measure space to replace the traditional probability space by discarding the normalization coefficient. And a new measure of detection delay, which is based on the corresponding measure space, is proposed. The likelihood ratio statistics are replaced by measure ratio statistics. In a word, the method we proposed are based on the finite measure not the probability space. Moreover, we know that the difference between measure space and probability space is the normalization coefficient, so traditional likelihood ratio statistics are special cases of our method. Note that, we consider unweighted network sequences here.

The rest of this paper is organized as follows. Section 2 states the method we use
in this paper. Section 2.1 presents a performance measure for finite network data, $J_N(T)$, to evaluate how well a sequential test detects changes in a finite network observations. Section 2.2 gives the optimal sequential test under the performance measure we defined. Our results are illustrated by comparison of the numerical simulations of different sequential tests in Section 3, and the optimal sequential test we give obviously have better performance than other 3 sequential tests. Section 3.1 is the case for independent and dependent finite sequences for networks in finite measure space. Section 3.2 is the case for independent and dependent finite sequences for networks in traditional probability space. Section 4 includes some concluding remarks. Proofs of the theorems are given in the Appendix.

2 Optimal sequential tests for finite sequences of network under finite measure

In this section, we first briefly describe the differences between probability space and measure space. Then we construct the optimal sequential tests for $N$ network observations.

Consider the cases such as the exponential family of random graph models (ERGMs) which is proposed in Frank and Strauss (1986), Frank (1991) and Wasserman and Pattison (1996).

$$P(X = x) = \frac{\exp(\theta^T h(x))}{Z(\theta)}$$

$X$ represents a network, $h(X)$ are the crucial features of the network.

When the normalization coefficient is difficult to deal with, in the probability space, the statistics, such as CUSUM-type, cannot be used. To avoid this, we consider finite measure space $(\Omega, \mathcal{F}, M)$, we just discard the normalization coefficient,
since there is no need to guarantee that $M(\Omega) = 1$ in finite measure space.

And as in the probability space, we also have measure density functions and conditional measure density functions for network objects as follows.

- Suppose that there is a network set $\Omega$, let $M$ be a finite measure, assume that $M$ is differentiable in the usual sense in calculus. Let $m$ be the derivative of $M$.

  \[
  M(A) = \int_A m(x)dx \quad A \in \mathcal{F}
  \]

  $x$ is the network object, $\mathcal{F}$ is $\sigma$-field. In the discrete case, we use $\sum$ to replace $\int$. Then $m$ is the corresponding measure density function.

- The conditional measure density functions

  \[
  m(x|y) = \frac{m(x,y)}{m(y)}
  \]

Moreover, in this paper, we consider unweighted network sequences. The joint measure density function is similar. Suppose that there are finite dependent network observations, denoted by $\{X_k, 0 \leq k \leq N\}$. Then let $d$ denotes the number of nodes in each network observation. In this paper, we consider the change-point problem for network sequences as follows

- All the networks in sequences have a common number of nodes $d$, which is a constant. Moreover, without loss of generality, we assume $N \geq 2$.

- Pre-change and post-change measure density functions are $m_0$ and $m_1$, and conditional measure density functions of the $j$-th observation $X_j$ for $1 \leq j \leq n$ are $m_{0j}$ and $m_{1j}$, which are known. And the measures above are all finite.
Let $\tau = k \ (1 \leq k \leq N)$ be the change-point time, then the joint measure density function $m_k$ can be written as

$$m_k(X_0, X_1, ..., X_N) = m_0(X_0) \prod_{j=1}^{k-1} m_{0j}(X_j|X_{j-1}, ..., X_0) \prod_{j=k}^{N} m_{1j}(X_j|X_{j-1}, ..., X_0)$$

where $m_{0j}(X_j|X_{j-1}, ..., X_0)$ and $m_{1j}(X_j|X_{j-1}, ..., X_0)$ are respectively the pre-change and the post-change conditional measure densities of the $j$-th observation $X_j$ for $1 \leq j \leq n$. When $\tau = k > N$, i.e., a change never occurs in $N$ observations $X_1, X_2, ..., X_N$. And the corresponding joint measure function is denoted by $M_k$.

### 2.1 Performance measures of sequential tests

There are some different performance measures for sequential test in Shiryaev (1963, 1978), Chow, Robbins and Siegmund (1971, P.108), Frisén (2003), Moustakides (1986) and Polunchenko and Tartakovsky (2010). These performance measures relate to the probability distribution $P_k$ and the probability expectation $E_k$ in probability space. So in finite measure space, we also have $M_k$ and $M_{E_k}$ when the change-point time $\tau = k \ (1 \leq k \leq N)$.

