Limit theorems for chains with unbounded variable length memory which satisfy Cramer condition

A. Logachev, A. Mogulskii, A. Yambartsev

November 18, 2019

Abstract

Here we obtain the exact asymptotics for large and moderate deviations, strong law of large numbers and central limit theorem for chains with unbounded variable length memory.

Key words: variable length memory chain, regeneration scheme, generalized renewal process, local limit theorem, large deviation principle, moderate deviation principle, rate function, Cramer condition.

1 Introduction

Let \( \mathcal{A} = \{0, 1, \ldots, d\} \) be a set of \( d \) symbols (characters) – an alphabet. Here we consider a class of chains \( r = (r_i, i \in \mathbb{Z}) \in \mathcal{A}^\mathbb{Z} \) which is a special case of so-called chains with unbounded variable length memory. These chains began to be actively studied after they were first introduced by Jorma Rissanenom [1] as an economic and universal way of data compression. The short and simple introduction to these processes can be found, for example, in [2]. They are used for modeling data in computer science [1], in biology [3], [4], in neuro-biology [6], [7], in linguistics [5]. We do not pretend for at least some sort of full review on these chains, and we restrict ourselves to some papers known to us by the activity of the research group NeuroMat under the guidance of Prof. A.Galves.

If we interpret \( \mathbb{Z} \) as a discrete time, then one can imagine such chains as a successive in time attribution of a character from the alphabet \( \mathcal{A} \) with probability which depends on the past (existing sequence of characters), or, more precisely, it depends on a part of the past,
a context. As a consequence such dependence can be represented as a context tree, where each vertex represent a context, and each vertex is associated with a probability distribution (on $\mathcal{A}$) of a new character. Markov chain with the state space $\mathcal{A}$ is a particular case of these chains. In this case the context tree has height 1 – we should know only the last character in order to decide the distribution of a new character. The existence of a stationary measure on $\mathcal{A}^\mathbb{Z}$ compatible with a family of transition probabilities determined by a context tree is the question which naturally arises. These question was answered and the short review can be find [2], where also methods of statistical inferences of context tree were provided.

In [8] the perfect simulation for such processes was constructed. The success of the algorithm (if the perfect simulation stops in a finite time) depends directly from the existence of a (finite) renewal time moment – the moment when the next and successive attributions of characters do not depend on the past. In the same paper the connection between renewal processes and the chains with variable length memory was established. This indicates to us that the large deviations results for this sort of chain can be obtained using the regeneration structure and the recently published results on large deviations for the renewal processes [9].

Despite the fact that for a complete definition and description of chains with unbounded variable length memory we need to introduce the notion of a context tree, in this article we restrict ourselves to an alternative description of the chain, because from the very beginning we will consider a particular case of such chains. Let us fix an initial configuration

$$r(0) = \{r_i(0)\}_{-\infty < i \leq 0},$$

where $r_i(0), -\infty < i \leq 0$ take values from the alphabet $\mathcal{A}$, which is binary alphabet $\mathcal{A} := \{0, 1\}$ in our case. We set the configuration change rule. Remind that at any time step we write exactly one character from the alphabet $\mathcal{A}$ at the end of existing sequence without changing it.

In order to set the transition rules, let first fix a number $v \in \mathbb{N}$ (one of the parameters of the chain). Consider the set of all words from $v$ characters ending with the character 1; the total number of such words is $2^{v-1}$; for any such word we assing their own order number $j, 1 \leq j \leq 2^{v-1}$. Let us set the sequence of positive numbers on this set of words

$$p_{kj} \in (0, 1), \quad k \in 0 \cup \mathbb{N}, \quad 1 \leq j \leq 2^{v-1}.$$

Now we are ready to describe the rules (transition probabilities) of adding a character from the right: let we have a configuration on the $n$-th step

$$r(n) = \{r_i(n)\}_{-\infty < i \leq n}.$$

Denote

$$m_n := \sup\{-\infty < i \leq n : r_i(n) = 1\}.$$

Then, at the next step the configuration $r(n) = \{r_i(n)\}_{-\infty < i \leq n}$ jump to the configuration

$$r(n+1) = \{r_i(n+1)\}_{-\infty < i \leq n+1}$$

by writing from the right a character 1, $r_{n+1}(n+1) = 1$, with probability $p_{k_nj_n}$, where $k_n = n - m_n, j_n$ – the number of word, which forms the sequence

$$r_{m_n-v+1}(n), r_{m_n-v+2}(n), \ldots, r_{m_n}(n).$$
Thus, the character $0, r_{n+1}(n+1) = 0$, will be adding with probability $1 - p_{k_n,j_n}$. Note that the previous sequence do not change:

$$\{r_i(n+1)\}_{-\infty < i \leq n} \equiv r(n).$$

Thus, the probability of the attributed character $r_{n+1}(n+1)$ depends on

1) the distance to the nearest character 1;

2) the word from $v-1$ letters, which stand on the left from this 1.

It is obvious that the random sequence $\{r_n(n)\}$ is not Markov chain, because the transition probability from $r_n(n)$ to $r_{n+1}(n+1)$ can depend, generally speaking, not only on the character $r_n(n)$, but also on values $r_{n-j}(n-j)$ for arbitrarily large $j \geq 0$.

For such defined process $r(n)$ define $R(n)$ the number of units adding from the right to the initial configuration $r(0)$ in $n$ steps:

$$R(n) := \sum_{k=1}^{n} r_k(k).$$

We are interested in the behaviour of the process $R(n)$ when $n \to \infty$. In the next section we prove low of large numbers, central limit theorem, local limit theorem, we establish also the large and moderate deviation principles.

Further we suppose that the following condition [A] holds true. The condition [A] composed by two items.

1. Inicial configuration $r(0)$ contains at least one unit.

2. There exist constants $1 > \delta_1 > \delta_2 > 0$ such that for all $k \in 0 \cup \mathbb{N}, 1 \leq j \leq 2^{v-1}$ the following inequalities holds

$$\delta_1 \geq p_{kj} \geq \delta_2.$$

The condition 1 is an obvious condition for existence of process and for implementation of transition probabilities. Note, however, that this condition can be omitted adding the probability $p_\infty \in (0,1)$ to attribute a character 1, when the sequence consists of only zeros. Condition 2 gives us the possibility of construction of arithmetic generalized renewal process which satisfy Cramer moment condition [C_0] and the condition of arithmeticity of [Z] (see Section 2).

