Maximum Approximate Likelihood Estimation in
Accelerated Failure Time Model for
Interval-Censored Data

November 19, 2019

Abstract

The approximate Bernstein polynomial model, a mixture of beta distributions,
is applied to obtain maximum likelihood estimates of the regression coefficients,
and the baseline density and survival functions in an accelerated failure time
model based on interval censored data including current status data. The rate
of convergence of the proposed estimates are given under some conditions for
uncensored and interval censored data. Simulation shows that the proposed
method is better than its competitors. The proposed method is illustrated by
fitting the Breast Cosmetic Data using the accelerated failure time model.

Key Words and Phrases: Accelerated Failure Time Model; Approximate
Likelihood; Beta mixture model; Current Status Data; Interval Censoring;
Smooth Estimation; Survival Curve.

1 Introduction

When a model in statistics involves some infinite-dimensional parameters such
as a totally unspecified underlying distribution, it should rather be called a
probability model or a non- or semi-parametric statistical problem to be not
confused with a working statistical model which is used to solve the problem.
Because the sample size is always finite a working model must have a finite dimensionality which can be unknown. The traditional parametric models are of known dimensions while many mixture models are of unknown dimensions.

Due to the lack of an appropriate approximate model for the unspecified underlying baseline distribution, it is much more difficult to estimate the AFT model than PH and PO models using maximum likelihood method based on interval censored data. Traditionally we use step-function to approximate an unknown smooth distribution function so that we have a finite-dimensional working model which is (discrete) multinomial model and results in empirical distribution, Kaplan-Meier estimator ([Kaplan & Meier, 1958], Turnbull estimator [Turnbull, 1976], and empirical likelihood method [Owen, 1988], and so on. This works because the step-functions are dense in the space of certain continuous functions. Despite the roughness of resulting maximum likelihood estimate, this approximate model works quite well for many complicated statistical problems including the analysis of incompletely observed data such as data containing censored, grouped, truncated, and even missing values. An important example is the analysis of interval-censored event time data using PH (Cox, 1972) and PO (Pettitt, 1982; Bennett, 1983) models although the semiparametric maximum likelihood estimate is not necessarily unique. However, if data are interval-censored it is impossible to find a semiparametric maximum likelihood estimate of the baseline distribution using this approach for AFT model ([Kalbfleisch & Prentice, 1980]), an important alternative to the PH and PO models. To the knowledge of the author, most inference procedures so far for AFT model with unspecified baseline distribution focus on the estimation of the regression coefficients (Tian & Cai, 2000) and the right-censored (Buckley & James, 1979; Tsiatis, 1990; Wei et al., 1990; Jin et al., 2003) or the current status data in biostatistics (Huang & Wellner, 1997) or the binary choice model in econometrics (Cosslett, 1983, 1987, 2004; Klein & Spady, 1993).

A few most relevant works to this paper include [Hanson & Johnson, 2004], [Komárek et al., 2005], and [Zhang & Davidian, 2008]. The first proposed a Bayesian semiparametric AFT model for estimating survival and density functions, the second used B-splines with penalties to smooth the error density with some candidate parametric models, and the latter proposed smooth estimates of survival function for PH, PO and AFT models using the so-called seminonparametric (SNP) density ([Gallant & Nychka, 1987]) which is a truncated Hermite series approximation of a density function. However Bernstein polynomials seem much better dense functions than step-functions and others for the purpose of building working statistical models ([Guan, 2017]). This Bernstein polynomial approximation is actually a mixture of some specified beta distributions with shapes related to the degree. This model has been successfully applied to grouped, contaminated, multivariate, and interval censored data ([Guan, 2017, 2019a,b], [Wang & Guan, 2019]). This model shall be applied to find maximum likelihood estimates of the regression coefficients, and the density and survival functions in the AFT model.
2 Methodology