Similarity, $M_{E_k}$ is the finite measure expectation, which is a first order moment based on joint measure density function. That is

$$M_{E_k}(\xi) = \int \xi dM_k$$

where $M_k$ is the joint measure when $\tau = k \leq N$.

Furthermore, $M_{E_0}$ denotes the measure expectation with the pre-change joint measure density $m_0(x_0, x_1, ..., x_N)$.

**Remark 1** It is easy to known that the measure expectations $M_{E_k}$ have the similar
properties as in probability space.

Let \( T \in \mathcal{T}_N \) be a sequential test, the definition is

\[
T = \min\{1 \leq k \leq N + 1 : Y_k \geq l_k(c)\}.
\]

\[
Y_k = (Y_{k-1} + w_k)\Lambda_k, Y_0 = 0, Y_{N+1} = Y_N
\]

where \( \Lambda_k = \frac{m_{1k}(X_k|X_{k-1},...,X_0)}{m_{0k}(X_k|X_{k-1},...,X_0)} \), \( \mathcal{T}_N \) is a set of all of the sequential tests satisfying \( 1 \leq T \leq N + 1 \) and \( \{T \leq n\} \in \mathcal{F}_n = \sigma\{X_k, 0 \leq k \leq n\} \) for \( 1 \leq n \leq N \). Following the idea of the randomization probability of the change time and the definition of describing the average detection delay proposed by Moustakides (2008), we define a performance measure \( J_N(\cdot) \), which is based on measure expectations, to evaluate the detection performance of each sequential test \( T \in \mathcal{T}_N \) in the following

\[
J_N(T) = \frac{\sum_{k=1}^{N+1} \text{ME}_k(w_k(T-k)^+)\text{ME}_0(\sum_{k=1}^{T} v_k)}{\sum_{k=1}^{N+1} \text{ME}_0(v_kI(T \geq k))} \tag{2}
\]

where \( w_k(Y_{k-1}), v_k(Y_{k-1}) \) are weights, which are functions of \( Y_{k-1} \).

For the CUSUM test statistics, which is widely used in quality detection. Moreover, it is simple, which is as follows

\[
Y_k = \max\{1, Y_{k-1}\}\Lambda_k, Y_0 = 0, Y_{N+1} = Y_N \tag{3}
\]

for \( 1 \leq k \leq N \), where \( \Lambda_k = \frac{m_{1k}(X_k|X_{k-1},...,X_0)}{m_{0k}(X_k|X_{k-1},...,X_0)}\). And it is a special case with \( w_k = (1 - Y_{k-1})^+ \).

The performance measure in (2), \((T-k)^+\) denotes the detection delay. Note that \( Y_k = \Lambda_k \) when \( Y_{k-1} < 1 \), or, \((1-Y_{k-1})^+ > 0\), that is, we will newly detect the change of network starting from \( k \). So it is reasonable to let the weight of the detection delay as \( w_k = (1 - Y_{k-1})^+ \). At the same time, if we set the weight \( v_k = 1 \), then
the numerator and denominator of the measure $J_N(T)$ in (2) can be regarded as
the generalized out-of-control average run length ($ARL_1$) and in-control average run
length ($ARL_0$). For the numerical simulation in Section 3, we choose the CUSUM
test statistics with $w_k = (1 - Y_{k-1})^+, v_k = 1$.

2.2 Optimal sequential tests

In order to give the optimal network sequential tests, we first give a definition
about the optimal criterion of any sequential tests for finite observations under finite
measure space. After defining a new performance measures under finite measure,
we give the optimal sequential test, which is related to the control limit $l_k(c)$, so in
this section, we show the optimal control limit $l_k(c)$ under the performance measure
we defined.

**Definition 1** A sequential test $T^* \in \mathcal{T}_N$ with $ME_0(\sum_{k=1}^{T^*} v_k) \geq \gamma$ is optimal under
the performance measure $J_N(T)$ if

$$\inf_{T \in \mathcal{T}_N, ME_0(\sum_{k=1}^{T} v_k) \geq \gamma} J_N(T) = J_N(T^*) \quad (4)$$

where $\gamma$ satisfies $ME_0(v_1) < \gamma < ME_0(\sum_{k=1}^{N+1} v_k)$.

