ON HANKEL MATRICES COMMUTING WITH JACOBI MATRICES FROM THE ASKEY SCHEME

FRANTIŠEK ŠTAMPACH AND PAVEL ŠTOVÍČEK

Abstract. A complete characterization is provided of Hankel matrices commuting with Jacobi matrices which correspond to hypergeometric orthogonal polynomials from the Askey scheme. It follows, as the main result of the paper, that the generalized Hilbert matrix is the only prominent infinite-rank Hankel matrix which, if regarded as an operator on $\ell^2(\mathbb{N}_0)$, is diagonalizable by application of the commutator method with Jacobi matrices from the mentioned families.

1. Introduction and motivation

Operators acting on $\ell^2(\mathbb{N}_0)$ determined by a Hankel matrix

$$H = \begin{pmatrix} h_0 & h_1 & h_2 & h_3 & \ldots \\ h_1 & h_2 & h_3 & h_4 & \ldots \\ h_2 & h_3 & h_4 & h_5 & \ldots \\ h_3 & h_4 & h_5 & h_6 & \ldots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \quad (1)$$

with $h_k \in \mathbb{R}$, belong to one of the basic classes of linear operators whose general theory has been systematically developed during the last century [5, 6]. In contrast to other well-known classes such as Jacobi, Schrödinger, Toeplitz operators, etc., there are only very few known concrete Hankel matrices that admit an explicit diagonalization, i.e., whose spectral problem is explicitly solvable. In fact, concerning Hankel matrices of infinite rank, the authors were aware of only one such example - the famous (generalized) Hilbert matrix - until recently.

The (generalized) Hilbert matrix is the Hankel matrix (1) with $h_k = \frac{1}{k+t}, \quad k \in \mathbb{N}_0,$

where $t \notin -\mathbb{N}_0$ is a parameter. The Hilbert matrix determines a bounded operator $H_t$ on $\ell^2(\mathbb{N}_0)$ which can be, quite surprisingly, diagonalized fully explicitly. In full generality, the diagonalization of $H_t$ was obtained by Rosenblum in [7, 8]. Preliminary results appeared even earlier [3, 9], however. Rosenblum’s original approach relies on an idea of the so-called commutator method that was successfully applied to other operators later on, see [2, 11, 12].

The commutator method relies on two main steps. First, one has to find a commuting operator with simple spectrum and explicitly solvable spectral problem and, second, determine a spectral mapping. In the case of the Hilbert matrix, one may prefer to consider the transformed Hankel matrix with the entries $\tilde{h}_k = \frac{(-1)^k}{k+t}, \quad k \in \mathbb{N}_0,$

Obviously, the corresponding operator $\tilde{H}_t$ is unitarily equivalent to $H_t$ via unitary transform $U = \text{diag}(1, -1, 1, -1, \ldots)$. The operator $\tilde{H}_t$ can be readily shown to commute with a self-adjoint Jacobi operator $J_t$ given by a tridiagonal matrix $J_t$ with the entries

$$(J_t)_{n,n} = 2n(n+t), \quad (J_t)_{n,n+1} = (J_t)_{n+1,n} = (n+1)(n+t), \quad n \in \mathbb{N}_0, \quad (2)$$
which is the first ingredient for the commutator method to be applied. Indeed, the spectrum of a self-adjoint Jacobi operator is always simple. Moreover, up to an inessential addition of a multiple of the identity operator, the Jacobi operator \( J_t \) corresponds to a particular subfamily of orthogonal polynomials known as the continuous dual Hahn polynomials listed in the Askey hypergeometric scheme \([3]\). As a result, the spectral problem of \( J_t \) is explicitly solvable. Next, by a general fact, \( \tilde{H}_t = h(J_t) \) for a Borel function \( h \). The second step of the commutator method is to determine \( h \) which can be done with the aid of a known generating function formula for the continuous dual Hahn polynomials, see \([2]\) for details. The desired diagonalization of \( \tilde{H}_t \), and hence also of \( H_t \), then follows.

Of course, relying on the commutator method may seem rather restrictive. On the other hand, whenever the method turned out to be applicable it proved itself to be very powerful. In particular, as far as the Hilbert matrix is concerned, the authors are not aware of an alternative way of its diagonalization, other than a variant of the commutator method.

The Askey scheme of hypergeometric orthogonal polynomials \([3]\) can be viewed as a rich source of Jacobi operators with an explicitly solvable spectral problem. For instance, the Wilson polynomials standing at the top of the Askey scheme depend on four additional parameters and hence the same is true for the corresponding Jacobi matrix. Our initial goal was to explore thoroughly this reservoir while trying to find out whether the (generalized) Hilbert matrix is the only Hankel matrix which can be diagonalized with the aid of the commutator method with Jacobi matrices from the Askey scheme or whether there are other infinite-rank Hankel matrices having such a property. And this question was the main motivation for the current paper.

In this study, we distinguish nine families of Hermitian non-decomposable Jacobi matrices

\[
J = \begin{pmatrix}
\beta_0 & \alpha_0 & & \\
\alpha_0 & \beta_1 & \alpha_1 & \\
& \alpha_1 & \beta_2 & \alpha_2 \\
& & \alpha_2 & \beta_3 & \alpha_3 \\
& & & \ddots & \ddots \\
& & & & \ddots & \\
& & & & & \ddots
\end{pmatrix},
\tag{4}
\]

with \( \alpha_n > 0 \) and \( \beta_n \in \mathbb{R} \), corresponding to hypergeometric orthogonal polynomials from the Askey scheme whose measure of orthogonality is positive and supported on an infinite subset of \( \mathbb{R} \). These comprise Wilson, Continuous dual Hahn, Contnuous Hahn, Jacobi, Meixner–Pollaczek, Meixner, Laguerre, Charlier, and Hermite polynomials. On the other hand, Racah, Hahn, dual Hahn, Krawtchouk, Pseudo-Jacobi, and Bessel polynomials are excluded for the associated Jacobi matrices are finite or non-Hermitian. For each family, our main theorem determines the set of parameters for which there exists a nonzero Hankel matrix commuting with the Jacobi matrix in question. In addition, in these quite rare situations, the space of commuting Hankel matrices is always of dimension 2 with an explicitly described basis; see Theorem 1 below.

It may also seem that the set of Jacobi matrices, which we restrict our analysis to, is too special. However, from the viewpoint of the commutator method, whose principle ingredient is always a commuting operator with an explicitly solvable spectral problem, this restriction is reasonable. Naturally, it would be really interesting to have a general characterization of Jacobi matrices commuting with a nontrivial Hankel matrix. Such a problem was solved by Grünbaum in \([1]\) for finite Jacobi matrices commuting with Toeplitz matrices. However, as far as semi-infinite Jacobi and Hankel matrices are concerned, a solution of this problem seems to be out of reach at the moment.

This paper deals with the commutation equation with semi-infinite matrices on the algebraic level only. Passing to operators acting on \( \ell^2(\mathbb{N}_0) \), one would have to additionally require the columns (and hence the rows) of a Hankel matrix \( H \) to be square summable. In that case \( H \) defines a densely defined operator on \( \ell^2(\mathbb{N}_0) \) with the canonical basis in its domain. A consequence of our main theorem is that the (generalized) Hilbert matrix is the only infinite-rank Hankel matrix which can be diagonalized by application of the commutator method using Hermitian non-decomposable Jacobi matrices from the Askey scheme. More precisely, an immediate consequence of Theorem 1 is as follows:
Let \( H \) be a Hankel matrix with \( \ell^2 \)-columns and rank \( H > 1 \) and \( \mathcal{J} \) any Hermitian non-decomposable Jacobi matrix from the Askey scheme (concretely specified below). If \( H\mathcal{J} = \mathcal{J}H \) then \( H \) is a scalar multiple of the Hankel matrix \( \hat{H}_t \) with entries determined in (2) for some \( t \).

This statement is an answer to our original question and emphasizes even more the prominent role played by the Hilbert matrix.

In a bit more detail, our analysis reveals, too, that in all cases when the prominent Hankel matrix \( \hat{H}_t \) commutes with a Jacobi matrix \( \mathcal{J} \) corresponding to orthogonal polynomials from the Askey scheme the diagonal and the off-diagonal sequence of \( \mathcal{J} \) are polynomial functions of index of order 2 and 4, respectively. There is another family of orthogonal polynomials known as the Stieltjes–Carlitz polynomials with the corresponding Jacobi matrix of the same type but not included in the hypergeometric Askey scheme. Rather than to hypergeometric series these polynomials are intimately related to the Jacobian elliptic functions. This observation led the authors to apply the commutator method to Jacobi operators associated with the Stieltjes–Carlitz polynomials. This study resulted in a discovery of four new explicitly diagonalizable Hankel matrices. Their diagonalization is treated in a separate paper [10].

The article is organized as follows. In Section 2, the basic definitions of the considered Jacobi matrices from the Askey scheme as well as restrictions on the involved parameters are recalled. Then the main result is formulated in Theorem 1. Section 3 is devoted to an auxiliary result used in several particular proofs, especially in those corresponding to the most complicated cases. In Section 4 a proof of the main result is given. The mentioned families of orthogonal polynomials are treated case by case starting from the most complicated one (Wilson) and proceeding to simpler cases following the hierarchy of the Askey scheme. A more sophisticated approach is used for the first three families depending on 3 or 4 additional parameters while the remaining cases are treated using a rather elementary computational approach.

2. Notation and statement of the main result

In the notation, the Jacobi matrix associated with a particular family of orthogonal polynomials is distinguished by a corresponding superscript, i.e., we consider nine families of Jacobi matrices

\[ \mathcal{J} = \mathcal{J}^j, \quad \text{for } j \in \{W, CdH, CH, J, MP, M, L, C, H\}. \]

The entries of these matrices can depend on up to four parameters. For the chosen parametrization, we strictly follow [3]. The concrete definitions of the entries are listed below.

I) The Jacobi matrix \( \mathcal{J}^W \) associated with the Wilson polynomials:

\[ \alpha_n^W = \alpha_n^W(a, b, c, d) := \sqrt{A_n^W C_{n+1}^W}, \quad \beta_n^W = \beta_n^W(a, b, c, d) := A_n^W + C_n^W - a^2, \]

where

\[ A_n^W = A_n^W(a, b, c, d) := \frac{(n + a + b)(n + a + c)(n + a + d)(n + a + b + c + d - 1)}{(2n + a + b + c + d - 1)(2n + a + b + c + d - 2)}, \]

\[ C_n^W = C_n^W(a, b, c, d) := \frac{n(n + b + c - 1)(n + b + d - 1)(n + c + d - 1)}{(2n + a + b + c + d - 2)(2n + a + b + c + d - 1)}. \]

Though not obvious at first glance in the case of \( \beta_n^W \), the coefficients \( \alpha_n^W \) and \( \beta_n^W \) are both symmetric functions of the parameters \( a, b, c, d \). The parameters \( a, b, c, d \in \mathbb{C} \) are restricted so that one of the following holds:

1. \( \text{Re } a, \text{Re } b, \text{Re } c, \text{Re } d > 0 \) and the non-real parameters occur in complex conjugate pairs.
2. Up to a permutation of parameters, \( a < 0 \) and \( a + b, a + c, a + d \) positive or a pair of complex conjugates occur with positive real parts.
II) The Jacobi matrix $J_{\text{CdH}}$ associated with the **Continuous dual Hahn** polynomials:

$\alpha_n^{\text{CdH}} = \alpha_n^{\text{CdH}}(a, b, c) := \sqrt{A_n^{\text{CdH}}C_{n+1}^{\text{CdH}}}$ and $\beta_n^{\text{CdH}} = \beta_n^{\text{CdH}}(a, b, c) := A_n^{\text{CdH}} + C_{n+1}^{\text{CdH}} - a^2$, where

$A_n^{\text{CdH}} = A_n^{\text{CdH}}(a, b, c) := (n + a + b)(n + a + c)$,

$C_n^{\text{CdH}} = C_n^{\text{CdH}}(a, b, c) := n(n + b + c - 1)$.

