Large $N$ behaviour of the two-dimensional
Yang–Mills partition function

Thibaut Lemoine

November 19, 2019

Abstract

We compute the large $N$ limit of the partition function of the Euclidean Yang–Mills measure with structure group $SU(N)$ or $U(N)$ on all closed compact surfaces, orientable or not, excepted for the sphere and the projective plane. This limit is finite as opposed to the case of the sphere (it actually produces a free energy in the scale $\frac{1}{N^2}$, as discussed in [DN17, FMS11, LM15]) and presumably the projective plane. Some techniques used in the present work make rigorous the arguments used by Gross–Taylor [GT93] in the setting of QCD. We expect that the results we present might give an insight towards the master field on these surfaces, completing the works of Lévy [Lév17], Dahlqvist–Norris [DN17] and Hall [Hall18].

1 Introduction

In his seminal paper [tH74], ’t Hooft discovered that $SU(N)$ and $U(N)$ two-dimensional gauge theories become easier to understand in the limit $N \to \infty$, thanks to combinatorial simplifications. This led to a brand new field of interest in both physics and mathematics, described for instance by Gopakumar and Gross in [GG95] as the master field, a conjectural limiting object arising from gauge theory and matrix models. From a mathematical point of view, the framework of noncommutative probability, in particular free probability, is a natural
way to describe this master field. This object was described on the plane by Singer [Sin95] and then rigorously constructed in different ways by Xu [Xu97], Lévy [Lév17], as well as Anshelevich and Sengupta [AS12] as the deterministic limit of (random) observables distributed according to the Euclidean Yang–Mills measure. The latter was defined in [Lév03] and [Lév10] for any surface as the continuous limit of a lattice Yang–Mills measure; its normalisation constant, called the partition function, only depends on the topological nature of the underlying surface and the irreducible representations of the structure group. Constructing the master field on any reasonable\footnote{We will describe in the Section 1.1 what we consider to be ‘reasonable’ for a surface.} surface remains an open problem in general, although it has been done by Dahlqvist–Norris [DN17] for the sphere, and we think that a possible step towards this construction would be to study the large $N$ limit of Yang–Mills partition functions on such surfaces. This is exactly what this article is about. Let us mention that a step in another direction was done by Hall in [Hal18] using combinatorial properties of Yang–Mills measure on compact surfaces, in particular the associated Schwinger–Dyson equations, also known as Makeenko–Migdal equations.

### 1.1 Classification of compact surfaces

Throughout this article, a surface will denote a compact connected surface without boundary. Let us start by the standard theorem of classification of such surfaces, which can be found in [Mas91].

**Theorem 1.1.** Any surface is homeomorphic to either one of the following:

(i) The connected sum of $g$ 2-tori$^2$,

(ii) The connected sum of $g$ projective planes.

In the first case, the surface is said to be orientable and $g$ is called the genus of the surface. In the second case, the surface is said to be non-orientable, and we will also call $g$ its genus. The Euler characteristic of a surface of genus $g$ is equal to $2 - 2g$ when the surface is orientable and $2 - g$ when it is not.

### 1.2 The Yang–Mills partition function on a compact surface

Let $\lambda = (\lambda_1 \geq \ldots \geq \lambda_N) \in \mathbb{Z}^N$ be a non-increasing sequence of relative integers. We associate two real numbers to $\lambda$: the dimension

$$d_\lambda = \prod_{1 \leq i < j \leq N} \frac{\lambda_i - \lambda_j + j - i}{j - i} = \prod_{1 \leq i < j \leq N} \left(1 + \frac{\lambda_i - \lambda_j}{j - i}\right),$$

which is indeed a positive integer, and the quadratic Casimir number

$$c_2(\lambda) = \frac{1}{N} \left( \sum_{i=1}^{N} \lambda_i^2 + \sum_{1 \leq i < j \leq N} (\lambda_i - \lambda_j) \right).$$

These definitions are dictated by the representation theory of the unitary group $U(N)$: the $N$-tuple $\lambda$, which we will also call a highest weight in this paper, labels (up to isomorphism) an irreducible representation of $U(N)$ with dimension $d_\lambda$, and on which the Casimir operator of $U(N)$, that is, the Laplacian, acts by the scalar $-c_2(\lambda)$. We will use the notation

$$\hat{U}(N) = \{ (\lambda_1, \ldots, \lambda_N) \in \mathbb{Z}^N : \lambda_1 \geq \ldots \geq \lambda_N \}.$$
Let us fix two integers $N \geq 1$, $g \geq 0$ and a real number $T \in [0, +\infty)$. The partition function of the Yang–Mills theory on an orientable compact surface of genus $g$ and area $T$ with structure group $U(N)$ is defined\(^3\) as

$$Z_N(g, T) = \sum_{\lambda \in \hat{U}(N)} e^{-\frac{T}{2}c_2(\lambda)} \lambda^{2-2g}.$$ (3)

In order to define the partition function in the non-orientable setting, one needs to introduce the so-called Frobenius–Schur indicator.

**Definition 1.2.** Let $(\rho, V)$ be a complex finite-dimensional representation of a compact group $G$, with character $\chi$. Its Frobenius–Schur indicator $\iota_\chi$ is defined by

$$\iota_\chi = \int_G \chi(g^2) dg.$$ If $G = U(N)$ or $G = SU(N)$ and $\lambda$ is a highest weight of $G$, then $\iota_\lambda$ is defined as $\iota_\chi$ where $\chi$ is the character of an irreducible representation of highest weight $\lambda$.

The partition function on a non-orientable compact surface of area $T$ homeomorphic to the connected sum of $g$ projective planes is then defined\(^4\) by

$$Z_N^-(g, T) = \sum_{\lambda \in \hat{SU}(N)} e^{-\frac{T}{2}c_2(\lambda)} \lambda^{2-2g} (\iota_\lambda)^g.$$ (4)

These partition functions admit a special unitary variant, which differs from them in two ways: the summation is restricted to the $N$-tuples $\lambda = (\lambda_1 \geq \ldots \geq \lambda_{N-1} \geq \lambda_N = 0)$ of which the last element is 0, and the Casimir number is replaced by its special unitary version

$$c'_2(\lambda) = \frac{1}{N} \left( \sum_{i=1}^N \lambda_i^2 - \frac{1}{N} \left( \sum_{i=1}^N \lambda_i \right)^2 + \sum_{1 \leq i < j \leq N} (\lambda_i - \lambda_j) \right).$$ (5)

It is worth emphasizing that $c'_2(\lambda)$ is a non-negative real number. Indeed, an application of the Cauchy–Schwarz inequality shows that the first sum is larger than the absolute value of the second, and the third one is non-negative by definition of $\lambda$. We introduce

$$\hat{SU}(N) = \{ (\lambda_1, \ldots, \lambda_N) \in \mathbb{Z}^N : \lambda_1 \geq \ldots \geq \lambda_N = 0 \},$$

which is in bijection with the irreducible representations of $SU(N)$, and define

$$Z_N^+(g, T) = \sum_{\lambda \in \hat{SU}(N)} e^{-\frac{T}{2}c'_2(\lambda)} \lambda^{2-2g}.$$ (6)

$$Z_N'^-(g, T) = \sum_{\lambda \in \hat{SU}(N)} e^{-\frac{T}{2}c'_2(\lambda)} (\iota_\lambda)^g.$$ (7)

Let us notice that when $T = 0$, the summands in the cases of $U(N)$ and $SU(N)$ are the same, and only the set of summation changes. In this ‘zero-temperature’ (or ‘zero area’) situation, the partition function $Z_N^+(g, 0)$ was already studied by Witten [Wit91], and later by Zagier [Zag94] who called it Witten zeta function and denoted it by $\zeta_{SU(N)}(2g - 2)$. The denomination ‘zeta function’ comes from the remark that $Z_N^+(g, 0) = \zeta(2g - 2)$, where $\zeta$ is the Riemann zeta function.

\(^3\)Here, we take it as a definition; however, it follows from lattice gauge theory axioms and is derived for example in [FMS11, GT93, Wit91].

\(^4\)See [Wit91] for an explanation of the formula.
1.3 Statement of the results

The purpose of this paper is to establish the large $N$ limit of the partition functions defined in (3), (4), (6) and (7), depending on the orientability and the genus of the underlying surface. The case of the sphere has already been treated by Dahlqvist–Norris in [DN17], as they even constructed and characterised the master field. The two following theorems state the limit of orientable surfaces of genus 1 and higher, and non-orientable surfaces of genus 2 and higher. The next sections will then be devoted to the proofs of these theorems.

**Theorem 1.3** (Orientable limits). Let $\Sigma$ be an orientable surface of genus $g$.

(i) If $g \geq 2$, then, for all $T \in (0, +\infty)$, the following convergences hold:

$$
\lim_{N \to \infty} Z_N(g, T) = \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2} n^2} \quad \text{and} \quad \lim_{N \to \infty} Z'_N(g, T) = 1.
$$

Moreover,

$$
\lim_{N \to \infty} Z'_N(g, 0) = 1.
$$

(ii) If $g = 1$, then consider $T \in (0, +\infty)$ and set $q = e^{-\frac{T}{2}}$. The following convergences hold:

$$
\lim_{N \to \infty} Z_N(1, T) = \sum_{n \in \mathbb{Z}} q^{n^2} \prod_{m=1}^{\infty} \frac{1}{(1 - q^m)^2} \quad \text{and} \quad \lim_{N \to \infty} Z'_N(1, T) = \prod_{m=1}^{\infty} \frac{1}{1 - q^m}.
$$

**Theorem 1.4** (Non-orientable limits). Let $\Sigma$ be a non-orientable surface homeomorphic to the sum of $g$ projective planes.