Before giving the optimal sequential test, we need to show the corresponding
conditional measure expectations w.r.t. $M_k$, $0 \leq k \leq N$, which is similar as in
probability space. More details are as follow:

Let $\xi$ be an integrable random variable on $(\Omega, \mathcal{F}, M)$. Let $\mathcal{A}$ be a sub-$\sigma$-field
of $\mathcal{F}$. The conditional measure expectation of $\xi$ given $\mathcal{A}$ under measure $M_k$, de-
noted by $ME_k(\xi|\mathcal{A})$, is the a.s.-unique random variable satisfying the following two
conditions:
(i) $\text{ME}_k(\xi | A)$ is measurable in $(\Omega, A)$;

(ii) $\int_A \text{ME}_k(\xi | A) dM = \int_A \xi dM_k$ for any $A \in A$

**Remark 2** It is easy to obtain that the conditional measure expectations $\text{ME}_k(\cdot | A)$ have the similar properties as in probability space. In the proofs of theorems, we need to use these properties.

Motivated by Chow, Robbins and Siegmund (1971) we present a nonnegative random dynamic control limit $\{l_k(c), 0 \leq k \leq N+1\}$ that is defined by the following recursive equations

\begin{align*}
l_{N+1}(c) &= 0, \quad l_N(c) = cv_{N+1} \\
l_k(c) &= cv_{k+1} + \text{ME}_0 ([l_{k+1}(c) - Y_{k+1}]^+ | \mathcal{F}_k) \quad (5)
\end{align*}

for $0 \leq k \leq N - 1$, where $c > 0$ is a constant,

Now, by using the test statistics $Y_n, 1 \leq n \leq N + 1$, and the control limits $l_k(c), 1 \leq k \leq N + 1$, we define a sequential test $T^*(c, N)$ as follows

$$T^*(c, N) = \min \{1 \leq k \leq N + 1 : Y_k \geq l_k(c)\}. \quad (6)$$

It is clear that $T^*(c, N) \in \mathcal{F}_N$, $l_k(c) \geq cv_{k+1}$ and $l_k(c) \in \mathcal{F}_k$ for $0 \leq k \leq N$. The positive number $c$ can be regarded as an adjustment coefficient of the random dynamic control limit, as $l_k(c)$ is increasing on $c \geq 0$ with $l_k(0) = 0$ and $\lim_{c \to \infty} l_k(c) = \infty$ for $v_{k+1} > 0$. And $c$ control the value of $\text{ME}_0(\sum_{k=1}^{T^*(c, N)} v_k)$.

The following theorem shows that the sequential test $T^*(c, N)$ is optimal under the measure $\mathcal{J}_N(T)$.

**Theorem 1** Let $\gamma$ be a positive number satisfying $\text{ME}_0(v_1) < \gamma < \sum_{k=1}^{N+1} \text{ME}_0(v_k)$.

There exists a positive number $c_\gamma$ such that $T^*(c_\gamma, N)$ is optimal in the sense of (2)
with \( \mathbf{ME}_0(\sum_{k=1}^{T} v_k) = \gamma \); that is,

\[
\inf_{T \in \mathcal{T}_N, \mathbf{ME}_0(\sum_{k=1}^{T} v_k) \geq \gamma} J_N(T) = J_N(T^*(c, N)). \tag{7}
\]

In particular, if \( T \in \mathcal{T}_N \) satisfies \( T \neq T^*(c, N) \), that is, \( \mathbf{M}_0(T \neq T^*(c, N)) > 0 \) and \( \mathbf{ME}_0(\sum_{k=1}^{T} v_k) = \gamma \), then

\[
J_N(T) > J_N(T^*(c, N)). \tag{8}
\]

Here, the random dynamic control limit \( \{l_k(c), 0 \leq k \leq N + 1\} \) of the optimal control chart \( T^*(c, N) \) can be called an optimal dynamic control limit.

From Theorem 1 we know that for every measure \( \mathcal{J}_N(T) \) corresponding to the weights \( w_k, v_k \), we can construct an optimal control chart \( T^*(c, N) \) under the measure \( \mathcal{J}_N(T) \).

While Markov process is common, so we give a simple version of Theorem 1 when the at most order of Markov process is fixed. Since \( \mathbf{ME}_0([l_{k+1}(c) - Y_{k+1}]^+|\mathcal{F}_k) \) and \( v_{k+1} \) are measurable with respect to \( \mathcal{F}_k \), there are functions \( h_k = h_k(c, x_0, x_1, ..., x_k), \)

\( 0 \leq k \leq N - 1 \), and \( v_k = v_k(x_0, x_1, ..., x_{k-1}), 0 \leq k \leq N - 1 \), such that

\[
h_k = h_k(c, x_0, x_1, ..., x_k) = \mathbf{ME}_0([l_{k+1}(c) - Y_{k+1}]^+|X_k = x_k, X_{k-1} = x_{k-1}, ..., X_0 = x_0)
\]

for \( 0 \leq k \leq N - 1 \). Therefore, the optimal control limit \( l_k(c) \) in (5) can be written as

\[
l_k(c) = cv_{k+1}(X_0, X_1, ..., X_k) + h_k(c, X_0, X_1, ..., X_k)
\]

for \( 0 \leq k \leq N \).