Hence

$\alpha_n^{\text{CdH}} = \sqrt{(n + 1)(n + a + b)(n + a + c)(n + b + c)}$

and

$\beta_n^{\text{CdH}} = 2n^2 + (2a + 2b + 2c - 1)n + ab + ac + bc$.

Clearly, both $\alpha_n^{\text{CdH}}$ and $\beta_n^{\text{CdH}}$ are symmetric functions of $a, b, c$. The parameters $a, b, c \in \mathbb{C}$ are restricted such that one of the following holds:

1. $a, b, c$ are positive except possibly a pair of complex conjugates with positive real parts.
2. Up to a permutation of parameters, $a < 0$ and $a + b, a + c$ are positive or a pair of complex conjugates with positive real parts.

III) The Jacobi matrix $J_{\text{CH}}$ associated with the **Continuous Hahn** polynomials:

$\alpha_n^{\text{CH}} = \alpha_n^{\text{CH}}(a, b, c, d) := \sqrt{-A_n^{\text{CH}}C_{n+1}^{\text{CH}}}$ and $\beta_n^{\text{CH}} = \beta_n^{\text{CH}}(a, b, c, d) := i(\alpha_n^{\text{CH}} + C_n^{\text{CH}} + a)$, where

$A_n^{\text{CH}} = A_n^{\text{CH}}(a, b, c, d) := \frac{(n + a + b + c + d - 1)(n + a + c)(n + a + d)}{(2n + a + b + c + d - 1)(2n + a + b + c + d - 2)}$,

$C_n^{\text{CH}} = C_n^{\text{CH}}(a, b, c, d) := \frac{n(n + b + c - 1)(n + b + d - 1)}{(2n + a + b + c + d - 2)(2n + a + b + c + d - 1)}$.

In this case, $\alpha_n^{\text{CH}}$ and $\beta_n^{\text{CH}}$ are not symmetric functions of $a, b, c, d$ but remain invariant under the permutations of $(a, b, c, d)$ which are composed of two 2-cycles $(a, b, d, c)$, $(c, d, a, b)$, $(d, c, b, a)$. The parameters are supposed to be such that

$c = \tilde{a}, d = \tilde{b}$ and $\text{Re}a > 0, \text{Re}b > 0$.

Then $-A_n^{\text{CH}}C_{n+1}^{\text{CH}} > 0$ and $\beta_n \in \mathbb{R}$ for all $n \in \mathbb{N}_0$, indeed.

IV) The Jacobi matrix $J^J$ associated with the **Jacobi** polynomials:

$\alpha_n^J = \alpha_n^J(\alpha, \beta) := \sqrt{\frac{4(n + 1)(n + \alpha + 1)(n + \beta + 1)(n + \alpha + \beta + 1)}{(2n + \alpha + \beta + 1)(2n + \alpha + \beta + 2)^2(2n + \alpha + \beta + 3)}}$ (9)

and

$\beta_n^J = \beta_n^J(\alpha, \beta) := \frac{\beta^2 - \alpha^2}{(2n + \alpha + \beta)(2n + \alpha + \beta + 2)}$, (10)

where $\alpha, \beta > -1$.

V) The Jacobi matrix $J_{\text{MP}}$ associated with the **Meixner–Polaczek** polynomials:

$\alpha_n^{\text{MP}} = \alpha_n^{\text{MP}}(\lambda, \phi) := \sqrt{\frac{(n + 1)(n + 2)}{2\sin \phi}}$ and $\beta_n^{\text{MP}} = \beta_n^{\text{MP}}(\lambda, \phi) := \frac{n + \lambda}{\tan \phi}$, (11)

where $\lambda > 0$ and $\phi \in (0, \pi)$. For $\phi = \pi/2$, $\beta_n^{\text{MP}}$ is to be understood as zero for all $n \in \mathbb{N}_0$.

VI) The Jacobi matrix $J^M$ associated with the **Meixner** polynomials:

$\alpha_n^M = \alpha_n^M(c, \beta) := \frac{\sqrt{c(n + 1)(n + \beta)}}{1 - c}$ and $\beta_n^M = \beta_n^M(c, \beta) := \frac{n + (n + \beta)c}{1 - c}$, (12)

where $\beta > 0$ and $c \in (0, 1)$. 
VII) The Jacobi matrix $J^L$ associated with the Laguerre polynomials:

$$α_n^L = α_n^L(α) := \sqrt{(n+1)(n+α+1)} \quad \text{and} \quad β_n^L = β_n^L(α) := 2n+α+1,$$

where $α > -1$.

VIII) The Jacobi matrix $J^C$ associated with the Charlier polynomials:

$$α_n^C = α_n^C(α) := \sqrt{α(n+1)} \quad \text{and} \quad β_n^C = β_n^C(α) := n+α,$$

where $a > 0$.

IX) The Jacobi matrix $J^H$ associated with the Hermite polynomials:

$$α_n^H = \sqrt{\frac{n+1}{2}} \quad \text{and} \quad β_n^H = 0.$$

Note that for any $j \in \{W, CdH, CH, J, MP, M, L, C, H\}$, $α_n^j$ and $β_n^j$ may be both regarded as analytic functions in $n$ on a neighborhood of infinity. Hence, whenever convenient, $α_n^j$ and $β_n^j$ are extended to non-integer values of $n$.

Finally, by a commutant of $J$, we mean the space of semi-infinite matrices $A ∈ C^\infty,\infty$ commuting with $J$, i.e., $AJ = JA$ entrywise. Since $J$ is banded the matrix products $AJ$ and $JA$ are well defined for any $A ∈ C^\infty,\infty$. The special attention is paid to Hankel matrices commuting with a given Jacobi matrix $J$, therefore we define the Hankel commutant of $J$ by

$$\text{Comm}_H(J) := \{H ∈ C^\infty,\infty | JH = HJ \text{ and } H \text{ is a Hankel matrix}\}.$$

Clearly, $\text{Comm}_H(J)$ is a linear subspace of $C^\infty,\infty$.

Our main result characterizes $\text{Comm}_H(J^j)$ for $j \in \{W, CdH, CH, J, MP, M, L, C, H\}$. Only in very particular cases, $\text{Comm}_H(J^j)$ is nontrivial, i.e., there exists a nonzero Hankel matrix commuting with a Jacobi matrix from the Askey scheme.

**Theorem 1.** For any $j \in \{W, CdH, CH, J, MP, M, L, C, H\}$, the Hankel commutant $\text{Comm}_H(J^j)$ is either trivial or a two-dimensional space. Moreover, $\dim \text{Comm}_H(J^j) = 2$ if and only if $α_n^j$ and $β_n^j$ depend polynomially on $n$ and $α_{-1}^j = 0$.

Below, we characterize all situations when $\text{Comm}_H(J^j)$ is nontrivial by specifying parameters case by case. In each case, with $\text{Comm}_H(J^j)$ being nontrivial, we determine two sequences, $h^{(1)}$ and $h^{(2)}$, which define two Hankel matrices (as in (1)) that form a basis of $\text{Comm}_H(J^j)$.

(i) $\dim \text{Comm}_H(J^W) = 2$ if and only if, up to a permutation, the parameters $a, b, c, d$ fulfill

$$a = \frac{3}{4}, \quad b = \frac{t}{2} + \frac{4}{3}, \quad c = \frac{t}{2} - \frac{1}{4}, \quad d = \frac{1}{4},$$

for $t > 0$, and if that is the case, we have

$$h^{(1)}_k = \frac{(-1)^k}{k+t} \quad \text{and} \quad h^{(2)}_k = (-1)^k, \quad k ∈ \mathbb{N}_0.$$

(ii) $\dim \text{Comm}_H(J^{CdH}) = 2$ if and only if, up to a permutation, the parameters $a, b, c$ fulfill

$$a = b = \frac{1}{2}, \quad c = t - \frac{1}{2},$$

for $t > 0$, and $h^{(1)}$ and $h^{(2)}$ are as in the case (i).

(iii) $\dim \text{Comm}_H(J^{CH}) = 2$ if and only if the parameters $a, b, c, d$ fulfill

$$a = \bar{c} = \frac{1}{4} + it, \quad b = \bar{d} = \frac{3}{4} + it, \quad \text{or} \quad a = \bar{c} = \frac{3}{4} + it, \quad b = \bar{d} = \frac{1}{4} + it,$$

for $t ∈ \mathbb{R}$, and if that is the case, we have

$$h^{(1)}_k = \sin \frac{kπ}{2} \quad \text{and} \quad h^{(2)}_k = \cos \frac{kπ}{2}, \quad k ∈ \mathbb{N}_0.$
\( (iv) \, \text{Comm}_{H}(\mathcal{J}^J) \) is trivial for all \( \alpha, \beta > -1. \)
\( (v) \, \dim \text{Comm}_{H}(\mathcal{J}^{MP}) = 2 \) if and only if \( \lambda = 1/2 \) and \( \phi \in (0, \pi) \) arbitrary. If so we have
\[ h_k^{(1)} = \sin(k\phi) \quad \text{and} \quad h_k^{(2)} = \cos(k\phi), \quad k \in \mathbb{N}. \]
\( (vi) \, \dim \text{Comm}_{H}(\mathcal{J}^{M}) = 2 \) if and only if \( \beta = 1 \) and \( \epsilon \in (0, 1) \) arbitrary. If so we have
\[ h_k^{(1)} = (-1)^k k^{1/2} \quad \text{and} \quad h_k^{(2)} = (-1)^k c^{-k/2}, \quad k \in \mathbb{N}. \]
\( (vii) \, \dim \text{Comm}_{H}(\mathcal{J}^{L}) = 2 \) if and only if \( \alpha = 0 \) and we have
\[ h_k^{(1)} = (-1)^k \quad \text{and} \quad h_k^{(2)} = (-1)^k k, \quad k \in \mathbb{N}. \]
\( (viii) \, \text{Comm}_{H}(\mathcal{J}^{C}) \) is trivial for all \( a > 0. \)
\( (ix) \, \dim \text{Comm}_{H}(\mathcal{J}^{H}) = 2 \) and \( h^{(1)} \) and \( h^{(2)} \) are as in the case (iii).

**Remark** 2. Clearly, those restrictions of parameters which are dictated by requiring the Jacobi matrices from the Askey scheme to be Hermitian are not essential for every claim of Theorem 1. For example, it follows from the claim (ii) that the Jacobi matrix \( J_{0} \) defined in (3) and the Hankel matrix \( H_{0} \) whose entries are given by (2) commute for any parameter \( t > 0. \) Obviously this assertion can be extended to all \( t \in \mathbb{C} \setminus \{ -\mathbb{N}_0 \} \).

### 3. An auxiliary result

The following lemma will be used repeatedly below. Its statement can be of independent interest. It has been also applied in [10].

