Two tilts of higher spherical algebras

Adam Skowyrski

Faculty of Mathematics and Computer Science, Nicolaus Copernicus University, Chopina 12/18, 87-100 Toruń, Poland

Abstract. We introduce and study two exotic families of finite-dimensional algebras over an algebraically closed field. We prove that every such an algebra is derived equivalent to a higher spherical algebra studied by Erdmann and Skowroński in [10], and hence that it is a tame symmetric periodic algebra of period 4. This together with the results of [7, 10] shows that every trivial extension algebra of a tubular algebra of type $(2, 2, 2, 2)$ admits a family of periodic symmetric higher deformations which are tame of non-polynomial growth and have the same Gabriel quiver, answering the question recently raised by Skowroński.

1 Introduction

Throughout this article, $K$ will denote a fixed algebraically closed field. By an algebra we mean an associative finite-dimensional $K$-algebra with identity, which we assume to be basic and indecomposable. For an algebra $A$ we denote by $\text{mod} \ A$ the category of finite dimensional right $A$-modules, by $\text{ind} \ A$ its full subcategory formed by all indecomposable modules, and by $D$ the standard duality $D = \text{Hom}_{K}(-, K)$ on $\text{mod} \ A$. An algebra $A$ is called self-injective if $A_A$ is injective in $\text{mod} \ A$, or equivalently, the projective modules in $\text{mod} \ A$ are injective. A prominent class of self-injective algebras is provided by the symmetric algebras, for which $A$ and $D(A)$ are isomorphic as $A$-$A$-bimodules. Any algebra $A$ is a quotient algebra of its trivial extension $T(A) = A \ltimes D(A)$, which is a symmetric algebra.

For an algebra $A$, the module category of $\text{mod} \ A^e$ of its enveloping algebra $A^e = A^{\text{op}} \otimes_K A$ is naturally identified with the category of $A$-$A$-bimodules. By $\Omega_A$ we denote the syzygy operator on $\text{mod} \ A^e$, which assigns to a module $M$ in $\text{mod} \ A^e$ the kernel $\Omega_A(M)$ of a minimal projective cover of $M$ in $\text{mod} \ A^e$. An algebra is said to be periodic if $\Omega^n_A(A) \simeq A$ in $\text{mod} \ A^e$, for some $n \geq 1$, and if so, the minimal such $n$ is called the period of $A$. Periodic algebras are examples of self-injective algebras with periodic Hochschild cohomology.

Finding and possibly classifying symmetric and periodic algebras an important problem because its interesting connections with group theory, topology, singularity theory and cluster algebras. For details, we refer to the survey article [5] and the introductions of [2, 6, 8]. Dugas proved in [4] that every representation-finite self-injective algebra, different from $K$, is a periodic algebra. The representation-infinite periodic algebras of polynomial growth were
classified by Białkowski, Erdmann and Skowroński in [2]. We refer interested reader to the survey [20] for a description of these algebras.

We are concerned with the classification of all periodic symmetric tame algebras of non-polynomial growth. It is conjectured in [6, Problem] that every such an algebra is of period 4. There is a large class of tame symmetric periodic algebras of period 4, called the weighted surface algebras, which are associated to triangulations of compact real surfaces. Those algebras and their deformations are investigated in [6]–[10]. It is also conjectured by Erdmann and Skowroński (private communication) that the class of tame symmetric periodic algebras of period 4 consists (up to isomorphism) of weighted surface algebras - as defined in [9], their socle deformations (occurring only in characteristic 2) and a finite number of exceptional families of algebras given by quivers with the number of vertices dividing 6. Classifying all these exceptional algebras is currently and important problem.

The article is related to the representation theory of tubular algebras [12, 18] and the associated self-injective algebras of polynomial growth [14, 19], which have been recently shown to be periodic [2]. In particular, the trivial extensions $T(B)$ of tubular algebras $B$ provide a wide class of periodic symmetric algebras of polynomial growth. Among those there are only four families of algebras of period 4, namely $T(B_1(\mu)), T(B_2(\mu)), T(B_3(\mu))$ and $T(B_4(\mu))$, given by the tubular algebras $B_1(\mu), B_2(\mu), B_3(\mu), B_4(\mu), \mu \in K \setminus \{0, 1\}$, of type $(2, 2, 2, 2)$, described in [19, Example 3.3]. It was lately observed in [6, Lemma 6.2] that the algebras $T(B_4(\mu))$ are the tetrahedral algebras (associated to the natural triangulation of the tetrahedron), and in [9, Lemma 3.7] that the algebras $T(B_3(\mu))$ are the spherical algebras (given by a triangulation of sphere in $\mathbb{R}^2$ by four triangles). Further, it was proved in [7, 10] that both $T(B_3(\mu))$ and $T(B_4(\mu))$ admit higher deformations, called respectively, higher spherical and higher tetrahedral algebras, which form two exotic families of symmetric periodic tame algebras of non-polynomial growth of period 4. We note that these algebras are not isomorphic to weighted surface algebras but their Gabriel quivers are the Gabriel quivers of $T(B_3(\mu))$ and $T(B_4(\mu))$, respectively. On the other hand, the Gabriel quivers of $T(B_1(\mu))$ and $T(B_2(\mu))$ are the quivers $Q_E$ and $Q_F$ presented below, so also $T(B_1(\mu))$ and $T(B_2(\mu))$ are not weighted surface algebras. We also recall that, by general theory of tubular algebras (see [12, Section 1] and [18, Section 5]), the tubular algebras $B_i(\mu)$, for $i \in \{1, \ldots, 4\}$, are tilting equivalent and hence their trivial extensions $T(B_i(\mu)), i \in \{1, \ldots, 4\}$, are derived equivalent algebras [17].

The aim of the paper is to prove that the trivial extension algebras $T(B_1(\mu))$ and $T(B_2(\mu))$ also admit higher deformations with the Gabriel quivers $Q_E$ and $Q_F$, respectively, which form new exotic families of symmetric tame periodic algebras of period 4. This answers the question posed by Skowroński during his spring lectures in Toruń.

We present now these two families of algebras. Let $m \geq 2$ be a natural number and $\lambda \in K^* = K \setminus \{0\}$. The algebra $E(m, \lambda)$ is given by the quiver $Q_E$ of the form
and the relations:

(E1) $\alpha_1 \alpha_2 - \alpha_3 \alpha_4 + \beta_1 \beta_2 = 0$,

(E2) $\alpha_3 \alpha_4 \alpha_5 = \alpha_1 \alpha_2 \alpha_5 + \lambda (\alpha_1 \alpha_2 \alpha_5 \alpha_6)^{m-1} \alpha_1 \alpha_2 \alpha_5$,

(E3) $\gamma_0 \beta_1 = 0, \gamma_0 \alpha_3 = \alpha_5 \alpha_6 \alpha_3$ and $\gamma_0 \alpha_1 = \alpha_5 \alpha_6 \alpha_1 + \lambda (\alpha_5 \alpha_6 \alpha_1 \alpha_2)^{m-1} \alpha_5 \alpha_6 \alpha_1$,

(E4) $\alpha_2 \gamma_0 = \alpha_2 \alpha_5 \alpha_6 + \lambda (\alpha_2 \alpha_5 \alpha_6 \alpha_1)^{m-1} \alpha_2 \alpha_5 \alpha_6$ and

$$ (\alpha_2 \alpha_5 \alpha_6 \alpha_1)^{m-1} \alpha_2 \alpha_5 \alpha_6 \alpha_3 = 0,$$

(E5) $\alpha_4 \gamma_0 = \alpha_4 \alpha_5 \alpha_6$ and $\alpha_4 \alpha_5 \alpha_6 \alpha_1 (\alpha_2 \alpha_5 \alpha_6 \alpha_1)^{m-1} = 0$,

(E6) $\alpha_6 \alpha_3 \alpha_4 = \alpha_6 \alpha_1 \alpha_2 + \lambda (\alpha_6 \alpha_1 \alpha_2 \alpha_5)^{m-1} \alpha_6 \alpha_1 \alpha_2$,

(E7) $\beta_2 \gamma_0 = 0, \beta_2 \alpha_5 \alpha_6 \alpha_1 = 0, \beta_2 \alpha_5 \alpha_6 \alpha_3 = 0$ and $\beta_2 \alpha_5 \alpha_6 \beta_1 \beta_2 = 0$,

(E8) if a cycle $C$ at vertex $i$ in $Q_E$ is of length 3 or 4, then $\theta C^m = C^m \phi = 0$,

for all arrows $\theta, \phi$ with $t(\theta) = s(\phi) = i$.

The algebra $F(m, \lambda)$ is given by the quiver $Q_F$

and the following relations:
(F1) $\alpha_1\alpha_2 - \alpha_3\alpha_4 + \beta_1\beta_2 = 0$, $\alpha_1\alpha_2 - \alpha_3\alpha_4 + \beta_3\beta_4 + \lambda(\alpha_3\alpha_4\gamma_1)^{m-1}\alpha_3\alpha_4 = 0$,
(F2) $\alpha_2\gamma_1 = \alpha_2\gamma_2$ and $\gamma_2\alpha_1 = \gamma_1\alpha_1$,
(F3) $\alpha_4\gamma_2 = \alpha_4\gamma_1 + \lambda(\alpha_4\gamma_1\alpha_3)^{m-1}\alpha_4\gamma_1$ and $\gamma_2\alpha_3 = \gamma_1\alpha_3 + \lambda(\gamma_1\alpha_3\alpha_4)^{m-1}\gamma_1\alpha_3$,
(F4) $\beta_2\gamma_1 = 0$, $\beta_4\gamma_2 = 0$, $\gamma_1\beta_1 = 0$, and $\gamma_2\beta_3 = 0$,
(F5) $\beta_2\gamma_1\beta_2 = 0$ and $\beta_4\gamma_1\beta_3\beta_4 = 0$,
(F6) $\gamma_1\alpha_1\alpha_2 = \gamma_1\alpha_3\alpha_4$ and $\alpha_1\alpha_2\gamma_1 = \alpha_3\alpha_4\gamma_1$,
(F7) $(\alpha_3\alpha_4\gamma_1)^{m}\alpha_1 = 0$, $(\alpha_3\alpha_4\gamma_1)^{m}\alpha_3 = 0$, $\gamma_1(\alpha_3\alpha_4\gamma_1)^{m} = 0$, $\alpha_2(\gamma_1\alpha_3\alpha_4)^{m} = 0$ and $\alpha_4(\gamma_1\alpha_3\alpha_4)^{m} = 0$.