Note that the optimal control limit \( l_k(c) \) depends on the sequence of networks,
$X_0, X_1, \ldots, X_k$ for $0 \leq k \leq N$. We let the sequence of networks $\{X_k, 0 \leq k \leq N\}$ be at most a $p$-order Markov process; that is, both the pre-change network observations $X_0, X_1, \ldots, X_{k-1}$ and the post-change network observations $X_k, \ldots, X_N$ are $i$-order and $j$-order Markov processes with transition measure density functions $m_{0n}(x_n|x_{n-1}, \ldots, x_{n-i})$ and $m_{1m}(x_m|x_{m-1}, \ldots, x_{m-j})$, respectively, where $p = \max\{i, j\}$ and

$$m_{0n}(x_n|x_{n-1}, \ldots, x_{n-i}) = m_{0n}(x_n|x_{n-1}, \ldots, x_{n-i}, \ldots, x_0)$$

$$m_{1m}(x_m|x_{m-1}, \ldots, x_{m-j}) = m_{1m}(x_m|x_{m-1}, \ldots, x_{m-j}, \ldots, x_0)$$

for $i \leq n$ and $j \leq m$. We known that $p = 0$, means that the sequence of networks are mutually independent.

**Theorem 2** Let the sequence of networks $\{X_k, 0 \leq k \leq N\}$ be at most a $p$-order Markov process for $p \leq N$ and the weights $w_k = w_k(Y_{k-1})$ and $v_k = v_k(Y_{k-1})$ for $1 \leq k \leq N$. Then

(i) Let $p \geq 1$. The optimal control limit $\{l_k(c), 0 \leq k \leq N\}$ can be written as

$$l_k(c) = cv_{k+1}(Y_k) + ME_0\left([l_{k+1}(c) - (Y_k + w_{k+1}(Y_k))\Lambda_{k+1}]^+|Y_k, X_k, X_{k-1}, \ldots, X_{k-p+1}\right)$$

for $0 \leq k \leq N$.

(ii) Let $p = 0$ and $l_k(c) = l_k(c, Y_k)$, then we have

$$l_k(c) = l_k(c, Y_k) = cv_{k+1}(Y_k) + ME_0\left([l_{k+1}(c, Y_{k+1}) - (Y_k + w_{k+1}(Y_k))\Lambda_{k+1}]^+|Y_k\right)$$

for $0 \leq k \leq N$.

Theorem 2 is a special case of Theorem 1 when the observation sequence is a Markov process and at most order of this Markov process is fixed.
3 Comparison and analysis of simulation results

Suppose that there is a finite sequence of network and \( N = 60 \). In section 3.1, under finite measure space, we first give an example for independent samples condition by comparing four different sequential tests, \( T_{\text{cons}} \) with constant control limits, \( T_{\text{de}} \) with linear decrease control limits, \( T_{\text{in}} \) with linear increase control limits, and \( T^*(c) \) with optimal control limits \( l_k \) which is defined in this paper. Then we give an example for dependent samples condition, which is 1-order Markov process and we also compare the four different sequential tests. All of the above is based on CUSUM-type statistics and the number of nodes \( d = 10 \).

Note that traditional probability space is a special case, so when the normalization coefficient is computable for a network distribution, then we can use the probability space, we also give examples in Section 3.2 about independent and dependent Erdos-Rényi network sequences.

Moreover, in simulation, the performance measure \( J_N(T) \) with \( w_k = (1 - Y_{k-1})^+ \) and \( v_k = 1 \) for \( 1 \leq k \leq N \). And note that ME is proportional to \( E \), the ratio is fixed and unknown. For any test \( T \), \( E(T) \) is easily estimated by sample mean through simulation. So in the third column of tables, we replace \( \text{ME}_0(T) \) with \( E_0(T) \). For all of the results, \( E_0(T) \approx 40 \), and the four tests all have adjustment coefficient \( c \) to guarantee \( E_0(T) \approx 40 \), which is denoted by \( c_\gamma \) in tables.

The explanation of the simulation results is at the end of this section.