**Lemma 3.** Let \( p \) and \( q \) be complex functions which are meromorphic in a neighborhood of \( \infty \) and assume that the order of the pole at \( \infty \) equals 2 for both of them. Further let \( \epsilon \in \mathbb{C}, \epsilon \neq 0, \) and put, for \( z, w \in \mathbb{C} \) sufficiently large,
\[
M(z, w) := \begin{pmatrix} p(z + \epsilon) - p(w - \epsilon) & q(z + \epsilon) - q(w - \epsilon) \\ p(z - \epsilon) - p(w + \epsilon) & q(z - \epsilon) - q(w + \epsilon) \end{pmatrix}.
\]
Let us write the determinant of \( M(z, w) \) in the form
\[
\det M(z, w) = ((z - w)^2 - 4\epsilon^2) \delta(z, w).
\]
If at least one of the functions \( p(z) \) and \( q(z) \) is not a polynomial in \( z \) of degree 2 and the set of functions \( \{1, p, q\} \) is linearly independent, then one of the following two cases happens:
- \( \text{(i) for every } w \in \mathbb{C} \text{ sufficiently large there exists } \lim_{z \to \infty} \delta(z, w) \in \mathbb{C} \setminus \{0\}, \)
- \( \text{(ii) for every } w \in \mathbb{C} \text{ sufficiently large there exists } \lim_{z \to \infty} z\delta(z, w) \in \mathbb{C} \setminus \{0\}. \)

Consequently, for every \( w \in \mathbb{C} \) sufficiently large there exists \( R(w) > 0 \) such that for all \( z \in \mathbb{C}, |z| > R(w), \) the matrix \( M(z, w) \) is regular.

**Proof.** Without loss of generality we can assume that the leading coefficient in the Laurent expansion about \( \infty \) equals 1 for both \( p \) and \( q. \) So we can write
\[
p(z) = z^2 + \sum_{k=-1}^{\infty} p_k z^{-k}, \quad q(z) = z^2 + \sum_{k=-1}^{\infty} q_k z^{-k}.
\]
Let
\[
P(x, y) := \sum_{n=1}^{\infty} p_n \sum_{j=0}^{n-1} x^j y^{n-j-1}, \quad Q(x, y) := \sum_{n=1}^{\infty} q_n \sum_{j=0}^{n-1} x^j y^{n-j-1},
\]
and
\[
P_0(y) := P(0, y) = \sum_{n=1}^{\infty} p_n y^{n-1}, \quad Q_0(y) := Q(0, y) = \sum_{n=1}^{\infty} q_n y^{n-1}.
\]
Note that
\[
\frac{p(x) - p(y)}{x - y} = x + y + p_{-1} - \frac{1}{xy} P \left( \frac{1}{x}, \frac{1}{y} \right), \quad \frac{q(x) - q(y)}{x - y} = x + y + q_{-1} - \frac{1}{xy} Q \left( \frac{1}{x}, \frac{1}{y} \right). \quad (16)
\]
Clearly, \( p \) and \( q \) are polynomials of degree 2 if and only if \( P_0(y) = Q_0(y) = 0. \) Furthermore, the functions \( \{1, p, q\} \) are linearly dependent if and only if \( p(z) - p_0 = q(z) - q_0 \) for all
sufficiently large $z$, and this happens if and only if $p_{-1} = q_{-1}$ and $P_0(y) = Q_0(y)$ (the latter equation can be equivalently replaced by $P(x,y) = Q(x,y)$).

Thus we assume that either (1) $P_0(y) \neq Q_0(y)$ or (2) $P_0(y) = Q_0(y) \neq 0$ (equivalently, $P(x,y) = Q(x,y) \neq 0$) and $p_{-1} \neq q_{-1}$.

Put

$$\tilde{\delta}(u,v) := \delta\left(\frac{1}{u}, \frac{1}{v}\right).$$

We have to explore the properties of $\tilde{\delta}(u,v)$ for $u$ and $v$ sufficiently small. A straightforward computation based on (16) shows that

$$(1 - \epsilon^2 u^2)(1 - \epsilon^2 v^2)\tilde{\delta}(u,v)$$

$$= \left(\frac{u}{1 + \epsilon u} \cdot \frac{v}{1 - \epsilon v}\right) - (1 + \epsilon u)(1 - \epsilon v)Q\left(\frac{u}{1 - \epsilon u}, \frac{v}{1 + \epsilon v}\right)$$

$$- \left(1 + \epsilon u\right)(1 + \epsilon v)P\left(\frac{u}{1 + \epsilon u}, \frac{v}{1 - \epsilon v}\right) - (1 + \epsilon u)(1 - \epsilon v)P\left(\frac{u}{1 - \epsilon u}, \frac{v}{1 + \epsilon v}\right)$$

$$+ u^2 v^2 \left(P\left(\frac{u}{1 + \epsilon u}, \frac{v}{1 - \epsilon v}\right) - Q\left(\frac{u}{1 - \epsilon u}, \frac{v}{1 - \epsilon v}\right) \right).$$

(17)

We shall need the following simple observation. Let $f(u)$ be a holomorphic function in a neighborhood of 0 (and still assuming that $\epsilon \in \mathbb{C}$, $\epsilon \neq 0$). Then the function

$$(1 + \epsilon u)f\left(\frac{u}{1 - \epsilon u}\right) - (1 - \epsilon u)f\left(\frac{u}{1 + \epsilon u}\right)$$

vanishes identically in a neighborhood of 0 if and only if the same is true for $f(u)$.

Indeed, suppose that $f(u)$ does not vanishes identically in a neighborhood of 0 and let $n \in \mathbb{N}_0$ be the multiplicity of the root of $f(u)$ at $u = 0$. Then $f(u) = f_n u^n + O(u^{n+1})$ as $u \to 0$ where $f_n \in \mathbb{C}$, $f_n \neq 0$, and one immediately finds that

$$(1 + \epsilon u)f\left(\frac{u}{1 - \epsilon u}\right) - (1 - \epsilon u)f\left(\frac{u}{1 + \epsilon u}\right) = 2\epsilon(n + 1)f_n u^{n+1} + O(u^{n+2}).$$

From (17) it is seen that

$$(1 - \epsilon^2 u^2)(1 - \epsilon^2 v^2)\tilde{\delta}(u,v) = \left(1 + \epsilon v\right)\left(Q_0\left(\frac{v}{1 - \epsilon v}\right) - P_0\left(\frac{v}{1 - \epsilon v}\right)\right)$$

$$- (1 - \epsilon v)\left(Q_0\left(\frac{v}{1 + \epsilon v}\right) - P_0\left(\frac{v}{1 + \epsilon v}\right)\right) + \Phi(u,v)u$$

(18)

where $\Phi(u,v)$ is an analytic function for $u, v$ belonging to a neighborhood of 0. Hence, by the above observation, if $P_0(y) \neq Q_0(y)$ and $v \neq 0$ is sufficiently small then the leading coefficient in the asymptotic expansion of the RHS of (18), as $u \to 0$, is nonzero.

Consider now the case $P_0(y) = Q_0(y) \neq 0$ ($P(x,y) = Q(x,y) \neq 0$) and $p_{-1} \neq q_{-1}$. Then equation (17) simplifies to

$$(1 - \epsilon^2 u^2)(1 - \epsilon^2 v^2)\tilde{\delta}(u,v)$$

$$= \left(\frac{u}{1 - \epsilon u} \cdot \frac{v}{1 - \epsilon v}\right) - (1 + \epsilon u)(1 - \epsilon v)P\left(\frac{u}{1 - \epsilon u}, \frac{v}{1 + \epsilon v}\right).$$
From here it is seen that
\[
(1 - e^2 u^2)(1 - e^2 v^2)\delta(u, v) = (p_{-1} - q_{-1}) \left( (1 + e\nu)\nu_0 \left( \frac{v}{1 - e\nu} \right) - (1 - e\nu)\nu_0 \left( \frac{v}{1 + e\nu} \right) \right) v\nu + \Psi(u, v)u^2
\]
where \(\Psi(u, v)\) is an analytic function for \(u, v\) belonging to a neighborhood of 0.

Referring again to the above observation we conclude that the leading coefficient in the asymptotic expansion of the RHS of (19), as \(u \to 0\), is nonzero for all sufficiently small \(v \neq 0\).

\[\square\]

4. Proof of the main theorem

4.1. General equations. Consider semi-infinite matrices \(J\) and \(H\) indexed by \(m, n \in \mathbb{N}_0\) where \(J\) is a Jacobi matrix \([I]\) determined by two complex sequences \(\{\alpha_n\} \) and \(\{\beta_n\}\), with \(\alpha_n \neq 0\) for all \(n \geq 0\), and \(H\) is a Hankel matrix \([I]\). It is convenient and common to set \(\alpha_{-1} := 0\).

Matrices \(H\) and \(J\) commute if and only if it holds true that
\[
(\alpha_n - \alpha_m)h_{n+m+1} + (\beta_n - \beta_m)h_{n+m} + (\alpha_{n-1} - \alpha_{m-1})h_{n+m-1} = 0
\]
for all \(m, n \in \mathbb{N}_0\) (\(h_{-1}\) is arbitrary). In particular, letting \(m = 0\) we have
\[
(\alpha_n - \alpha_0)h_{n+1} + (\beta_n - \beta_0)h_n + \alpha_{n-1}h_{n-1} = 0
\]
for all \(n \in \mathbb{N}\). Taking into account the descending recurrence it is clear that, for any \(n \in \mathbb{N}_0\), if \(h_n = h_{n+1} = 0\), then \(h_0 = h_1 = \ldots = h_n = h_{n+1} = 0\).

4.2. Wilson. We shall need the asymptotic expansions of \(\alpha_n^W\) and \(\beta_n^W\):
\[
\alpha_n^W = \frac{n^2}{4} + \frac{sn}{4} + A_0 + O\left( \frac{1}{n} \right), \quad \beta_n^W = \frac{n^2}{2} + \frac{(s-1)n}{2} + B_0 + O\left( \frac{1}{n} \right) \quad \text{as} \quad n \to \infty,
\]
where \(s := a + b + c + d\) and \(A_0, B_0\) are constants. Explicitly,
\[
A_0 = \frac{1}{32} (-3 + 4a + 4b + 4c + 4d - 2a^2 - 4b^2 - 2c^2 - 2d^2 + 4ab + 4ac + 4ad + 4bc + 4bd + 4cd),
\]
\[
B_0 = \frac{1}{8} (-a^2 - b^2 - c^2 - d^2 + 2ab + 2ac + 2ad + 2bc + 2bd + 2cd).
\]

The following proposition is in fact an implication stated in Theorem \([I]\) ad (i). Its proof is more straightforward than that for the opposite direction.

Proposition 4. If \(\alpha_n^W\) and \(\beta_n^W\) depend both polynomially on \(n\), then \(\text{Comm}_H(J^W)\) is non-trivial if and only if \(\alpha_n^W = 0\). If so, \(\text{Comm}_H(J^W) = \text{span}(H^{(1)}, H^{(2)})\), where \(H^{(1)}\) and \(H^{(2)}\) are Hankel matrices determined by the sequences
\[
h^{(1)}_k = \frac{(-1)^k}{k+s-1} \quad \text{and} \quad h^{(2)}_k = (-1)^k, \quad k \in \mathbb{N}_0,
\]
respectively.