The paper is organized as follows: in Section 2 we introduce our definitions and notations, we provide the main result Theorem 2.2 (low of large numbers, central limit theorem, local moderate and large limit theorem and principle of moderate large deviations for $R(n)$); in Section 3 we prove Theorem 2.2 in Section 4 auxiliary lemmas are proved.
2 Main results, definitions, notations

To formulate and prove the main result we need some auxiliary processes which we define in this section.

For any state $r(n)$ we correspond the pair

$$Y(n) := (Y_1(n), Y_2(n)),$$

where $Y_1(n) := n - m_n$ (the distance to the nearest unit, or, what’s the same, the number of zeros before the nearest unit),

$$Y_2(n) := (r_{m_n-v+1}(n), r_{m_n-v+2}(n), \ldots, r_{m_n}(n))$$

(sequence of the nearest unit and $v - 1$ letters from its left).

Note, that the pair $Y(n) := (Y_1(n), Y_2(n))$ can transit with probability $p_{knj_n}$ into the pair

$$Y(n + 1) = (0, Y_2(n + 1)),$$

where

$$Y_2(n + 1) = \begin{cases}
(0, \ldots, 0, 1), & \text{if } Y_1(n) \geq v - 1, \\
(r_{m_n-v+1}(n), \ldots, r_{m_n}(n), 0, \ldots, 0, 1), & \text{if } Y_1(n) < v - 1,
\end{cases}$$

and with probability $1 - p_{knj_n}$ into the pair

$$Y(n + 1) = (Y_1(n) + 1, Y_2(n)).$$

In this way $Y(n + 1)$ is an random function on $Y(n)$. Thus, the sequence $\{Y(n)\}, n \geq 0$ is homogeneous Markov chain with phase state

$$\mathcal{Y} := \{y = (y_1, y_2) : y_1 \in 0 \cup \mathbb{N}, y_2 = (a_1, \ldots, a_v), a_1 \in \mathcal{A}, \ldots, a_{v-1} \in \mathcal{A}, a_v = 1\}.$$

Let us pick out the state

$$y_0 := (0, (0, \ldots, 0, 1)).$$

Note that the chain can jump in one step from any state $(y_1, y_2)$ to chosen state $y_0$, if the coordinate $y_1$ not less than $v - 1$.

Denote

$$\tau_1 := \min\{n > 0 : Y(n) = y_0\},$$

$$\tau_k := \min\{n > \tau_1 + \cdots + \tau_{k-1} : Y(n) = y_0\} - (\tau_1 + \cdots + \tau_{k-1}), \quad 2 \leq k.$$

Since $\{Y(n)\}$ is homogeneous Markov chain, the random variables $\tau_1, \ldots, \tau_k, \ldots$ are independent and, moreover, $\tau_k$ are identically distributed when $k \geq 2$.

Let $\zeta_k$ be the number of units added from the right during the time $n \in \{(T_{k-1} + 1, \ldots, T_k\},$ where

$$T_0 := 0, \quad T_k := T_{k-1} + \tau_k, \quad k \in \mathbb{N}.$$
In other words
\[
ζ_0 := 0, \quad ζ_k := \sum_{n=T_{k-1}+1}^{T_k} r_n(n) \quad \text{for} \quad k \in \mathbb{N}.
\]

By construction the random vectors \( ξ_k := (τ_k, ζ_k) \), \( k \in \mathbb{N} \) are independent, and \( ξ_k \) are identically distributed when \( k ≥ 2 \).

Let
\[
ν(0) := 0, \quad ν(n) := \max\{k ≥ 0 : T_k < n\} \quad \text{for} \quad k \in \mathbb{N}.
\]

Define generalized renewal process
\[
Z(n) := \sum_{k=0}^{ν(n)} ζ_k.
\]

Let the random vector \( ξ := (τ, ζ) \) has the distribution which coincides with distribution of vectors \( ξ_k := (τ_k, ζ_k) \) for \( k ≥ 2 \).

Since \( ζ_k ≤ τ_k \) a.s. when \( k ∈ \mathbb{N} \), then from Lemma 4.1 (see Section 4) it follows that for \( ξ_1 \) and \( ξ \) the Cramer’s condition \([C_0]\) holds true:
\[
E e^{δ|ξ_1|} ≤ E e^{2δτ_1} < ∞ \quad \text{and} \quad E e^{δ|ξ|} ≤ E e^{2δτ} < ∞, \quad \text{when} \quad δ < ρ/2,
\]
where \( ρ > 0 \) is the constant from Lemma 4.1.

From Lemma 4.2 (see Section 4) we obtain that the vector \( ξ \) satisfies the arithmeticity condition \([Z]\):

For any \( u ∈ \mathbb{Z}^2 \) the equality \( f(2πu) = 1 \) holds and for any \( u ∈ \mathbb{R}^2 \setminus \mathbb{Z}^2 \) the inequality \( |f(2πu)| < 1 \) holds, where for \( u = (u_1, u_2) ∈ \mathbb{R}^2 \) the function
\[
f(u) := E e^{i(u_1τ + u_2ζ)}
\]
is the characteristic function for \( ξ \).

Give the notation we need from the paper [9]
\[
a := \frac{Eζ}{Eτ}, \quad σ^2 := \frac{1}{aτ}E(ζ - aτ)^2, \quad aτ := Eτ,
\]
\[
ψ_1(λ, μ) := E e^{λτ_1 + μζ_1}, \quad ψ(λ, μ) := E e^{λτ + μζ},
\]
\[
A(λ, μ) := \ln ψ(λ, μ), \quad (λ, μ) ∈ \mathbb{R}^2,
\]
\[
D(θ, α) := \sup_{(λ, μ) ∈ A ≤ 0} \{λθ + μα\}, \quad A ≤ 0 := \{(λ, μ) : A(λ, μ) ≤ 0\},
\]
\[
D(α) := D(1, α).
\]

Denote \( \mathcal{B} \) the Borel \( σ \)-algebra of subsets of \( \mathbb{R} \). For an arbitrary set \( B ∈ \mathcal{B} \) we denote \([B]\) and \((B)\) its closure and interior correspondingly.