Let $T$ be an event time and $X$ be an associated $d$-dimensional covariate with distribution $H(x)$ on $\mathcal{X}$. Let $f(t \mid x)$ and $S(t \mid x)$ be, respectively, the density and survival functions of failure time $T$ given $X = x$. The AFT model can be specified as

$$f(t \mid x) = f(t \mid x; \gamma) = e^{-\gamma^T x} f(t e^{-\gamma^T x} \mid 0), \quad t \in [0, \infty),$$

where $\gamma \in \mathbb{R}^d$. Let $\gamma_0 \in \mathbb{R}$ be the true value of $\gamma$. The AFT model (1) is equivalent to

$$S(t \mid x; \gamma) = S(te^{-\gamma^T x} \mid 0), \quad t \in [0, \infty).$$

Thus this is actually a scale regression model. The AFT model can also be written as linear regression $\log(T) = \gamma^T x + \varepsilon$. It is clear that one can choose any $x_0$ in $\mathcal{X}$ as baseline by transform $\bar{x} = x - x_0$. If $f(t \mid 0)$ has support $[0, \tau_0)$, $\tau_0 \leq \infty$, then $f(t \mid x)$ has support $[0, \tau_0 e^{\gamma^T x})$. We define $\tau = \max\{\tau_0 e^{\gamma^T x} : x \in \mathcal{X}\}$ if $\tau_0 < \infty$ and $\tau = \infty$ otherwise. The above AFT model can also be written as

$$f(t \mid x; \gamma) = e^{-\gamma^T x f_0(te^{-\gamma^T x})}, \quad S(t \mid x; \gamma) = S_0(te^{-\gamma^T x}),$$

where $f_0(t) = f(t \mid 0)$ and $S_0(t) = S(t \mid 0) = \int_0^t f_0(u)du$. Clearly, the above model is also true for the transformed failure time $T^* = aT$ for any $a > 0$.

With interval censoring, the observable random variables are $Z = (\Delta, X, Y)$, where $Y = (Y_1, Y_2)$ and $\Delta$ is the censoring indicator, i.e., uncensored $T = Y = Y_1 = Y_2$ if $\Delta = 0$, and interval censored $T \in Y = (Y_1, Y_2), 0 \leq Y_1 < Y_2 \leq \infty$, if $\Delta = 1$. For Case 1 interval censored data, i.e., the current status or doubly censored data, $Y = (0, U]$ or $Y = (U, \infty)$. In this case the distribution function of the examination time $U$ given $X = x$ is denoted by $G(u \mid x)$. As in Huang & Wellner (1997) we reduce the cases with more than two examination times to the case with two examination times, i.e., the Case 2 interval censored data, and denote the joint distribution function of the observed examination times $U = (U_1, U_2)$ given $X = x$ by $G(u \mid x)$.

For an observation $z = (\delta, x, y = (y_1, y_2))$, the exact full loglikelihood, up to an additive term independent of $(\gamma, f_0)$, is

$$\ell(\gamma, f_0; z) = (1 - \delta) \log f(y \mid x; \gamma) + \delta \log \{S(y_1 \mid x; \gamma) - S(y_2 \mid x; \gamma)\}$$

$$= (1 - \delta)(-\gamma^T x + \log f_0(y e^{-\gamma^T x})) + \delta \log \{S_0(y_1 e^{-\gamma^T x}) - S_0(y_2 e^{-\gamma^T x})\}.$$  \(2\)

Let $z_i = (\delta_i, x_i, y_i = (y_{i1}, y_{i2})), i = 1, \ldots, n$, be independent observations of $Z$. The loglikelihood of the data is $\ell(\gamma, f_0) = \sum_{i=1}^n \ell(\gamma, f_0; z_i)$. The Hessian matrix is $H_n(\gamma, f_0) = \partial^2 \ell(\gamma, f_0)/\partial \gamma \partial \gamma^T = \sum_{i=1}^n \partial^2 \ell(\gamma, f_0; z_i)/\partial \gamma \partial \gamma^T.$
The exact full likelihood $\ell(\gamma, f_0)$ cannot be maximized unless $f_0$ and $S_0$ are specified. Because $y$ and $x$ cannot be separated, step-function approximation does not work and it is also impossible to obtain a partial likelihood as that of Cox (1972).