Proof. Suppose \(\alpha_n^W\) and \(\beta_n^W\) are polynomials in \(n\). Then the form of the polynomials is seen from the asymptotic formulas \([22]\) in which the Landau symbol becomes zero. Plugging these expressions into \([20]\) and canceling the common term \((n - m)\) one arrives at a recurrence equation for the entries of the Hankel matrix \(H\) in which the indices occur in the combination \(m + n\) only. Writing \(k\) instead of \(m + n\), the recurrence reads
\[
(k + s)h_{k+1} + 2(k + s - 1)h_k + (k + s - 2)h_{k-1} = 0, \quad k \in \mathbb{N}.
\]
Its two linearly independent solutions are given by \([23]\). Consequently, any \(H \in \text{Comm}_H(J^W)\) has to be a linear combination of \(H^{(1)}\) and \(H^{(2)}\). Moreover, it is easy to see that any such \(H\), if nontrivial, can commute with \(J^W\) if and only if \(\alpha_n^W = 0\).

\[\square\]
In order to complete the proof of Theorem 4 and (i) we have to prove the implication opposite to that stated in Proposition 3. To this end, we need the following equivalent condition for a polynomial dependence of $\alpha_n^W$ and $\beta_n^W$ on $n$ to hold true.

**Lemma 5.** The following two statements are equivalent:

1. $\alpha_n^W$ and $\beta_n^W$ depend both polynomially on $n \in \mathbb{N}_0$.
2. There exists a constant $\omega$ such that
   \[ \beta_n^W - \alpha_n^W = -\alpha_{n-1}^W + \omega, \quad \forall n \in \mathbb{N}. \] (24)

Moreover, statement (2) can be true only if $\omega = 1/16$.

**Proof.** If $\alpha_n^W$ and $\beta_n^W$ depend both polynomially on $n$ then the form of the polynomials can be deduced from the asymptotic formulas (22) in which the Landau symbols vanish identically. The implication (1) $\Rightarrow$ (2) is then a matter of a straightforward calculation showing that (24) holds provided we let $\omega = 1/16$.

The opposite implication (2) $\Rightarrow$ (1) is more tedious. From (22) one finds that
\[ \beta_n^W - \alpha_n^W = -\alpha_{n-1}^W + \omega = \omega - \frac{1}{16} + O\left(\frac{1}{n}\right) \text{ as } n \to \infty. \]
Hence necessarily $\omega = 1/16$.

Further we deduce from (24) some necessary conditions on the parameters $a, b, c, d$. The equation implies that
\[ \left((\beta_n^W + \omega)^2 - (\alpha_n^W)^2 - (\alpha_{n-1}^W)^2\right)^2 - 4(\alpha_n^W)^2(\alpha_{n-1}^W)^2 = 0, \quad \forall n \in \mathbb{N}. \] (25)

We temporarily denote by $f(n)$ the left-hand side of (25). From (5), (6) and (7) it is seen that $f(n)$ is a rational function of $n$. Since $f(n)$ has infinitely many roots it vanishes identically as a complex function. This is equivalent to saying that the rational function $f(n)$ has no poles and vanishes at infinity.

Let us check possible poles of $f(n)$. From (25) and (5), (6), (7) it is clear that $f(n)$ can occur only at the points $z_j = (4 - j - s)/2, j = 1, 2, 3, 4, 5$. Here we still denote $s = a + b + c + d$.

As a necessary condition, we require that, looking at the Laurent expansion of $f(n)$ around each isolated singularity $z_j$, the coefficient corresponding to the highest possible order of the pole that can occur in the expansion vanishes. Doing so we shall confine ourselves only to points $z_1$ and $z_2$, however, since it turns out that inspection of the remaining points does not lead to additional constraints.

As far as the singular point $z_1 = (3 - s)/2$ is concerned, this singularity may occur only in the term $(\alpha_{n-1}^W)^2$, and it does not occur in $\beta_n^W$ and $(\alpha_n^W)^2$. By inspection of the left-hand side of (25) one readily obtains a condition on the residue
\[ \text{Res}_{n=z_1}(\alpha_{n-1}^W)^2 = 0, \text{ equivalently, Res}_{n=z_2}(\alpha_n^W)^2 = 0. \]

Using the explicit definition of $(\alpha_n^W)^2$ it is straightforward to derive that the residue is zero if and only if
\[ ((a + b + c - d)^2 - 1) ((a - b + c - d)^2 - 1) ((a - b - c + d)^2 - 1) (s - 3)(s - 1) = 0. \] (26)

As for the singular point $z_2 = (2 - s)/2$, this pole may occurred in $\beta_n^W$ with order 1 and in $(\alpha_{n-1}^W)^2$ with order 2, but not in $(\alpha_n^W)^2$. An inspection of the left-hand side of (24) shows that the coefficient standing at $(n - z_2)^2$ in the Laurent expansion around $z_2$ of $(\beta_n^W)^2 - (\alpha_{n-1}^W)^2$ must be zero. As one can check, $\text{Res}_{n=z_2} A_{n-1}^W = -\text{Res}_{n=z_2} C_n^W$ and therefore this condition reduces to
\[ \text{Res}_{n=z_2} C_n^W = 0. \]

This is true if and only if
\[ (a + b - c - d)(a - b + c - d)(a - b - c + d)(s - 2) = 0. \] (27)

Equations (26) and (27) imply a finite number of constraints on the parameters $a, b, c, d$ which can be discussed case by case. Given that $\alpha_n^W$ and $\beta_n^W$ are symmetric in $a, b, c, d$ it suffices to consider the following four cases covering all possibilities up to a permutation of the parameters:
In order to complete the discussion successfully we will also take into account the asymptotic behavior of \( \beta_n - \alpha_n - \alpha_{n-1} + 1/16 \) at infinity.

In case (i) we have \( b = 1/2 - a, d = 1/2 - c \). Then a computation shows that
\[
\beta_n - \alpha_n - \alpha_{n-1} + \frac{1}{16} = \frac{(4a - 1)(4c - 1)2}{256} \frac{1}{n^2} + O\left(\frac{1}{n^3}\right) \text{ as } n \to \infty.
\]
Hence we have to put either \( a = 1/4 \) or \( c = 1/4 \) but the two choices differ just by a permutation of parameters. We obtain
\[
\alpha_n \left(a, \frac{1}{2} - a, \frac{1}{2}, \frac{1}{4}\right) = \frac{1}{64} (4n + 4a + 1)(4n - 4a + 3),
\]
\[
\beta_n \left(a, \frac{1}{2} - a, \frac{1}{2}, \frac{1}{4}\right) = \frac{1}{32} (16n^2 - 16a^2 + 8a + 1).
\]

In case (ii) we have \( b = 3/2 - a, d = 3/2 - c \). Then a computation shows that
\[
\beta_n - \alpha_n - \alpha_{n-1} + \frac{1}{16} = \frac{(4a - 3)(4c - 3)2}{256} \frac{1}{n^2} + O\left(\frac{1}{n^3}\right) \text{ as } n \to \infty.
\]
Hence we have to put either \( a = 3/4 \) or \( c = 3/4 \) but again the two choices differ by a permutation of parameters. We obtain
\[
\alpha_n \left(a, \frac{3}{2} - a, \frac{3}{4}, \frac{3}{4}\right) = \frac{1}{64} (4n + 4a + 3)(4n - 4a + 9),
\]
\[
\beta_n \left(a, \frac{3}{2} - a, \frac{3}{4}, \frac{3}{4}\right) = \frac{1}{32} (16n^2 + 32n - 16a^2 + 24a + 9).
\]

In case (iii) we have \( b = 3/2 - a, d = 1/2 - c \). Then a computation shows that
\[
\beta_n - \alpha_n - \alpha_{n-1} + \frac{1}{16} = \frac{(4a - 3)(4c - 3)2}{256} \frac{1}{n^2} + O\left(\frac{1}{n^3}\right) \text{ as } n \to \infty.
\]
Now we have to distinguish two sub-cases. In sub-case (iii)a we let \( a = 3/4, b = 3/4, d = 1/2 - c \), and we obtain
\[
\alpha_n \left(\frac{3}{4}, \frac{3}{4}, c, \frac{1}{2} - c\right) = \frac{1}{64} (4n - 4c + 5)(4n + 4c + 3),
\]
\[
\beta_n \left(\frac{3}{4}, \frac{3}{4}, c, \frac{1}{2} - c\right) = \frac{1}{32} (16n^2 + 16n - 16c^2 + 8c + 5).
\]

In sub-case (iii)b we let \( b = 3/2 - a, c = 1/4, d = 1/4 \), and we obtain
\[
\alpha_n \left(a, \frac{3}{2} - a, \frac{1}{4}, \frac{1}{4}\right) = \frac{1}{64} (4n - 4a + 7)(4n + 4a + 1),
\]
\[
\beta_n \left(a, \frac{3}{2} - a, \frac{1}{4}, \frac{1}{4}\right) = \frac{1}{32} (16n^2 + 16n - 16a^2 + 24a - 3).
\]

In case (iv) we have \( d = a - 1/2, c = b - 1/2 \). Then a computation shows that
\[
\beta_n - \alpha_n - \alpha_{n-1} + \frac{1}{16} = \frac{(4a - 3)(4b - 3)2}{256} \frac{1}{n^2} + O\left(\frac{1}{n^3}\right) \text{ as } n \to \infty.
\]
Hence we have to put either \( a = 3/4 \) or \( b = 3/4 \) but again the two choices differ by a permutation of parameters. We obtain
\[
\alpha_n \left(\frac{3}{4}, b, b - \frac{1}{2}, \frac{1}{4}\right) = \frac{1}{8} (n + 1)(2n + 4b - 1),
\]
\[
\beta_n \left(\frac{3}{4}, b, b - \frac{1}{2}, \frac{1}{4}\right) = \frac{1}{16} (8n^2 + 4(4b - 1)n + 8b - 3).
We conclude that the four discussed cases show that whenever \((\alpha_n^W, \beta_n^W)\) holds then \(\alpha_n^W\) and \(\beta_n^W\) are polynomials in \(n\).

**Remark 6.** As a matter of fact, in the second part of the proof of Lemma 5 we have found all configurations of the parameters, up to a permutation, when \(\alpha_n^W\) and \(\beta_n^W\) are polynomials in \(n\). But not in all found cases the requirement is met that the polynomial for \(\alpha_n^W\) vanishes at \(n = -1\). Imposing in addition this requirement we are left with the following admissible configurations of the parameters \((a, b, c, d)\), again up to a permutation:

\[
\begin{align*}
(i) \; (-1/4, 3/4, 1/4, 1/4), \\
(ii) \; (1/4, 5/4, 3/4, 3/4), \\
(iii) \; (3/4, 3/4, 1/4, 1/4), \\
(iv) \; (3/4, b, b - 1/2, 1/4).
\end{align*}
\]

But (i), (ii) and (iii) are particular cases of (iv), possibly up to a permutation: (i) for \(b = 1/4\), (ii) for \(b = 5/4\), (iii) for \(b = 3/4\). Moreover, taking the constrains on the parameters \(a, b, c, d\) given below equation (3) into account, case (iv) is admissible only if \(b > 1/4\). By writing \(b = 1/4 + t/2\), for \(t > 0\), we obtain the parametrization used in claim (i) of Theorem 4.

Now we are ready to prove the opposite implication of Theorem 4.

**Proposition 7.** If \(\text{Comm}_H(J^W)\) is nontrivial, then \(\alpha_n^W\) and \(\beta_n^W\) depend polynomially on \(n\) and \(\alpha_{n-1} = 0\).