(i) If $g \geq 3$, then, for all $T \in (0, +\infty)$, the following convergences hold:

$$
\lim_{N \to \infty} Z_N^- (g, T) = \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2} n^2} \quad \text{and} \quad \lim_{N \to \infty} Z'_N^- (g, T) = 1.
$$

Moreover,

$$
\lim_{N \to \infty} Z'_N^- (g, 0) = 1.
$$

(ii) If $g = 2$, then consider $T \in (0, +\infty)$ and set $q = e^{-\frac{T}{2}}$. The following convergences hold:

$$
\lim_{N \to \infty} Z_N^- (2, T) = \sum_{n \in \mathbb{Z}} q^{n^2} \prod_{m=1}^{\infty} \frac{1}{1 - q^{2m}} \quad \text{and} \quad \lim_{N \to \infty} Z'_N^- (2, T) = \prod_{m=1}^{\infty} \frac{1}{1 - q^{2m}}.
$$

Before proving these theorems, let us make a few remarks.

• The limit of the partition function in the unitary case for $g \geq 2$ is the common value of $Z_1(g, T)$ for all $g \geq 0$, and it is also a value of the Jacobi theta function. Indeed, recall that this function is defined by setting, for all complex numbers $z$ and $\tau$ with $\Im(\tau) > 0$,

$$
\vartheta(z; \tau) = \sum_{n \in \mathbb{Z}} e^{i\pi n^2 \tau + 2i\pi nz}.
$$

The irreducible representations of $U(1)$ are indexed by integers $n \in \mathbb{Z}$, and as $U(1)$ is abelian, they all have dimension 1. Moreover, the Casimir number $c_2(n)$ is simply equal to $n^2$, therefore the partition function $Z_1(g, T)$ can be written

$$
Z_1(g, T) = \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2} n^2},
$$

which is $\vartheta(0; iT/2\pi)$ by definition of the theta function.
• It could be said that the limiting value of the partition functions $Z_N'(g,T)$ is also the value $Z_1'(g,T)$, understood as the partition function associated with the trivial group SU(1), with a unique irreducible representation of dimension 1 and Casimir number 0.

• Numerical simulations suggest that for all $g \geq 2$ and all $T \geq 0$, the sequences $(Z_N(g,T))$ and $(Z_N'(g,T))$ might be non-increasing from $N = 2$. This would be an interesting fact, that we are not yet able to establish.

• Using the Jacobi triple product formula

$$\sum_{n \in \mathbb{Z}} q^{n^2} = \prod_{m=1}^{\infty} (1 - q^{2m})(1 + q^{2m-1})^2,$$

the limits of $Z_N(1,T)$ and $Z_N^{-}(2,T)$ can be rewritten as infinite products:

$$\lim_{N \to \infty} Z_N(1,T) = \prod_{m=1}^{\infty} \frac{(1 + q^m)(1 + q^{2m-1})^2}{1 - q^m}$$

$$\lim_{N \to \infty} Z_N^{-}(2,T) = \prod_{m=1}^{\infty} (1 + q^{2m-1})^2$$

It does not particularly enlightens the nature of the first limit but it simplifies the second one, and makes both of them easier to approximate numerically, because only one parameter tends to infinity.

We now turn to the proofs of Theorem 1.3, which is given in Section 2, and Theorem 1.4, which is given in Section 3.

2 Orientable surfaces

2.1 Orientable surfaces of genus $g \geq 2$

2.1.1 The special unitary case

We will start by proving Theorem 1.3.(i) in the special unitary case. Let us first reduce the problem to the case where $T = 0$ and $g = 2$.

**Lemma 2.1.** For all $g \geq 0$, all $T \geq 0$, and all $N \geq 1$, we have

$$1 \leq Z_N'(g,T) \leq Z_N'(2,0).$$

It follows from this lemma that the special unitary case of Theorem 1.3.(i) is implied by the assertion

$$\lim_{N \to \infty} Z_N'(2,0) = 1,$$

which we will prove in this section.

**Proof of Lemma 2.1.** The $N$-tuple $(0,\ldots,0)$ has dimension 1 and Casimir number 0. Thus, it contributes 1 to the partition function $Z_N'(g,T)$, which explains the first inequality. The second inequality is an immediate consequence of the fact that all Casimir numbers are non-negative, and that all dimensions are positive integers. \(\square\)

Our goal is now to prove (8). We will deduce it from the following fact about Witten zeta functions.
Proposition 2.2. For all real $s > 1$, one has

$$\sup_{N \geq 1} \zeta_{su(N)}(s) = \sup_{N \geq 1} \sum_{\lambda \in \text{SU}(N)} d^{-s}_\lambda < \infty.$$ 

More precisely,

$$\lim_{N \to \infty} \zeta_{su(N)}(s) = 1 \text{ and } \lim_{N \to \infty} \sum_{\lambda \in \text{SU}(N) \setminus \lambda \neq (0,...,0)} d^{-s}_\lambda = 0.$$

The proof of this proposition relies on three lemmas.

Lemma 2.3. For all $s > 1$ and all $N \geq 1$, one has

$$\sum_{\lambda \in \text{SU}(N)} d^{-s}_\lambda \leq \prod_{1 \leq i < j \leq N} \frac{m_i + \ldots + m_{j-1}}{j - i}, \quad (9)$$

Proof. Let us choose $s > 1$ and $N \geq 1$. In the left-hand side of (9), which is a sum over $\lambda_1 \geq \ldots \geq \lambda_N \geq 0$, let us make the change of variables

$$m_1 = \lambda_1 - \lambda_2 + 1, \ldots, m_{N-1} = \lambda_{N-1} - \lambda_N + 1.$$

The new variables $m_1, \ldots, m_{N-1}$ are now independent, and positive. Using (1), we find

$$d_\lambda = \prod_{1 \leq i < j \leq N} \frac{m_i + \ldots + m_{j-1}}{j - i}, \quad (10)$$

so that

$$\sum_{\lambda_1 \geq \ldots \geq \lambda_N = 0} d^{-s}_\lambda \leq \sum_{m_1, \ldots, m_{N-1} \geq 1} \prod_{1 \leq i < j \leq N} \frac{(j - i)^s}{(m_i + \ldots + m_{j-1})^s}$$

$$= \sum_{m_1, \ldots, m_{N-1} \geq 1} \prod_{k=1}^{N-1} \prod_{i=1}^{k} \frac{(k - i + 1)^s}{(m_i + \ldots + m_k)^s} \quad (k = j - 1)$$

Since $m_i + \ldots + m_{k-1} \geq k - i$, we obtain

$$\sum_{\lambda_1 \geq \ldots \geq \lambda_N = 0} d^{-s}_\lambda \leq \sum_{m_1, \ldots, m_{N-1} \geq 1} \prod_{k=1}^{N-1} \prod_{i=1}^{k} \frac{(k - i + 1)^s}{(m_k + k - i)^s}$$

$$= \sum_{m_1, \ldots, m_{N-1} \geq 1} \prod_{k=1}^{N-1} \frac{(k + m_k - 1)^{-s}}{k}$$

$$= \prod_{k=1}^{N-1} \sum_{n \geq k} \binom{n}{k}^{-s},$$

which is the announced upper bound. 

Lemma 2.4. For all real $s > 1$,

$$\sum_{k \geq 1} \sum_{n \geq k} \binom{n}{k}^{-s} < \infty.$$
Proof. We use the fact that for \( k \) between 2 and \( n - 2 \), the inequality \( \binom{n}{k} \geq \binom{n}{2} \) holds. Thus,

\[
\sum_{k \geq 1} \sum_{n > k} \binom{n}{k}^{-s} \leq 2^{-s} + \sum_{n=3}^{\infty} \left( \frac{2}{n^s} + \frac{n-3}{n^s(n-1)^s} \right)
\]

which is indeed finite for \( s > 1 \). \( \square \)

Lemma 2.5. Let \( \lambda \) be an element of \( \widehat{SU}(N) \). If \( \lambda = (0, \ldots, 0) \) then \( d_\lambda = 1 \), otherwise \( d_\lambda \geq N \).

Proof. Let us use again the variables \( m_1, \ldots, m_{N-1} \) introduced in the proof of Lemma 2.3. It is manifest on the expression (10) of \( d_\lambda \) that this dimension is increasing in each of the variables \( m_1, \ldots, m_r \). The case where each of these variables is equal to 1 is the case where \( \lambda = (0, \ldots, 0) \) and \( d_\lambda = 1 \). Any other irreducible representation has a dimension that is at least equal to the dimension of one of the representations

\( \lambda_1 = (1, 0, \ldots, 0), \lambda_2 = (1, 1, 0, \ldots, 0), \ldots, \lambda_{N-1} = (1, \ldots, 1, 0) \).