3.1 Comparison of simulation of independent network observations in finite measure space

Let \( \{X_k, 0 \leq k \leq 60\} \) be an independent network observations sequence with a pre-change measure density function \( m_0(X_k) = \exp(-2 * \text{edges}(X_k)) \) and a post-change
measure density function \( m_1(X_k) = \exp(-2.2 \ast \text{edges}(X_k)) \) for \( 0 \leq k \leq 60 \). The function \( \text{edges} \) is a term used in Exponential Family Random Graph Models, which means the number of edges in a network.

\[
\text{edges}(X) = \begin{cases} 
\frac{1}{2} \sum_{i,j=1}^{d} X_{ij} & \text{X is undirected} \\
\sum_{i,j=1}^{d} X_{ij} & \text{X is directed}
\end{cases}
\]

There are many terms in ERGMs and many linear combination of these terms. The example we give is the simplest. The ratio \( \Lambda_k \) of the pre-change and post-change measure density functions \( m_0(x) \) and \( m_1(x) \) is

\[
\Lambda_k = \frac{m_1(X_k)}{m_0(X_k)} = e^{-0.2 \ast \text{edges}(X_k)}
\]

for \( 1 \leq k \leq 60 \). We compare the performance of four tests, the first one is \( T_{cons} \) with constant control limits

\[
T_{cons} = \min\{1 \leq k \leq N + 1 : Y_k \geq c\}
\]

The second test, \( T_{de} \) denotes a test with decrease control limits as follows

\[
T_{de} = \min\{1 \leq k \leq N + 1 : Y_k \geq c_k\}
\]

\[
c_k = c + 0.005 \ast (61 - k)
\]

And \( T_{in} \) denotes a test with increase control limits as follows

\[
T_{in} = \min\{1 \leq k \leq N + 1 : Y_k \geq c\}
\]

\[
c_k = c + 0.005 \ast (k + 1)
\]
The last one is the optimal test \( T^*(c) \) with \( T^*(c) = \min\{1 \leq k \leq N+1 : Y_k \geq l_k(c)\} \).

The simulation result for independent finite ERGM network observations is shown in Table 1. All of the results are based on \( 10^5 \) repititions.

**Table 1** Simulation of four tests for independent finite network observations.

### 3.2 Comparison of simulation of dependent network observations in finite measure space

Let \( \{X_k, 0 \leq k \leq 60\} \) be a dependent network observation sequence. We note that if there is no cross term of \( X_k \) and \( X_{k-1} \) in \( m(X_k|X_{k-1}) \), then the network observations are independent obviously. So, here we let pre-change measure density function \( m_0(X_k|X_{k-1}) = \exp(-0.08 \ast \text{edges}(X_{k-1}) \ast \text{edges}(X_k)) \) and a post-change measure density function \( m_1(X_k|X_{k-1}) = \exp(-0.10 \ast \text{edges}(X_{k-1}) \ast \text{edges}(X_k)) \) for \( 0 \leq k \leq 60 \). The ratio \( \Lambda_k \) of the pre-change and post-change measure density functions is

\[
\Lambda_k = \frac{m_1(X_k|X_{k-1})}{m_0(X_k|X_{k-1})} = e^{-0.02 \ast \text{edges}(X_{k-1}) \ast \text{edges}(X_k)}
\]

for \( 1 \leq k \leq 60 \). We compare the performance of four tests, which the same as independent case above.

The simulation result of dependent finite ERGM network observations is shown in Table 2. All of the results are based on \( 10^4 \) repititions.

### 3.3 Comparison of simulation of independent network observations in probability space

Let \( \{X_k, 0 \leq k \leq 60\} \) be an independent network observation sequence. Moreover, before the change point, the networks are Erdos-Rényi networks with link probability 0.5, and the link probability equals to 0.6 after the change point. We compare the performance of four tests, the first one is \( T_{cons} \) with constant control limits

\[
T_{cons} = \min\{1 \leq k \leq N + 1 : Y_k \geq c\}
\]

The second test, \( T_{de} \) denotes a test with decrease control limits as follows

\[
T_{de} = \min\{1 \leq k \leq N + 1 : Y_k \geq c_k\}
\]

\[
c_k = c + 0.05 \times (61 - k)
\]

And \( T_{in} \) denotes a test with increase control limits as follows

\[
T_{in} = \min\{1 \leq k \leq N + 1 : Y_k \geq c_k\}
\]

\[
c_k = c + 0.05 \times (k + 1)
\]

The last one is the optimal test \( T^*(c) \) with \( T^*(c) = \min\{1 \leq k \leq N + 1 : Y_k \geq l_k(c)\} \)

The simulation result of independent finite Erdos-Rényi network observations is
shown in Table 3. All of the results are based on $10^5$ repititions.

3.4 Comparison of simulation of depedent network observations in probability space

Let $\{X_k, 0 \leq k \leq 60\}$ be a dependent network observation sequence. Given $X_{k-1}, X_k$ is a Erdos-Rényi network. Before the change point, the link probability is $\frac{\text{edges}(X_{k-1})}{d(d-1)/2}$, and the link probability equals to $\frac{\text{edges}(X_{k-1})}{d(d-1)}$ after the change point.