**Proof.** We shall proceed by contradiction. Remember, however, as observed in Proposition 4, if \(\alpha_n^W\) and \(\beta_n^W\) depend both polynomially on \(n\) but \(\alpha_{n-1}^W \neq 0\) then \(\text{Comm}_H(J^W)\) is trivial. Hence to get a contradiction we assume that \(\text{Comm}_H(J^W)\) is nontrivial and either \(\alpha_n^W\) or \(\beta_n^W\) is not a polynomial in \(n\).

Furthermore, without loss of generality we can assume that entries \(h_n\) of a nonzero Hankel matrix \(H\) commuting with \(J^W\) are real. We shall also make use of the fact that \(\alpha_n^W\) and \(\beta_n^W\) may be both regarded as analytic functions in \(n\) for \(n \) sufficiently large.

Along with (29) we consider the equation

\[
(\alpha_{n-1} - \alpha_{m+1})h_{n+m+1} + (\beta_{n-1} - \beta_{m+1})h_{n+m} + (\alpha_{n-2} - \alpha_{m})h_{n+m-1} = 0. 
\]

Let again \(s := a + b + c + d\). From the asymptotic behavior

\[
\alpha_n^W = \frac{n^2}{4} + \frac{8n}{4} + O(1), \quad \beta_n^W = \frac{2^n}{2} + \frac{(s-1)n}{2} + O(1), \quad \alpha_{n-1}^W = \frac{n^2}{4} + \frac{(s-2)n}{4} + O(1),
\]

as \(n \to \infty\), it is clear that none of the sets of functions in \(n\), \(\{\alpha_n^W, \beta_n^W\}\) or \(\{\alpha_{n-1}^W, 1\}\) in \(\{\alpha_n^W, \alpha_{n-1}^W\}\), is linearly dependent.

Let

\[
\delta_1(n, m) := \det \left( \begin{array}{ccc} \beta_n^W - \beta_m^W & \alpha_n^W - \alpha_m^W \\ \beta_{n-1}^W - \beta_{m+1}^W & \alpha_{n-1}^W - \alpha_{m+1}^W \end{array} \right), \quad \delta_2(n, m) := -\det \left( \begin{array}{ccc} \alpha^n_W - \alpha_m^W & \alpha_{n-1}^W - \alpha_{m}^W \\ \alpha_{n-1}^W - \alpha_{m}^W & \alpha_{n-2}^W - \alpha_m^W \end{array} \right), \quad \delta_3(n, m) := \det \left( \begin{array}{ccc} \alpha^n_W - \alpha_m^W & \beta^n_W - \beta_m^W \\ \alpha_{n-1}^W - \alpha_{m+1}^W & \beta_{n-1}^W - \beta_{m+1}^W \end{array} \right).
\]

According to Lemma 3 for all \(m\) sufficiently large there exists \(R_m \in \mathbb{N}\) such that for all \(n \geq R_m\), \(\delta_1(n, m) \neq 0\) and \(\delta_3(n, m) \neq 0\). Then, by equations (20) and (28), the vectors

\[
(h_{n+r+1}, h_{n+m}, h_{n+m-1}) \quad \text{and} \quad (\delta_1(n, m), \delta_2(n, m), \delta_3(n, m))
\]

are linearly dependent.

We can assume that \(R_m\) is so large that \(\alpha_n^W - \alpha_m^W > 0\) for all \(n \geq R_m\). Referring to (20) and (21), one can see that the former of the two vectors in (30) is necessarily nonzero, too. Otherwise \(h_n = 0\) identically. Hence \(\delta_2(n, m) \neq 0\) implies that \(h_{n+m-1} \neq 0\) for \(n \geq R_m\). This in turn implies that \(\delta_2(n, m) \neq 0\) for \(n \geq R_m\). Note that, consequently, \(\alpha_n^W\) cannot be a polynomial since otherwise \(\delta_2(n, m) = 0\) identically.

Fix sufficiently large \(m \in \mathbb{N}\). Then for all \(n \in \mathbb{N}_0\), \(n \geq m_0 := R_m + m\), it we have

\[
h_{n+1} = \psi(n)h_n, \quad \text{with} \quad \psi(n) := \frac{\delta_1(n - m, m)}{\delta_2(n - m, m)}.
\]
It is of importance that $\psi(n)$ can be regarded as a meromorphic function of $n$ in a neighborhood of $\infty$. Particularly, $\psi(n)$ has an asymptotic expansion to all orders as $n \to \infty$.

In view of Lemma 3 there are only three possible types of asymptotic behavior of $\psi(n)$ as $n \to \infty$:

(I) $\psi(n) = \lambda_1 \left(1 + O\left(\frac{1}{n}\right)\right)$,

(II) $\psi(n) = \lambda_2 n \left(1 + O\left(\frac{1}{n}\right)\right)$,

(III) $\psi(n) = \frac{\lambda_3}{n} \left(1 + O\left(\frac{1}{n}\right)\right)$,

where $\lambda_j \neq 0$ for $j = 1, 2, 3$. From here one can deduce the asymptotic behavior of

$$h_n = h_{m_0} \prod_{k=m_0}^{n-1} \psi(k).$$

In case (I) we have

$$h_n = c_1 \lambda_1^n n^{\sigma_1} \left(1 + O\left(\frac{1}{n}\right)\right) \text{ as } n \to \infty,$$

for some $c_1, \sigma_1 \in \mathbb{R}$, $c_1 \neq 0$. In case (II) we have

$$h_n = c_2 \lambda_2^n n^{\sigma_2} \left(1 + O\left(\frac{1}{n}\right)\right) \text{ as } n \to \infty,$$

for some $c_2, \sigma_2 \in \mathbb{R}$, $c_2 \neq 0$. In case (III) we have

$$h_n = \frac{c_3 \lambda_3^n}{n} n^{\sigma_3} \left(1 + O\left(\frac{1}{n}\right)\right) \text{ as } n \to \infty,$$

for some $c_3, \sigma_3 \in \mathbb{R}$, $c_3 \neq 0$.

Rewriting (20) and taking into the account the asymptotic behavior of $\alpha_n^W$ and $\beta_n^W$, we obtain

$$h_{n+1} + \frac{\beta_n^W - \beta_m^W}{\alpha_n^W - \alpha_m^W} h_n + \frac{\alpha_{n-m}^W - \alpha_m^W}{\alpha_{n-m}^W - \alpha_m^W} h_{n-1}$$

$$= h_{n+1} + 2 \left(1 + O\left(\frac{1}{n}\right)\right) h_n + \left(1 + O\left(\frac{1}{n}\right)\right) h_{n-1} = 0. \tag{31}$$

It is readily seen that the asymptotic behavior of $h_n$ of type (II) and (III) is incompatible with (31). Hence the only admissible asymptotic behavior of $h_n$ is that of type (I). Without loss of generality we can suppose that $c_1 = 1$. Moreover, from (31) it is also seen that $\lambda_1$ should solve the equation $\lambda_1^2 + 2\lambda_1 + 1 = 0$ whence $\lambda_1 = -1$. Furthermore, for the sake of simplicity we will drop the index in $\sigma_1$. Thus we obtain

$$h_n = (-1)^n (n + 1)^\sigma \varphi(n) \tag{32}$$

where

$$\varphi(n) = 1 + O\left(\frac{1}{n}\right) \text{ as } n \to \infty. \tag{33}$$

As a matter of fact, $\varphi(n)$ has an asymptotic expansion to all orders as $n \to \infty$.

Plugging (32) into (20) we obtain

$$\left(\alpha_n^W - \alpha_m^W\right) \left(1 + \frac{1}{n + 1}\right)^\sigma \varphi(n + 1) - (\beta_n^W - \beta_m^W) \varphi(n)$$

$$+ \left(\alpha_{n-1}^W - \alpha_{m-1}^W\right) \left(1 - \frac{1}{n + 1}\right)^\sigma \varphi(n - 1) = 0. \tag{34}$$

The asymptotic expansion of the LHS of (34) as $n \to \infty$, with $m$ being fixed but otherwise arbitrary, while taking into account (58) and (22) and substituting for $s$, $A_0$, $B_0$, yields the expression

$$\beta_m^W - \alpha_m^W - \alpha_{m-1}^W + \frac{\sigma (\sigma + 1)}{4} + \frac{1}{16} + O\left(\frac{1}{n}\right).$$
Hence

\[ \beta^W_n - \alpha^W_n - \alpha^W_{n-1} + \frac{\sigma(\sigma + 1)}{4} + \frac{1}{16} = 0, \text{ for all } m \in \mathbb{N}_0. \]

Lemma 8 implies that \( \beta^W_n \) and \( \alpha^W_n \) depend both polynomially on \( n \), a contradiction. □

In summary, as far as the Jacobi matrix \( J^W \) is concerned, the equivalence stated in Theorem 4 ad (i) means two implications which are established by Propositions 4 and 7. Along with Remark 6 this concludes the proof of Theorem 1 ad (i).

4.3. Continuous dual Hahn. The approach used in the case of Wilson polynomials can be also applied in the case of Continuous dual Hahn polynomials with no essential difference. Due to the considerably simpler form of the Jacobi parameters \( \alpha_n^{\text{CdH}} \) and \( \beta_n^{\text{CdH}} \) (but the same order of the asymptotic behavior for \( n \to \infty \)), some parts of the proof simplify significantly. Observe that \( \beta_n^{\text{CdH}} \) is a polynomial in \( n \) for all values of the parameters \( a, b, c \). Namely, we have

\[ \beta_n^{\text{CdH}} = 2n^2 + (2s - 1)n + \tilde{s}, \quad \text{(35)} \]

where we denote \( s := a + b + c \) and \( \tilde{s} := ab + ac + bc \). In addition,

\[ \alpha_n^{\text{CdH}} = n^2 + 2s + 1 \left( \frac{2n + 4s - 1}{8} + O\left(\frac{1}{n}\right) \right), \quad \text{as } n \to \infty. \quad \text{(36)} \]

Proposition 8. If \( \alpha_n^{\text{CdH}} \) depends polynomially on \( n \), then \( \text{Comm}(J^{\text{CdH}}) \) is nontrivial. More precisely, if that is the case, \( \text{Comm}(J^{\text{CdH}}) = \langle \mathcal{H}^{(1)}, \mathcal{H}^{(2)} \rangle \), where \( \mathcal{H}^{(1)} \) and \( \mathcal{H}^{(2)} \) are Hankel matrices determined by the sequences

\[ h_k^{(1)}(n) = \frac{(-1)^k}{k + s - 1/2} \quad \text{and} \quad h_k^{(2)}(n) = (-1)^k, \quad k \in \mathbb{N}_0, \quad \text{(37)} \]

depends polynomially on \( n \) if and only if two of the parameters \( a, b, c \) are equal to \( 1/2 \). In this case, \( \alpha_n^{\text{CdH}} = 0 \) automatically. Assuming that \( \alpha_n^{\text{CdH}} \) is a polynomial in \( n \), the Landau symbol in (36) is identically vanishing. Plugging this expression together with (35) into (29), one infers that any \( \mathcal{H} \in \text{Comm}(J^{\text{CdH}}) \), with \( \mathcal{H}_{m,n} = h_{m+n}, \) if and only if \( \{h_n\} \) is a solution of the three-term recurrence

\[ (k + s + 1/2)h_{n+1} + (2k + 2s - 1)h_{n} + (k + s - 3/2)h_{n-1} = 0, \quad k \in \mathbb{N}. \]

The two linearly independent solutions of the above recurrence are given by (37) and the proof follows. □

Lemma 9. The following two statements are equivalent:

(1) \( \alpha_n^{\text{CdH}} \) depends polynomially on \( n \).