In the case where $\tau_0 = \infty$ or $\tau_0$ unknown we choose $\tau_n > y_{(n)} = \max\{y_{i1}, y_{j2} : y_{j2} < \infty; i, j = 1, \ldots, n\}$ so that $S(\tau_n)$ and $\max_{x \in X} S(\tau_n \mid x)$ are believed very small. Then we approximate $f_0(t)$ and $S_0(t)$ on $[0, \tau_n]$, respectively, by

$$
f_0(t) \approx f_m(t; p) = \frac{1}{\tau_n} \sum_{j=0}^{m} p_j \beta_{mj} \left( \frac{t}{\tau_n} \right), \quad t \in [0, \tau_n];
$$

$$
S_0(t) \approx S_m(t; p) = \sum_{j=0}^{m} p_j \tilde{B}_{mj} \left( \frac{t}{\tau_n} \right), \quad t \in [0, \tau_n],
$$

where $\beta_{mj}(t) = (m+1)(n)^j (1-t)^{m-j}$, $\tilde{B}_{mj}(t) = 1 - \int_{0}^{t} \beta_{mj}(u) du$, $j = 0, \ldots, m$, $S_m(\infty; p) = 0$, and $p = (p_0, \ldots, p_m)^T$ satisfies constraint

$$
p \in S_m \equiv \left\{ u = (u_0, \ldots, u_m)^T : u_j \geq 0, \; j = 0, \ldots, m, \; \sum_{j=0}^{m} u_j = 1 \right\}. \quad (3)
$$

Then $f(t \mid x; \gamma)$ and $S(t \mid x; \gamma)$ can be approximated, respectively, by

$$
f_m(t \mid x; \gamma, p) = e^{-\gamma^T x} f_m \left( te^{-\gamma^T x}; p \right)
$$

$$
= \frac{e^{-\gamma^T x}}{\tau_n} \sum_{j=0}^{m} p_j \beta_{mj} \left( e^{-\gamma^T x} \frac{t}{\tau_n} \right), \quad t \in [0, \tau_n e^{-\gamma^T x}]; \quad (4)
$$

$$
S_m(t \mid x; \gamma, p) = S_m \left( te^{-\gamma^T x}; p \right)
$$

$$
= \sum_{j=0}^{m} p_j \tilde{B}_{mj} \left( e^{-\gamma^T x} \frac{t}{\tau_n} \right), \quad t \in [0, \tau_n e^{-\gamma^T x}]. \quad (5)
$$

The likelihood $\ell(\gamma, f_0)$ can be approximated by $\ell_m(\gamma, p) = \sum_{i=1}^{n} \ell_m(\gamma, p; z_i)$, where

$$
\ell_m(\gamma, p; z) = (1 - \delta) \left\{ -\gamma^T x + \log \sum_{j=0}^{m} p_j \beta_{mj}(y e^{-\gamma^T x} / \tau_n) - \log \tau_n \right\}
$$

$$
+ \delta \log \{ S_m(y_1 \mid x; \gamma, p) - S_m(y_2 \mid x; \gamma, p) \}. \quad (6)
$$

If $\tau_0$ is known, we choose $\tau_n = \tau_0$. If data are right-censored then $y_{j2} = \tau_n$. If $\tau_n \neq 1$ we divide all the observed times by $\tau_n$. Thus we assume in the rest of this section that $\tau_n = 1$.

For a given degree $m$, let $(\hat{\gamma}, \hat{p})$ be a maximizer of $\ell_m(\gamma, p)$. The change-point method (Guo, 2016) applies for finding an optimal degree $m$. For
Theorem 1. For any fixed $\gamma$, $y_i = \hat{m}$, $\ell_i = \ell_m(\gamma, \hat{p})$, where $m_i = m_0 + i$. The optimal degree is $\hat{m} = \min \{ \frac{\log \ell_i - \ell_0}{i} \}_{i=1}^k \{ R(m_i) \}$, where $R(m_i) = k \log \left( \frac{\ell_i - \ell_0}{i} \right) - i \log \left( \frac{\ell_k - \ell_0}{k} \right) - (k - i) \log \left( \frac{\ell_k - \ell_i}{k - i} \right)$, $i = 1, \ldots, k - 1$ and $R(m_k) = 0$. With an optimal degree $m = \hat{m}$, $\theta = (\gamma, \hat{p})$ is called a maximum approximate Bernstein likelihood estimator (MABLE) of $\theta = (\gamma, p)$. The resulting MABLEs of $f(t \mid x)$ and $S(t \mid x)$ are, respectively, $f_\theta(t \mid x) = f_m(t \mid x; \gamma, \hat{p})$ and $S_B(t \mid x) = S_m(t \mid x; \gamma, \hat{p})$. The variance-covariance matrix of $\hat{\gamma}$ can be estimated by $\hat{\Sigma}_\gamma = -n \{ H_m(\hat{\gamma}; f_m(\cdot; \hat{p})) \}^{-1}$.