The simulation result of dependent finite Erdos-Rényi network observations is shown in Table 4. All of the results are based on $10^4$ repititions.

Next, we give a explanation about the numerical simulation results in the above four tables. The fist two tables are for general independent and dependent ERGMs. The last two tables are for specific Erdos-Rényi random networks. The first column shows that we compare four different sequential tests, the adjustment coefficient is
shown in the second column to guarantee that $\text{ME}_0(\cdot) \approx \gamma$, in tables we use $E_0(\cdot)$ to replace it. The fourth column is the focus of our attention, the smallest of $J_N(T)$, the better of the sequential test. We find that the optimal sequential tests in four tables all have the smallest $J_N(T)$, which is consistent with Theorem 1. Note that the method in this paper can be applied in many networks, as long as we know the distribution of the networks either in probability space or in general finite measure space. Further, the sequence of networks in Section 3.2 and Section 3.4 can be $p$-order, while in simulation we choose 1-order networks. And in simulation, we try to make sure $E_0(\cdot) \approx 40$, but in Table 1 and Table 3, for the constant control limits, $E_0(\cdot) = 41.8339, 41.3517$, that’s because if we adjust the constant $c$ a little bit, the corresponding $E_0(\cdot)$ is far from 40. There are many different control limits, in this paper we choose relatively representative control limits.

The usual CUSUM control chart we use in quality detection is constant control limits. From the simulation, we can conclude that under the performance measure we defined, constant control limits maybe not good enough, sometimes the increase control limits and decrease control limits have better performance, which indicates that finding an optimal dynamic control limits is necessary. The optimal sequential test we defined is the guidance for how to give the suitable or optimal dynamic control limits. Indeed we can conclude that the optimal control limits are a.s. decrease.

4 Concluding remarks

For the ERGMs models, and probabilistic graphical models, the normalization coefficient is difficult to compute, there are many method to approximate them, which needs complexity computations. We choose a finite measure to define correspond-
ing measure ratio statistics for sequential test problem is a method to solve the difficulty. Measure ratio statistics can also show the difference between pre-change and post-change distribution. And we can also give optimal sequential test under finite measure. All of the definition about finite measure space comes from Shao, J. (2003).

When the pre-change and post-change measure density functions are known, it is simple. However, if the post-change measure density function is unknown, the problem may be more difficult, and would be considered later. If the number of parameters in ERGMs is large, it maybe results in dimension curse, which is also worthy to be considered.

The proofs of Thoerem in Appendix refers to Dong Han, Fugee Tsung, and Jinguo Xian(2019). The expectations and conditional expectations for the change-point \( k(1 \leq k \leq N) \) are extend to measure expectations \( ME_k \) and conditional measure expectations \( ME_k(\cdot|\mathcal{A}) \).

References

APPENDIX : PROOFS OF THEOREMS

Proof of Theorem 1. Since \((T - k)^+ = \sum_{m=k+1}^{N+1} I(T \geq m)\) for \(T \in \mathfrak{T}_N\),
\(I(T \geq m) \in \mathfrak{F}_{m-1}\), and the joint measure density function

\[
m_k(X_0, X_1, ... X_N) = m_0(X_0) \prod_{j=1}^{k-1} m_{0j}(X_j|X_{j-1}, ..., X_0) \prod_{j=k}^{N} m_{1j}(X_j|X_{j-1}, ..., X_0)
\]

for the change-point \(1 \leq k \leq N\). \(ME_k\) is 1-order moment based the joint measure
density function above. Then we have

\[
\sum_{k=1}^{N} ME_k \left(w_k(T - k)^+\right) = ME_0 \left(\sum_{k=1}^{N} \sum_{m=k+1}^{N+1} w_k I(T \geq m) \prod_{j=k}^{m-1} \Lambda_j\right)
\]

\[
= ME_0 \left(\sum_{m=1}^{N} Y_m I(T \geq m + 1)\right) = ME_0 \left(\sum_{m=1}^{T} Y_{m-1}\right), \quad (A. 1)
\]

for all \(T \in \mathfrak{T}_N\). The second equality comes from the following equality

\[
Y_m = [Y_{m-1} + w_m] \Lambda_m = \sum_{k=1}^{m} w_k \prod_{j=k}^{m} \Lambda_j
\]

for \(1 \leq m \leq N\).

Let \(T^* = T^*(c) = T^*(c, N)\) and

\[
\xi_n = \sum_{k=1}^{n} (Y_{k-1} - cv_k), \quad (A. 2)
\]

where \(c > 0\). This is divided into three steps to complete the proof of Theorem 1.