(2) There exists a constant \( \omega \) such that

\[ \beta_n^{\text{CdH}} - \alpha_n^{\text{CdH}} - \alpha_{n-1}^{\text{CdH}} + \omega = 0, \quad \forall n \in \mathbb{N}_0. \quad \text{(38)} \]

Moreover, statement (2) can be true only if \( \omega = 1/4 \).

Proof. The implication (1)⇒(2): If \( \alpha_n \) is a polynomial in \( n \) then, up to a permutation of the parameters, \( a = b = 1/2 \), whence

\[ \alpha_n^{\text{CdH}} = (n + 1) \left( n + 1 + \frac{c}{2} \right) \]

and

\[ \beta_n^{\text{CdH}} = n \left( n + \frac{1}{2} + c \right) + (n + 1) \left( n + 1 + \frac{c}{2} \right) - \frac{1}{4} = \alpha_{n-1} + \alpha_n - \frac{1}{4}. \]

The implication (2)⇒(1): The equation \( \beta_n^{\text{CdH}} \) means that the sequence \( \{\alpha_n^{\text{CdH}}\} \) obeys a two-term recurrence with a right-hand side,

\[ \alpha_n^{\text{CdH}} + \alpha_{n-1}^{\text{CdH}} = \phi_n, \]

where \( \phi_n := \beta_n^{\text{CdH}} + \omega \) is a polynomial in \( n \) of degree 2 with the leading coefficient equal to 2. It follows that

\[ \alpha_{n+2}^{\text{CdH}} - \alpha_{n+1}^{\text{CdH}} - \alpha_n^{\text{CdH}} + \alpha_{n-1}^{\text{CdH}} = \phi_{n+2} - 2\phi_{n+1} + \phi_n = 4. \]
Hence \( \alpha_n^{CH} \) must be of the form
\[
\alpha_n^{CH} = A + Bn + C(-1)^n + n^2
\]
where \( A, B, C \) are some constants. At the same time, we know that the square of \( \alpha_n^{CH} \) is a polynomial in \( n \) of degree 4. Whence
\[
C(A + Bn + n^2) = 0, \quad \forall n \in \mathbb{N}_0.
\]
Necessarily, \( C = 0 \) and so \( \alpha_n^{CH} = A + Bn + n^2 \).

**Proposition 10.** If \( \text{Comm}_H(J^{CH}) \) is nontrivial, then \( \alpha_n^{CH} \) depends polynomially on \( n \).

**Proof.** The proof is based on Lemma 3 and follows the same steps as the proof of Proposition 4. Therefore we just briefly address several points specific for this case.

For a contradiction, we suppose that a nonzero Hankel matrix \( H \) commuting with \( J^{CH} \) exists but \( \alpha_n^{CH} \) is not a polynomial in \( n \). It follows from (39) that
\[
\alpha_n^{CH} = n^2 + \frac{2s - 3}{2} n - \frac{4s - 4\bar{s} - 3}{8} + O\left(\frac{1}{n}\right), \quad \text{as } n \to \infty.
\]
This together with (33) and (36) implies that none of the sets of functions in \( n, \{\alpha_n, \beta_n, 1\} \) or \( \{\beta_n, \alpha_{n-1}, 1\} \) or \( \{\alpha_n, \alpha_{n-1}, 1\} \), is linearly dependent.

Now, using exactly the same reasoning as in the proof of Proposition 4 while considering \( \alpha_n^{CH} \) and \( \beta_n^{CH} \) instead of \( \alpha_n^{W} \) and \( \beta_n^{W} \), one can argue that (35) is necessarily true. By Lemma 3 this means a contradiction. \( \square \)

### 4.4. Continuous Hahn

One has, as \( n \to \infty \),
\[
\alpha_n^{CH} = \frac{n}{4} + \frac{a + b + c + d}{8} + O\left(\frac{1}{n}\right) \quad \text{and} \quad \beta_n^{CH} = \frac{i(a + b - c - d)}{4} + O\left(\frac{1}{n}\right). \tag{39}
\]

**Proposition 11.** If \( \alpha_n^{CH} \) and \( \beta_n^{CH} \) depend both polynomially on \( n \), then \( \text{Comm}_H(J^{CH}) \) is nontrivial if and only if \( \alpha_n^{CH} = 0 \). If so, \( \text{Comm}_H(J^{CH}) = \text{span}(H^{(1)}, H^{(2)}) \), where \( H^{(1)} \) and \( H^{(2)} \) are Hankel matrices determined by the sequences
\[
h^{(1)}_k = \sin \frac{k\pi}{2} \quad \text{and} \quad h^{(2)}_k = \cos \frac{k\pi}{2}, \quad k \in \mathbb{N}_0, \quad \tag{40}
\]
respectively.

**Proof.** The proof is again analogous to the proof of Proposition 4. Assuming that \( \alpha_n^{CH} \) and \( \beta_n^{CH} \) are polynomials, we can deduce the form of the polynomials from (39), and the general equation (20) implies that any \( H \in \text{Comm}_H(J^{CH}) \), with entries \( H_{m,n} = h_{m+n} \), must fulfill the simple recurrence
\[
h_{k+1} + h_{k-1} = 0, \quad k \in \mathbb{N},
\]
whose two linearly independent solutions are given by (40). Now it suffices to notice that such \( H \) is necessarily trivial if \( \alpha_n^{CH} \neq 0 \). On the contrary, if \( \alpha_n^{CH} = 0 \) then any solution of the above recurrence defines a Hankel matrix which commutes with \( J^{CH} \). \( \square \)

**Proposition 12.** If \( \text{Comm}_H(J^{CH}) \) is nontrivial then \( \alpha_n^{CH} \) depends polynomially on \( n \).

**Proof.** Let us proceed by contradiction and assume that \( \alpha_n^{CH} \) is not a polynomial in \( n \) but (20) has a nonzero solution \( h_n \). Without loss of generality we can suppose \( h_n \) to be real. On a neighborhood of infinity we can expand
\[
\alpha_n^{CH} = \frac{n}{4} + A_0 + A(n), \quad \text{where } A(n) = \sum_{k=1}^{\infty} \frac{A_k}{n^k}.
\]

By our assumption, \( A(n) \) cannot vanish identically. Keeping notation (20), with \( \alpha_n^{CH} \) and \( \beta_n^{CH} \) instead of \( \alpha_n^{W} \) and \( \beta_n^{W} \), we have, for a fixed \( m \),
\[
\delta_2(n, m) := -\det\begin{pmatrix}
\alpha_n^{CH} - \alpha_m^{CH} & \alpha_{n-1}^{CH} - \alpha_{m+1}^{CH} \\
\alpha_n^{CH} - \alpha_{m-1}^{CH} & \alpha_{n-2}^{CH} - \alpha_{m}^{CH}
\end{pmatrix}
= \frac{A(m+1) - 2A(m) + A(m-1)}{4} n + O(1), \quad \text{as } n \to \infty.
\]
If $A(n) = A_k n^{-k} + O(n^{-k-1})$, with $A_k \neq 0$, then

$$A(m+1) - 2A(m) + A(m-1) = A_k k(k+1) n^{-k-2} + O(n^{-k-3}), \quad \text{as } m \to \infty.$$ 

Hence for all sufficiently large $m$ there exists

$$\lim_{n \to \infty} \frac{\delta_1(n,m)}{n} =: C_m \in \mathbb{R}\setminus\{0\}. \quad (41)$$ 

In particular, there exists $R_m \geq 0$ such that for all $n \geq R_m$, $\delta_2(n,m) \neq 0$.

One can argue, similarly as in the proof of Proposition 7, that the vectors (30) are linearly dependent. Moreover, for $m$ sufficiently large and $n \geq R_m$ both of them are nonzero (note that $R_m$ can be chosen large enough so that the coefficient $\alpha_n - \alpha_m$ occurring in (20) is nonzero for all $n \geq R_m$).

It follows that $\beta_n^{\text{CH}}$ cannot be a polynomial since if so, $\beta_n^{\text{CH}}$ would be a constant as seen from (39), and then $\delta_1(n,m) = \delta_2(n,m) = 0$ identically. Consequently, $h_n$ would vanish for all sufficiently large and hence for all $n$. Thus, we can expand $\beta_n$ as a function of $n$ near infinity as

$$\beta_n = B_0 + B(n), \quad \text{where } B(n) = \sum_{k=1}^{\infty} \frac{B_k}{n^k},$$

$B_0 = i(a + b - c - d)/4$ and $B(n)$ does not vanish identically. This property in particular implies that $\beta_n^{\text{CH}} - \beta_m^{\text{CH}} \neq 0$ for all sufficiently large $m$.

Now we can check the asymptotic behavior of $\delta_1(n,m)$ and $\delta_2(n,m)$ for $m$ fixed and $n$ large. We have, as $n \to \infty$,

$$\delta_1(n,m) := \det \left( \begin{array}{cc} \beta_n^{\text{CH}} - \beta_m^{\text{CH}} & \beta_n^{\text{CH}} - \beta_m^{\text{CH}} \\ \beta_n^{\text{CH}} - \beta_m^{\text{CH}} & \beta_n^{\text{CH}} - \beta_m^{\text{CH}} \end{array} \right) = \frac{\beta_n^{\text{CH}} - \beta_m^{\text{CH}}}{4} n + O(1),$$

$$\delta_2(n,m) := \det \left( \begin{array}{cc} \alpha_n^{\text{CH}} - \alpha_m^{\text{CH}} & \alpha_n^{\text{CH}} - \alpha_m^{\text{CH}} \\ \alpha_n^{\text{CH}} - \alpha_m^{\text{CH}} & \alpha_n^{\text{CH}} - \alpha_m^{\text{CH}} \end{array} \right) = \frac{-\beta_n^{\text{CH}} + \beta_m^{\text{CH}}}{4} n + O(1).$$

Fix $m$ sufficiently large. Then

$$\lim_{n \to \infty} \frac{h_{n+1}}{h_{n-1}} = \lim_{n \to \infty} \frac{h_{n+m+1}}{h_{n+m-1}} = \lim_{n \to \infty} \frac{\delta_1(n,m)}{\delta_2(n,m)} = -1.$$ 

In view of (11), we also have

$$\lim_{n \to \infty} \frac{h_{n+1}}{h_n} = \lim_{n \to \infty} \frac{h_{n+m+1}}{h_{n+m}} = \lim_{n \to \infty} \frac{\delta_1(n,m)}{\delta_2(n,m)} = \frac{\beta_n^{\text{CH}} - \beta_m^{\text{CH}}}{4C_m} =: D \in \mathbb{R}\setminus\{0\}.$$ 

Then

$$\lim_{n \to \infty} \frac{h_{n+1}}{h_{n-1}} = \lim_{n \to \infty} \frac{h_{n+1}}{h_n} \frac{h_n}{h_{n-1}} = D^2.$$ 

Hence $D^2 = -1$, a contradiction. \qed

The next lemma summarizes configurations of the parameters when $\alpha_n^{\text{CH}}$ is a polynomial in $n$.