Following [10], we denote by $S(m,\lambda)$ the higher spherical algebra (see Section 2 for details). The following theorem is the main result of the article.

**Theorem 1.1.** For any $m \geq 2$ and $\lambda \in K^*$, the algebras $E(m,\lambda)$, $F(m,\lambda)$ and $S(m,\lambda)$ are derived equivalent.

Applying general facts on derived equivalences of algebras (see theorems presented in Section 3), we obtain the following theorem.

**Theorem 1.2.** Let $E = E(m,\lambda)$ and $F = F(m,\lambda)$, for some $m \geq 2$ and $\lambda \in K^*$. Then the following statements hold:

1. $E$ and $F$ are finite dimensional algebras with $\dim_K E(m,\lambda) = 25m + 13$ and $\dim_K F(m,\lambda) = 16m + 16$.
2. $E$ and $F$ are symmetric algebras.
3. $E$ and $F$ are periodic algebras of period 4.
4. $E$ and $F$ are tame algebras of non-polynomial growth,

We also mention that families $E(m,\lambda)$ and $F(m,\lambda)$ reveal new exotic pieces of classification problem for algebras of generalized quaternion type [8] as well as of solution for the problem raised in [10]. For the relevant background on the representation theory of associative algebras we refer to [1, 11, 21, 22].

## 2 Higher spherical algebras

This section is devoted to outline basic facts about higher spherical algebras [10] needed in further considerations.
For a natural number $m \geq 2$ and $\lambda \in K^*$ we denote by $S(m, \lambda)$ the algebra given by the quiver of the following form

and the relations:

1. $\beta \nu \delta = \beta \gamma \sigma + \lambda (\beta \gamma \sigma \alpha)^{m-1} \beta \gamma \sigma$,  
2. $\nu \delta \alpha = \gamma \sigma \alpha + \lambda (\gamma \sigma \alpha \beta)^{m-1} \gamma \sigma \alpha$,  
3. $\sigma \rho \omega = \sigma \alpha \beta + \lambda (\sigma \alpha \beta \gamma)^{m-1} \sigma \alpha \beta$,  
4. $\rho \omega \gamma = \alpha \beta \gamma + \lambda (\alpha \beta \gamma \sigma)^{m-1} \alpha \beta \gamma$,  
5. $\alpha \beta \nu = \rho \omega \nu$,  
6. $\delta \alpha \beta = \delta \rho \omega$,  
7. $\omega \gamma \sigma = \omega \nu \delta$,  
8. $\gamma \sigma \rho = \nu \delta \rho$,  
9. $(\alpha \beta \gamma \sigma)^m \alpha = 0$,  
10. $(\gamma \sigma \alpha \beta)^m \gamma = 0$.

For further calculations we will use some additional relations in $S(m, \lambda)$. It follows from [10, Lemma 4.1] that the following relations hold in $S(m, \lambda)$:

1'. $(\beta \gamma \sigma \alpha)^{m-1} \beta \gamma \sigma \rho = 0$ and $(\alpha \beta \gamma \sigma \rho)^m \rho = 0$,  
2'. $\omega \gamma \sigma \alpha (\beta \gamma \sigma \alpha)^{m-1} = 0$ and $\omega (\gamma \sigma \alpha \beta)^m = 0$,  
3'. $(\sigma \alpha \beta \gamma)^{m-1} \sigma \alpha \beta \nu = 0$ and $(\gamma \sigma \alpha \beta)^m \nu = 0$,  
4'. $\delta \alpha \beta \gamma (\sigma \alpha \beta \gamma)^{m-1} = 0$ and $\delta (\alpha \beta \gamma \sigma)^m = 0$,  
5'. $(\rho \omega \nu \delta)^r = (\alpha \beta \gamma \sigma)^r$ and $(\nu \delta \rho \omega)^r = (\gamma \sigma \alpha \beta)^r$, for any $r \in \{2, \ldots, m\}$.

In the rest part of the paper we will frequently refer to above relations and relations for $E(m, \lambda)$ and $F(m, \lambda)$ presented in the introduction.

Let $S = S(m, \lambda)$ be a fixed higher spherical algebra, with $m \geq 2$ and $\lambda \in K^*$. Denote by $e_1, \ldots, e_6$ the complete set of all pairwise orthogonal primitive idempotents in $S$. The modules $P_i = e_i S, \ldots, P_6 = e_6 S$ form a complete set of pairwise nonisomorphic indecomposable projective $S$-modules. For $i \in \{1, 2, 3, 4\}$, let $X_i$ be the unique cycle of length 4 in $Q_S$ around $i$ formed by the arrows $\alpha, \beta, \gamma, \sigma$. Similarly, if $i \in \{5, 6\}$, we denote by $X_i$ the unique cycle of length 4 in $Q_S$ around $i$ formed by the arrows $\rho, \omega, \nu, \delta$.  

5
Remark. For any cycle $X_i'$ of length 4 in $Q_S$ around $i$, the difference $X_i - X_i'$ in $S$ is zero or it belongs to $KX_i^m$ and $X_i^k = (X_i')^k$, for $k \in \{2, \ldots, m\}$. Moreover, from relations (1)-(10) and (1')-(5') above, we obtain that $\theta X_i^m = X_i^m \psi = 0$, for all arrows $\theta, \psi$ in $Q_S$ with $t(\theta) = s(\psi) = i$. Note also that, if $i \in \{1, \ldots, 6\}$, then any two paths $p_1, p_2$ from $i$ to $j$ in $Q_S$ give $X_i^k p_1 = X_i^k p_2$ and $p_1 X_i^k = p_2 X_i^k$ in $S$, if $k \in \{1, \ldots, m\}$. Further observations are based directly on [10, see proof of Proposition 4.2]. Consider the following paths in $Q_S$:

$$X_{12} = \alpha, X_{13} = \alpha \beta, X_{14} = \alpha \beta \gamma, X_{15} = \alpha \beta \nu, X_{16} = \rho, \bar{X}_{13} = \rho \omega$$

$$X_{21} = \beta \gamma \sigma, X_{23} = \beta, X_{24} = \beta \gamma, X_{25} = \beta \nu, X_{26} = \beta \gamma \sigma \rho,$$

$$X_{31} = \gamma \sigma, X_{32} = \gamma \sigma \alpha, X_{34} = \gamma, X_{35} = \nu, X_{36} = \gamma \sigma \rho, \bar{X}_{31} = \nu \delta$$

$$X_{41} = \sigma, X_{42} = \sigma \alpha, X_{43} = \sigma \alpha \beta, X_{45} = \sigma \alpha \beta \nu, X_{46} = \sigma \rho,$$

$$X_{51} = \delta, X_{52} = \delta \alpha, X_{53} = \delta \rho \omega, X_{54} = \delta \rho \omega \gamma, X_{56} = \delta \rho,$$

$$X_{61} = \omega \nu \delta, X_{62} = \omega \nu \delta \alpha, X_{63} = \omega, X_{64} = \omega \gamma, X_{65} = \omega \nu$$

and write $X_{ij}^r$ for path of the form $X_i'X_j$. For any $i, j \in \{1, \ldots, 6\}$, we pick a $K$-basis $S_{ij}$ of $e_i S e_j$ as described below. For $i \in \{1, \ldots, 6\}$, we take $S_{ii} = \{X_i^r; 0 \leq r \leq m\}$, whereas

$S_{13} = \{X_{13}^r; 0 \leq r \leq m-1\} \cup \{\bar{X}_{13}\}$ and $S_{31} = \{X_{31}^r; 0 \leq r \leq m-1\} \cup \{\bar{X}_{31}\}$.

Moreover, if $(i, j)$ is one of pairs $(2, 6)$, $(6, 2)$, $(4, 5)$ or $(5, 4)$, then we put $S_{ij} = \{X_{ij}^r; 0 \leq r \leq m-2\}$. For the remaining pairs of indices $S_{ij} = \{X_{ij}^r; 0 \leq r \leq m-1\}$.

In particular, it follows that the Cartan matrix of $S = S(m, \lambda)$ is of the form

$$C_S = [c_{ij}^S] = \begin{bmatrix}
    m+1 & m & m+1 & m & m & m \\
m & m+1 & m & m & m & m-1 \\
m+1 & m & m+1 & m & m & m \\
m & m & m+1 & m & m & m \\
m & m & m & m-1 & m+1 & m \\
m & m-1 & m & m & m+1 & m
\end{bmatrix}.$$

Finally, we recall one of the main results from [10, see Theorem 1].

**Theorem 2.1.** Let $S = S(m, \lambda)$ be a higher spherical algebra. Then the following statements hold

1. $S$ is a finite dimensional algebra with $\dim_K S = 36m + 4$.
2. $S$ is a tame symmetric algebra of non-polynomial growth.
3. $S$ is a periodic algebra of period 4.
3 Derived equivalences of algebras

In this section, we recall some basic facts on derived equivalences of algebras.

For an algebra $A$ we denote by $C_A$ the category of bounded complexes $X = (X^n, d^n)_{n \in \mathbb{Z}}$ ($X^n$ are modules in mod $A$ and $d^n = d^n_X : X^n \to X^{n-1}$ homomorphisms of $A$-modules) with usually understood morphisms between them. Two morphisms $f, g : X \to Y$ in $C_A$ are said to be homotopic, which is denoted by $f \sim g$, provided that there is a collection $(s_n)_{n \in \mathbb{Z}}$ of homomorphisms $s_n : X^n \to Y^{n+1}$ in mod $A$ with $f^n - g^n = s_n - d^n_X + d^{n+1}_Y s_n$, for any $n \in \mathbb{Z}$. By $K^b(\text{mod } A)$ we denote the homotopy category of bounded complexes (over $A$), whose objects are the same as in $C_A$, whereas morphisms are homotopy classes of morphisms in $C_A$. Further, we recall that the derived category $D^b(\text{mod } A)$ of $A$ is the localization of $K^b(\text{mod } A)$ with respect to quasi-isomorphisms. It is well-known that both $K^b(\text{mod } A)$ and $D^b(\text{mod } A)$ admit structure of a triangulated $K$-category with suspension functor being the left shift functor $(-)[1]$.