These representations, which are the exterior powers of the standard representation of \( SU(N) \), have dimensions

\( d_{\lambda_k} = \binom{N}{k} \geq N, k \in \{1, \ldots, N-1\} \).

Thus, \( d_\lambda \geq N \), as expected. \( \square \)

We can now prove Proposition 2.2.

Proof of Proposition 2.2. The bound obtained in Lemma 2.3 can be rewritten as

\[
\sum_{\lambda_1 \geq \cdots \geq \lambda_{N-1} = 0} d_{\lambda}^{-s} \leq \prod_{k=1}^{N-1} \left[ 1 + \sum_{n > k} \binom{n}{k}^{-s} \right] \leq \exp \sum_{k=1}^{\infty} \sum_{n > k} \binom{n}{k}^{-s}
\]

and this last bound, independent of \( N \), is finite by Lemma 2.4. This proves the first assertion.

For the second, let us introduce a real \( s' \in (1, s) \) and use Lemma 2.5. We find

\[
\sum_{\lambda \in \widehat{SU}(N)} d_{\lambda}^{-s} \leq N^{-(s-s')} \sum_{\lambda \in \widehat{SU}(N)} d_{\lambda}^{-s'},
\]

which tends to 0 as \( N \) tends to infinity. \( \square \)

We can finally turn to the proof of (8), and therefore of the special unitary variant of Theorem 1.3.(i).

Proof of Theorem 1.3.(i) in the special unitary case. On one hand, Lemma 2.1 states that

\( Z_N'(2, 0) \geq 1 \).

On the other hand,

\( Z_N'(2, 0) = \sum_{\lambda \in \widehat{SU}(N)} d_\lambda^2 = 1 + \sum_{\lambda \neq (0, \ldots, 0)} d_\lambda^2 \).

Using Lemma 2.5, we find

\[
Z_N'(2, 0) \leq 1 + N^{-\frac{1}{2}} \sum_{\lambda \neq (0, \ldots, 0)} d_\lambda^{-\frac{3}{2}} \leq 1 + N^{-\frac{1}{2}} \sup_{N \geq 1} \sum_{\lambda \in \widehat{SU}(N)} d_\lambda^{-\frac{3}{2}}.
\]
Thanks to Proposition 2.2, this implies
\[
\limsup_{N \to \infty} Z_N'(2,0) \leq 1
\]
and this concludes the proof of (8), hence of Theorem 1.3.(i) in the special unitary case. \(\square\)

### 2.1.2 The unitary case

We treat the unitary case of Theorem 1.3.(i) using our understanding of the special unitary case, and the bijection

\[
\Phi : \left\{ \widehat{SU(N)} \times \mathbb{Z} \rightarrow \widehat{U(N)} \right\} (\lambda,n) \mapsto \lambda + n = (\lambda_1 + n, \ldots, \lambda_N + n).
\]

We will keep throughout this section the notation \(\lambda\) for an element of \(\widehat{SU(N)}\), \(n\) for an element of \(\mathbb{Z}\) and \(\lambda + n\) for the corresponding element of \(\widehat{U(N)}\).

The first observation is the following. We use the notation \(|\lambda| = \lambda_1 + \ldots + \lambda_N\).

**Lemma 2.6.** We have the equality
\[
c_2(\lambda + n) = c'_2(\lambda) + \left(n + \frac{|\lambda|}{N}\right)^2.
\]

**Proof.** The proof is a simple verification using the definitions (2) and (5) of \(c_2\) and \(c'_2\). \(\square\)

It is the contribution of the highest weights of the form \(0 + n = (n, \ldots, n)\) which produces the Jacobi theta function in the unitary part of Theorem 1.3.(i). We will prove that the contribution of all other elements of \(\widehat{U(N)}\) vanishes in the large \(N\) limit.

**Proof of Theorem 1.3.(i) in the unitary case.** Let us consider \(g \geq 2\) and \(T > 0\). We split the partition function \(Z_N(g,T)\) into two parts
\[
Z_N(g,T) = \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2}n^2} + \sum_{\lambda \in \widehat{SU(N)}} \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2}c_2(\lambda + n)} d_{\lambda + n}.
\]

The first part corresponds to highest weights of the form \((n, \ldots, n)\), which have Casimir numbers \(n^2\) and dimension 1. The second part is the contribution of all the other highest weights. To compute it, we observe that \(d_{\lambda+n} = d_\lambda\) and we use Lemma 2.6. We find
\[
0 \leq Z_N(g,T) - \vartheta(0; iT/2\pi) \leq \sum_{\lambda \in \widehat{SU(N)}} \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2}(n+|\lambda|/N)^2} e^{-\frac{T}{2}c'_2(\lambda)} d_{\lambda}^{2-2g}.
\]

The sum between the brackets is bounded independently of \(N\), for example, in a very elementary way, by \(C = 1 + \vartheta(0; iT/2\pi)\). Hence, the right-hand side is bounded by
\[
C \sum_{\lambda \in \widehat{SU(N)}} d_{\lambda}^{2-2g} = C(\zeta_{\text{su}}(2g-2) - 1)
\]
which, thanks to Proposition 2.2, converges to 0. \(\square\)
2.2 Genus 1: the torus

Our proof of the convergence of the partition function when \( g \geq 2 \) was based on our study of the dimensions of the irreducible representations of \( \mathfrak{su}(N) \), expressed in Proposition 2.2. A glance at (3) shows that when \( g = 1 \), these dimensions do not appear anymore in the partition function, and to treat this case we need to use completely different estimates. In this section, we will prove that \( Z_N(1, T) \) still admits a finite limit for \( T > 0 \), but this limit will turn out to be different from the one described in Theorem 1.3.(i). In particular, it will involve the classical generating function of integer partitions. Recall that if we denote, for each \( n \geq 0 \), by \( p(n) \) the number of partitions of the integer \( n \), we have the equality of formal series in the variable \( t \):

\[
\sum_{\alpha} t^{\lambda(\alpha)} = \sum_{n \geq 0} p(n) t^n = \prod_{m=1}^{\infty} \frac{1}{1 - t^m},
\]

where the first sum is over all integer partitions \( \alpha \). Before entering the technical details, let us explain the idea of the proof of Theorem 1.3.(ii), at least in the special unitary case. In the present situation where \( g = 1 \), the partition function is

\[
Z_N'(1, T) = \sum_{\lambda \in \hat{\mathfrak{su}}(N)} e^{-c_1'2(\lambda)T} = \sum_{\lambda \in \hat{\mathfrak{su}}(N)} q^{c_1'(\lambda)},
\]

using the notation \( q = e^{-\frac{T}{2}} \). The problem is thus to identify which highest weights of \( \mathfrak{su}(N) \) keep, in the large \( N \) limit, a bounded quadratic Casimir number, and bring a non-zero contribution to the partition function. We claim, although this statement is not very precise at this stage, that these highest weights are those depicted in Fig. 1 (in the special unitary case, we need to look at the right part of this figure). They are the highest weights that are flat up to a small\(^5\) perturbation at each end, represented by two partitions \( \alpha \) and \( \beta \) of length \( \ll N/2 \). Let us call these highest weights almost flat. A similar description was proposed by Gross–Taylor in [GT93], but in the case where the perturbations remain finite, and their goal was rather to obtain a \( 1/N \) expansion of the partition function than to find its large \( N \) limit. The smaller the length of \( \alpha \) and \( \beta \), the flatter the highest weight: typically we will consider \( \alpha \) and \( \beta \) of length \( \ll \sqrt{N} \). Using the notation \( \lambda(\alpha, \beta) \) introduced in Fig. 1, and the notation \( |\alpha| \) (resp. \( |\beta| \)) for the sum of the components of \( \alpha \) (resp. \( \beta \)), the main estimate will be a refinement of the equality

\[
c_1'(\lambda(\alpha, \beta)) = |\alpha| + |\beta| + O(N^{-1})
\]

with an explicit expression of the error in terms of \( \alpha \) and \( \beta \). The outline of the proof is then the following:

\[
Z_N'(1, T) \approx \sum_{\lambda \in \hat{\mathfrak{su}}(N)} q^{c_1'(\lambda)} \approx \sum_{\lambda, \alpha, \beta \text{ of length } \ll \sqrt{N}} q^{c_1'(\lambda, \alpha, \beta)} \approx \sum_{\alpha, \beta \text{ of length } \ll \sqrt{N}} q^{\text{max of } |\alpha|, |\beta|}
\]

and the last sum tends to the square of the generating function of integer partitions when \( N \to \infty \).

2.2.1 Almost flat highest weights

From two integer partitions \( \alpha = (\alpha_1 \geq \cdots \geq \alpha_r > 0) \) and \( \beta = (\beta_1 \geq \cdots \geq \beta_s > 0) \) of respective lengths \( r \) and \( s \), and an integer \( n \in \mathbb{Z} \), we can form, for all \( N \geq r + s + 1 \), the highest

\(^5\)Small compared to \( N \) but not necessarily finite.
weight
\[ \lambda_N(\alpha, \beta, n) = (\alpha_1 + n, \ldots, \alpha_r + n, n, \ldots, n - \beta_s, \ldots, n - \beta_1) \in \hat{U}(N), \]

which we also denote by \( \lambda(\alpha, \beta, n) \) when there is no doubt on the value of \( N \). We extend this definition in the obvious way to the cases where one or both of the partitions \( \alpha \) and \( \beta \) are the empty partition.