Now we give the definition of the Large Deviation Principle (LDP).
**Definition 2.1.** The sequence of random variables $s_n$ satisfies LDP in $\mathbb{R}$ with rate function $I = I(y) : \mathbb{R} \to [0, \infty]$ and normalized function $\varphi(n) : \lim_{n \to \infty} \varphi(n) = \infty$, if for any $c \geq 0$ the set $\{y \in \mathbb{R} : I(y) \leq c\}$ is compact and for any set $B \in \mathcal{B}$ the following inequalities holds true

$$\limsup_{n \to \infty} \frac{1}{\varphi(n)} \ln P(s_n \in B) \leq -I([B]),$$

$$\liminf_{n \to \infty} \frac{1}{\varphi(n)} \ln P(s_n \in B) \geq -I((B)),$$

where $I(B) = \inf_{y \in B} I(y)$, $I(\emptyset) = \infty$.

Denote $\Phi_{0,\sigma^2}$ the normal distribution with parameters $(0, \sigma^2)$, and by $\Rightarrow$ we denote the convergence in distribution.

Let us give now the main result of our work.

**Theorem 2.2.** Let the condition [A] holds true. Then

1. **(strong low of large numbers)** When $n \to \infty$

$$\frac{R(n)}{n} \to a \text{ a.s.}$$

2. **(central limit theorem)** When $n \to \infty$

$$\frac{R(n) - an}{\sqrt{n}} \Rightarrow \Phi_{0,\sigma^2}.$$

3. **(local theorem in regions of normal, moderate and large deviations)** There exists $\Delta > 0$ such that if $x \in 0 \cup \mathbb{N}$, $\lim_{n \to \infty} \frac{\hat{x}}{n} = \alpha_0$ and $|\alpha_0 - a| \leq \Delta$, then

$$P(R(n) = x) = \frac{1}{\sqrt{n}} \psi_1(\lambda(\alpha_0), \mu(\alpha_0)) C_H(1, \alpha_0) e^{-nD(\hat{x})} (1 + o(1)),$$

where

$$I(\alpha_0) = \sum_{l=1}^{\infty} e^{\lambda(\alpha_0) l} E(e^{\mu(\alpha_0) R(l)}, \tau \geq l \mid Y(0) = y_0),$$

and $C_H(\theta, \alpha)$ is the positive function, which is continuous in a neighborhood of the point $(\theta, \alpha) = (1, \alpha_0)$ and it is known explicitly from Theorem 2.1 and 2.1A [9].

4. **(local theorem in regions of normal and moderate deviations)** If $x \in 0 \cup \mathbb{N}$ and $\lim_{n \to \infty} \frac{\hat{x}}{n} = a$, then the following equality holds true

$$P(R(n) = x) = \frac{1}{\sigma \sqrt{2\pi n}} e^{-nD(\hat{x})} (1 + o(1)).$$
5. (moderate deviation principle) Let the sequence \( \kappa := \kappa_n, \kappa \in \mathbb{R} \) satisfies the conditions
\[
\lim_{n \to \infty} \frac{\kappa_n}{n} = 0, \quad \lim_{n \to \infty} \frac{\kappa}{\sqrt{n}} = \infty.
\]
Then the sequence of random variables \( \tilde{R}(n) := \frac{R(n) - an}{\kappa} \) satisfies LDP with normalized function \( \varphi(n) := \frac{\kappa^2}{n} \) and rate function
\[
I(y) := \frac{y^2}{2\sigma^2}.
\]

3 Proof of Theorem 2.2

Proof of statements 1) and 2). Since \( \zeta_k \leq \tau_k \) a.s. when \( k \in \mathbb{N} \), then the following inequality holds
\[
Z(n) \leq R(n) \leq Z(n) + \tau_{v(n)+1}.
\]
Using Lemma 4.4 and Borel-Cantelli lemma, when \( n \to \infty \), it is easy to see that
\[
\frac{\tau_{v(n)+1}}{\sqrt{n}} \to 0 \text{ a.s.}
\]
Thus the statements 1) and 2) follow from the inequality (1) and corresponding results for \( Z(n) \) (see [12] Theorem 11.5.2 pp.332 and Theorem 10.6.2 pp. 311).

Proof of statement 3). Consider
\[
L_n(x) := \sum_{k=1}^{\infty} \sum_{l=1}^{[\ln^2 n]} P(R(n) = x, T_k = n-l, \tau_{k+1} \geq l)
\]
\[
= \sum_{k=1}^{\infty} \sum_{l=1}^{[\ln^2 n]} \sum_{s=0}^{l} P(Z_k = x-s, R(n) - Z_k = s, T_k = n-l, \tau_{k+1} \geq l).
\]
Note that if \( T_k = n-l \), then the random variable \( Z_k \) uniquely defined by the values of Markov chain \( Y(m) \) when \( m < n-l \), but the random variables \( R(n) - Z_k \) and \( \tau_{k+1} \) depend on the values of the chain \( Y(m) \) when \( m > n-l \). Therefore, by the inclusion
\[
\{\omega : T_k = n-l\} \subseteq \{\omega : Y(n-l) = y_0\}
\]
the following equality holds
\[
P(Z_k = x-s, R(n) - Z_k = s, \tau_{k+1} \geq l \mid T_k = n-l)
= P(Z_k = x-s \mid T_k = n-l)P(R(n) - Z_k = s, \tau_{k+1} \geq l \mid T_k = n-l).
\]