Two algebras $A$ and $B$ are called derived equivalent if and only if the derived categories $D^b(\text{mod } A)$ and $D^b(\text{mod } B)$ are equivalent as triangulated categories.

Note also that the full subcategory $K_A := K^b(\text{proj } A)$ of $K^b(\text{mod } A)$ formed by all (bounded) complexes of projective modules in mod $A$ has a structure of triangulated category induced from the shift in homotopy category. Moreover, if $T$ is a complex in $K_A$, then $T$ is said to be a tilting complex, if the following conditions are satisfied:

(T1) $\text{Hom}_{K_A}(T, T[i]) = 0$, for all integers $i \neq 0$,

(T2) $\text{add}(T)$ generates $K_A$ as triangulated category.

Further we have the following handy criterion for verifying derived equivalence of algebras, due to J. Rickard [15, Theorem 6.4].

**Theorem 3.1.** Two algebras $A$ and $B$ are derived equivalent if and only if there exists a tilting complex $T$ in $K_A$ such that $\text{End}_{K_A}(T) \cong B$.

Finally, thanks to Happel [11] see III.1.3-1.4 we have the following alternating sum formula allowing to compute dimensions of morphisms spaces in homotopy category between summands of tilting complexes.

**Theorem 3.2.** Let $A$ be an algebra and $Q, R$ two complexes in $K_A$ for which $\text{Hom}_{K_A}(Q, R[i]) = 0$, for all integers $i \neq 0$. Then

$$\dim_K \text{Hom}_{K_A}(Q, R) = \sum_{r, s \in \mathbb{Z}} (-1)^{r-s} \dim_K \text{Hom}_A(Q^r, R^s).$$

Note that the following two theorems (see [17, Corollary 5.3] and [5, Theorem 2.9]) are of importance.

**Theorem 3.3.** Let $A$ and $B$ be two derived equivalent algebras. Then $A$ is symmetric if and only if $B$ is symmetric.
Theorem 3.4. Let \( A \) and \( B \) be two derived equivalent algebras. Then \( A \) is periodic if and only if \( B \) is periodic, and if this is the case, then they have the same period.

Because in the class of self-injective algebras, derived equivalence implies stable equivalence (see [16, Corollary 2.2] or [17, Corollary 5.3]), one may conclude from [3, Theorems 4.4 and 5.6] and [13, Corollary 2] that the following theorem holds.

Theorem 3.5. Let \( A \) and \( B \) be two derived equivalent self-injective algebras. Then the following equivalences hold.

1. \( A \) is tame if and only if \( B \) is tame.
2. \( A \) is of polynomial growth if and only if \( B \) is of polynomial growth.

4 Two tilting complexes over higher spherical algebras

In this section we define two particular complexes over a given higher spherical algebra \( S = S(m, \lambda) \), with \( m \geq 2 \), \( \lambda \in K^* \), and we prove that these are tilting complexes in \( K_S \).

We stick to the notations settled in Section 2 for idempotents \( e_i \in S \) and projective modules \( P_i = e_iS \) in \( \text{ind}S \) (also for elements of their bases). We identify arrows \( \rho : i \to j \) in \( Q_S \) (or in general, elements in \( e_iSe_j \)) with associated homomorphisms \( \rho : P_j \to P_i \) of indecomposable projective \( S \)-modules, given by left multiplication by \( \rho \). For every \( i \in \{1, \ldots, 6\} \), we will denote by \( P_i \) the stalk complex in \( K_S \) of the form

\[
0 \to P_i \to 0
\]

concentrated in degree 0. Moreover, consider the following two 2-term complexes \( \bar{P}_4 \) and \( \bar{P}_5 \) concentrated in degrees 1 and 0.

\[
\bar{P}_4 : 0 \to P_4 \xrightarrow{\gamma} P_3 \xrightarrow{0} \quad \text{and} \quad \bar{P}_5 : 0 \to P_5 \xrightarrow{\nu} P_3 \xrightarrow{0} .
\]

The following technical lemma describes morphisms in \( K_S \) between defined complexes and their shifts. In most cases a morphism in \( K_S \) between those complexes is given by a single homomorphism \( \psi : P_i \to P_j, i, j \in \{1, \ldots, 6\} \), in \( \text{proj}S \) identified with an element (a combination of paths) in \( e_iSe_i \).

Lemma 4.1. (a) For any \( \psi \) in \( e_4Se_i \) (respectively, in \( e_5Se_i \)), the corresponding homomorphism \( f_0 = \psi : P_i \to P_4 \) (respectively, \( P_1 \to P_5 \)) induces morphism \( P_i \to P_4[-1] \) (respectively, morphism \( P_1 \to P_5[-1] \)) in \( C_S \) if and only if \( \gamma \psi = 0 \) (respectively, \( \nu \psi = 0 \)) in \( S \); moreover, this holds iff \( \psi \in KX_i^{m} \) (respectively, \( \psi \in KX_i^{m} \)).

(b) Every element \( \psi \in e_5Se_i \) induces morphism \( P_1 \to P_4 \) (respectively, morphism \( P_1 \to P_5 \)) in \( C_S \) and such a morphism is homotopic to 0 if and only if \( \psi \in \gamma S \) (respectively, \( \psi \in \nu S \)).

8
(c) Let $X$ be a complex in $\mathcal{C}_S$ with $X^1 = P_i$, $i \in \{1, \ldots, 6\}$, and $X^n = 0$, for $n \leq 0$. Then every element $\psi \in e_i S e_4$ (respectively, in $e_i S e_5$) induces morphism $f = f_1 : P_4 \rightarrow X$ (respectively, morphism $P_5 \rightarrow X$) in $\mathcal{C}_S$ and $f \simeq 0$ if $\psi \in S \gamma$ (respectively, $\psi \in S \nu$).

(d) For $\rho_0 \in e_3 S e_3$ and $\rho_1 \in e_5 S e_4$ (respectively, $\rho_1 \in e_4 S e_5$), the pair $f = (\rho_1, \rho_0)$ defines a morphism $P_4 \rightarrow P_3$ (respectively, $P_5 \rightarrow P_4$) in $\mathcal{C}_S$ iff $\nu \rho_1 = \rho_0 \gamma$ (respectively, $\gamma \rho_1 = \rho_0 \nu$) and in the case, $f \simeq 0$ iff there is $\psi' \in e_5 S e_3$ with $\rho_0 = \nu \psi'$ and $\rho_1 = \psi' \gamma$ (respectively, there is $\psi' \in e_4 S e_3$ with $\rho_0 = \gamma \psi'$ and $\rho_1 = \rho' \nu$).

(e) An element $\phi \in e_i S e_3$ induces morphism in $\mathcal{C}_S$ of the form $P_4 \rightarrow P_1$ (respectively, of the form $P_5 \rightarrow P_1$) if and only if $\phi \gamma = 0$ (respectively, $\phi \nu = 0$) in $S$. This is the case iff $i = 1$ and $\phi \in K(\rho \omega - \alpha \beta - \lambda(\alpha \beta \gamma \sigma)^{m-1} \alpha \beta)$ (respectively, $\phi \in K(\rho \omega - \alpha \beta)$) or $\rho \in K X^i_3$.

Proof. Observe that conditions b), d) and first equivalences in a) and e) follow immediately from definition of morphisms in $\mathcal{C}_S$ and homotopy relation (note also that composition of morphisms corresponds to appropriate multiplying of elements in $S$). Let us sketch the proof of remaining equivalences in a) and e). Observe first that, if $i \in \{2, 6\}$, then for any $\phi \in e_i S e_3$ both $\phi \gamma$ and $\phi \nu$ are nonzero. Next, for $i = 3$, it is also easy to check that the only generator $\phi = X^k_3$ of $e_i S e_3$ with $\phi \gamma = \phi \nu = 0$ is $\phi = X^m_3$, so it remains to consider the case $i = 1$. Then, for any base element $\phi = X^k_1$ with $k \in \{0, \ldots, m - 1\}$ we have $\phi \gamma = X^k_4$ and $\phi \nu = X^k_5$, whereas $X_{13} \gamma = X^0_{14} + \lambda X^{m-1}_{14}$ and $X_{13} \nu = X^0_{15}$. As a result, for any element $\phi \in e_i S e_3$, we have $\phi \nu = 0$ if and only if $\phi \in K(\rho \omega - \alpha \beta)$. In a very similar way, we deduce that $\phi \gamma = 0$ if and only if $\phi$ belongs to $K(X_{13} - X^0_{13} - \lambda X^{m-1}_{13})$, which finishes the proof of e). It is straightforward calculation to check that for any $\phi \in e_4 S e_4$ we have: $\gamma \phi = 0$ if and only if $\phi = 4$ and $\phi \in K X^m_4$. Similarly, for $\phi \in e_5 S e_4$.

Now, we may almost directly deduce the following proposition.

**Proposition 4.2.** The following two complexes

$$T^{(1)} = P_1 \oplus P_2 \oplus P_3 \oplus P_4 \oplus \bar{P}_4 \oplus P_6$$

and

$$T^{(2)} = P_1 \oplus P_2 \oplus P_3 \oplus \bar{P}_4 \oplus \bar{P}_5 \oplus P_6$$

in $\mathcal{C}_S$ are tilting complexes.