**Lemma 13.** $\alpha_n^{\text{CH}}$ depends polynomially on $n$ for the following values of parameters only:

1. $a = b = \frac{1}{4} + it$ and $c = d = \frac{1}{4} - it$, for $t \in \mathbb{R}$, in which case

   $$\alpha_n^{\text{CH}} = \frac{1}{4} \left( n + \frac{1}{2} \right).$$

2. $a = b = \frac{3}{4} + it$ and $c = d = \frac{3}{4} - it$, for $t \in \mathbb{R}$, in which case

   $$\alpha_n^{\text{CH}} = \frac{1}{4} \left( n + \frac{3}{2} \right).$$

3. $a = \frac{1}{4} + it$, $b = \frac{3}{4} + it$ and $c = \frac{1}{4} - it$, $d = \frac{3}{4} - it$, for $t \in \mathbb{R}$, or one can interchange $a$ with $b$ and $c$ with $d$. In both cases,

   $$\alpha_n^{\text{CH}} = \frac{1}{4} (n + 1).$$
Moreover, \( \beta_n^{\text{CH}} = (a + b - c - d)/4 \) in each case (I)-(III).

**Remark 14.** Note that \( \alpha_{-1}^{\text{CH}} = 0 \) only in case (III).

**Proof.** Bearing in mind the restriction (3), we temporarily reparameterize the coefficients as follows:

\[
\alpha := \Re a, \quad \beta := \Re b, \quad \phi := \Im a - \Im b, \quad \theta := \Im a + \Im b,
\]

where \( \alpha, \beta > 0 \) and \( \phi, \theta \in \mathbb{R} \). As a shortcut we again put \( s := a + b + c + d = 2\alpha + 2\beta \). We have

\[
\alpha_n = \frac{(n + 1)(n + 2\alpha)(n + 2\beta)(n + s - 1)(2n + s + 2i\phi)(2n + s - 2i\phi)}{4(2n + s - 1)(2n + s + 1)}.
\]

(42)

If \( \alpha_n^{\text{CH}} \) is a polynomial in \( n \), then it is of degree 1 with the leading coefficient equal to 1/4 as is obvious from (39). In that case, it is immediately seen from (42) that \( \phi = 0 \) and hence

\[
\alpha_n^{\text{CH}} = \frac{(n + 1)(n + 2\alpha)(n + 2\beta)(n + s - 1)}{4(2n + s - 1)(2n + s + 1)}.
\]

Then by an elementary inspection of possible cancellation and requiring the above expression to be the square of a polynomial in \( n \), one readily finds that there are only four possible configurations for \( \alpha \) and \( \beta \). Namely, \( \alpha = \beta = 1/4 \), \( \alpha = \beta = 3/4 \), \( \alpha = 1/4 \) and \( \beta = 3/4 \), or \( \alpha = 3/4 \) and \( \beta = 1/4 \). Moreover, in each case, \( \beta_n^{\text{CH}} = -\theta/2 \). The lemma follows. \( \square \)

In summary, one implication of the equivalence in Theorem 11 ad (iii) is established by Proposition 11. Conversely, if \( \text{Comm}_H(J^J) \) is nontrivial then \( \alpha_n^{\text{CH}} \) depends polynomially on \( n \), by Proposition 12. In this case, \( \beta_n^{\text{CH}} \) is a polynomial in \( n \), as it follows from Lemma 13. The proof of Theorem 11 ad (iii) is then completed by Proposition 11, Lemma 13, and Remark 13.

4.5. **Jacobi.** The proof of Theorem 11 ad (iv) asserting that \( \text{Comm}_H(J^J) \) is trivial for any admissible choice of the parameters \( \alpha, \beta \) is more elementary than in the foregoing cases but computationally rather demanding. Despite the fact that the coefficients \( \alpha_n^J \) and \( \beta_n^J \) are given by less complicated expressions derivations of some asymptotic formulas used in the course of the proof are best done with the aid of a convenient computer algebra system (CAS). To our opinion, any commonly used CAS will do.

In order to obtain slightly less complicated expressions, we use a new parametrization: \( c := \alpha + \beta \) and \( d := \beta - \alpha \). The coefficients (9) and (10) take the form

\[
\alpha_n^J = \sqrt{\frac{(n + 1)(2n + c + d + 2)(2n + c - d + 2)(n + c + 1)}{(2n + c + 1)(2n + c + 2)^2(2n + c + 3)}},
\]

(43)

and

\[
\beta_n^J = \frac{cd}{(2n + c)(2n + c + 2)},
\]

(44)

where we can assume that \( c > -2 \) and \( d \geq 0 \) without loss of generality. Indeed, since \( \alpha_n^J(\alpha, \beta) = \alpha_n^J(\beta, \alpha) \) and \( \beta_n^J(\alpha, \beta) = -\beta_n^J(\beta, \alpha) \) for all \( n \in \mathbb{N}_0 \), a sequence \( h_n \) is a solution of (20) if and only if \(-1)^n h_n \) is a solution of the same equation with interchanged parameters \( \alpha \) and \( \beta \). Therefore we may assume \( \beta \geq \alpha \).

Writing

\[
\alpha_n^J = \frac{1}{2} + A(n)
\]

we have

\[
A(n) = \frac{1 - c^2 - d^2}{16 n^2} - \frac{(1 - c^2 - d^2)(c + 2)}{16 n^3} + \left(\frac{(1 - c^2 - d^2)(13 c^2 + d^2 + 48 c + 51)}{256} + \frac{c^2 d^2}{64}\right) \frac{1}{n^4} + O\left(\frac{1}{n^5}\right), \quad \text{as} \quad n \to \infty.
\]

(45)
Furthermore,
\[ \beta_n^j = \frac{cd}{4n^2} - \frac{cd (c + 1)}{4n^3} + \frac{cd (3c^2 + 6c + 4)}{16n^4} - \frac{cd (c^3 + 3c^2 + 4c + 2)}{8n^5} + O\left(\frac{1}{n^6}\right), \text{ as } n \to \infty. \] (46)

We again assume that a nontrivial real solution \( h \) to (20) exists, with the coefficients \( \alpha_n \) and \( \beta_n \) being given by (43) and (44). Moreover, we keep the notation (29) using, however, the coefficients \( \alpha_n^j, \beta_n^j \) rather than \( \alpha_n^W, \beta_n^W \). The asymptotic formulas lead us to distinguish four cases.

1) Case \( c^2 + d^2 = 1, cd = 0 \). Then we have three possible configurations of the parameters: \( c = 0, d = 1 \) or \( c = -1, d = 0 \) or \( c = 1, d = 0 \). In any case \( \alpha_n^j = 1/2 \) is a constant sequence. This means that the boundary condition \( \alpha_1^j = 0 \) is not fulfilled and therefore \( \text{Comm} (J^j) \) is trivial.

2) Case \( c^2 + d^2 \neq 1, cd = 0 \). Then \( \beta_n^j = 0 \) identically and equations (20) and (28) simplify to

\[
(\alpha_n - \alpha_m)h_{n+m+1} + (\alpha_{n-1} - \alpha_{m-1})h_{n+m-1} = 0,
(\alpha_{n-1} - \alpha_m)h_{n+m+1} + (\alpha_{n-2} - \alpha_m)h_{n+m-1} = 0.
\] (47)

From (43) it is seen that

\[ \delta_2(n, m) = -\det\left( \begin{array}{cc} \alpha_n^j - \alpha_m^j & \alpha_{n-1}^j - \alpha_{m-1}^j \\ \alpha_{n-1}^j - \alpha_m^j & \alpha_{n-2}^j - \alpha_m^j \end{array} \right) = A(m+1)A(m-1) - A^2(m) + O\left(\frac{1}{m^7}\right), \] (48)

as \( n \to \infty \). Moreover,

\[ A(m+1)A(m-1) - A^2(m) = \frac{(1 - c^2 + d^2)^2}{128m^6} + O\left(\frac{1}{m^7}\right), \quad \text{as } m \to \infty. \] (49)

Consequently, whenever \( c^2 + d^2 \neq 1 \) then for all sufficiently large \( m \in \mathbb{N} \) there exists \( R_m \in \mathbb{N} \) such that \( \delta_2(n, m) \neq 0 \) for all \( n \geq R_m \). It readily follows from (17) that \( h_n = 0 \) for all sufficiently large \( n \). Then necessarily \( h_n = 0 \) for all \( n \in \mathbb{N}_0 \) (see (21)), a contradiction.

3) Case \( c^2 + d^2 \neq 1, cd \neq 0 \). In this case, too, we have \( \delta_2(n, m) \neq 0 \) for \( n \geq R_m \) provided \( m \) is sufficiently large. Moreover, the asymptotic expansions (43), (44) are valid. In addition, as \( n \to \infty \), we have

\[ \delta_1(n, m) = \det\left( \begin{array}{c} \beta_n^j - \beta_m^j \\ \beta_{n-1}^j - \beta_{m+1}^j \end{array} \right) = \beta_n^j A(m) - \beta_{m+1}^j A(m-1) + O\left(\frac{1}{n^7}\right), \] (50)

and

\[ \delta_3(n, m) = \det\left( \begin{array}{c} \alpha_n^j - \alpha_m^j \\ \alpha_{n-1}^j - \alpha_{m+1}^j \\ \beta_n^j - \beta_{m+1}^j \end{array} \right) = \beta_{m+1}^j A(m) - \beta_m^j A(m+1) + O\left(\frac{1}{n^7}\right). \] (51)

Using (43), (44) one derives that

\[ \beta_n^j A(m) - \beta_{m+1}^j A(m-1) = \frac{cd (c^2 + d^2 - 1)}{64m^6} + O\left(\frac{1}{m^7}\right), \quad \text{as } m \to \infty, \] (52)

and

\[ \beta_{m+1}^j A(m) - \beta_m^j A(m+1) = \frac{cd (c^2 + d^2 - 1)}{64m^6} + O\left(\frac{1}{m^7}\right), \quad \text{as } m \to \infty. \] (53)

Hence for all sufficiently large \( m \in \mathbb{N} \) there exists \( R_m \in \mathbb{N} \) such that for all \( n \geq R_m \) and \( j = 1, 2, 3, \delta_j(n, m) \neq 0 \).

Similarly as in the proof of Proposition 7 we can infer from here some information about the asymptotic behavior of \( h_n \) as \( n \to \infty \). We only sketch the basic steps. Fix sufficiently large \( m \in \mathbb{N} \) but otherwise arbitrary. The vectors (60) are linearly dependent and therefore for all \( n \in \mathbb{N}, n \geq m_0 := R_m + m \), we have

\[ h_{n+1} = \psi(n)h_n, \quad \text{with } \psi(n) := \frac{\delta_1(n - m, m)}{\delta_2(n - m, m)}. \]
From (48) and (50) it is seen that \( \psi(n) = \lambda(1 + O(n^{-2})) \) for some \( \lambda \neq 0 \). Whence

\[
h_n = h_{n_0} \prod_{k=n_0}^{n-1} \psi(k) = \gamma \lambda^n \left(1 + O\left(\frac{1}{n}\right)\right), \quad n \to \infty,
\]

where \( \gamma \neq 0 \) is a constant. Without loss of generality we can assume that \( \gamma = 1 \). Moreover, referring to (50), (51),

\[
\gamma = 0 \text{ is a constant. Without loss of generality we can assume that } \gamma = 1.
\]

From here, when considering the limit \( h \to \infty \) as in asymptotic analysis (54) of

\[
Owing to our assumption (55) with the same result, namely

\[
Hence (\ref{eq:55}) with the asymptotic expansion (50), (51) remains valid as they are. The following asymptotic expansions, as \( m \to \infty \), had to be reconsidered, however:

\[
\beta^1_m A(m) + A(m - 1) = 0. \quad m \in \mathbb{N}_0.
\]

Referring again to (45), (46) and checking the asymptotic expansion, as \( m \to \infty \), we find that

\[
\pm \beta^1_m A(m) + A(m - 1) = -\frac{(c + d)^2 - 1}{8 m^2} + O\left(\frac{1}{m^3}\right).
\]

Hence \( (c + d)^2 = 1 \). With this equation the asymptotic expansion simplifies and we obtain

\[
\pm \beta^1_m A(m) + A(m - 1) = \mp \frac{3cd}{16 m^4} + O\left(\frac{1}{m^5}\right).
\]

Owing to our assumption \( cd \neq 0 \) we arrive at a contradiction.