The derivatives of $\ell_m(\gamma, p; z)$ with respect to $p$ are

$$
\frac{\partial \ell_m(\gamma, p; z)}{\partial p} = (1 - \delta) \beta_m(y e^{-\gamma^T x}) - \sum_{j=0}^m p_j \beta_m(y e^{-\gamma^T x}) \left\{ B_m(y_1 e^{-\gamma^T x}) - B_m(y_2 e^{-\gamma^T x}) \right\} \frac{1}{S_m(y_1 \mid x; \gamma, p) - S_m(y_2 \mid x; \gamma, p)},
$$

$$
\frac{\partial^2 \ell_m(\gamma, p; z)}{\partial p \partial p^T} = -\left\{ (1 - \delta) \beta_m(y e^{-\gamma^T x}) \right\} \left( \sum_{j=0}^m p_j \beta_m(y e^{-\gamma^T x}) \right) \left\{ B_m(y_1 e^{-\gamma^T x}) - B_m(y_2 e^{-\gamma^T x}) \right\} \frac{1}{S_m(y_1 \mid x; \gamma, p) - S_m(y_2 \mid x; \gamma, p)}^{\otimes 2},
$$

where $v^{\otimes 2} = vv^T$ for a column vector $v$, $\beta_m(u) = \{ \beta_{m0}(u), \ldots, \beta_{mm}(u) \}^T$ and $B_m(u) = \{ B_{m0}(u), \ldots, B_{mm}(u) \}^T$. Denote

$$
\Psi_j(\gamma, p) = \frac{1}{n} \sum_{i=1}^n \frac{\partial \ell_m(\gamma, p; z_i)}{\partial p_j}, \quad j = 0, \ldots, m.
$$

Theorem 1. For any fixed $\gamma$ suppose $y_{i2} e^{-\gamma^T x_i} \leq 1$ for all observed $(x_i, (y_{i1}, y_{i2}))$ with $y_{i2} < \infty$. Then $\hat{p}(\gamma)$ is a maximizer of $\ell_m(\gamma, p)$ if and only if

$$
\Psi_j(\gamma, \hat{p}(\gamma)) \leq 1, \quad j = 0, \ldots, m
$$

for all $j = 0, \ldots, m$ with equality if $\hat{p}_j > 0$.

It is clear that under certain conditions $\frac{\partial^2 \ell_m(\gamma, p)}{\partial p \partial p^T}$ is a negative and negative definite matrix. We have fixed-point iteration

$$
p_j^{[s+1]} = p_j^{[s]} \Psi_j(\gamma, p^{[s]}), \quad j = 0, \ldots, m, \quad s = 0, 1, 2, \ldots, \infty.
$$

If $y_{i2} e^{-\gamma^T x_i} \leq 1$ for all observed $(x_i, (y_{i1}, y_{i2}))$ with $y_{i2} < \infty$ then $\Psi_j(\gamma, p) \geq 0$ for all $j = 0, \ldots, m$ and $p \in S_m$. Similar to the proof of Theorem 4 of Peters, Jr. & Walker [1978] we can prove the convergence of $p^{[s]}$.

Theorem 2. For any fixed $\gamma$ suppose $y_{i2} e^{-\gamma^T x_i} \leq 1$ for all observed $(x_i, (y_{i1}, y_{i2}))$ with $y_{i2} < \infty$. If $p^{[0]}$ is in the interior of $S_m$, the sequence $\{ p^{[s]} \}$ of $[12]$ converges to the maximum approximate profile likelihood estimate (MAPLE) $\hat{p}(\gamma)$. 5
Algorithm for Finding \((\hat{\gamma}, \hat{p})\) for a fixed \(m\): Let \(\hat{\gamma}\) be an estimate of \(\gamma\) such as those proposed by Jin et al. (2003) and Tian & Cai (2006).