Proof. First we prove that $T^{(2)}$ is a tilting complex. Denote by $T_1, \ldots, T_6$ its indecomposable direct summands in order fixed above. Then it follows directly from a) above that $\text{Hom}_{\mathcal{C}_S}(T_k, (T_4 \oplus T_5)[-1]) = 0$, for any $k \neq 4$ and 5, hence also $\text{Hom}_{\mathcal{C}_S}(T_1 \oplus T_2 \oplus T_3 \oplus T_5, (T_1 \oplus T_2)[i]) = 0$, for $i < 0$, and consequently, for all integers $i \neq 0$, because $(T_4 \oplus T_5)[i]$, for $i > 0$, is concentrated in positive degrees, while $T_k$ with $k \neq 4, 5$, in degree 0. Trivially, we have $\text{Hom}_{\mathcal{C}_S}(T_k, T_j[i]) = 0$, for any integer $i \neq 0$ and $k, j \in \{1, 2, 3, 6\}$, so $\text{Hom}_{\mathcal{C}_S}(T_1 \oplus T_2 \oplus T_3 \oplus T_6, T^{(3)}[i]) = 0$, for all $i \neq 0$.

Further, if any complex $X$ of the form $X = T_k[1]$ satisfies $X^n = 0$, for all $n \leq 0$ and $X^1 = P_t$ with $t \neq 4, 5$. But $e_3 S e_4 = e_3(\text{rad } S) e_4 \subset S \gamma$, as
well as $e_3S e_5 = e_3(\text{rad } S) e_5 \subset S \nu$, because all nontrivial paths ending at 4 (or 5) pass through $\gamma$ (respectively, through $\nu$), so we conclude from c) in the previous Lemma that $\text{Hom}_{K_S}(T_1 \oplus T_5, T^{(2)}[1]) = 0$, and hence we have $\text{Hom}_{K_S}(T_1 \oplus T_5, T^{(2)}[i]) = 0$, for any $i > 0$. Obviously, if $k \neq 4, 5$, we obtain $\text{Hom}_{K_S}(T_1 \oplus T_5, T_k[i]) = 0$, for any $i < 0$, and finally $\text{Hom}_{K_S}(T_k, T_l[-1]) = 0$, for all $k, l \in \{4, 5\}$, since every such chain map $T_k \to T_l[-1]$ is given by an element $\psi \in e_i S e_3 = e_i(\text{rad } S) e_3$ with $\gamma \psi \neq 0$ or $\nu \psi \neq 0$, if $l = 4$ or 5, respectively; see also Lemma 4.1(a). It follows that $\text{Hom}_{K_S}(T_1 \oplus T_5, T^{(2)}[i]) = 0$, also for all $i < 0$.

Concluding, we obtain that $\text{Hom}_{K_S}(T^{(2)}, T^{(2)}[i]) = 0$, for any integer $i \neq 0$, and consequently, $T^{(2)}$ satisfies condition (T1) from definition of a tilting complex.

Now, it remains to see that the identity homomorphism on $P_3$ induces two morphisms (in degree 0) of complexes $f : T_3 \to T_4$ and $g : T_3 \to T_3$ and mapping cones $C_f$ and $C_g$ (of $f$ and $g$), are complexes in $K_S$, of the following forms

$$P_3 \oplus P_3 \xrightarrow{[1 \gamma]} P_3 \quad \text{and} \quad P_3 \oplus P_5 \xrightarrow{[1 \nu]} P_3$$

But then projections $P_3 \oplus P_4 \to P_4$ and $P_3 \oplus P_5 \to P_5$ induce morphisms (in degree 1) of the forms $f' : C_f \to P_4[1]$ and $g' : C_g \to P_5[1]$, for which cones $C_f'$ and $C_g'$ are easy to check being exact, so $f'$ and $g'$ are quasi-isomorphisms, and thus homotopy equivalences (we deal with bounded above and below complexes of projective $S$-modules). This means that $C_f \cong P_4[1]$ and $C_g \cong P_5[1]$ in $K_S$, and therefore triangulated category generated by $\text{add}(T^{(2)})$ contains all stalk complexes $P_i$, for $i \in \{1, \ldots, 6\}$, together with their shifts. Consequently, $\text{add}(T^{(2)})$ generates $K_S$ as a triangulated category, and hence $T^{(2)}$ is indeed a tilting complex in $K_S$.

Let now $T_1, \ldots, T_6$ be all indecomposable direct summands of $T^{(1)}$ ordered as in the statement. Using analogues of above arguments one can easily prove that also $T^{(1)}$ satisfies condition (T2). For (T1), observe that $\text{Hom}_{K_S}(T_k, T_k[i]) = 0$, for all $k, l \neq 5$ and $i \neq 0$, because all these complexes are stalk in degree 0. Finally, note that every chain map $\phi : T_5 \to T_k[1]$ is given by an element $\phi \in e_k S e_5$, hence for $k \neq 5$ we have $\phi \in S \nu$, and so $\phi \sim 0$, by Lemma 4.1(a). This shows $\text{Hom}_{K_S}(T_5, T_k[i]) = 0$, for all $k \neq 5$ and $i \neq 0$. Including the above considerations for $T^{(2)}$, we have $\text{Hom}_{K_S}(T_5, T_5[i]) = 0$, for $i \neq 0$, thus $\text{Hom}_{K_S}(T_5, T^{(1)}[i]) = 0$, for any integer $i \neq 0$. Direct calculation on bases of spaces $e_5 S e_k$, with $k \neq 5$, shows that for any nonzero $\phi \in e_5 S e_k$ we have $\nu \phi \neq 0$. As a result, we obtain $\text{Hom}_{K_S}(T_k, T_5[-1]) = 0$, and consequently, $\text{Hom}_{K_S}(T_k, T_5[i]) = 0$, for any $k \neq 5$ and $i \neq 0$. It is now clear that $\text{Hom}_{K_S}(T^{(1)}, T^{(1)}[i]) = 0$, for all integers $i \neq 0$, that is, $T^{(1)}$ satisfies (T1), and therefore it is indeed a tilting complex in $K_S$. \hfill \Box

5 Proof of Theorem 1.1

Since we have already constructed appropriate tilting complexes in $K_S$, we conclude from Theorem 5.1 that the algebra $S = S(m, \lambda)$ is derived equivalent to both algebras $E := \text{End}_{K_S}(T^{(1)})$ and $F := \text{End}_{K_S}(T^{(2)})$. According to Theorems 4.3 and 5.4, it remains to show that there are isomorphisms $E \cong E(m, \lambda)$
and $F \cong F(m, \lambda)$ of $K$-algebras, and then Theorems 1.1 and 1.2 will automatically follow (showing isomorphisms we will also compute dimensions of $E$ and $F$).

The following two lemmas are devoted to compute Cartan matrices of algebras $E$ and $F$.

**Lemma 5.1.** The Cartan matrix $C_F$ of $F$ is of the form

\[
\begin{pmatrix}
  m+1 & m & m+1 & 1 & 1 & m \\
  m & m+1 & m & 0 & 0 & m-1 \\
  m+1 & m & m+1 & 1 & 1 & m \\
  1 & 0 & 1 & 2 & 0 & 0 \\
  1 & 0 & 1 & 0 & 2 & 0 \\
  m & m-1 & m & 0 & 0 & m+1
\end{pmatrix}.
\]

**Proof.** Denote by $c_{ij}$ the $(i,j)$ entry of $C_F$ and by $T_1, \ldots, T_6$ all indecomposable direct summands of tilting complex $T = T^{(2)}$, ordered as presented in Proposition 4.2. By definition $E$ is the endomorphism algebra of $T$, so modules $\tilde{P}_i := \text{Hom}_K(c_i, T_i)$, for $i \in \{1, \ldots, 6\}$, form a complete set of pairwise non-isomorphic indecomposable projective modules in ind $F$, and moreover there are isomorphisms of vector spaces $\text{Hom}_E(\tilde{P}_i, \tilde{P}_j) \cong \text{Hom}_K(c_i, T_j)$. Consequently, for all $i, j \in \{1, \ldots, 6\}$ we have $c_{ij} = \dim_K \text{Hom}_K(c_i, T_j)$ and complexes $T_i, T_j$ satisfy assumptions of Theorem 3.2. Therefore we can directly calculate ($c_{ij}^S$ denote the corresponding entry of Cartan matrix $C_S$ of $S$) that:

- $c_{ij} = \dim_K \text{Hom}_K(c_i, P_j) = \dim_K \text{Hom}_S(P_i, P_j) = c_{ij}^S$, for any $i, j \in \{1, 2, 3, 6\}$,
- for $i \in \{4, 5\}$ and $j \in \{1, 2, 3, 6\}$, we have
  \[c_{ij} = \dim_K \text{Hom}_K(c_i, P_j) = \dim_K \text{Hom}_S(P_i, P_j) - \dim_K \text{Hom}_S(P_i, P_j) = c_{ij}^S - c_{ij}^S = c_{ij}^S,\]
- similarly, $c_{ij} = \dim_K \text{Hom}_K(c_i, P_j) = c_{ij}^S - c_{ij}^S$, if $i \in \{1, 2, 3, 6\}$ and $j \in \{4, 5\}$
- and $c_{ij} = c_{ij}^S - c_{ij}^S - c_{ij}^S + c_{ij}^S$, for $i, j \in \{4, 5\}$.

As a result, for any $j \in \{1, 2, 3, 6\}$, we obtain

\[c_{4j} = c_{3j}^S - c_{4j}^S = c_{3j}^S - c_{5j}^S = c_{5j} = \begin{cases} 1, & \text{when } j \in \{1, 3\} \\ 0, & \text{when } j \in \{2, 4\} \end{cases}\]

and, if $i \in \{1, 2, 3, 6\}$, then $c_{4i} = c_{3i}^S - c_{4i}^S = c_{3i}^S - c_{5i}^S = c_{5i} = c_{4i}$.