We can also form the highest weight
\[ \lambda_N(\alpha, \beta) = \lambda_N(\alpha, \beta, 0) \in \hat{SU}(N), \]
with the convention that \( \lambda_N(\alpha, \varnothing) = \lambda_N(\alpha, \varnothing, 0) = (\alpha_1, \ldots, \alpha_r, 0) \).

These constructions are illustrated in Fig. 1 below. The reader may have noticed that the definition of \( \lambda_N(\alpha, \beta, n) \) still makes sense when \( N = r + s \) and wonder why we exclude this case. The reason is that under the stronger assumption \( N \geq r + s + 1 \), it is possible to recover \( \alpha \) and \( \beta \) unambiguously from the data of \( \lambda_N(\alpha, \beta, n) \), \( r \) and \( s \). A counterexample with \( r = s = 1 \) and \( N = 2 \) is given in Fig. 2. Without the data of \( r \) and \( s \), there are usually multiple ways of writing a highest weight in the form \( \lambda_N(\alpha, \beta, n) \), see also Fig. 2. Finally, it should be emphasized that every highest weight of \( U(N) \) or \( SU(N) \) can be written as \( \lambda_N(\alpha, \beta, n) \) or \( \lambda_N(\alpha, \beta) \).

Figure 1: From two partitions \( \alpha \) and \( \beta \) and an integer \( n \in \mathbb{Z} \), we can form the highest weights \( \lambda(\alpha, \beta, n) \in \hat{U}(N) \) (on the left) and \( \lambda(\alpha, \beta) \in \hat{SU}(N) \) (on the right).

Figure 2: On the left: the highest weight \((4, 0)\) can be written in several ways as \( \lambda_2(\alpha, \beta) \) with \( \alpha \) and \( \beta \) of length 1. On the right: the highest weight \((4, 3, 2, 1, 1, 0)\) is equal to \( \lambda_7((2, 1, 1), (2, 1, 1)) \) as well as to \( \lambda_7((3, 2, 2, 1), (1)) \).

The construction above has a kind of ‘dual process’, that is, the decomposition of any highest weight of \( U(N) \) or \( SU(N) \) as \( \lambda(\alpha, \beta, n) \) or \( \lambda(\alpha, \beta) \). In the case of \( SU(N) \), this process is based on the observation that for all \( M_1, M_2 \geq 0 \), the map
\[ \hat{SU}(M_1 + 1) \times \hat{SU}(M_2 + 1) \rightarrow \hat{SU}(M_1 + M_2 + 1) \]
\[ (\alpha, \beta) \mapsto \lambda_{M_1+M_2+1}(\alpha, \beta) \]

is a bijection. We have to make a slightly different construction depending on the parity of \( N \): let \( \lambda \in \hat{SU}(N) \).
If \( N = 2M + 1 \), then there is a unique \( \alpha_\lambda \in \widehat{SU}(M + 1) \) and a unique \( \beta_\lambda \in \widehat{SU}(M + 1) \) such that 
\[ \lambda = \lambda_N(\alpha_\lambda, \beta_\lambda), \]
therefore we take \( M_1 = M_2 = M \) in (14).

If \( N = 2M \), then there is a unique \( \alpha_\lambda \in \widehat{SU}(M) \) and a unique \( \beta_\lambda \in \widehat{SU}(M + 1) \) such that 
\[ \lambda = \lambda_N(\alpha_\lambda, \beta_\lambda), \]
therefore we take \( M_1 = M - 1 \) and \( M_2 = M \) in (14).

In the case of \( U(N) \) we have seen that any any highest weight can be written as \( \lambda + n \) with \( \lambda \in \widehat{SU}(N) \) and \( n \in \mathbb{Z} \), hence we have the decomposition 
\[ \lambda + n = \lambda_N(\alpha_\lambda, \beta_\lambda) + n. \]

The Casimir number of a highest weight can be expressed conveniently through this decomposition, as we will show below. First, let us recall the definition of the content of a box of a diagram, which is mentioned in particular in [Sta99, VO04].

**Definition 2.7.** Let \( \alpha = (\alpha_1 \geq \cdots \geq \alpha_r \geq 0) \) be a non-increasing sequence of integers, seen as a Young diagram. For any box \((i,j)\) of this diagram, that is, any \((i,j)\) such that \( j \leq \alpha_i \), we call the content of the box \((i,j)\) the quantity 
\[ c(i,j) = j - i. \]
We also define the total content \( K(\alpha) \) of \( \alpha \) as the sum of the contents of the boxes of \( \alpha \).

An example is given on Fig. 3.

![Figure 3: Filling of the boxes of (3, 3, 2, 1) with their respective contents. The Young diagram is represented here in the so-called Russian way, where the content of a box is its abscissa.](image)

The main result of this section is the following.

**Proposition 2.8.** Let \( \alpha \) and \( \beta \) be two partitions of respective lengths \( r \) and \( s \). Let \( n \) be an integer. Then, provided \( N \geq r + s \), we have

\[ c_2(\lambda_N(\alpha, \beta, n)) = |\alpha| + |\beta| + n^2 + \frac{2}{N} (K(\alpha) + K(\beta) + n(|\alpha| - |\beta|)) \]  
(15)

in the unitary case, and

\[ c'_2(\lambda_N(\alpha, \beta)) = |\alpha| + |\beta| + \frac{2}{N} (K(\alpha) + K(\beta)) + \frac{1}{N^2} (|\alpha| - |\beta|)^2 \]  
(16)

in the special unitary case.

**Proof.** Let us start with the unitary case. Using the definition of Casimir number and the definition of \( \lambda(\alpha, \beta, n) \), we obtain

\[
Nc_2(\lambda_N(\alpha, \beta, n)) = \sum_{i=1}^r \alpha_i^2 + \sum_{1 \leq i < j \leq r} (\alpha_i - \alpha_j) + 2n|\alpha| + \sum_{i=1}^s \beta_i^2 + \sum_{1 \leq i < j \leq s} (\beta_i - \beta_j) - 2n|\beta|
\]
\[ + |\alpha|(N - r - s) + |\beta|(N - r - s) + \sum_{1 \leq i \leq r} (\alpha_i + \beta_j) + Nc^2, \]

11
which can be rearranged into

\[
Nc_2(\lambda_N(\alpha, \beta, n)) = N(|\alpha| + |\beta| + n^2) + 2n(|\alpha| - |\beta|) + \sum_{i=1}^{r} \alpha_i^2 + \sum_{1 \leq i < j \leq r} (\alpha_i - \alpha_j) - r|\alpha| \\
+ \sum_{i=1}^{s} \beta_i^2 + \sum_{1 \leq i < j \leq s} (\beta_i - \beta_j) - s|\beta|.
\]

On the other hand,

\[
K(\alpha) = \frac{r}{2} \sum_{i=1}^{r} \alpha_i(\alpha_i + 1) - i\alpha_i = \frac{1}{2} \left( \sum_{i=1}^{r} \alpha_i^2 + \sum_{1 \leq i < j \leq r} (\alpha_i - \alpha_j) - r|\alpha| \right)
\]

and we find (15) as announced.

Concerning the special unitary case, we simply need to subtract from \(c_2(\lambda)\) the quantity \(\frac{1}{N^2} (\sum \lambda_i)^2\), which leads to

\[
c_2(\lambda_N(\alpha, \beta)) = c_2(\lambda_N(\alpha, \beta, \beta_1)) - \frac{1}{N^2} (|\alpha| - |\beta| + Nn)^2
\]

from which (16) follows easily.

The proof of Theorem 1.3.(ii) will rely on two estimates of the Casimir number: one that helps proving the convergence of the sum of \(q^{c_2(\lambda)}\) over almost flat highest weights \(\lambda\) to the expected limit, and one that helps controlling the sum over remaining highest weights.

**Lemma 2.9.** Let \(\lambda \in \tilde{SU}(N)\). Set \(k = |\alpha_\lambda| + |\beta_\lambda|\). Then the following inequalities hold:

\[
k - \frac{k^2}{N} \leq c'_2(\lambda) \leq k + \frac{k^2}{N}, \quad (17)
\]

\[
k \leq c'_2(\lambda). \quad (18)
\]

**Proof.** We start from the expression of \(c'_2(\lambda) = c'_2(\lambda_N(\alpha_\lambda, \beta_\lambda))\) given by (16). The point is to bound \(K(\alpha_\lambda)\) and \(K(\beta_\lambda)\).

The list of the contents of the boxes of \(\alpha_\lambda\) taken row after row and from left to right in each row (as on the left of Fig. 4) is a sequence \(x_1, \ldots, x_{|\alpha_\lambda|}\) such that \(|x_i| \leq i - 1\) for each \(i \in \{1, \ldots, |\alpha_\lambda|\}\). It follows that

\[-|\alpha_\lambda|(|\alpha_\lambda| - 1) \leq 2K(\alpha_\lambda) \leq |\alpha_\lambda|(|\alpha_\lambda| - 1).
\]

This implies immediately

\[2|K(\alpha_\lambda) + K(\beta_\lambda)| \leq k^2,
\]

and (17), after observing that \(0 \leq (|\alpha_\lambda| - |\beta_\lambda|)^2 \leq (|\alpha_\lambda| + |\beta_\lambda|)^2 = k^2\).