Step I. Show that

\[
ME_0(\xi_T) \geq ME_0(\xi_{T^*}) \quad (A. 3)
\]

for all \(T \in \mathfrak{T}_N\) and the strict inequality of (A.3) holds for all \(T \in \mathfrak{T}_N\) with \(T \neq T^*\).

To prove (A.3), by Lemma 3.2 in Chow, Robbins and Siegmund (1971), we extend
to measure space, that is we only need to prove the following two inequalities:

\[
\text{ME}_0(\xi_{T^*}|\mathcal{F}_n) \leq \xi_n \quad \text{on} \quad \{T^* > n\} \quad (A.4)
\]

and

\[
\text{ME}_0(\xi_T|\mathcal{F}_n) \geq \xi_n \quad \text{on} \quad \{T^* = n, T > n\} \quad (A.5)
\]

for each \(n \geq 1\).

Let \(B_{m,n+1}(N) = \{Y_k < l_k(c), n + 1 \leq k \leq m\}\) for \(n + 1 \leq m \leq N\), as in Dong Han, Fugee Tsung, and Jinguo Xian (2019), we can verify that in measure space we have

\[
l_n(c) = cv_{n+1} + \text{ME}_0\left(\sum_{m=n+1}^{N} B_{m,n+1}(N)[cv_{m+1} - Y_m]|\mathcal{F}_n\right) \quad (A.6)
\]

and

\[
\text{ME}_0\left(\sum_{m=n+1}^{N} I(T > m)[cv_{m+1} - Y_m]|\mathcal{F}_n\right) \leq (l_n(c) - cv_{n+1})I(T > n) \quad (A.7)
\]

for \(0 \leq n \leq N\) and \(T \in \mathcal{T}_N\).

In fact, the proof of (A.6) and (A.7) is same as in Dong Han, Fugee Tsung, and Jinguo Xian (2019), the conditional measure expectations \(\text{ME}_k(\cdot|\mathcal{A})\) also have the properties in probability space.

From (A.6) and the definition of \(\xi_n\) in (A.2), it follows that

\[
I(T^* > n)\text{ME}_0(\xi_{T^*} - \xi_n)|\mathcal{F}_n) = I(T^* > n)\sum_{m=n}^{N} \text{ME}_0(I(T^* > m)[\xi_{m+1} - \xi_m]|\mathcal{F}_n)
\]

\[
= I(T^* > n)[Y_n - cv_{n+1} + \sum_{m=n+1}^{N} \text{ME}_0(I(B_{m,n+1})(Y_m - cv_{m+1})]|\mathcal{F}_n)
\]

\[
= I(T^* > n)(Y_n - l_n(c)) < 0 \quad (A.8)
\]
for $1 \leq n \leq N$. The last inequality comes from the definition of $T^*$. This means that (A.4) holds for $1 \leq n \leq N$.

By (A.7), we have

$$I(T^* = n)I(T > n)\ME_0(\xi_T - \xi_n) | \tilde{\mathcal{F}}_n)$$

$$= I(T^* = n) \sum_{m=n}^{N} \ME_0(\xi_{m+1} - \xi_m) | \tilde{\mathcal{F}}_n)$$

$$= I(T^* = n) \sum_{m=n+1}^{N} \ME_0\left(I(T > m) | Y_m - cv_{m+1} \right) | \tilde{\mathcal{F}}_n)$$

$$\geq I(T^* = n) \sum_{m=n+1}^{N} \ME_0\left(I(T > m) | Y_m - cv_{m+1} \right) | \tilde{\mathcal{F}}_n)$$

$$= I(T^* = n) I(T > n) [Y_n - cv_{n+1}] \geq 0.$$

(A.9)

That is, (A.5) holds for $1 \leq n \leq N$. By (A.4) and (A.5), we know that the inequality in (A.3) holds for all $T \in \mathcal{T}_N$. Furthermore, from (A.8) and (A.9), it follows that the strict inequality in (A.3) holds for all $T \in \mathcal{T}_N$ with $T \neq T^*$.

**Step II.** Show that the test we defined in this paper is optimal under the performance measure $\mathcal{J}_N$.

As $\ME_0(v_1) < \gamma < \sum_{k=1}^{N+1} \ME_0(v_k)$, it follows that there is at least a $k$ satisfying $k \geq 2$ such that $\ME_0(v_k) > 0$. Let $k^* = \max\{2 \leq k \leq N + 1 : \ME_0(v_k) > 0\}$, we have

$$\ME_0\left(\sum_{k=1}^{T^*} v_k \right) = \sum_{k=1}^{k^*} \ME_0(v_k I(T^* \geq k)) = \ME_0(v_1) + \sum_{k=2}^{k^*} \ME_0(v_k I(T^* \geq k)).$$