Finally, simple checking shows that

\[c_{44} = c_{33}^S - c_{34}^S - c_{43}^S + c_{44}^S = c_{55} = m + 1 - m - m + m + 1 = 2\]

and $c_{45} = c_{54} = m + 1 - m - m + m - 1 = 0$, which completes the proof. \qed
Lemma 5.2. The Cartan matrix $C_E$ of $E$ is of the form

$$
\begin{bmatrix}
  m + 1 & m & m + 1 & m & 1 & m \\
  m & m + 1 & m & m & 0 & m - 1 \\
  m + 1 & m & m + 1 & m & 1 & m \\
  m & m & m & m & 1 & m \\
  1 & 0 & 1 & 1 & 2 & 0 \\
  m & m - 1 & m & m & 0 & m + 1
\end{bmatrix}
$$

Proof. As before, we denote by $c_{ij}$ the corresponding entry of $C_E$. Obviously, it follows from Theorem 3.2 that for stalk complexes $T_i, T_j$, with $i, j \neq 5$, we have $\dim_K \text{Hom}_{K}^s(T_i, T_j) = \dim_K \text{Hom}_{S}(P_i, P_j)$, and therefore $c_{ij} = c_{ij}^S$. For any $j \neq 5$, we deduce also from Theorem 3.2 that

$$c_{5j} = \dim_K \text{Hom}_{K}^s(P_5, P_j) = \dim_K \text{Hom}_{S}(P_3, P_j) - \dim_K \text{Hom}_{S}(P_5, P_j) = c_{3j}^S - c_{5j}^S,$$

and so the fifth row of $C_E$ is of the form $[1 \ 0 \ 1 \ 2 \ 0]$ (it follows from the last proof that $c_{55} = \dim_K \text{Hom}_{K}^s(T_5, T_5) = 2$). In a similar way, applying Theorem 3.2 to complexes $T_i \neq 5$ and $T_5$, we deduce that $c_{55} = c_{55}^S$, so the fifth column is equal to transpose of fifth row, and the proof is now complete. \(\square\)

In the next two lemmas we shall investigate Gabriel quivers.

Lemma 5.3. The Gabriel quivers of $F$ and $F(m, \lambda)$ coincide.

Proof. We fix order (and labeling) of vertices in $Q_E$ induced by order of direct summands $T_1, \ldots, T_6$ of tilting complex $T = T^{(2)}$. For $i, j \in \{1, \ldots, 6\}$ let $F_{ij}$ denote the $K$-vector space $U/V$, where $U$ is a subspace of $\text{Hom}_{K}^s(T_i, T_j)$ formed by all non-isomorphisms and $V$ its subspace containing all compositions of two nonisomorphisms $T_i \to T' \to T_j$ with $T'$ an object in $\text{add}(T)$. It is well known that $F_{ij}$ is isomorphic to $\text{rad}_F(T_i, T_j)/\text{rad}_E^2(T_i, T_j) \simeq e_j(\text{rad} F)e_i/e_j^2 F)e_j$, so in particular, the number $q_{ij}$ of arrows $i \to j$ in $Q_F$ is equal to $\dim_K F_{ji}.$

First, we consider arrows $\alpha, \beta, \rho, \omega$ in $Q_S$ and the corresponding homomorphisms $\alpha : P_2 \to P_1$, $\beta : P_3 \to P_2$, $\rho : P_6 \to P_1$ and $\omega : P_3 \to P_6$ in $\text{proj} S$. It is clear that then the induced morphisms of stalk complexes $\tilde{\alpha}_1 : T_2 \to T_1$, $\tilde{\alpha}_2 : T_3 \to T_2$, $\tilde{\alpha}_3 : T_6 \to T_1$ and $\tilde{\alpha}_4 : T_3 \to T_6$ give unique generators of spaces $F_{21}, F_{32}, F_{61}$ and $F_{36}$, so $q_{12} = q_{23} = q_{56} = q_{63} = 1.$ For instance, any nonisomorphism $f : T_2 \to T_1$ in $K_S$ is given by an element $f$ in $e_1 \text{rad} S e_2$, and if $f$ factors through $\text{add}(T)$, then it factors through $\text{add}(T_2 \oplus T_6)$, because every path in $Q_S$ from $1$ to $2$ which is passing through vertex $3$ it must went through vertex $2$ or $6$. Consequently, $Q_{21} \simeq e_1(\text{rad} S)e_2/e_1(\text{rad}^2 S)e_2$, and hence, there is exactly $q_{12} = 1$ arrow $1 \to 2$ in $Q_F$, denoted by $a_{11}$ (the same as corresponding homomorphism $\alpha_1 = \text{Hom}_{K_S}(T_1, \tilde{\alpha}_1) : P_2 \to P_1$). Similar arguments imply the remaining equalities and the following ones $q_{13} = q_{21} = q_{26} = q_{32} = q_{36} = q_{61} = q_{62} = 0$. Note also that directly from Cartan matrix of $F$ one may read that $q_{24} = q_{25} = q_{42} = q_{45} = q_{46} = q_{52} = q_{54} = q_{56} = q_{64} = q_{65} = 0$. 12
Further, it follows from Lemma 4.1(b), that the unique (up to scalar) nonzero morphism $T_3 \to T_4$ (respectively, $T_3 \to T_5$) in $K_S$ is induced by identity on $P_3$, which will be denoted, respectively, by $\beta_1 : T_3 \to T_4$ and $\beta_2 : T_3 \to T_5$. It is easy to check that those maps do not factorize through $\text{add}(T)$, so we have irreducible morphisms $\beta_1 : \tilde{P}_3 \to \tilde{P}_4$ and $\beta_2 : \tilde{P}_3 \to \tilde{P}_5$ in proj $F$, and hence arrows $\beta_1 : 4 \to 3$ and $\beta_2 : 5 \to 3$ in $Q_F$ (in particular, $q_{41} = q_{53} = 1$).

Next, observe that any nonzero morphism $T_1 \to T_4$ (respectively, $T_1 \to T_5$) is nonisomorphism and it factorizes through $\tilde{\beta}_1$ (respectively, through $\tilde{\beta}_2$), hence through $T_3$, and therefore $q_{41} = q_{51} = 0$.

Next, consider the following relations in $S$

$$\beta_1 = \rho \omega - \alpha \beta, \beta_3 = \beta_1 - \lambda(\alpha \beta \gamma \sigma)^{m-1} \alpha \beta \in e_1 S e_3$$

and $\gamma_1 = \nu \delta, \gamma_2 = \gamma \sigma + \lambda(\gamma \sigma \alpha \beta)^{m-1} \gamma \sigma \in e_3 S e_1$. Then the corresponding homomorphisms $\beta_1, \beta_3 : P_3 \to P_1$ and $\gamma_1, \gamma_2 : P_1 \to P_3$ in proj $S$ induce morphisms $\beta_1 : T_3 \to T_1, \beta_3 : T_4 \to T_1$ and $\gamma_1, \gamma_2 : T_1 \to T_3$ in $K_S$. We claim that induced homomorphisms $\beta_1 : \tilde{P}_3 \to \tilde{P}_1, \beta_3 : \tilde{P}_4 \to \tilde{P}_1$ and $\gamma_1, \gamma_2 : \tilde{P}_1 \to \tilde{P}_3$ are irreducible in proj $F$ and $q_{14} = q_{15} = 1$ and $q_{31} = 2$.

Note that $c_{15}^F = c_{14}^F = 0$, so directly from Lemma 4.1(e) we can deduce that there is a nonzero morphism $T_4 \to T_i$ (respectively, $T_5 \to T_i$) if and only if $i = 3$ or $1$, and moreover, it is induced (up to scalar) respectively, by $X_3$, if $i = 3$ and by $\beta_3$ (respectively, $\tilde{\beta}_1$), for $i = 1$. In particular, it is easy to see that $\beta_1$ and $\beta_3$ are irreducible in proj $F$, so $q_{14} = q_{15} = 1$. Moreover, one may check that $\gamma_1 \beta_1 = -\lambda X_3^m$, hence morphisms $T_4 \to T_3$ (in $T_3 \to T_3$) factors through $\tilde{\beta}_3$ ($\tilde{\beta}_1$), and therefore $q_{33} = q_{35} = 0$.

Now, observe that each linear generator $X_{21}^k$ of $e_3 S e_1$, $k \in \{1, \ldots, m - 1\}$, is a path passing through vertex 2 (or 6), so the induced morphism $T_1 \to T_3$ in $K_S$ factors through $T_2$, and hence $q_{13} \leq 2$. It is not hard to prove that both $\gamma_1$ and $\gamma_2$ (viewed as morphisms $T_1 \to T_3$ in $K_S$) do not factorize through $\text{add}(T)$ (it is enough to see that $\nu \delta, \gamma \sigma$ are paths of length 2 in $K Q_S$, while morphisms $T_1 \to T_3$ in $K_S$ which factorize through a summand $T_i$ of $T$ are induced by combinations of paths of length at least 3). Consequently, corresponding homomorphisms $\gamma_1$ and $\gamma_2$ are irreducible in proj $F$. Clearly, $\gamma_1, \gamma_2$ are linearly independent as elements in $e_3 S e_1$, hence also as morphisms $T_1 \to T_3$ in $K_S$ (note that here $\text{Hom}_{K_S}(T_1, T_3) = \text{Hom}_{C_S}(T_1, T_3) = \text{Hom}_S(P_1, P_3)$). As a result, we obtain that indeed $q_{31} = 2$, and irreducible homomorphisms $\gamma_1, \gamma_2$ in proj $F$ induce two arrows $\gamma_1, \gamma_2 : 3 \to 1$ in $Q_F$.

To end, let us also mention that there are no loops in $Q_F$. Indeed, since there is no loop in any vertex $i \in \{1, 2, 3, 6\}$ and every cycle $X_i^k$ in $i$ passes through 3, we deduce that $q_{ii} = 0$, for $i \in \{1, 2, 3, 6\}$. Moreover, easy calculation involving bases of $e_4 S e_4$ and $e_3 S e_3$ shows that $\text{Hom}_{C_S}(T_4, T_4)$ admits a $K$-basis formed by chain maps $f^k = (f_1^k, f_0^k)$, for $k \in \{0, 1, \ldots, m - 1\}$, $f_1$ and $f_0$, where $f^k$ is given by $f_1^k = X_4^k : P_4 \to P_4$ and $f_0^k = X_3^k : P_3 \to P_3$, while $f_1 = (X_3^m, 0)$ and $f_0 = (0, X_3^m)$. One can directly verify that the following homotopies hold: $f_0 \simeq f_1$ and $f_0 \simeq 0$, for any $k \in \{1, \ldots, m - 1\}$ (see Lemma 4.1(d)). It follows that $\text{Hom}_{K_S}(T_4, T_4)$ has a basis given by two homotopy classes, one of $f_0$ and one
of \( f^0 \). In particular, \( f_0 \) yields unique generator of \( \text{rad}_F(\bar{P}_3, \bar{P}_3) \) (over \( K \)), which factors through \( T_3 \) (even, through \( \beta_4 \)), and hence \( q_{44} = 0 \). Similar arguments show that \( q_{55} = 0 \). This completes the proof.