Let us turn to the proof of (18). We will establish a different lower bound on \(K(\alpha_\lambda)\) and \(K(\beta_\lambda)\). For this, let us list the contents of the boxes of \(\alpha_\lambda\), now taken column after column and from top to bottom in each column (as on the right of Fig. 4). It is now a sequence \(x_1, \ldots, x_{|\alpha_\lambda|}\) of integers that along each column of \(\alpha\) decreases by 1 at each step, and at each change of column jumps to a positive integer. The crucial point is that the height of the columns of \(\alpha_\lambda\) is bounded by the integer that we called \(M_1\) at the beginning of this section, and that is in any
case not greater than $\frac{N}{2}$. The contribution of each column is thus bounded below by $-\frac{N}{4}$ times the number of boxes in this column. It follows that

$$K(\alpha_\lambda) \geq -\frac{N}{4}|\alpha_\lambda|,$$

and a similar argument holds for $\beta_\lambda$. The result follows again from (16).

Let us fix a real $\gamma \in (0, \frac{1}{2})$. We split the set of highest weights of SU($N$) in four disjoint subsets:

$$
\begin{align*}
\Lambda_{N,1}^\gamma &= \{ \lambda \in \widehat{\text{SU}}(N) : |\alpha_\lambda| \leq N\gamma, |\beta_\lambda| \leq N\gamma \}, \\
\Lambda_{N,2}^\gamma &= \{ \lambda \in \widehat{\text{SU}}(N) : |\alpha_\lambda| > N\gamma, |\beta_\lambda| \leq N\gamma \}, \\
\Lambda_{N,3}^\gamma &= \{ \lambda \in \widehat{\text{SU}}(N) : |\alpha_\lambda| \leq N\gamma, |\beta_\lambda| > N\gamma \}, \\
\Lambda_{N,4}^\gamma &= \{ \lambda \in \widehat{\text{SU}}(N) : |\alpha_\lambda| > N\gamma, |\beta_\lambda| > N\gamma \}. 
\end{align*}
$$

In this framework, (17) can be refined as the following for any $\lambda \in \Lambda_{N,1}^\gamma$:

$$|\alpha_\lambda| + |\beta_\lambda| - 4N^{2\gamma-1} \leq c_2(\lambda) \leq |\alpha_\lambda| + |\beta_\lambda| + 4N^{2\gamma-1} + 4N^{2\gamma-2}.$$  

(20)

The set $\Lambda_{N,1}^\gamma$ is the set of highest weights that we think of as being almost flat. The proof of Theorem 1.3.(ii) in the unitary and special unitary cases will consist more or less in proving the following assertions:

- The partition function can be decomposed as

$$Z_N = S_{N,1} + S_{N,2} + S_{N,3} + S_{N,4},$$

with $S_{N,i} = \sum_{\lambda \in \Lambda_{N,i}^\gamma} q^{c_2(\lambda)}$ for $1 \leq i \leq 4$.

- $S_{N,1}$ converges, when $N \to \infty$, to the limit stated in Theorem 1.3.(ii).

- $S_{N,2}$, $S_{N,3}$ and $S_{N,4}$ all converge to 0.

This scheme of proof highlights the importance of almost flat highest weights in the large $N$ asymptotics of Yang–Mills measure on the torus: they are somehow the only weights contributing to the limit of its partition function.

### 2.2.2 The special unitary case

**Proof of theorem 1.3.(ii) in the special unitary case.** Let us fix $\gamma \in (0, \frac{1}{2})$ and define the sets $(\Lambda_{N,i}^\gamma)_{1 \leq i \leq 4}$ as in Section 2.2.1. For each $i \in \{1, 2, 3, 4\}$, we set

$$S_{N,i}^\gamma = \sum_{\lambda \in \Lambda_{N,i}^\gamma} q^{c_2(\lambda)},$$

with $S_{N,1}^\gamma = \sum_{\lambda \in \Lambda_{N,1}^\gamma} q^{c_2(\lambda)}$ for $1 \leq i \leq 4$. The remaining terms are defined similarly.

This completes the proof of Theorem 1.3.(ii) in the special unitary case.
and from (18) we have

$$Z'_N(1, T) = S'_{N,1} + S'_{N,2} + S'_{N,3} + S'_{N,4}.$$  

For $N$ large enough, any partition of an integer not greater than $N^\gamma$ has less than $\frac{N}{2}$ positive parts. Thus, if $\alpha$ and $\beta$ are any two such partitions, the highest weight $\lambda_N(\alpha, \beta)$ is well defined, and belongs to $\Lambda^\gamma_{N,1}$. As a consequence, for $N$ large enough,

$$\Lambda^\gamma_{N,1} = \{\lambda_N(\alpha, \beta), \alpha \vdash r, \beta \vdash s : r \leq N^\gamma, s \leq N^\gamma\},$$

and

$$S'_{N,1} = \sum_{|\alpha|,|\beta| \leq N^\gamma} q^{c_2(\lambda(\alpha, \beta))}.$$  

From (20), we deduce that

$$q^{4N^{2\gamma - 1} + 4N^{2\gamma - 2}} \sum_{|\alpha|,|\beta| \leq N^\gamma} q^{|\alpha| + |\beta|} \leq S'_{N,1} \leq q^{-4N^{2\gamma - 1}} \sum_{|\alpha|,|\beta| \leq N^\gamma} q^{|\alpha| + |\beta|}.$$  

Since $2\gamma - 1$ is negative, the powers of $q$ in front of the sums on either side tend to 1 as $N$ tends to infinity. On the other hand, the sum over $\alpha$ and $\beta$ tends, as $N$ tends to infinity, to the square of the generating function of partitions defined in (11). Hence,

$$\lim_{N \to \infty} S'_{N,1} = \lim_{N \to \infty} \sum_{|\alpha|,|\beta| \leq N^\gamma} q^{|\alpha| + |\beta|} = \left(\sum_\alpha q^{|\alpha|}\right)^2 = \prod_{m=1}^\infty (1 - q^m)^{-2}.$$  

In a second step, we prove that the three other contributions to $Z'_N(1, T)$ vanish as $N$ tends to infinity. For this, we use (18). Let us treat the case of $S'_{N,2}$, the case of $S'_{N,3}$ being perfectly similar, and the case of $S'_{N,4}$ even simpler. Let us remark that, as opposed to the case of $\Lambda^\gamma_{N,1}$, we only have the inclusion

$$\Lambda^\gamma_{N,2} \subset \{\lambda_N(\alpha, \beta), \alpha \vdash r, \beta \vdash s : r \leq N^\gamma, s > N^\gamma\},$$

but it will be enough to get an adequate upper bound. Indeed,

$$0 \leq S'_{N,2} \leq \sum_{|\alpha| \leq N^\gamma, |\beta| > N^\gamma} q^{c_2(\lambda(\alpha, \beta))},$$

and from (18) we have

$$\sum_{|\alpha| \leq N^\gamma, |\beta| > N^\gamma} q^{c_2(\lambda(\alpha, \beta))} \leq \sum_{|\alpha| \leq N^\gamma, |\beta| > N^\gamma} q^{\frac{1}{2}(|\alpha| + |\beta|)} \leq \sum_{|\alpha|} q^{\frac{1}{2}|\alpha|} \sum_{k > N^\gamma} p(k)q^{\frac{k}{2}}.$$  

The first sum of right-hand side is finite, and the second sum, as a remainder of a convergent series, tends to 0 as $N$ tends to infinity. This concludes the proof.  

2.2.3 The unitary case

The proof of Theorem 1.3.(ii) in the unitary case will rely on the same tools as the special unitary case, that is, the use of almost flat highest weights, combined with the bijection $\Phi : (\lambda, n) \mapsto \lambda + n$ introduced in Section 2.1. In particular, Lemma 2.6 will be of great help in order to control the convergence of $Z_N(1, T)$ using the convergence of $Z'_N(1, T)$.  