Step 0: Start with an initial guess \(\gamma^{(0)} = \hat{\gamma}\) of \(\gamma\). Use (11) with \(\gamma = \gamma^{(0)}\) and the uniform initial \(p^{[0]} = u_m \equiv (1, \ldots, 1)/(m+1)\) to get \(p^{(0)} = \hat{p}(\gamma)\). Set \(s = 0\).

Step 1: Obtain \(\gamma^{(s+1)}\) with fixed \(p = p^{(s)}\) using the Newton-Raphson method starting with \(\gamma^{[0]} = \gamma^{(s)}\).

Step 2: Choose \(\gamma = \gamma^{(s+1)}\). Then use (11) with \(p^{[0]} = u_m\) to get \(p^{(s+1)} = \hat{p}(\gamma)\). Set \(s = s + 1\).

Step 3: Repeat Steps 1 and 2 until convergence. The final \(\gamma^{(s)}\) and \(p^{(s)}\) are taken as \((\hat{\gamma}, \hat{p})\).

If \(\ell_m(\gamma, p)\) is concave as a function of \(\gamma\) then the above algorithm is a point-to-point map and the solution set contains single point. Convergence of \((\gamma^{(s)}, p^{(s)})\) to \((\hat{\gamma}, \hat{p})\) is guaranteed by the Global Convergence Theorem (Zangwill, 1969). Proposition 3 in Section 5 suggests that if \(n\) is large and \(f_m\) is close to \(f_0\) then \(\ell_m(\gamma, p)\) is concave with respect to \(\gamma\) in a neighborhood of \(\gamma_0\).

3 Simulation

We compare the proposed method only with the parametric method for general interval censored data and semiparametric competitors whose implementation in R are available such as the rank and the least squares method for right-censored data. In all simulation studies, samples of sizes \(n = 30, 50, 100\) were generated from Weibull distributions with baseline \((x = 0)\) shape 2 and scale 2 according to the AFT model with covariates, \(X = (X_1, X_2)\), where \(X_1\) and \(X_2\) are independent, \(X_1\) is uniform\((-1, 1)\) and \(X_2 = \pm 1\) is uniform, with coefficients \(\gamma^T = (\gamma_1, \gamma_2) = (0.5, -0.5)\). The optimal degrees were chosen from \(\{3, \ldots, 25\}\) with \(\tau_n = 12\). Function ic_par() of R package icenReg (Anderson-Bergman, 2017) was used to obtain parametric maximum likelihood estimates.

In the first simulation study, the proposed method is compared with the parametric method based on Case \(k\) data, where for uncensored censored data \(k = 0\), for current status data \(k = 1\), and interval censored data with \(k\) examinations. For current status data, the examination time \(U\) is uniform\((0, 3.66)\) so that \(P(U > T) = 50\%\). The general interval censored data with \(k\) examinations were generated using the function simIC_weib() of icenReg with default arguments when \(k = 2\), and with inspections = 5, inspectLength = 1 when \(k = 5\). The censoring probability is 70\% for the interval censored data with two or more examinations. Each sample was used to estimate \(\gamma, f(\cdot | 0)\) and
Table 1: Simulated root mean (integrated) squared errors of estimates of the regression coefficients (the baseline density and survival functions at \( \mathbf{x} = \mathbf{0} \)) using the proposed estimators and the parametric maximum likelihood estimators (in parentheses) based on Case \( k \) interval censored data

| \( k \) | \( n \) | \( \gamma_1 \) | \( \gamma_2 \) | \( f(\cdot | \mathbf{0}) \) | \( S(\cdot | \mathbf{0}) \) |

4 Breast Cosmesis Data

This dataset as described in Finkelstein & Wolfe (1985) and Finkelstein (1986) is used to study the cosmetic effects of cancer therapy. The time-to-breast-retractions in months ($T$) were subject to interval censoring and were measured for 94 women among them 46 received radiation only ($X = 0$) (25 right-censored, 3 left-censored and 18 interval censored) and 48 received radiation plus chemotherapy ($X = 1$) (13 right-censored, 2 left-censored and 33 interval censored). The right-censored event times were for those women who did not experienced cosmetic deterioration. The therapy effect on the event time was assessed by many authors. For example, Hanson & Johnson (2004) fitted the data by a Bayesian AFT model using the mixture of Dirichlet processes (Antoniak 1974) to approximate the baseline survival function and obtained an estimated effect 0.57; Tian & Cai (2006) fitted the data by the AFT model using a Markov chain Monte Carlo based resampling method and obtained an estimated effect 0.52 with standard error 0.16; and Zhang & Davidian (2008) used a so-called “seminonparametric density” estimator of Gallant & Nychka (1987) and obtained estimated effect 0.95 with standard error 0.280.