We get analogous result for the remaining algebra.

**Lemma 5.4.** The Gabriel quivers of \( E \) and \( E(m, \lambda) \) coincide.

**Proof.** As before, we abbreviate \( T = T^{(1)} \), and for any \( i \in \{1, \ldots, 6\} \), by \( \bar{P}_i \) we denote the projective module \( \text{Hom}_{K[S]}(T, T_i) \) in \( \text{ind} \ E \) corresponding to \( i \)-th summand \( T_i \) of \( T \) (with order of summands as presented in previous section). First, let us consider the following homomorphisms in \( \text{proj} \ S \)

\[
\begin{align*}
\alpha_1 &= \alpha : P_2 \rightarrow P_1, \\
\alpha_2 &= \beta : P_3 \rightarrow P_2, \\
\alpha_3 &= \rho : P_6 \rightarrow P_1, \\
\alpha_4 &= \omega : P_3 \rightarrow P_5, \\
\alpha_5 &= \gamma : P_4 \rightarrow P_3 \quad \text{and} \quad \alpha_6 = \sigma : P_1 \rightarrow P_4
\end{align*}
\]

induced by arrows in \( \alpha, \beta, \rho, \omega, \gamma \) and \( \sigma \) in \( Q_S \). It is clear from the last proof that for any \( i \in \{1, \ldots, 6\} \) homomorphism \( \alpha_i : P_k \rightarrow P_l \) induce morphism \( \bar{\alpha}_i : T_k \rightarrow T_l \) which does not factor through \( \text{add}(T) \), and hence homomorphism \( \alpha_i = \text{Hom}_{K[S]}(T, \bar{\alpha}_i) : \bar{P}_k \rightarrow \bar{P}_l \) is irreducible in \( \text{proj} \ E \).

Moreover, let \( \gamma_0 : P_1 \rightarrow P_3 \) be a homomorphism in \( \text{proj} \ S \) given by path \( \gamma_1 = \nu \delta \) in the notation from the proof of previous Lemma. Using arguments presented there, one may easily see that \( \gamma_0 \) induces unique (up to scalar) morphism \( \bar{\gamma}_0 : T_1 \rightarrow T_3 \) which does not factor through \( \text{add}(T) \) (\( \gamma_2 \) gives morphism which factors through \( T_4 = P_4 \)). In consequence, corresponding homomorphism \( \gamma_0 = \text{Hom}_{K[S]}(T, \bar{\gamma}_0) : \bar{P}_1 \rightarrow \bar{P}_3 \) is irreducible in \( \text{proj} \ E \), and hence, we have exactly one arrow \( 1 \rightarrow 3 \) in \( Q_E \), denoted also by \( \gamma_0 \). As in the previous proof we can now deduce that \( \alpha_1, \ldots, \alpha_6 \) and \( \gamma_0 \) are all arrows in \( Q_E \) between vertices \( i, j \neq 5 \).

Finally, we can repeat arguments used in the last proof and conclude that the remaining arrows \( \beta_1 : 1 \rightarrow 5 \) and \( \beta_2 : 5 \rightarrow 3 \) in \( Q_E \) are induced from morphisms \( \beta_1 : T_5 \rightarrow T_1 \) and \( \beta_2 : T_3 \rightarrow T_5 \) given, respectively, by \( \beta_1 = \rho \omega - \alpha \beta \) and \( \beta_2 \) the identity on \( P_3 \). Now, the required claim follows.

**Lemma 5.5.** The following relations hold in \( F \)

1. \( \alpha_1 \alpha_2 - \alpha_3 \alpha_4 + \beta_1 \beta_2 = 0 \) and \( \alpha_1 \alpha_2 - \alpha_3 \alpha_4 + \beta_3 \beta_4 + \lambda(\alpha_3 \alpha_4 \gamma_1)^{m-1} \alpha_3 \alpha_4 = 0. \)
2. \( \alpha_2 \gamma_1 = \alpha_2 \gamma_2 \) and \( \gamma_2 \alpha_1 = \gamma_1 \alpha_1. \)
3. \( \alpha_4 \gamma_2 = \alpha_4 \gamma_1 + \lambda(\alpha_4 \gamma_1 \alpha_3)^{m-1} \alpha_4 \gamma_1 \) and \( \gamma_2 \alpha_3 = \gamma_1 \alpha_3 + \lambda(\gamma_1 \alpha_3 \alpha_4)^{m-1} \gamma_1 \alpha_3. \)
(4) $\beta_2 \gamma_1 = \beta_4 \gamma_2 = \gamma_1 \beta_1 = \gamma_2 \beta_3 = 0$.

(5) $\beta_2 \gamma_2 \beta_1 \beta_2 = \beta_4 \gamma_1 \beta_3 \beta_4 = 0$.

(6) $\gamma_1 \alpha_1 \alpha_2 = \gamma_1 \alpha_3 \alpha_4$ and $\alpha_1 \alpha_2 \gamma_1 = \alpha_3 \alpha_4 \gamma_1$.

(7) $(\alpha_3 \alpha_4 \gamma_1)^m \alpha_1 = (\alpha_3 \alpha_4 \gamma_1)^m \alpha_3 = \gamma_1 (\alpha_3 \alpha_4 \gamma_1)^m = 0$ and $\alpha_2 (\gamma_1 \alpha_3 \alpha_4)^m = \alpha_4 (\gamma_1 \alpha_3 \alpha_4)^m = 0$.

Proof. The relations in (1) follow directly from definition of irreducible homomorphisms corresponding to arrows in $Q_F$. Easy calculation shows that $\alpha_2 \gamma_1 - \alpha_2 \gamma_2 = \beta \nu \delta - \beta \gamma \sigma = -\lambda (\beta \gamma \sigma \alpha)^{m-1} \beta \gamma \sigma = 0$ and $\gamma_1 \alpha_1 - \gamma_2 \alpha = \nu \delta \alpha - \gamma \sigma \alpha - \lambda (\gamma \sigma \alpha \beta)^{m-1} \gamma \sigma \alpha = 0$, by Section 2 (1)-(2). Therefore (2) holds. Further

$$\alpha_4 \gamma_2 - \alpha_4 \gamma_1 - \lambda (\alpha_4 \gamma_1 \alpha_3)^{m-1} \alpha_4 \gamma_1 = \omega \gamma \sigma - \omega \nu \delta + \lambda \omega (\gamma \sigma \alpha \beta)^{m-1} \gamma \sigma - (\omega \nu \delta \rho)^{m-1} \omega \nu \delta = 0,$$

because in $S$, we have $\omega (\gamma \sigma \alpha \beta)^{m-1} \gamma \sigma = \omega (\nu \delta \rho \omega)^{m-1} \omega \gamma \sigma$ and $\omega \nu \delta = \omega \nu \delta$, by Section 2 (7). In a similar way one may check that the second relation in (3) follows from (8) in Section 2.

For (4) observe that since $\beta_2$ and $\beta_4$ are induced by indentity on $P_3$, we may identity morphisms $r_1 : T_1 \to T_5$ and $r_2 \equiv r_4 : T_1 \to T_4$ are homotopic to 0, by Lemma 4.1b. Note also that $\gamma_1 \beta_1 = \nu \delta (\rho \omega - \alpha \beta) = \nu \delta (\rho \omega - \delta \alpha \beta) = 0$, due to Section 2 (6) and $\gamma_2 \beta_1 = (\gamma \sigma + \lambda X_3^{m-1})(\rho \omega - \alpha \beta) = \gamma \sigma \rho \omega - \gamma \sigma \alpha \beta + \lambda X_3^{m-1} \gamma (\rho \omega - \sigma \alpha \beta) = \lambda X_3^{m} + \lambda^2 X_3^{2m-1} = \lambda X_3^{m}$, by Section 2 (3), (10) and remarks. Now it is clear that

$$\gamma_2 \beta_3 = \gamma_2 (\beta_2 - \lambda X_3^{m-1}) = \lambda X_3^{m} - \lambda (\gamma \sigma + \lambda X_3^{m-1}) X_3^{m-1}$$

is equal to 0 in $F$, because $\gamma \sigma X_3^{m-1} = \gamma \sigma X_3^{m-1} \alpha \beta = X_3^{m}$, while $X_3^{m+1} X_3^{m-1} = X_3^{m-1} \gamma \sigma X_3^{m-1} \alpha \beta = X_3^{m+1} \gamma \sigma X_3^{m-1} \alpha \beta = X_3^{m+1}$, again by Section 2 (10) (note: $m \geq 2$ implies $2m - 1 > m$). This proves that all relations in (4) hold.

Moreover, relation $\beta_2 \gamma_2 \beta_1$ (respectively, $\beta_4 \gamma_1 \beta_3$) in $F$ corresponds to a morphism $T_5 \to T_5$ (respectively, $T_4 \to T_4$), which is given by single homomorphism $P_5 \to P_3$ identified, respectively, with $\gamma_2 \beta_1 = (\gamma \sigma + \lambda (\gamma \sigma \alpha \beta)^{m-1} \gamma \sigma)(\rho \omega - \alpha \beta) = \lambda X_3^{m}$ (by Section 2 (3)) and with $\gamma_1 \beta_3 = -\nu \delta (\alpha \beta \gamma \sigma)^{m-1} \alpha \beta = -\lambda X_3^{m}$ (by (4) above; see also remarks in Section 2). Therefore, using Lemma 4.1b) we deduce that both relations $r_1 = \beta_2 \gamma_2 \beta_1 \beta_2$ and $r_2 = \beta_4 \gamma_1 \beta_3 \beta_3$ hold in $F$, since corresponding morphisms $\tilde{r}_1 : T_3 \to T_5$ and $\tilde{r}_2 : T_3 \to T_4$ are induced by a cycle in $e_3 S e_3$ which factorizes both through $\gamma$ and $\nu$ respectively. This implies (5).