14
Proof of Theorem 1.3.(ii) in the unitary case. Let $\lambda \in \hat{\mathrm{SU}}(N)$. Thanks to Lemma 2.6 and Proposition 2.8, it appears that, for all $n \in \mathbb{Z}$,

$$c_2(\lambda + n) = c'_2(\lambda) + \left(n + \frac{|\lambda|}{N}\right)^2 = c'_2(\lambda) + \left(n + \frac{|\alpha| - |\beta|}{N} + (\beta,1)^2\right),$$

so that we can write, up to a change of index $n \leftarrow n - (\beta,1)$,

$$Z_N(1,T) = \sum_{\lambda \in \hat{\mathrm{SU}}(N)} \left(\sum_{n \in \mathbb{Z}} q^{\left(n + \frac{|\alpha| - |\beta|}{N}\right)^2}\right) q_{c'_2}(\lambda).$$

(21)

The main difference with the case of $\mathrm{SU}(N)$ is that the sum over $n$ in the special unitary case. We define, for $1 \leq i \leq 4$,

$$S_{N,i} = \sum_{\lambda \in \Lambda_{N,i}} \left(\sum_{n \in \mathbb{Z}} q^{\left(n + \frac{|\alpha| - |\beta|}{N}\right)^2}\right) q_{c'_2}(\lambda),$$

and we obtain the following decomposition:

$$Z_N(1,T) = S_{N,1} + S_{N,2} + S_{N,3} + S_{N,4}.$$ 

Let $\lambda$ be an element of $\Lambda_{N,1}$. From the fact that $||\alpha| - |\beta|| \leq |\alpha| + |\beta| \leq 2N^\gamma$ we get

$$n^2 - 4nN^\gamma \leq \left(n + \frac{|\alpha| - |\beta|}{N}\right)^2 \leq n^2 + 4nN^\gamma + 4N^2\gamma - 2.$$ 

(22)

For the same reason as in the special unitary case, for $N$ large enough we have

$$S_{N,1} = \sum_{|\alpha|,|\beta| \leq N^\gamma} \left(\sum_{n \in \mathbb{Z}} q^{\left(n + \frac{|\alpha| - |\beta|}{N}\right)^2}\right) q_{c'_2}(\lambda_N(\alpha,\beta));$$

Then, equations (20) and (22) yield

$$q^{4N^2\gamma - 1} \left(\sum_{n \in \mathbb{Z}} q^{n^2 - 4nN^\gamma - 1}\right) \sum_{|\alpha|,|\beta| \leq N^\gamma} q^{||\alpha| + |\beta||} \leq S_{N,1}$$

(23)

and

$$S_{N,1} \leq q^{-4N^2\gamma - 1} \left(\sum_{n \in \mathbb{Z}} q^{n^2 - 4nN^\gamma - 1}\right) \sum_{|\alpha|,|\beta| \leq N^\gamma} q^{||\alpha| + |\beta||}. $$

(24)

The sums $\sum_{n \in \mathbb{Z}} q^{n^2 \pm 4nN^\gamma - 1}$ in both cases tend to $\sum_{n \in \mathbb{Z}} q^{n^2}$ by dominated convergence, because $\gamma - 1 < 0$. The remaining terms in both inequalities (23) and (24) behave in the same way as in the proof of Theorem 1.3.(ii) in the special unitary case. This proves that

$$\lim_{N \to \infty} S_{N,1} = \sum_{n \in \mathbb{Z}} q^{n^2} \prod_{m=1}^{\infty} \frac{1}{(1 - q^m)^2}.$$
Now let us treat the cases of $S_{N,2}$, $S_{N,3}$ and $S_{N,4}$. The arguments are the same for the three of them, so we only choose to detail the case of $S_{N,2}$. We have, using equation (18),

$$0 \leq S_{N,2} \leq \sum_{|\alpha| \leq N^\gamma, |\beta| > N^\gamma} \left( \sum_{n \in \mathbb{Z}} q^{\left( n + |\alpha| - |\beta| \right)^2 / N^2} \right) q^{\frac{1}{2}(|\alpha| + |\beta|)} ,$$

and the sum between brackets can be bounded independently from $N$, $|\alpha|$ and $|\beta|$ by $C = 1 + \vartheta(0; iT/2\pi)$, thus

$$0 \leq S_{N,2} \leq C \sum_{\alpha} q^{\frac{1}{2}|\alpha|} \sum_{|\beta| > N^\gamma} q^{\frac{1}{2}|\gamma|} = C \sum_{\alpha} q^{\frac{1}{2}|\alpha|} \sum_{k > N^\gamma} \frac{p(k)q^k}{k^2} \to 0 ,$$

as $N \to \infty$.

This concludes the proof as in the special unitary case.

3 Non-orientable surfaces

We now turn to the study of non-orientable surfaces. Let us recall that, according to Theorem 1.1, any such surface can be constructed as the connected sum of projective planes. In order to estimate the large $N$ asymptotics of its associated partition function, we need to compute the Frobenius–Schur indicator associated to any highest weight of $U(N)$ or $SU(N)$.

Let $(\rho, V)$ a complex finite-dimensional representation of a compact group $G$ with character $\chi$. Recall that $\rho$ is said to be:

(i) Real if it exists a symmetric $G$-invariant nondegenerate bilinear form;

(ii) Quaternionic if it exists a skew-symmetric $G$-invariant nondegenerate bilinear form;

(iii) Complex if there is no $G$-invariant nondegenerate bilinear form.

The value of $\iota_\chi$ is actually linked to this classification, as stated by the following Proposition, which can be found in [BtD95, Prop.6.8].

**Proposition 3.1.** Let $(\rho, V)$ be a complex finite-dimensional representation of a compact group $G$, with character $\chi$. Its Frobenius–Schur indicator is given by:

$$\iota_\chi = \begin{cases} 
1 & \text{if } \rho \text{ is real;} \\
0 & \text{if } \rho \text{ is complex;} \\
-1 & \text{if } \rho \text{ is quaternionic.}
\end{cases} \quad (25)$$

The next result allows us to decide when an irreducible representation of $U(N)$ or $SU(N)$ is real, complex or quaternionic, based on its highest weight.

**Proposition 3.2.** Let $\lambda = (\lambda_1 \geq \cdots \geq \lambda_N)$ be a highest weight of $U(N)$ (or $SU(N)$ if we fix $\lambda_N = 0$). Let $m_i = \lambda_i - \lambda_{i+1} \in \mathbb{N}$ for every $i \in \{1, \ldots, N-1\}$. An irreducible representation of $U(N)$ or $SU(N)$ with highest weight $\lambda$ is:

- Complex if there exists $i$ such that $m_i \neq m_{N-i}$;
- Real if $m_i = m_{N-i}$ for all $i \in \{1, \ldots, [N/2]\}$ and one of the following properties is satisfied:
  - $N \not\equiv 2[4]$;
  - $N \equiv 2[4]$ and $m_{2k+1}$ is even;
Quaternionic if $N \equiv 2[4]$, $m_i = m_{N-i}$ for all $i \in \{1, \ldots, N/2\}$ and $m_{2k+1}$ is odd.

Proof. The proof is given for SU($N$) in [FH91, Prop.26.24]. Now, if $\lambda_N \neq 0$, we define $\mu \in SU(N)$ by setting $\mu_i = \lambda_i - \lambda_N$. It can be verified that a representation of $U(N)$ with highest weight $\lambda$ is real (resp. complex, quaternionic) if and only if a representation of $SU(N)$ with highest weight $\mu$ is real (resp. complex, quaternionic), and for any $i \in \{1, \ldots, N\}$ the value of $m_i$ is the same for $\lambda$ and $\mu$ by definition.

If we apply this proposition to the construction $\lambda = \lambda_N(\alpha, \beta)$, it yields the following result.

Corollary 3.3. Let $\lambda \in \widehat{SU}(N)$ and $n \in \mathbb{Z}$.

(i) If $N = 2M + 1$ is odd, then an irreducible representation of $SU(N)$ (resp. $U(N)$) with highest weight $\lambda$ (resp. $\lambda + n$) is complex if and only if $\alpha \neq \beta$.

(ii) Assume that $N = 2M$ is even. Let $\alpha = \alpha_\lambda \in \widehat{SU}(M)$ and $\beta = \beta_\lambda \in \widehat{SU}(M + 1)$, and set $\tilde{\beta} = (\beta_1 - \beta_M, \ldots, \beta_{M-1} - \beta_M, 0) \in \widehat{SU}(M)$. Then an irreducible representation of $SU(N)$ (resp. $U(N)$) with highest weight $\lambda$ (resp. $\lambda + n$) is complex if and only if $\alpha \neq \tilde{\beta}$.

(iii) For all integer partitions $\alpha$ and $\beta$, all $n \in \mathbb{Z}$, and for $N$ large enough, the highest weight $\lambda \in \widehat{SU}(N)$ as defined by (13) is not quaternionic.

The main point of this corollary is that highest weights that are not symmetric are complex and therefore do not contribute to the non-orientable partition function because their Frobenius–Schur indicator vanishes. We can also notice that quaternionic representations with almost flat highest weight do not appear in the large $N$ scale, and that the partition function becomes a sum of nonnegative terms.

3.1 Non-orientable surfaces of genus $g \geq 3$

3.1.1 The special unitary case

The proof of Theorem 1.4.(i) will be based on the same reasoning as for orientable surfaces of genus $g \geq 2$, that is, using Proposition 2.2 to show that the contribution of all other highest weights than $(0, \ldots, 0)$ vanish in the large $N$ limit. However, the case of non-orientable surfaces with $g = 3$ will need a finer control, as we will see later. In particular, for even values of $N$ and $g = 3$ the following inequality is needed.