4) Case \( c^2 + d^2 = 1, \ cd \neq 0 \). Discussion of this case is similar to the foregoing one, but some leading terms in the above asymptotic expansions disappear and this is why we have to reconsider some formulas. First of all, we now have, as \( n \to \infty \),

\[
A(n) = \frac{c^2 d^2}{64 n^4} + \frac{(c + 2) c^2 d^2}{32 n^5} + O\left(\frac{1}{n^6}\right),
\]

while the asymptotic expansion (46) of \( \beta^1_m \) remains as it is. Furthermore, for a fixed \( m \in \mathbb{N}_0 \),

\[
\delta_2(n, m) = -\det \left(\begin{array}{cc}
\alpha^1_n - \alpha^1_m & \alpha^1_{n-1} - \alpha^1_{m+1} \\
\alpha^1_{n-1} - \alpha^1_m & \alpha^1_{n-2} - \alpha^1_{m-1}
\end{array}\right) = A(m+1)A(m-1) - A^2(m) + O\left(\frac{1}{n^4}\right),
\]

and the asymptotic expansions (50), (51) remain valid as they are. The following asymptotic expansions, as \( m \to \infty \), had to be reconsidered, however:

\[
A(m+1)A(m-1) - A^2(m) = \frac{c^4 d^4}{1024 m^{10}} + O\left(\frac{1}{m^{11}}\right),
\]

\[
\beta^1_m A(m) - \beta^1_{m+1} A(m - 1) = -\frac{c^3 d^3}{128 m^7} + O\left(\frac{1}{m^8}\right),
\]

\[
\beta^1_{m+1} A(m) - \beta^1_m A(m + 1) = \frac{c^3 d^3}{128 m^7} + O\left(\frac{1}{m^8}\right).
\]

From (56) we conclude that in this case, too, for all sufficiently large \( m \in \mathbb{N} \) there exists \( R_m \in \mathbb{N} \) such that for all \( n \geq R_m \) and \( j = 1, 2, 3 \), \( \delta_j(n, m) \neq 0 \). It follows that the asymptotic analysis (51) of \( h_n \), as \( n \to \infty \), is still applicable. Whence, up to a constant multiplier, \( h_n = \lambda^n \left(1 + O(n^{-1})\right) \) for some \( \lambda \in \mathbb{R}, \lambda \neq 0 \). We can again compute \( \lambda^2 \) as in (55), with the same result, namely

\[
\lambda^2 = \frac{\beta^1_m A(m) - \beta^1_{m+1} A(m - 1)}{\beta^1_{m+1} A(m) - \beta^1_m A(m + 1)}.
\]

This time letting \( m \to \infty \) and taking into account (56) we get \( \lambda^2 = -1 \) which is not possible.
4.6. Meixner–Pollaczek, Meixner, Laguerre, Charlier and Hermite. The remaining cases will be directly treated using a necessary condition for the existence of a nontrivial commuting Hankel matrix.

Shifting indices in the general commutation equation (20), one gets the equation (28) and further

\[(\alpha_{n-2} - \alpha_{m+2})h_{n+m+1} + (\beta_{n-2} - \beta_{m+2})h_{n+m} + (\alpha_{n-3} - \alpha_{m+1})h_{n+m-1} = 0.\]

These three equations can have a nontrivial solution only if

\[D(m, n) := \det \begin{pmatrix} \alpha_n - \alpha_m & \beta_n - \beta_m & \alpha_{n-1} - \alpha_{m-1} \\ \alpha_{n-1} - \alpha_{m+1} & \beta_{n-1} - \beta_{m+1} & \alpha_{n-2} - \alpha_m \\ \alpha_{n-2} - \alpha_{m+2} & \beta_{n-2} - \beta_{m+2} & \alpha_{n-3} - \alpha_m - 1 \end{pmatrix} = 0,\] (57)

for all \(m, n \in \mathbb{N}, n \geq 2\). In particular, if \(\beta_n = 0\) for all \(n \in \mathbb{N}_0\), it follows from (20) that the necessary condition for existence of a nontrivial commuting Hankel matrix reads

\[\delta_2(m, n) := -\det \begin{pmatrix} \alpha_n - \alpha_m & \alpha_{n-1} - \alpha_{m-1} \\ \alpha_{n-1} - \alpha_{m+1} & \alpha_{n-2} - \alpha_m \end{pmatrix} = 0, \quad \forall m, n \in \mathbb{N}.\] (58)

4.6.1. Meixner–Pollaczek. Assume first that \(\phi \neq \pi/2\). The leading terms of the asymptotic expansions of \(\alpha_n^{\text{MP}}\) and \(\beta_n^{\text{MP}}\) are

\[\alpha_n^{\text{MP}} = \frac{n}{2 \sin \phi} + O(1) \quad \text{and} \quad \beta_n^{\text{MP}} = -\frac{n}{\tan \phi} + O(1), \quad \text{as} \ n \to \infty.\]

Consequently, for \(m \in \mathbb{N}\) fixed,

\[D(m, n) = C_m(\lambda, \phi)n + O(1), \quad n \to \infty.\]

By a simple linear algebra the function \(C_m(\lambda, \phi)\) can be readily computed,

\[C_m(\lambda, \phi) = \frac{\cos \phi}{4 \sin^3 \phi} \left[ (\alpha_{m+1}^{\text{MP}} - \alpha_m^{\text{MP}})^2 - (\alpha_{m+2}^{\text{MP}} - \alpha_{m+1}^{\text{MP}})(\alpha_m^{\text{MP}} - \alpha_{m-1}^{\text{MP}}) \right.\]

\[\left. + \alpha_{m+2}^{\text{MP}} - 3\alpha_{m+1}^{\text{MP}} + 3\alpha_m^{\text{MP}} - \alpha_{m-1}^{\text{MP}} \right],\]

where \(\alpha_n^{\text{MP}} := 2 \sin(\phi)\alpha_n^{\text{MP}} = \sqrt{(n+1)(n+2\lambda)}\). Further, the asymptotic expansion of the above expression in the square brackets equals

\[-\frac{(1 - 2\lambda)^4}{32m^6} + O \left( \frac{1}{m^4} \right), \quad m \to \infty.\]

Consequently, if \(\text{Comm}_H(\mathcal{J}^{\text{MP}})\) is nontrivial, then \(C_m(\lambda, \phi) = 0\) for all \(m \in \mathbb{N}\) which particularly implies that \(\lambda = 1/2\).

If \(\phi = \pi/2\), then \(\beta_n^{\text{MP}} = 0\) for all \(n \in \mathbb{N}_0\), and one proceeds similarly using (58) instead of (57). The resulting formula reads

\[\delta_2(m, n) = c_m(\lambda)n + O(1), \quad n \to \infty,\]

where

\[c_m(\lambda) = \frac{(1 - 2\lambda)^2}{16m^4} + O \left( \frac{1}{m^2} \right), \quad m \to \infty.\]

Thus one again concludes that \(\lambda = 1/2\), if \(\text{Comm}_H(\mathcal{J}^{\text{MP}})\) is nontrivial.

Assume on the other hand that \(\lambda = 1/2\). Note that \(\lambda = 1/2\) if and only if \(\alpha_n^{\text{MP}}\) is a nonzero polynomial in \(n\). Then \(\alpha_{-1}^{\text{MP}} = 0\). Plugging \(\alpha_n^{\text{MP}}\) and \(\beta_n^{\text{MP}}\), given by (11) with \(\lambda = 1/2\), into (20) we arrive at the second order difference equation

\[h_{k+1} - 2\cos(\phi)h_k + h_{k-1} = 0, \quad k \in \mathbb{N},\]

whose two linearly independent solutions are

\[h_k^{(1)} = \sin(k\phi) \quad \text{and} \quad h_k^{(2)} = \cos(k\phi).\]

Consequently, \(\text{dim Comm}_H(\mathcal{J}^{\text{MP}}) = 2\) and the two Hankel matrices determined by the sequences \(h^{(1)}\) and \(h^{(2)}\) form a basis of \(\text{Comm}_H(\mathcal{J}^{\text{MP}})\).
4.6.2. Meixner. In all remaining cases, the approach is completely analogous to the case of the Meixner–Pollaczek polynomials. Therefore we mention only several most important points. In the case of the Meixner coefficients defined by (12) one obtains
\[
\lim_{n \to \infty} D(m,n) \frac{c}{n} = \frac{c(c+1)(1-\beta)^4}{32(1-c)^5m^6} + O\left(\frac{1}{m^7}\right),
\]
as \(m \to \infty\). Since \(c \in (0, 1)\) necessarily \(\beta = 1\), if \(\text{Comm}_H(J^M)\) nontrivial.

Assuming on the other hand that \(\beta = 1\) and plugging (12) into (20), one arrives at the three-term recurrence
\[
h_{k+1} + (c^{1/2} + c^{1/2})h_k + h_{k-1} = 0, \quad k \in \mathbb{N},
\]
whose two linearly independent solutions are
\[
h_k^{(1)} = (-1)^k c^{k/2} \quad \text{and} \quad h_k^{(2)} = (-1)^k c^{-k/2}.
\]

4.6.3. Laguerre. Using (13) in (57), one computes
\[
\lim_{n \to \infty} D(m,n) \frac{\alpha}{n} = \frac{\alpha^4}{16m^6} + O\left(\frac{1}{m^7}\right),
\]
as \(m \to \infty\). Hence \(\text{Comm}_H(J^L)\) can be nontrivial only for \(\alpha = 0\). On the other hand, if \(\alpha = 0\), one deduces from (20) the recurrence
\[
h_{k+1} + 2h_k + h_{k-1} = 0, \quad k \in \mathbb{N},
\]
whose two linearly independent solutions are
\[
h_k^{(1)} = (-1)^k \quad \text{and} \quad h_k^{(2)} = (-1)^k k.
\]

4.6.4. Charlier. Note that \(\alpha^C_n\) defined in (14) is never a polynomial in \(n\) for \(a \neq 0\). In that case one obtains
\[
\lim_{n \to \infty} D(m,n) \frac{a}{n} = \frac{a}{8m^4} + O\left(\frac{1}{m^5}\right), \quad \text{as} \quad m \to \infty.
\]
Since \(a \neq 0\) determinant \(D(m,n)\) cannot vanish identically and therefore \(\text{Comm}_H(J^C)\) is trivial.

4.6.5. Hermite. Substituting from (15) into the equation (20), one obtains the second order recurrence
\[
h_{k+1} + h_{k-1} = 0, \quad k \in \mathbb{N},
\]
whose two linearly independent solutions are
\[
h_k^{(1)} = \sin \frac{k\pi}{2} \quad \text{and} \quad h_k^{(2)} = \cos \frac{k\pi}{2}.
\]