The estimated survival curves are shown in Figure 1 where $\hat{S}_E$ and $\hat{S}_B$ represent, respectively, the NPMLE and the MABLE of $S$ based on each of the two samples, and $\hat{S}_B(\cdot | x)$ represents the proposed estimate based on the combined sample using AFT model or the estimate of Guan (2019b) using PH model. From this figure it can be seen that, although the two models give similar estimates for radiation and chemotherapy and for radiation only up to about 45 months, the AFT model fit the data better for months 45 through 60. It is reasonable to believe that the survival probability at month 60 is significantly larger than 0 due to nature and the high percentage of right-censored observations. The AFT model gives an estimated effect 0.572 with standard error 0.123. This is almost the same as the posterior median obtained by Hanson & Johnson (2004) and close to those in Tian & Cai (2006) but quite different from...
5 Asymptotic Results

The following assumptions are needed.

(A.1). The support $\mathcal{X}$ of covariate $X$ is compact and $\mathbb{E}(XX^\top)$ is positive definite.

(A.2). For each $\tau_n > 0$, there exist $\rho > 0$ and $p_0 = (p_{01}, \ldots, p_{0m})^T$ such that $p_{0i} \geq 0$ ($i = 0, \ldots, m$), $\sum_{i=0}^mp_{0i} = \pi(x_0)$ and, uniformly in $t \in [0, \tau_n]$,

$$\frac{f_m(t; p_0) - f_0(t)}{f_0(t)} = O(m^{-\rho/2}).$$

The positive definiteness of $\mathbb{E}(XX^\top)$ is equivalent to $\Pr(c^T X = 0) < 1$ for all nonzero $c \in \mathbb{R}^d$. If the right-hand-side of (12) is zero for some $m = m_0$, i.e., $f_m(t; p_0) = f_0(t)$ for all $t \in [0, \tau_n]$, then (A.2) is true for all $m \geq m_0$ with a zero right-hand-side of (12) (see Lemma 2.2 of Guan, 2017).
Proposition 3. Suppose that $\gamma = \gamma_0$, $f_0$ has continuous second derivative on $[0, \tau_0)$ and $E(T^2 \mid X = 0) < \infty$ if $\tau_0 = \infty$, $\tau_0^2 f_0(\tau_0) + \tau_0 f_0(\tau_0) \leq 0$ if $\tau_0 < \infty$. Then, as $n \to \infty$, $n^{-1} H_n(\gamma, f_0)$ converges almost surely to $H(\gamma, f_0)$ which is negative semi-definite. Moreover, under Assumption (A.1) if $\lim_{n \to \infty} n_0/n < 1$ or $\lim_{n \to \infty} n_0/n = 1$ but $\Pr\{f_0(T) = c_0/T \mid X = 0\} < 1$ for all $c_0 > 0$, then $H(\gamma, f_0)$ is negative definite.

Remark 1. Under the conditions of Proposition 3, for $n$ large enough $H_n(\gamma, f_0)$ is almost surely negative definite in a neighborhood of $\gamma_0$.

Remark 2. The condition $\tau_0^2 f_0(\tau_0) + \tau_0 f_0(\tau_0) \leq 0$ is fulfilled if given $X = 0$ the time $T$ has a truncated Weibull distribution with shape $\sigma$ and scale $\kappa$ on $[0, \tau_0]$, $W_{\tau_0}(\sigma, \kappa)$, and $\tau_0 \geq \kappa$.

We shall study the large sample property of the proposed estimation under the following conditions regarding to uncensored, Case 1, and Case 2 interval censored data.

Condition 0. The event time $T$ is uncensored, $\tau_n \leq \tau < \infty$, $S_0(\tau_n) = \mathcal{O}(n^{-1})$, and $|f_0(\theta_t)/f_0(t) - 1| \leq C_0 |1 - \theta|$ for all $t \in [0, \tau_n]$, $\theta > 0$ and some constant $C_0$ independent of $x_0 \in X$.