7
Applying (2) and (3) we obtain

\[ L_n(x) = \sum_{k=1}^{\infty} \sum_{l=1}^{[\ln^2 n]} \sum_{s=0}^{l} P(Z_k = x-s, R(n) - Z_k = s, T_k = n-l, \tau_{k+1} \geq l) \]

\[ = \sum_{k=1}^{\infty} \sum_{l=1}^{[\ln^2 n]} \sum_{s=0}^{l} P(Z_k = x-s | T_k = n-l) P(R(n) - Z_k = s, \tau_{k+1} \geq l | T_k = n-l) P(T_k = n-l) \]

\[ = \sum_{k=1}^{\infty} \sum_{l=1}^{[\ln^2 n]} \sum_{s=0}^{l} P(Z_k = x-s, T_k = n-l) P(R(n) - Z_k = s, \tau_{k+1} \geq l | T_k = n-l). \]  \hspace{1cm} (4)

Note that

\[ P(R(n) - Z_k = s, \tau_{k+1} \geq l | T_k = n-l) = P(R(l) = s, \tau \geq l | Y(0) = y_0). \]

Thus, from equality (4) it is follows that

\[ L_n(x) = \sum_{l=1}^{[\ln^2 n]} \sum_{s=0}^{l} P(R(l) = s, \tau \geq l | Y(0) = y_0) \sum_{k=1}^{\infty} P(Z_k = x-s, T_k = n-l). \]  \hspace{1cm} (5)

Since \( P(T_0 = n-l) = 0 \) when \( 0 \leq l \leq [\ln^2 n] \), then from Theorem 2.2 \[9\] it is follows, when \( n \to \infty \), that

\[ \sum_{k=1}^{\infty} P(Z_k = x-s, T_k = n-l) = \sum_{k=0}^{\infty} P(Z_k = x-s, T_k = n-l) \]

\[ = \frac{1}{\sqrt{n}} \psi_1 \left( \lambda \left( \frac{\alpha}{\theta} \right), \mu \left( \frac{\alpha}{\theta} \right) \right) C_H(\theta, \tilde{\alpha}) e^{-nD(\theta, \tilde{\alpha})} (1 + o(1)), \]

where

\[ \tilde{\alpha} := \frac{x-s}{n}, \quad \theta := \frac{n-l}{n}. \]

Since the function \( \psi_1(\lambda(\alpha), \mu(\alpha)) \) is continuous in a neighborhood of the point \( \alpha = a \), and the function \( C_H(\theta, \alpha) \) is continuous in a neighborhood of the point \( (\theta, \alpha) = (1, a) \), then, for sufficiently small \( \Delta \) and \( n \to \infty \) the following equality holds true

\[ \sum_{k=1}^{\infty} P(Z_k = x-s, T_k = n-l) = \frac{1}{\sqrt{n}} \psi_1(\lambda(\alpha_0), \mu(\alpha_0)) C_H(1, \alpha_0) e^{-nD(\theta, \tilde{\alpha})} (1 + o(1)). \]  \hspace{1cm} (6)

Applying Lemma 4.6 (see Section 4) and considering that \( 0 \leq s \leq l \leq [\ln^2 n] \) and \( |\alpha_0 - a| < \Delta \), from the equality (6) we obtain

\[ \sum_{k=1}^{\infty} P(Z_k = x-s, T_k = n-l) \]

\[ = \frac{1}{\sqrt{n}} \psi_1(\lambda(\alpha_0), \mu(\alpha_0)) C_H(1, \alpha_0) e^{-nD(\tilde{\theta} + \tilde{\alpha}) + (\lambda(\tilde{\theta} + \tilde{\alpha}) + \varepsilon_0)} (1 + o(1)). \]  \hspace{1cm} (7)
Show that
\[
\lim_{n \to \infty} \sum_{l=1}^{\lfloor \ln^2 n \rfloor} \sum_{s=0}^{l} P(R(l) = s, \tau \geq l \mid Y(0) = y_0) e^{(\lambda(n \frac{s}{n}) + \varepsilon_n)l + (\mu(n \frac{s}{n}) + \theta_n)s} = \sum_{l=1}^{\infty} e^{\lambda(\alpha_0)l} E(e^{(\mu(\alpha_0)R(l))} \mid \tau \geq l \mid Y(0) = y_0) =: I(\alpha_0). \tag{8}
\]

Due to the fact that
\[
\lim_{n \to \infty} e^{(\lambda(n \frac{s}{n}) + \varepsilon_n)l + (\mu(n \frac{s}{n}) + \theta_n)s} = e^{\lambda(\alpha_0)l + \mu(\alpha_0)s}
\]
the equality \[8\] will be proved if we can show that the series
\[
\sum_{l=1}^{\infty} \sum_{s=0}^{l} P(R(l) = s, \tau \geq l \mid Y(0) = y_0) e^{(\lambda(n \frac{s}{n}) + \varepsilon_n)l + (\mu(n \frac{s}{n}) + \theta_n)s} \tag{9}
\]
converges.

Note that if \( \tau \geq l \), then \( \zeta \geq R(l) \), thus
\[
\sum_{l=1}^{\infty} \sum_{s=0}^{l} P(R(l) = s, \tau \geq l \mid Y(0) = y_0) e^{(\lambda(n \frac{s}{n}) + \varepsilon_n)l + (\mu(n \frac{s}{n}) + \theta_n)s} = \sum_{l=1}^{\infty} e^{(\lambda(n \frac{s}{n}) + \varepsilon_n)l} E(e^{(\mu(n \frac{s}{n}) + \theta_n)R(l)} \mid \tau \geq l \mid Y(0) = y_0) \tag{10}
\]
\[
\leq \sum_{l=1}^{\infty} e^{(\lambda(n \frac{s}{n}) + \varepsilon_n)l} E(e^{(\mu(n \frac{s}{n}) + \theta_n)\zeta} \mid \tau \geq l \mid Y(0) = y_0).
\]

Due to the Cramer’s condition \([C_0]\) for sufficiently small \( \Delta > 0 \) and sufficiently large \( n \)
\[
E(e^{2(\mu(n \frac{s}{n}) + \theta_n)\zeta} \mid Y(0) = y_0) < \infty
\]
and there exists \( \rho > 0 \) such that
\[
E(e^{2(\lambda(n \frac{s}{n}) + \varepsilon_n + \rho)\tau} \mid Y(0) = y_0) < \infty.
\]