By the definition of $\{l_k(c), 1 \leq k \leq N + 1\}$ and $T^*$, we know that

$$\lim_{c \to 0} \sum_{k=2}^{k^*} \ME_0(v_k I(T^* \geq k)) = 0$$

$$\lim_{c \to \infty} \sum_{k=2}^{k^*} \ME_0(v_k I(T^* \geq k)) = \sum_{k=2}^{k^*} \ME_0(v_k)$$
As \( \sum_{k=2}^{k^*} \text{ME}_0(v_k I(T^* \geq k)) \) is continuous and increasing on \( c \), it follows that there is a positive number \( c_\gamma \) such that
\[
\text{ME}_0(\sum_{k=1}^{T^*(c_\gamma)} v_k) = \sum_{k=1}^{k^*} \text{ME}_0(v_k I(T^* \geq k)) = \gamma. \tag{A. 10}
\]

Let
\[
\tilde{c}_\gamma = J_{M,N}(T^*(c_\gamma)) = c_\gamma - \frac{\text{ME}_0(l_0(c_\gamma))}{\text{ME}_0(\sum_{m=1}^{T^*(c_\gamma)} v_m)}.
\]

If \( J_N(T) \geq c_\gamma \), then \( J_N(T) \geq \tilde{c}_\gamma = J_N(T^*(c_\gamma)) \). If \( J_N(T) < c_\gamma \), then, by (A.1), (A.3), and \( \text{ME}_0(\sum_{m=1}^{T} v_m) \geq \gamma \), we have
\[
(J_N(T) - c_\gamma)\gamma \geq \left[ \frac{\text{ME}_0(\sum_{m=1}^{T} Y_{m-1})}{\text{ME}_0(\sum_{m=1}^{T} v_m)} - c_\gamma \right] \text{ME}_0(\sum_{m=1}^{T} v_m)
= \left[ \text{ME}_0(\sum_{m=1}^{T} Y_{m-1}) - c_\gamma \text{ME}_0(\sum_{m=1}^{T} v_m) \right]
\geq \left[ \text{ME}_0(\sum_{m=1}^{T^*(c_\gamma)} Y_{m-1}) - c_\gamma \text{ME}_0(\sum_{m=1}^{T^*(c_\gamma)} v_m) \right]
= \left[ \frac{\text{ME}_0(\sum_{m=1}^{T^*(c_\gamma)} Y_{m-1})}{\text{ME}_0(\sum_{m=1}^{T^*(c_\gamma)} v_m)} - c_\gamma \right] \text{ME}_0(\sum_{m=1}^{T^*(c_\gamma)} v_m)
= \left[ J_N(T^*(c_\gamma)) - c_\gamma \right] \gamma.
\]

This means that \( J_N(T) \geq J_N(T^*(c_\gamma)) \) for all \( T \in \mathfrak{T}_N \) with \( \text{ME}_0(\sum_{m=1}^{T} v_m) \geq \gamma \).

The strict inequality of Theorem 1 comes from the strict inequality in (A.3) when \( T \neq T^*(c_\gamma) \) with \( \text{ME}_0(\sum_{m=1}^{T} v_m) = \text{ME}_0(\sum_{m=1}^{T^*(c_\gamma)} v_m) = \gamma \). This completes the proof of Theorem 1.

**Proof of Theorem 2.** As \( Y_k = (Y_{k-1} + w_k(Y_{k-1}))\Lambda_k \) for \( 1 \leq k \leq N \), it follows that \( (Y_k, X_k), 0 \leq k \leq N \), is at most a two-dimensional \( p \)-order Markov process. Let \( p \geq 1 \). By the definition of the optimal control limits, we have

\[
l_k(c) = cv_{k+1}(Y_k) + \text{ME}_0\left( [l_{k+1}(c) - (Y_k + w_{k+1}(Y_k))\Lambda_{k+1}]^+ | Y_k, X_k, ..., X_0 \right) \tag{A. 11}
\]
for $0 \leq k \leq p - 1$ and

$$l_k(c) = cv_{k+1}(Y_k)$$

$$+ \mathsf{ME}_0 \left( [l_{k+1}(c) - (Y_k + w_{k+1}(Y_k))\Lambda_{k+1}]^+|Y_k, X_k, \ldots, X_{k-p+1} \right)$$

for $p \leq k \leq N$. Let $p = 0$, we have similarly

$$l_k(c) = l_k(c, Y_k)$$

$$= cv_{k+1}(Y_k) + \mathsf{ME}_0 \left( [l_{k+1}(c, Y_{k+1}) - (Y_k + w_{k+1}(Y_k))\Lambda_{k+1}]^+|Y_k \right)$$

for $0 \leq k \leq N$.