Finally, we will provide arguments for relations in (6) and (7). First, as an immediate consequence of (5)-(6) in Section 2 we obtain that $\alpha_1 \alpha_2 \gamma_1 - \alpha_3 \alpha_4 \gamma_1 = (\alpha \beta - \rho \omega) \nu \delta = 0$ and $\gamma_1 \alpha_1 \alpha_2 - \gamma_1 \alpha_3 \alpha_4 = \nu \delta (\alpha \beta - \rho \omega) = 0$, and hence (6) follows. Now, recall that the cycle $\alpha_3 \alpha_4 \gamma_1$ (respectively, $\gamma_1 \alpha_3 \alpha_4$) in $F$ corresponds to the cycle $X_1$ (respectively, $X_3$) in $S$ (in the notation from Section 2), so applying Section 2 (5), we conclude that $(\alpha_3 \alpha_4 \gamma_1)^k = X_1^k$ and $(\gamma_1 \alpha_3 \alpha_4)^k = X_3^k$, for all
Lemma 5.6. The following relations hold in $E$

\begin{align*}
(8) & \quad \alpha_1 \alpha_2 - \alpha_3 \alpha_4 + \beta_1 \beta_2, \\
(9) & \quad \alpha_3 \alpha_4 \alpha_5 = \alpha_1 \alpha_2 \alpha_5 + \lambda(\alpha_1 \alpha_2 \alpha_5 \alpha_6)^{m-1} \alpha_1 \alpha_2 \alpha_5, \\
(10) & \quad \gamma_0 \beta_1 = 0, \gamma_0 \alpha_3 = \alpha_5 \alpha_6 \alpha_3 \ and \ \gamma_0 \alpha_1 = \alpha_5 \alpha_6 \alpha_1 + \lambda(\alpha_5 \alpha_6 \alpha_1 \alpha_2)^{m-1} \alpha_5 \alpha_6 \alpha_1, \\
(11) & \quad \alpha_2 \gamma_0 = \alpha_2 \alpha_5 \alpha_6 + \lambda(\alpha_2 \alpha_5 \alpha_6 \alpha_1)^{m-1} \alpha_2 \alpha_5 \alpha_6 and \\
& \quad (\alpha_2 \alpha_5 \alpha_6 \alpha_1)^{m-1} \alpha_2 \alpha_5 \alpha_6 \alpha_3 = 0, \\
(12) & \quad \alpha_4 \gamma_0 = \alpha_4 \alpha_5 \alpha_6 and \ \alpha_4 \alpha_5 \alpha_6 \alpha_1 (\alpha_2 \alpha_5 \alpha_6 \alpha_1)^{m-1} = 0, \\
(13) & \quad \alpha_6 \alpha_3 \alpha_4 = \alpha_6 \alpha_1 \alpha_2 + \lambda(\alpha_6 \alpha_1 \alpha_2 \alpha_5)^{m-1} \alpha_6 \alpha_1 \alpha_2, \\
(14) & \quad \beta_2 \gamma_0 = 0, \beta_2 \alpha_5 \alpha_6 \alpha_1 = \beta_2 \alpha_5 \alpha_6 \alpha_3 = 0 \ and \ \beta_2 \alpha_5 \alpha_6 \beta_1 \beta_2 = 0, \\
(15) & \quad \text{if a cycle } C \text{ at vertex } i \text{ in } Q_E \text{ is of length } 3 \ or \ 4, \ \text{then } \theta C^m = C^m \phi = 0, \ \text{for all arrows } \theta, \phi \text{ with } t(\theta) = s(\phi) = i.
\end{align*}

Proof. (8) is obvious from definition of irreducible homomorphisms corresponding to arrows of $Q_E$. For (9) it suffices to use Section 2 (4), whereas (10) is an immediate consequence of (6), (8) and (2) in Section 2 respectively. Further (11) follows from Section 2 (1) and (1'). To see (12) it is enough to apply Section 2 (7) and (2'). Now, Section 2 (3) implies (13), while (14) is easily obtained from Lemma 4.1), and (8), (2) and (3) in Section 2. Finally, to prove (15) we need only to observe that any cycle in $Q_E$ of length 3 or 4 is given by a single cycle in $Q_S$ of length 4 or 4m. Then this condition holds by (14) above and remarks in Section 2 (see also previous proof).

Now, we may finish the proof by showing appropriate bases of algebras $E(m, \lambda)$ and $F(m, \lambda)$.

Lemma 5.7. $C_{F(m, \lambda)} = C_F$ and $\dim_K F(m, \lambda) = 16m + 16$

Proof. We abbreviate $F = F(m, \lambda)$ for most part. First of all, observe that relations (F1)-(F7) defining $F(m, \lambda)$ imply also the following relations

\begin{align*}
(1') & \quad \alpha_3 \alpha_4 \gamma_1 \alpha_1 \alpha_2 = \alpha_3 \alpha_4 \gamma_1 \alpha_3 \alpha_4 \ and \ \alpha_3 \alpha_4 \gamma_1 \beta_1 = \alpha_3 \alpha_4 \gamma_1 \beta_3 = 0, \\
(2') & \quad \alpha_2 \gamma_1 \beta_1 = \alpha_2 \gamma_1 \beta_3 = 0 \ and \ (\alpha_2 \gamma_1 \alpha_1)^{m-1} \alpha_2 \gamma_1 \alpha_3 = 0, \\
(3') & \quad \gamma_1 \alpha_3 \alpha_4 \gamma_1 \beta_1 = \gamma_1 \alpha_3 \alpha_4 \gamma_1 \beta_3 = 0 \ and \ \gamma_1 \alpha_3 \alpha_4 \gamma_1 = \gamma_1 \alpha_3 \alpha_4 \gamma_2, \\
(4') & \quad \beta_4 \gamma_1 \alpha_1 = \beta_4 \gamma_1 \alpha_3 = \beta_4 \gamma_1 \beta_1 = 0.
\end{align*}
(5') $\beta_2 \gamma_2 \alpha_1 = \beta_2 \gamma_2 \alpha_3 = \beta_2 \gamma_2 \beta_3 = 0$,

(6') $\alpha_4 \gamma_1 \beta_1 = \alpha_4 \gamma_1 \beta_3 = 0$ and $(\alpha_4 \gamma_1 \alpha_3)^{m-1} \alpha_4 \gamma_1 \alpha_1 = 0$,

(7') for every vertex $i$ and any cycle $C$ of length in $Q_F$ with source and terget 
1, we have $C^m \phi = 0 = \theta C^m$, for all arrows $\phi, \theta$ in $Q_F$ with $t(\theta) = s(\phi) = i$.

We shall give some brief comments on the above relations. Note first that 
(4') and (5') follow from (2), (4) and second relation in (3). Moreover, first 
relation in (1') is a direct consequence of (6), while the rest follow from (6), (2) 
and (4). From (2) and (4) we may easily deduce first two relations in (2'), and 
for the remaining one, observe that (2), (3) and (6) imply

$$
\lambda(\alpha_2 \gamma_1 \alpha_3)^{m-1} \alpha_2 \gamma_1 \alpha_3 = \lambda \alpha_2 (\gamma_1 \alpha_1 \alpha_2)^{m-1} \gamma_1 \alpha_3 = \alpha_2 (\gamma_1 \alpha_3 \alpha_4)^{m-1} \gamma_1 \alpha_3 = \\
= \alpha_2 (\gamma_2 \alpha_3 - \gamma_1 \alpha_3) = (\alpha_2 \gamma_2 - \alpha_2 \gamma_1) \alpha_3 = 0,
$$

so this also holds. In a similar way one may postmultiply the first relation from 
(3) by $\alpha_1$ and use (2) to obtain that the last relation from (6') holds. Now, 
applying (4), we get the first relation from (6') and the second is obtained by 
using (4) and the first relation in (3) twice, and then (7). Finally, first two 
relations in (3') are consequences of (6'), and the last follows from (7), because, 
by (3), the difference $\alpha_3 \alpha_4 \gamma_1 - \alpha_3 \alpha_4 \gamma_2$ is $\lambda(\alpha_3 \alpha_4 \gamma_1)^m$. It is enough to show that 
(7') holds. Since (2) and (5) hold in $F$ we may restrict our considerations 
to cycles in vertex $i \in \{1, 2, 3, 6\}$. On the other hand, if $C$ and $C'$ are 
two different cycles in $Q_F$ of length 3 in vertex $i \in \{1, 2, 3, 6\}$, then it follows from 
(3) and (2) that either $C = C'$ or $C - C'$ is $m$-th power of $C$ or $C'$ up to 
scalar multiplication, and consequently, we get $C^m = (C')^m$. Therefore, we 
only need to check condition (7') for one chosen cycle $C$ in a given vertex $i$.

If $C = \alpha_3 \alpha_4 \gamma_1$ is a cycle in $i = 1$, then $\gamma_2 C^m = \gamma_2 (\alpha_1 \alpha_2 \gamma_1)^m = \gamma_1 C^m$, by (2), 
so combining this with (7) and (1'), we conclude that $C^m \phi = \theta C^m = 0$, for all 
arrows $\phi$ (respectively, $\theta$) with source (respectively, target) in $i = 1$. Because 
$\gamma_1 \alpha_3 \alpha_4 = \gamma_2 \alpha_1 \alpha_2$, due to (6) and (2), one may deduce from (4), (7) and previous 
case ($i = 1$), that (7') is satisfied also for the cycle $C = \gamma_1 \alpha_3 \alpha_4$ in vertex 3. The 
remaining cases follows from previous ones.