Therefore, using Cauchy-Bunyakovsky and Chebyshev inequalities, we obtain
\[
E(e^{(\mu(n \frac{s}{n}) + \theta_n)\zeta}, \tau \geq l \mid Y(0) = y_0)
\]
\[
\leq (Ee^{2(\mu(n \frac{s}{n}) + \theta_n)\zeta} \mid Y(0) = y_0)^{\frac{1}{2}} (P(\tau \geq l \mid Y(0) = y_0))^{\frac{1}{2}}
\]
\[
\leq (Ee^{2(\mu(n \frac{s}{n}) + \theta_n)\zeta} \mid Y(0) = y_0)^{\frac{1}{2}} (Ee^{2(\lambda(n \frac{s}{n}) + \varepsilon_n + \rho)\tau} \mid Y(0) = y_0)^{\frac{1}{2}} e^{-(\lambda(n \frac{s}{n}) + \varepsilon_n + \rho)l}
\]
\[
=: K e^{-(\lambda(n \frac{s}{n}) + \varepsilon_n + \rho)l}. \tag{11}
\]

Using \[10\], \[11\], we obtain
\[
\sum_{l=1}^{\infty} \sum_{s=0}^{l} P(R(l) = s, \tau \geq l \mid Y(0) = y_0) e^{(\lambda(n \frac{s}{n}) + \varepsilon_n)l + (\mu(n \frac{s}{n}) + \theta_n)s} \leq K \sum_{l=1}^{\infty} e^{-\rho l} < \infty.
\]

9
Thus, the series (9) converges, hence the equality (8) holds true.

From (5), (7) and (8) it is follows that
\[
L_n(x) = 1 \sqrt{n} \psi_1(\lambda(\alpha_0), \mu(\alpha_0))C_H(1, \alpha_0) I(\alpha_0) e^{-nD(\frac{x}{n})}(1 + o(1)).
\] (12)

It is obvious that the following inequality holds
\[
L_n(x) \leq P(R(n) = x) \leq L_n(x) + P(R(n) = x, \tau_{\nu(n)+1} \geq \ln^2 n).
\] (13)

From Lemma 4.5 (see Section 4) it is follows that
\[
P(R(n) = x, \tau_{\nu(n)+1} \geq \ln^2 n) \leq \tilde{C} e^{-nD(\frac{x}{n}) - \gamma \ln^2 n}.
\] (14)

From (12), (13) and (14) it is follows that
\[
P(R(n) = x) = (1 + o(1))L_n(x) = 1 \sqrt{n} \psi_1(\lambda(\alpha_0), \mu(\alpha_0))C_H(1, \alpha_0) I(\alpha_0) e^{-nD(\frac{x}{n})}(1 + o(1)).
\] (15)

Proof of statement 4). Due to the fact that \((\lambda(a), \mu(a)) = (0, 0)\) and the function \(I(\alpha)\) is continuous in a neighborhood of the point \(\alpha = a\) we will have
\[
I(a) = \sum_{l=1}^{\infty} e^{\lambda(a)l} E(e^{\mu(a)R(l)}, \tau \geq l \mid Y(0) = y_0)
\]
\[
= \sum_{l=1}^{\infty} P(\tau \geq l \mid Y(0) = y_0) = E(\tau \mid Y(0) = y_0).
\] (16)

From Lemma 2.1 (see [9]) it is follows that
\[
C_H(1, a) = \frac{1}{E(\tau \mid Y(0) = y_0)\sigma \sqrt{2\pi}}.
\]

Hence, from (15) and (16) we obtain
\[
P(R(n) = x) = \frac{1}{\sigma \sqrt{2\pi n}} e^{-nD(\frac{x}{n})}(1 + o(1)).
\]

Proof of statement 5). From Consequence 3.2 (see [10]) it is follows that the sequence of random variables \(\tilde{Z}(n) := \frac{Z(n) - a}{\kappa}\) satisfies LDP with normalized function \(\varphi(n) = \frac{\kappa^2}{n}\) and rate function \(I(y)\).

Using Lemma 4.4, for any \(\varepsilon > 0\) we will have
\[
\lim_{n \to \infty} \frac{n}{\kappa^2} \ln P(|\tilde{R}(n) - \tilde{Z}(n)| > \varepsilon) \leq \lim_{n \to \infty} \frac{n}{\kappa^2} \ln P(\tau_{\nu(n)+1} > \kappa \varepsilon)
\]
\[
\leq \lim_{n \to \infty} \frac{n}{\kappa^2} \ln e^{-\frac{4}{\kappa}} = -\lim_{n \to \infty} \frac{n \rho \varepsilon}{4\kappa} = -\infty.
\]

Therefore from Theorem 4.2.13 (see [11]) we obtain that the sequences \(\tilde{R}(n)\) and \(\tilde{Z}(n)\) satisfy the same LDP. \(\square\)
4 Auxiliary Results

Lemma 4.1. For any $k, n \in \mathbb{N}$ the following inequality holds

$$P(\tau_k \geq n) \leq Ce^{-\rho n}, \quad (17)$$

where

$$C := \frac{1}{1 - (1 - \delta_1)^{v-1}\delta_2}, \quad \rho := \frac{1}{v} \ln C. \quad (18)$$

Proof. Due to the fact that the process $Y(n)$ is markovian it is sufficient to prove Lemma 4.1 for $\tau_1$ with an arbitrary initial condition. We fix some initial state $Y(0) = (y_1, y_2)$. Since $C > 1$, $Ce^{-\rho n} = C^{1-\frac{\rho}{v}}$, then for $n \leq v$ the right-hand side of inequality (17) is not less than 1, therefore (17) obviously holds true.