Condition 1. The event time $T$ is subject to Case 1 interval censoring, and given $X = x$ the examination time $U$ has cdf $G(\cdot | x)$ on $[\tau_1, \tau_u]$, $0 < \tau_1 < \tau_u < \tau_n \leq \tau \leq \infty$.

Condition 2. The event time $T$ is subject to Case 2 interval censoring, given $X = x$ the observed examination times $U = (U_1, U_2)$ have joint cdf $G(\cdot | x)$ on $\{(u_1, u_2) \in \mathbb{R}^2: 0 < \tau_1 \leq u_1 < u_2 \leq \tau_u\}$, and $\tau_u < \tau_n \leq \tau \leq \infty$.

Under (A.1) Condition 0 is satisfied if given $X = 0$ the time $T$ has a truncated Weibull distribution $W_{\tau_0}(\sigma, \kappa)$ on $[0, \tau_0]$. In the following we assume that $\Pr(Y_{\gamma_0} e^{-\gamma_0 x} \leq \tau) = 1$. We define distance $D_i^2(\gamma, p)$ under Condition $i$, $i = 0, 1, 2$, in the following.

$$D_0^2(\gamma, p) = (\gamma - \gamma_0)^T E(XX^t)(\gamma - \gamma_0) + \lambda_0^2(\gamma, p),$$

$$D_1^2(\gamma, p) = E\left\{ \frac{\{S_m(Ue^{-\gamma x}; p) - S_0(Ue^{-\gamma x})\}^2}{S_0(Ue^{-\gamma x}) \{1 - S_0(Ue^{-\gamma x})\}} \right\},$$

$$D_2^2(\gamma, p) = E\left\{ \frac{W(U, X; \theta)^t A(U, X) W(U, X; \theta)}{S_0(U_1 e^{-\gamma_0 x}) - S_0(U_2 e^{-\gamma_0 x})} \right\},$$

where

$$\lambda_0^2(\gamma, p) = \int_{X} \int_{0}^{\tau_0} \left\{ \frac{f_m(t e^{-\gamma x}; p)}{f_0(t)} - 1 \right\}^2 f_0(t) dtdH(x),$$

$$W(u, x; \theta) = \left\{ S_m\left( \frac{u_1}{e^{\gamma x}}; p \right) - S_0\left( \frac{u_1}{e^{\gamma x}} \right), S_m\left( \frac{u_2}{e^{\gamma x}}; p \right) - S_0\left( \frac{u_2}{e^{\gamma x}} \right) \right\}^T,$$
and \( \mathbf{A}(u, x) = \{ A_{ij}(u, x) \} \) is a symmetric matrix with entries
\[
A_{11}(u, x) = \left\{ \frac{1 - S_0(u_2 e^{-\gamma_0 x})}{1 - S_0(u_1 e^{-\gamma_0 x})} \right\}, \quad A_{12}(u, x) = -1, \quad A_{22}(u, x) = \frac{S_0(u_1 e^{-\gamma_0 x})}{S_0(u_2 e^{-\gamma_0 x})}.
\]

We have the following results about the rate of convergence in terms of the above distances.

**Theorem 4.** Let \( n_k \) be the number of observations that are subject to Case \( k \) censoring and \( \rho_k = \lim_{n \to \infty} n_k/n \), \( k = 0, 1, 2 \). Under Assumptions (A.1) and (A.2) if Conditions 0, 1, and 2 are fulfilled and \( m = Cn^{1/\rho} \) for some constant \( C \) then, for any \( \alpha > 1 \),
\[
\sum_{k=0}^{2} \rho_k D_k^2(\hat{\gamma}, \hat{p}) = O\left\{ (\log \log n)\alpha/n \right\}, \text{ almost surely.}
\]