Let $\tilde{e}_1, \dotsc, \tilde{e}_6$ denote all primitive idempotents in $F$ corresponding to vertices 
of $Q_F$. Now we will explicitly describe base $B_i$, for every projective module 
$P_i := \tilde{e}_i F$ in ind $F$, $i \in \{1, \dotsc, 6\}$.

First observe that all paths in $Q_F$ of length 1 starting in vertex 1 are precisely 
the arrows $\alpha_1, \alpha_3, \beta_1$ and $\beta_3$. The Paths of length 2 are $\alpha_1 \alpha_2, \alpha_3 \alpha_4, \beta_1 \beta_2$ and 
$\beta_3 \beta_4$, but viewed as elements of $F$ both $\beta_1 \beta_2$ and $\beta_3 \beta_4$ are linear combinations 
of $\alpha_1 \alpha_2, \alpha_3 \alpha_4$ and $(\alpha_3 \alpha_4 \gamma_1)^m \lambda \alpha_3 \alpha_4$, by (1). Next, it is easy to see that all 
paths in $Q_F$ of length 3 starting in 1 are equal modulo $I$ to a linear combination 
of cycles $\alpha_3 \alpha_4 \gamma_1$ and $(\alpha_3 \alpha_4 \gamma_1)^m$. On the other hand, by (7') and (1') above, 
every path in $Q_F$ of the form $(\alpha_3 \alpha_4 \gamma_1)^r \psi$ with $r \geq 1$ and $\phi = \beta_1$ or $\beta_3$, is equal 
to $0$ in $F$, as well as every path of the form $(\alpha_3 \alpha_4 \gamma_1)^m \psi$, for an arrow $\psi$ in 
$Q_F$ with source in 1. Moreover, we have $(\alpha_3 \alpha_4 \gamma_1)^k \alpha_1 \alpha_2 = (\alpha_3 \alpha_4 \gamma_1)^k \alpha_3 \alpha_4$, for
r ∈ {1, . . . , m − 1}, also by (1'), and consequently, the following subset of F

\[ B_1 = \{ \beta_1, \beta_3, \alpha_1 \alpha_2, (\alpha_3 \alpha_4 \gamma_1)^m \} \cup \{ (\alpha_3 \alpha_4 \gamma_1)^r \phi; \ \phi \in B'_1, 0 \leq r \leq m − 1 \}, \]

where \( B'_1 = \{ \epsilon_1, \alpha_1, \alpha_3, \alpha_3 \alpha_4 \} \), is a K-basis of projective module \( \tilde{P}_1 = \tilde{e}_1 F \) in ind \( F \). Using similar arguments involving (7') and (3') we conclude that projective module \( \tilde{P}_3 \) in ind \( F \) has K-basis given as follows

\[ B_3 = \{ \gamma_2, \gamma_2 \beta_1, \gamma_1 \beta_3, (\gamma_1 \alpha_3 \alpha_4)^m \} \cup \{ (\gamma_1 \alpha_3 \alpha_4)^r \phi; \ \phi \in B'_3, 0 \leq r \leq m − 1 \}, \]

with \( B'_3 = \{ \epsilon_3, \gamma_1, \gamma_1 \alpha_3, \gamma_1 \alpha_1 \} \). As a result, the first and the third column of \( C_E \) is of the form \([ m + 1 \ m \ m + 1 \ 1 \ 1 \ m ]^t\).

Further, it is easy to verify that relations presented in (7'), (2') and (6') (see also (2)-(3)) imply that indecomposable projective modules \( P_2 \) and \( P_6 \) in ind \( F \) admit bases defined in the following way

\[ B_2 = \{ (\alpha_2 \gamma_1 \alpha_1)^r \phi; \ \phi \in B'_2, 0 \leq r \leq m − 1 \} \cup \{ (\alpha_2 \gamma_1 \alpha_1)^m \} \cup \{ (\alpha_2 \gamma_1 \alpha_1)^r \phi; \ \phi \in B'_2, 0 \leq r \leq m − 2 \}, \]

and

\[ B_6 = \{ (\alpha_4 \gamma_1 \alpha_3)^r \phi; \ \phi \in B'_6, 0 \leq r \leq m − 1 \} \cup \{ (\alpha_4 \gamma_1 \alpha_3)^m \} \cup \{ (\alpha_4 \gamma_1 \alpha_3)^r \phi; \ \phi \in B'_6, 0 \leq r \leq m − 2 \}, \]

where \( B'_2 = \{ \epsilon_2, \alpha_2, \alpha_2 \gamma_1 \} \) and \( B'_6 = \{ \epsilon_6, \alpha_4, \alpha_4 \gamma_1 \} \).

Finally, as a direct consequence of (4'), (5') and (4)-(5) we obtain that bases of \( \tilde{P}_4 \) and \( \tilde{P}_5 \) are, respectively, of the form

\[ B_4 = \{ \beta_4 \gamma_1, \beta_4, \epsilon_4, \beta_4 \gamma_1 \beta_3 \} \]

and

\[ B_5 = \{ \beta_2 \gamma_2, \beta_2, \epsilon_5, \beta_2 \gamma_2 \beta_1 \}. \]

The proof is now complete. \( \square \)

Finally, let us describe Cartan matrix of algebra \( E(m, \lambda) \).

**Lemma 5.8.** \( C_{E(m, \lambda)} = C_E \) and \( \dim_K E(m, \lambda) = 25m + 13 \).

**Proof.** As in previous proof we denote the algebra \( E(m, \lambda) \) by \( E \), by \( \tilde{e}_i = \epsilon_i + I_E \) the idempotent in \( E \) corresponding to trivial path \( \epsilon_i \) in \( Q_E \), and by \( \tilde{P}_t \) the projective module \( \tilde{e}_i E \) in ind \( E \). First, postmultiplying (8) and using (14) we obtain \( \alpha_1 \alpha_2 \gamma_0 − \alpha_3 \alpha_4 \gamma_0 = −\beta_1 \beta_2 \gamma_0 = 0 \) and so \( \alpha_1 \alpha_2 \gamma_0 = \alpha_3 \alpha_4 \gamma_0 = \alpha_3 \alpha_4 \alpha_5 \alpha_6 \) in \( E \), by (12). Further, by (9), we have

\[ \alpha_3 \alpha_4 \alpha_5 \alpha_6 = \alpha_1 \alpha_2 \alpha_5 \alpha_6 + \lambda(\alpha_1 \alpha_2 \alpha_5 \alpha_6)^m, \]

and then (15) implies that \( \alpha_1 \alpha_2 \alpha_5 \alpha_6 \beta_1 = \alpha_3 \alpha_4 \alpha_5 \alpha_6 \beta_1 = \alpha_3 \alpha_4 \gamma_0 \beta_1 = 0 \), due to (10). Moreover, (13) gives \( \alpha_5 \alpha_6 \alpha_3 \alpha_1 − \alpha_5 \alpha_6 \alpha_1 \alpha_2 = \lambda(\alpha_5 \alpha_6 \alpha_1 \alpha_2)^m \), hence
using (15) again we deduce that $\alpha_1\alpha_2\alpha_5\alpha_6\alpha_1\alpha_2 = \alpha_1\alpha_2\alpha_5\alpha_6\alpha_3\alpha_4$. It follows that $K$-basis of $P_1$ is of the form

$$B_1 = \{(\alpha_1\alpha_2\alpha_5\alpha_6)^r \psi; \quad \psi \in B'_1, 0 \leq r \leq m - 1\} \cup \{(\alpha_1\alpha_2\alpha_5\alpha_6)^m\},$$

where $B'_1 = \{\epsilon_1, \alpha_1, \alpha_1\alpha_2, \alpha_1\alpha_2\alpha_5, \alpha_3\}$. Now, applying (8), (10) and (13)-(15) we may similarly prove that

$$\gamma_0\alpha_2 = \gamma_0\alpha_4 = \alpha_5\alpha_6\alpha_3\alpha_4 = \alpha_5\alpha_6\alpha_1\alpha_2 + \lambda(\alpha_5\alpha_6\alpha_1\alpha_2)^m,$$

and consequently, we get that $P_2$ has basis of the form

$$B_2 = \{(\alpha_2\alpha_5\alpha_6\alpha_1)^r \psi; \quad \psi \in B'_2, 0 \leq r \leq m - 1\} \cup \{(\alpha_2\alpha_5\alpha_6\alpha_1)^m\} \cup \{(\alpha_2\alpha_5\alpha_6\alpha_3)^{r - 2}; \quad 0 \leq r \leq m - 2\},$$

where $B'_2 = \{\epsilon_2, \alpha_2, \alpha_2\alpha_5, \alpha_2\alpha_5\alpha_6\}$. This is also clear from (12) that $P_6$ admits a basis given as follows

$$B_6 = \{(\alpha_4\alpha_5\alpha_6\alpha_3)^r \psi; \quad \psi \in B'_6, 0 \leq r \leq m - 1\} \cup \{(\alpha_4\alpha_5\alpha_6\alpha_3)^m\} \cup \{(\alpha_4\alpha_5\alpha_6\alpha_1)^{r - 2}; \quad 0 \leq r \leq m - 2\},$$

with $B'_6 = \{\epsilon_6, \alpha_4, \alpha_4\alpha_5, \alpha_4\alpha_5\alpha_6\}$. Simple computations involving (9) (or (13)) show that base of $P_4$ may be choosen in the following way

$$B_4 = \{(\alpha_6\alpha_1\alpha_2\alpha_5)^r \psi; \quad \psi \in B'_4, 0 \leq r \leq m - 1\} \cup \{(\alpha_6\alpha_1\alpha_2\alpha_5)^m\},$$

for $B'_4 = \{\epsilon_4, \alpha_6, \alpha_6\alpha_1, \alpha_6\alpha_1\alpha_2, \alpha_6\alpha_3\}$. Finally, using all relations from (14) we immediately obtain that $P_5$ has basis of the form

$$B_5 = \{\epsilon_5, \beta_2, \beta_2\alpha_5, \beta_2\alpha_5\alpha_6, \beta_2\alpha_5\alpha_6\alpha_1\},$$

and the proof is now finished. □