Proposition 3.4. Let $N = 2M$ be an integer. For $\lambda \in \widehat{SU}(N)$, if we set $\alpha = \alpha_\lambda \in \widehat{SU}(M)$ and $\beta = \beta_\lambda \in \widehat{SU}(M + 1)$, as well as $\tilde{\beta} = (\beta_1 - \beta_M, \ldots, \beta_{M-1} - \beta_M, 0) \in \widehat{SU}(M)$ as in Corollary 3.3.(ii), then

$$d_\lambda \geq \left(1 + \frac{\beta_M}{M}\right)^M d_\alpha d_{\tilde{\beta}}.$$

Proof. Using Equation (1) and the fact that

$$\lambda = \lambda_N(\alpha, \beta) = (\alpha_1 + \beta_1, \ldots, \alpha_{M-1} + \beta_1, \beta_1, \beta_M - \beta_1, \ldots, \beta_2 - \beta_1, 0),$$

the proof follows directly from the previous result.
it is clear that \( d_\lambda \geq d_\alpha d_\beta \). Moreover,

\[
d_\beta = \prod_{1 \leq i < j \leq M+1} \left( 1 + \frac{\beta_i - \beta_j}{j - i} \right)
= \prod_{i=1}^{M} \left( \frac{\beta_i}{M+1-i} \right) d_\beta
\geq \left( \frac{\beta M}{M} \right)^M d_\beta.
\]

Combining both inequalities gives the expected result. \(\square\)

**Proof of Theorem 1.4. (i).** The highest weight \((0, \ldots, 0)\) is associated to the trivial representation, which is real by Proposition 3.1 and has dimension 1 and Casimir number 0. We can then rewrite

\[
Z_N'(g, T) = 1 + \sum_{\lambda \in \tilde{SU}(N)} q c_{\lambda}^2 d_\lambda^{2-g} (t_\lambda)^g,
\]

and the remaining sum can be bounded as follows:

\[
\left| \sum_{\lambda \in \tilde{SU}(N)} q c_{\lambda}^2 d_\lambda^{2-g} t_\lambda \right| \leq \sum_{\lambda \in \tilde{SU}(N)} q c_{\lambda}^2 d_\lambda^{2-g}.
\]

If \( g \geq 4 \), then the right-hand side has been proved to converge to 0 as \( N \to \infty \) in section 2.1, hence the result follows.

Now, if \( g = 3 \), we need to refine the analysis in order to get the convergence. From Corollary 3.3, it appears that \( \lambda \in SU(N) \) contributes to the partition function if and only if it is symmetric. The case \( N = 2M + 1 \) is easier to prove, so we start with it. As \( t_\lambda = 0 \) if \( \lambda \) is associated with a complex representation, we have

\[
Z_N'(3, T) = 1 + \sum_{\lambda \in \tilde{SU}(N)} q c_{\lambda}^2 d_\lambda^{-1} (t_\lambda)^3,
\]

which means that

\[
\left| Z_N'(3, T) - 1 \right| = \left| \sum_{\alpha \in \tilde{SU}(M+1)} q c_{\lambda}^2 (\lambda_N(\alpha, \alpha)) d_\alpha^{-1} (t_\alpha)^3 \right|
\leq \sum_{\alpha \in \tilde{SU}(M+1)} q c_{\lambda}^2 (\lambda_N(\alpha, \alpha)) d_\alpha^{-2}
\leq \zeta_{SU}(M)(2),
\]

where in the first inequality we used the fact that \( d_{\lambda_N(\alpha, \alpha)} \geq d_\alpha^2 \). Then, letting \( M \) tend to infinity and using Proposition 2.2, we have indeed

\[
\lim_{M \to \infty} Z_{2M+1}'(3, T) = 1.
\]
Now consider $N = 2M$. Let $\tilde{\beta} = (\beta_1 - \beta_M, \ldots, \beta_{M-1} - \beta_M, 0)$. Corollary 3.3 states that $\lambda = \lambda_N(\alpha, \beta)$ contributes to the partition function if and only if $\alpha = \tilde{\beta}$. It implies:

$$|Z'_N(3, T) - 1| = \left| \sum_{(\alpha, \beta) \in \hat{SU}(M) \times \hat{SU}(M+1)} q^{\frac{1}{2} \langle (\lambda_N(\alpha, \beta), t_{\lambda_N(\alpha, \beta)} \rangle} d^{-1}_{\lambda_N(\alpha, \beta)} |. $$

We can then apply Proposition 3.4 to get

$$|Z'_N(3, T) - 1| \leq \sum_{\alpha \in \hat{SU}(M+1)} \left( 1 + \frac{n}{M} \right)^{-M} \sum_{\alpha \neq (0, \ldots, 0)} d^{-1}_{\alpha} \sum_{n \in \mathbb{N}} e^{-T c_2(\lambda + n) d_{\lambda + n}^2 - g d_{\lambda + n}^2}. $$

The first sum is bounded because $\left( 1 + \frac{n}{M} \right)^{-M} \leq e^{-n}$ for any $n, M$, and the second one converges, following the same argument as in the case $N = 2M + 1$. We finally get

$$\lim_{M \to \infty} Z'_{2M}(3, T) = 1.$$

Finally, we have shown that

$$\lim_{M \to \infty} Z'_{2M}(3, T) = \lim_{M \to \infty} Z'_{2M+1}(3, T) = 1,$$

which concludes the proof. $\square$

### 3.1.2 The unitary case

As for the special unitary case, the proof of the unitary case for non-orientable surfaces of genus $g \geq 3$ is similar to the one of orientable surfaces of genus $g \geq 2$. Indeed, the point is to show that only constant highest weights contribute to the large $N$ limit.

**Proof of Theorem 1.4.(i) in the unitary case.** Let us consider $g \geq 3$ and $T > 0$. We split the partition function $Z'_N(g, T)$ into two parts

$$Z'_N(g, T) = \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2} n^2} + \sum_{\lambda \in \hat{SU}(N) \atop \lambda \neq (0, \ldots, 0)} e^{-\frac{T}{2} c_2(\lambda + n) d_{\lambda + n}^2 - g d_{\lambda + n}^2}. $$

Let us assume that $g \geq 4$. Following the arguments used in the orientable case with $g = 2$, we find

$$0 \leq |Z_N(g, T) - \vartheta(0; iT/2\pi)| \leq \sum_{\lambda \in \hat{SU}(N) \atop \lambda \neq (0, \ldots, 0)} \left( \sum_{n \in \mathbb{Z}} e^{-\frac{T}{2} (n+|\lambda|/N)^2} \right) e^{-\frac{T}{2} c_2(\lambda) d_{\lambda}^2 - g}. $$

The sum between the brackets is bounded by $C = 1 + \vartheta(0; iT/2\pi)$ and the other sum is bounded in absolute value by $\zeta_{\text{su}(N)}(g - 2) - 1$, which converges to 0. Hence, the whole right-hand side converges to 0.
If \( g = 3 \) we need a special analysis similar to the one in the special unitary case. Using Corollary 3.3. any \( \lambda \in \mathbb{U}(N) \) contributes to \( Z_N^*(3, T) \) if and only if it is symmetric. Let us first assume that \( N = 2M + 1 \). Then, we can write

\[
Z_N^*(3, T) = \vartheta(0; iT/2\pi) + \sum_{\lambda \in \mathbb{SU}(N)} \sum_{\lambda \neq (0, \ldots, 0)} \sum_{n \in \mathbb{Z}} q^{(\lambda + n)^2} d^{-1}_\lambda (\tau_\lambda)^3,
\]

therefore

\[
0 \leq |Z_N^*(3, T) - \vartheta(0; iT/2\pi)| \leq \sum_{\lambda \in \mathbb{SU}(N)} \sum_{\lambda \neq (0, \ldots, 0)} \left( \sum_{n \in \mathbb{Z}} q^{(\lambda + n)^2} \right) q^{c_2(\lambda)} d^{-1}_\lambda
\]

\[
\leq \sum_{\alpha \in \mathbb{SU}(M+1)} \left( \sum_{n \in \mathbb{Z}} q^{(\lambda_N(\alpha, \alpha) N)^2} \right) q^{c_2(\lambda_N(\alpha, \alpha))} d^{-2}_{\lambda_N(\alpha, \alpha)}.
\]

The right-hand side converges to 0 for the same reason as in the case \( g \geq 4 \). Now, let us assume that \( N = 2M \). Let \( \tilde{\beta} \) be defined as before. We have

\[
0 \leq |Z_N^*(3, T) - \vartheta(0; iT/2\pi)| \leq \sum_{(\alpha, \beta) \in \mathbb{SU}(M) \times \mathbb{SU}(M+1)} \left( \sum_{n \in \mathbb{Z}} q^{(\lambda_N(\alpha, \beta) N)^2} \right) q^{c_2(\lambda_N(\alpha, \beta))} d^{-1}_{\lambda_N(\alpha, \beta)}.
\]

Proposition 3.4, plus similar arguments as before, yield

\[
|Z_N^*(3, T) - \vartheta(0; iT/2\pi)| \leq (1 + \vartheta(0; iT/2\pi)) \sum_{n \in \mathbb{N}} \left( 1 + \frac{n}{M} \right)^{-M} \sum_{\alpha \in \mathbb{SU}(M+1)} d^{-2}_\alpha,
\]

and the right-hand side converges to zero. We proved the convergence for odd and even values of \( N \) to the same quantity, which concludes the case \( g = 3 \). \( \square \)

### 3.2 Genus 2: the Klein Bottle

The Klein bottle is the non-orientable equivalent to the torus, as we will see, in the sense that the dimensions of the irreducible representations do not appear in the formula of the partition function. Hence, the proof of Theorem 1.4.(ii) is using almost flat highest weights as well.