We prove now the inequality (17) when $n \geq v + 1$. Denote $k := \left[\frac{n}{v}\right]$ and for $l = 0, 1, \ldots, k - 1$ we consider the events

$$A_l := \{\omega : r_{vl+1}(n) = 0, \ldots, r_{vl+v-1}(n) = 0, r_{vl+v}(n) = 1\}.$$

Denote $B$ the complement to the set $\bigcup_{l=0}^{k-1} A_l$:

$$B := \bigcap_{l=0}^{k-1} \overline{A_l}.$$

Since it is obvious that

$$\{\tau_1 < n\} \supset \bigcup_{l=0}^{k-1} A_l,$$

then we obtain

$$\{\tau_1 \geq n\} \subseteq B.$$

Hence we have

$$P_n := P(\tau_1 \geq n \mid Y(0) = (y_1, y_2))$$

$$\leq P(B \mid Y(0) = (y_1, y_2)) = P\left(\bigcap_{l=0}^{k-1} \overline{A_l} \mid Y(0) = (y_1, y_2)\right)$$

$$= P\left(\overline{A_0} \mid Y(0) = (y_1, y_2)\right) \prod_{l=1}^{k-1} P\left(\overline{A_l} \mid \bigcap_{i=0}^{l-1} \overline{A_i}, Y(0) = (y_1, y_2)\right).$$

Since by condition [A] each cofactor in the right-hand side has the following upper bound

$$1 - (1 - \delta_1)^{v-1}\delta_2 = \frac{1}{C},$$

then we have

$$P_n \leq \left(\frac{1}{C}\right)^k \leq \left(\frac{1}{C}\right)^{\frac{\rho}{v} - 1} = Ce^{-\rho n}.$$

$\square$
Lemma 4.2. For any $u \in \mathbb{Z}^2$ the equality $f(2\pi u) = 1$ holds true, and for any $u \in \mathbb{R}^2 \setminus \mathbb{Z}^2$ the inequality $|f(2\pi u)| < 1$ holds, where

$$f(u) := E e^{i(u_1 \tau + u_2 \zeta)}$$

is characteristic function for $\xi$.

**Proof.** Since $\tau$ and $\zeta$ are integers numbers, then, it is obvious, that for $u \in \mathbb{Z}^2$ the equality $f(2\pi u) = 1$ holds true. We show that for any $u \in \mathbb{R}^2 \setminus \mathbb{Z}^2$ the inequality $|f(2\pi u)| < 1$ holds true.

Suppose that it is not true, then there exists $(u_1, u_2) \in \mathbb{R}^2 \setminus \mathbb{Z}^2$ such that $|E e^{2\pi i(u_1 \tau + u_2 \zeta)}| = 1$. Note that equality $|E e^{2\pi i(u_1 \tau + u_2 \zeta)}| = 1$ is equivalent to the fact that there exists $k \in \mathbb{R}$ such that

$$2\pi(u_1 \tau + u_2 \zeta) = k \mod (2\pi) \; \text{a.s.}$$

From Condition [A] it is follows that

$$P(\zeta = 1, \tau = s + 1) \geq (1 - \delta_1)^s \delta_2 > 0,$$

$$P(\zeta = 2, \tau = s + 1) \geq \delta_2 (1 - \delta_1)^{s-1} \delta_2 > 0,$$

$$P(\zeta = 1, \tau = s + 2) \geq (1 - \delta_1)^s \delta_2 > 0.$$

Thus, if or hypothesis is true, then should exist $k_1 \in \mathbb{Z}$, $k_2 \in \mathbb{Z}$, $k_3 \in \mathbb{Z}$ such that the following inequalities holds true

$$\begin{cases} 2\pi(u_1(s + 1) + u_2) = k + 2\pi k_1 \\ 2\pi(u_1(s + 1) + 2u_2) = k + 2\pi k_2 \\ 2\pi(u_1(s + 2) + u_2) = k + 2\pi k_3. \end{cases}$$

Divide each equality by $2\pi$. Subtracting from the 2nd equality the 1st we obtain $u_2 = k_2 - k_1 \in \mathbb{Z}$; substracting from the 3rd equality the 1st, we obtain $u_1 = k_3 - k_1 \in \mathbb{Z}$. The resulting contradiction completes the proof. $\square$

For the vector $(\tilde{\lambda}, \tilde{\mu})$ such that $\psi(\tilde{\lambda}, \tilde{\mu}) = 1$, we consider the sequence of random vectors $(\hat{\tau}_k, \hat{\zeta}_k)$, $k \in \mathbb{N}$, whose joint distribution is given as follows

$$P((\hat{\tau}_1, \hat{\zeta}_1) \in A_1, \ldots, (\hat{\tau}_k, \hat{\zeta}_k) \in A_k, \ldots) := \frac{1}{\psi_1(\tilde{\lambda}, \tilde{\mu})} \prod_{k=1}^{\infty} E(e^{\tilde{\lambda}\tau_k + \tilde{\mu}\zeta_k}; (\tau_k, \zeta_k) \in A_k). \quad (18)$$

Let $\hat{\tau}_0 := 0$, $\hat{\zeta}_0 := 0$, $\hat{\nu}(0) := 0$. Denote

$$\hat{T}_k := \sum_{l=0}^{k} \hat{\tau}_l, \quad \hat{\nu}(n) := \max\{k \geq 0 : \hat{T}_k < n\}.$$

Lemma 4.3. Let $\gamma + \tilde{\lambda} + \tilde{\mu} < \rho$, then there exists the constant $\hat{C} > 0$, such that for any $n \in \mathbb{N}$ the following inequality holds true

$$E e^{\gamma \hat{\nu}(n) + 1} < \hat{C} n.$$
Proof. Since random variables \( \hat{\tau}_{k+1} \hat{T}_k \) are independent, then

\[
E_1 := E(e^{\hat{\tau}_{\nu(n)+1}}) = E(e^{\hat{\gamma}_1; \hat{\tau}_1 \geq n}) + \sum_{k=1}^{\infty} E(e^{\hat{\gamma}_{k+1}; \hat{T}_k < n \leq \hat{T}_{k+1}}) \\
\leq \frac{1}{\psi_1(\hat{\lambda}, \hat{\mu})}E e^{\gamma_{\tau_1}} + E e^{\gamma + \hat{\lambda} \tau + \hat{\mu} \zeta} \sum_{k=1}^{\infty} P(\hat{T}_k < n).
\]