#### 3.2.1 The special unitary case

*Proof of Theorem 1.4.(ii) in the special unitary case.* From Corollary 3.3 and Proposition 3.1 we deduce that \( \lambda \in \mathbb{SU}(2M) \) (resp. \( \mathbb{SU}(2M + 1) \) has a nonzero Frobenius–Schur indicator if and only if \( \alpha = \beta \) (resp. \( \alpha = \beta \)), where \( \alpha = \alpha_\lambda \) and \( \beta = \beta_\lambda \) are defined as in Section 2.2.1, and \( \beta = (\beta_1 - \beta_M, \ldots, \beta_{M-1} - \beta_M, 0) \in \mathbb{SU}(M) \).

Let \( \gamma \in (0, \frac{1}{2}) \), and the subsets \( (\Lambda_{N,i})_{1 \leq i \leq 4} \) of \( \mathbb{SU}(N) \) defined as in Section 2.2.1. We define, for \( 1 \leq i \leq 4 \),

\[
S'_{N,i} = \sum_{\lambda \in \Lambda_{N,i}} \ell^2_\lambda q^{c_2(\lambda)} = \sum_{\lambda \in \Lambda_{N,i}} q^{c_2(\lambda)},
\]

where \( \ell_\lambda \) is symmetric.
and we obtain the following decomposition:

\[ Z'_N(1, T) = S'_{N,1} + S'_{N,2} + S'_{N,3} + S'_{N,4}. \]

- If \( N = 2M + 1 \), then the symmetry condition is equivalent to the fact that \( \alpha = \beta \) and we can simplify equation (16) into

\[ c'_2(\lambda_N(\alpha, \alpha)) = 2|\alpha| + \frac{4K(\alpha)}{N}, \]

for any \( \alpha \) of length \( r \) and \( N \geq 2r \). Let us recall the estimation

\[ |2K(\alpha)| \leq |\alpha|(|\alpha| - 1), \]

which leads, for \( \lambda = \lambda(\alpha, \alpha) \in \Lambda^\gamma_{N,1} \), to

\[ |c'_2(\lambda) - 2|\alpha|| \leq 4N^{2\gamma - 1}. \] (26)

Recall that we found in the proof of Theorem 1.3.(ii) that, for \( N \) large enough,

\[ \Lambda^\gamma_{N,1} = \{\lambda_N(\alpha, \beta), \alpha \vdash r, \beta \vdash s : r \leq N^\gamma, s \leq N^\gamma\}. \]

We then get from this equality and from (26) the estimate

\[ q^{4N^{2\gamma - 1}} \sum_{|\alpha| \leq N^\gamma} q^{2|\alpha|} \leq S'_{N,1} \leq q^{-4N^{2\gamma - 1}} \sum_{|\alpha| \leq N^\gamma} q^{2|\alpha|}, \] (27)

and both bounds converge to the expected quantity \( \prod_{m=1}^\infty \frac{1}{1 - q^{2m}} \).

- If \( N = 2M \), then the symmetry condition is equivalent to the fact that \( \alpha = \tilde{\beta} \) and under this condition we have

\[ \left\{ \begin{array}{l} |\alpha| \leq N^\gamma \\ |\beta| \leq N^\gamma \end{array} \right\} \Leftrightarrow \left\{ \begin{array}{l} |\alpha| \leq N^\gamma \\ \beta_M \leq N^\gamma - |\alpha| \end{array} \right\}. \]

Furthermore, equation (20) becomes

\[ 2|\alpha| + M\beta_M - 4N^{2\gamma - 1} \leq c'_2(\lambda) \leq 2|\alpha| + M\beta_M + 4N^{2\gamma - 1} + 4N^{2\gamma - 2}. \]

We obtain that

\[ q^{4N^{2\gamma - 1} + 4N^{2\gamma - 2}} \sum_{|\alpha| \leq N^\gamma} \left( \sum_{n \in N^\gamma - |\alpha|} q^{Mn} \right) q^{2|\alpha|} \leq S'_{N,1}, \]

\[ S'_{N,1} \leq q^{-4N^{2\gamma - 1}} \sum_{|\alpha| \leq N^\gamma} \left( \sum_{n \in N^\gamma - |\alpha|} q^{Mn} \right) q^{2|\alpha|}. \] (28)

The sums between brackets in both inequalities are bounded between 1 and \( \sum_{n \in \mathbb{Z}} q^{Mn} \). The latter converges to 1 as \( M \) tends to infinity, by dominated convergence (it is clearly bounded by the geometric series \( \sum_{n \in \mathbb{N}} q^n \)). It finally appears that both bounds of \( S'_{N,1} \) in (28) converge to

\[ \prod_{m=1}^\infty \frac{1}{1 - q^{2m}}. \]

By similar arguments as the ones used in the case of the torus, we can prove that \( S'_{N,2}, S'_{N,3} \) and \( S'_{N,4} \) all converge to 0 as the remainders of convergent series. This concludes the proof. \( \square \)
3.2.2 The unitary case

Proof of Theorem 1.4.(ii) in the unitary case. Let $\lambda$ be an element of $\tilde{\text{SU}}(N)$. Recall that we found in the proof of Theorem 1.3.(ii) in the unitary case that, for all $n \in \mathbb{Z}$,

$$c_2(\lambda + n) = c_2^g(\lambda) + \left(n + \left|\frac{\lambda}{N}\right|\right)^2 = c_2^g(\lambda) + \left(n + \frac{|\lambda| - |\beta\lambda|}{N} + (\beta\lambda)_1\right)^2,$$

so that we can write, modulo a change of index $n \leftrightarrow n - (\beta\lambda)_1$,

$$Z_N(2, T) = \sum_{\lambda \in \tilde{\text{SU}}(N)} \left(\sum_{n \in \mathbb{Z}} q^{\left(n + \frac{|\lambda| - |\beta\lambda|}{N}\right)^2 \ell_{\lambda+n}}\right) c_2^g(\lambda). \quad (29)$$

Let $\gamma \in (0, \frac{1}{2})$, and the subsets $(\Lambda_{N,i})_{1 \leq i \leq 4}$ of $\tilde{\text{SU}}(N)$ as in the special unitary case. We define, for $1 \leq i \leq 4$,

$$S_{N,i} = \sum_{\lambda \in \Lambda_{N,i}} \left(\sum_{n \in \mathbb{Z}} q^{\left(n + \frac{|\lambda| - |\beta\lambda|}{N}\right)^2 \ell_{\lambda+n}}\right) c_2^g(\lambda),$$

and we obtain the following decomposition:

$$Z_N(1, T) = S_{N,1} + S_{N,2} + S_{N,3} + S_{N,4}.$$

Let $\lambda$ be an element of $\Lambda_{N,1}$. From corollary 3.3 we deduce that $\ell_{\lambda+n} \neq 0$ if and only if $\alpha \neq \beta$ if $N$ is odd or $\alpha \neq \bar{\beta}$ if $N$ is even, where $\alpha = \alpha_\lambda$ and $\beta = \beta_\lambda$ satisfy $\lambda = \lambda_N(\alpha, \beta)$ and $\bar{\beta} = (\beta_1 - \beta_M, \ldots, \beta_{M-1} - \beta_M, 0) \in \text{SU}(M)$. In the following, we will assume that this condition is satisfied by $\lambda + n$ so that it contributes to the partition function.

- If $N = 2M + 1$, then $n + \frac{|\alpha| - |\beta|}{N} = n$ and

$$S_{N,1} = \left(\sum_{n \in \mathbb{Z}} q^{n^2}\right) \sum_{\lambda = \lambda(\alpha, \beta) \in \Lambda_{N,1}} c_2^g(\lambda). \quad (30)$$

We get then back to the SU($N$) case which was previously proved.

- If $N = 2M$, let $\bar{\beta} = (\beta_1, \ldots, \beta_{M-1}, 0)$ as in the $g \geq 3$ case, then $n + \frac{|\alpha| - |\beta|}{N} = n - \frac{M\beta_M}{N}$ and $\beta_M = 0$ if $N$ is large enough because $\lambda$ is almost flat. Hence,

$$S_{N,1} = \left(\sum_{n \in \mathbb{Z}} q^{n^2}\right) \sum_{\lambda = \lambda(\alpha, \beta) \in \Lambda_{N,1}} c_2^g(\lambda). \quad (31)$$

Once again, we get back to the SU($N$) case which was previously proved.

With similar arguments as in the previous proofs, we can prove that $S_{N,2}$, $S_{N,3}$ and $S_{N,4}$ all converge to 0 as they are remainders of convergent series. Finally, using the convergence results from the SU($N$) case, we see that the limit of $S_{2M,1}$ and $S_{2M+1,1}$ is the same, which is the one stated in Theorem 1.4.(ii), and it is therefore the limit of $Z_N(2, T)$. \hfill \square

Acknowledgements

The author would like to thank his PhD advisor, Thierry Lévy, for introducing him to Yang–Mills theory but also for all his help in writing this article. He would also like to thank Antoine Dahlqvist for several helpful discussions about the partition function on the torus.