Due to the fact that by arithmeticity the inequality \( \hat{T}_k \geq n \) a.s. when \( k \geq n \). Therefore, using Lemma 4.1 and inequality \( \tau_k \geq \zeta_k \) a.s., we obtain

\[
E_1 \leq \frac{1}{\psi_1(\hat{\lambda}, \hat{\mu})}E e^{\gamma_{\tau_1}} + E e^{\gamma + \hat{\lambda} \tau + \hat{\mu} \zeta} \sum_{k=1}^{\infty} P(\hat{T}_k < n) \\
\leq \frac{C e^{(\gamma - \rho)}}{\psi_1(\hat{\lambda}, \hat{\mu})} 1 - e^{(\gamma - \rho)} + \frac{C e^{(\gamma + \hat{\lambda} + \hat{\mu} - \rho)}}{1 - e^{(\gamma + \hat{\lambda} + \hat{\mu} - \rho)}} n.
\]

\[
\square
\]

Lemma 4.4. Let \( \lim_{n \to \infty} \kappa_n = \infty \). Then for sufficiently large \( n \in \mathbb{N} \) the following holds true

\[
P(\tau_{\nu(n)+1} \geq \kappa_n) \leq e^{-\frac{\rho}{4} \kappa_n}.
\]

Proof. Since random variables \( \tau_{k+1} \) and \( T_k \) are independent, then

\[
P(\tau_{\nu(n)+1} \geq \kappa_n) \leq P(\tau_1 \geq \kappa_n) + \sum_{k=1}^{\infty} P(\tau_{k+1} \geq \kappa_n, T_k < n \leq T_{k+1}) \\
\leq P(\tau_1 \geq \kappa_n) + P(\tau \geq \kappa_n) \sum_{k=1}^{\infty} P(T_k < n).
\]

Due to the arithmeticity the inequality \( T_k \geq n \) holds true almost surely when \( k \geq n \). By Lemma 4.1 and Chebyshev inequality for sufficiently large \( n \) we obtain

\[
P(\tau_{\nu(n)+1} \geq \kappa_n) \leq \frac{E e^{\frac{\rho}{4} \tau_1}}{e^{\frac{\rho}{4} \kappa_n}} + n \frac{E e^{\frac{\rho}{4} \tau}}{e^{\frac{\rho}{4} \kappa_n}} \leq e^{-\frac{\rho}{4} \kappa_n}.
\]

\[
\square
\]

Lemma 4.5. There exist constants \( \Delta > 0, \tilde{C} > 0, \tilde{\gamma} > 0 \) such that for \( x \in 0 \cup \mathbb{N}, \alpha := \frac{x}{n}, n \geq 1, |\alpha - a| \leq \Delta \) the following inequality holds true

\[
P(R(n) = x, \tau_{\nu(n)+1} \geq \ln^2 n) \leq \tilde{C} e^{-n D(\alpha) - \tilde{\gamma} \ln^2 n}.
\]
Proof. By Theorem 2.1, [9], it is follows that for sufficiently small $\Delta$ there exists $\lambda(\alpha)$ and $\mu(\alpha)$ such that $(\lambda(\alpha), \mu(\alpha)) \in A^{\leq 0}, A(\lambda(\alpha), \mu(\alpha)) = 0$ and

$$D(\alpha) = \lambda(\alpha) + \alpha \mu(\alpha).$$

Denote

$$B_n := \{\omega : \tau_{\nu(n)+1} \geq \ln^2 n\}.$$

We have

$$\mathbf{P}(R(n) = x, \tau_{\nu(n)+1} \geq \ln^2 n) = \mathbf{P}(R(n) = x, B_n, \nu(n) = 0) + \mathbf{P}(R(n) = x, B_n, \nu(n) \geq 1) := P_0 + P_1.$$

From Lemma [4.1] it is follows that

$$P_0 \leq \mathbf{P}(\tau_1 \geq n) \leq C e^{-\rho n}.$$ 

Since the function $D(\alpha)$ is continuous in a neighborhood of the point $\alpha = a$ and $D(a) = 0$, then for sufficiently small $\Delta > 0$ and $\alpha : |\alpha - a| \leq \Delta$ the following inequality holds

$$P_0 \leq C e^{-\rho n} \leq C e^{-D(\alpha)n - c\ln^2 n}. \quad (19)$$

Denote $Z_k := \sum_{l=1}^{k} \zeta_l$.

Estimate from above $P_1$. For $\lambda = \lambda(\alpha), \mu = \mu(\alpha)$ we obtain

$$P_1 = \mathbf{P}(R(n) = x, B_n, \nu(n) \geq 1) = \sum_{k=1}^{\infty} \mathbf{P}(R(n) = x, B_n, \nu(n) = k)$$

$$= \sum_{k=1}^{\infty} \mathbf{P}(R(n) = x, \tau_{k+1} \geq \ln^2 n, T_k < n \leq T_{k+1})$$

$$= e^{-D(\alpha)n} \sum_{k=1}^{\infty} \mathbf{E}(e^{-\lambda(T_{k+1}-n) - \mu(Z_{k+1}-x) + \lambda T_{k+1} + \mu Z_{k+1}}; R(n) = x, \tau_{k+1} \geq \ln^2 n, T_k < n \leq T_{k+1}). \quad (20)$$

Note that if $T_{k+1} \geq n$ and $R(n) = x$, then $x + \zeta_{k+1} \geq Z_{k+1}$, therefore from (20) it is follows that

$$P_1 \leq e^{-D(\alpha)n} \sum_{k=1}^{\infty} \mathbf{E}(e^{\lambda|\tau_{k+1}| + \mu|\zeta_{k+1}| + \lambda T_{k+1} + \mu Z_{k+1}}; R(n) = x, \tau_{k+1} \geq \ln^2 n, T_k < n \leq T_{k+1})$$

$$\leq e^{-D(\alpha)n} \sum_{k=1}^{\infty} \mathbf{E}(e^{\lambda|\hat{\tau}_{k+1}| + \mu|\hat{\zeta}_{k+1}|}; \hat{\tau}_{k+1} \geq \ln^2 n, \hat{T}_k < n \leq \hat{T}_{k+1}), \quad (21)$$

where the joint distribution of random variables $(\hat{\tau}_k, \hat{\zeta}_k), k \in \mathbb{N}$ has the form (compare with [18])

$$\mathbf{P}((\hat{\tau}_1, \hat{\zeta}_1) \in A_1, \ldots, (\hat{\tau}_k, \hat{\zeta}_k) \in A_k, \ldots) := \frac{1}{\psi_1(\lambda(\alpha), \mu(\alpha))} \prod_{k=1}^{\infty} \mathbf{E}(e^{\lambda(\alpha)\tau_k + \mu(\alpha)\zeta_k}; (\tau_k, \zeta_k) \in A_k), \quad (22)$$

14
Making the summation in the inequality (21) we obtain
\[ P_1 \leq e^{-D(n)} \mathbb{E}(e^{\lambda |\tau_{\nu(n)} + 1| + \mu|\hat{\zeta}_{\nu(n)} + 1|}; \hat{\tau}_{\nu(n)} + 1 \geq \ln^2 n). \]

Since \( \tau_k \geq \zeta_k \) a.s., then from (22) it is follows that \( \hat{\tau}_k \geq \zeta_k \) a.s. Therefore, using Cauchy-Schwarz-Bunjakowski inequality we obtain
\[ P_1 \leq e^{-D(n)n} \left( \mathbb{E}e^{2(\lambda + |\mu|)\hat{\tau}_{\nu(n)} + 1} \right) \frac{1}{2} \left( \mathbb{P}(\hat{\tau}_{\nu(n)} + 1 \geq \ln^2 n) \right)^{\frac{1}{2}}. \]  

(23)

From Consequence 2.1, \( \mathbb{E}(\mathbb{E}) \), it is follows that \( (\lambda(a), \mu(a)) = (0, 0) \), therefore due to the continuity in the point \( \alpha = 0 \) of the function \( D(\alpha) \) for sufficiently small \( \Delta > 0 \) the following inequality \( 3(|\lambda(\alpha)| + |\mu(\alpha)|) < \rho \) holds true.

Thus, from Lemma 4.3 it is follows that there exists a constant \( C_1 > 0 \) such that
\[ \mathbb{E}e^{2(\lambda + |\mu|)\hat{\tau}_{\nu(n)} + 1} \leq C_1 n. \]

Using Lemma 4.3 and Chebyshev inequality for some \( C_2 > 0, \gamma > 0 \) we obtain
\[ \mathbb{P}(\hat{\tau}_{\nu(n)} + 1 \geq \ln^2 n) < C_2 e^{-\gamma \ln^2 n}. \]

From inequalities (19), (23) it is follows that for sufficiently large \( n \)
\[ \mathbb{P}(R(n) = x, \tau_{\nu(n)} + 1 \geq \ln^2 n) \leq C e^{-D(n)\ln^2 n} + C_2 e^{-\gamma \ln^2 n} \leq C e^{-D(n)\ln^2 n} + \sqrt{C_1 C_2} e^{-D(n)\frac{\gamma}{2} \ln^2 n}. \]

\( \square \)

**Lemma 4.6.** There exists \( \Delta > 0 \) such that if \( \lim_{n \to \infty} \frac{a}{n} = \alpha_0, \ |a - \alpha_0| \leq \Delta, \) then the following holds
\[ -nD\left(1 - \frac{m}{n}, \frac{x}{n} - \frac{y}{n}\right) = -nD\left(1, \frac{x}{n}\right) + \left(\lambda\left(\frac{x}{n}\right) + \epsilon_n\right)m + \left(\mu\left(\frac{x}{n}\right) + \theta_n\right)y, \]
where functions \( \epsilon_n = \epsilon_n(m, y), \theta_n = \theta_n(m, y) \) satisfy
\[ \beta_n := \max_{(m, y) \in B_n} \{|\epsilon_n(m, y)| + |\theta_n(m, y)|\} = o(1) \text{ when } n \to \infty, \]
where \( B_n := \{(m, y) \in \mathbb{Z}^2 : 1 \leq m \leq [n\kappa_n], 1 \leq |y| \leq [n\kappa_n]\}, \kappa_n = o(1) \text{ when } n \to \infty. \)

**Proof.** For sufficiently small \( \Delta \) if \( |a - \alpha_0| \leq \Delta, \) then the function \( D(\alpha) \) is analytic in some neighborhood of the point \( \alpha_0. \) Therefore, due to the fact that \( D(\theta, \alpha) = \theta D(\frac{\alpha}{\theta}) \) the function \( D(\theta, \alpha) \) is analytic in some neighborhood of the point \( (1, \alpha_0). \) It means that for sufficiently large \( n \) the function can be represented as a Taylor series in a neighborhood of the point \( (1, \frac{a}{n}) \). Therefore we have
\[ -nD\left(1 - \frac{m}{n}, \frac{x}{n} - \frac{y}{n}\right) = -nD\left(1, \frac{x}{n}\right) + \lambda\left(\frac{x}{n}\right)m + \mu\left(\frac{x}{n}\right)y - nM_1, \]
(25)
where $M_1$ is the remainder term in Lagrange’s form

Denote

$$D''_{(1,1)}(x,y) := \frac{\partial^2}{\partial^2 x} D(x,y), \quad D''_{(1,2)}(x,y) := \frac{\partial^2}{\partial x \partial y} D(x,y), \quad D''_{(2,2)}(x,y) := \frac{\partial^2}{\partial^2 y} D(x,y).$$

Then there exist $u \in [1 - \frac{m}{n}, 1], \, u \in [\frac{x}{n} - \frac{m}{n}, \frac{x}{n}]$ such that

$$|M_1| \leq 2 \max(|D''_{(1,1)}(u,v)|, |D''_{(1,2)}(u,v)|, |D''_{(2,2)}(u,v)|) \left(\frac{m^2}{n^2} + \frac{y^2}{n^2}\right) := K\left(\frac{m^2}{n^2} + \frac{y^2}{n^2}\right).$$

Therefore, from (25) it is follows that there exist $\varepsilon_n(m,y), \theta_n(m,y)$ such that

$$|\varepsilon_n(m,y)| \leq \frac{m}{n}, \quad |\theta_n(m,y)| \leq \frac{y}{n}$$

and the equality (24) holds.

$\square$