**Theorem 5.** Under the conditions of Theorem 4, if \( n_0 = n \), then \( \chi_0^2(\gamma_0, \hat{p}) = O\left\{ (\log \log n)^{\alpha}n^{-1+4/\rho} \right\} \) and \( \| \hat{\gamma} - \gamma \|^2 = O\left\{ (\log \log n)^{\alpha}/n \right\} \), almost surely, for any \( \alpha > 1 \); if \( n_0 = 0 \), and \( \hat{\gamma} \) is an estimate such that \( \| \hat{\gamma} - \gamma_0 \|^2 = O(n^{-1+\epsilon}) \) for some \( \epsilon > 0 \), then the MAPLE \( \hat{p}(\hat{\gamma}) \) satisfies
\[
\sum_{k=1}^{2} \rho_k D_k^2(\gamma_0, \hat{p}) = O(n^{-1+\epsilon+2/\rho})
\]
whenever \( \epsilon' > \epsilon \).

**Remark 3.** From this theorem it follows that if \( \rho \) is large then the convergence rate of \( \sum_{k=1}^{2} \rho_k D_k^2(\gamma_0, \hat{p}) \) can be very close to \( O(n^{-1}) \) when \( \hat{\gamma} \) is asymptotically normal.

### 6 Concluding Remarks

The proposed approximate likelihood method is even better than some parametric methods based on models with known and fixed dimension due to the lack of robustness of such when sample size is small which is often the case in survival analysis of rare disease and reliability analysis for expensive product. Thus approximated models with unknown dimension enjoy the properties of efficiency and nonparametric robustness.

7 Appendix

7.1 Proof of Theorem 1

Proof. If \( y_2 e^{-\gamma^T x} \leq 1 \), then the negative-definiteness of \( \partial^2 \ell_m(\gamma; \mathbf{p}, z) / \partial \mathbf{p} \partial \mathbf{p}^T \) implies that \( \ell_m(\gamma; \mathbf{p}) \) is strictly concave on the compact and convex set \( \mathcal{S}_m \), for the fixed \( \gamma \). By the optimality condition for convex optimization (\() \) we have that \( \hat{\mathbf{p}} \) is the unique maximizer of \( \ell_m(\gamma; \mathbf{p}) \) if and only if

\[
\nabla \ell_m(\gamma; \hat{\mathbf{p}})^T (\mathbf{p} - \hat{\mathbf{p}}) \leq 0, \quad \text{for all } \mathbf{p} \in \mathcal{S}_m, \tag{16}
\]

where \( \nabla \ell_m(\gamma; \mathbf{p}) = \partial \ell_m(\gamma; \mathbf{p}) / \partial \mathbf{p} \). Therefore \( \hat{\mathbf{p}} \) is a maximizer of \( \ell_m(\gamma; \mathbf{p}) \) for the fixed \( \gamma \) if and only if

\[
\Psi_j(\gamma, \hat{\mathbf{p}}) \leq n^{-1} \nabla \ell_m(\gamma, \hat{\mathbf{p}})^T \hat{\mathbf{p}} = 1, \tag{17}
\]

for all \( j \in \mathbb{Z}_n^m \) with equality if \( \hat{p}_j > 0 \). The proof is complete. \( \square \)

7.2 Proof of Theorem 2

Proof. Following the proof of Theorems 1 and 2 and the Corollary of Peters, Jr. & Walker (1978) we define \( \Pi = \text{diag}(\mathbf{p}) \) and \( \Psi(p, \gamma) = \Pi \Psi(p, \gamma) \), where \( \Psi(p, \gamma) = [\Psi_1(p, \gamma), \ldots, \Psi_m(p, \gamma)]^T \). Then \( \Psi(p, \gamma) = n^{-1} \Pi \nabla \ell_m(\gamma; \mathbf{p}) \). Its gradient is

\[
\nabla \Psi(p, \gamma) = \frac{\partial \Psi(p, \gamma)}{\partial \mathbf{p}} = \frac{1}{n} \text{diag}\{\nabla \ell_m(\gamma, \mathbf{p})\} + \frac{1}{n} \Pi \frac{\partial \nabla \ell_m(\gamma, \mathbf{p})}{\partial \mathbf{p}},
\]

\[
= \frac{1}{n} \text{diag}\left\{ \frac{\partial \ell_m(\gamma, \mathbf{p})}{\partial \mathbf{p}} \right\} + \frac{1}{n} \Pi \frac{\partial^2 \ell_m(\gamma, \mathbf{p})}{\partial \mathbf{p} \partial \mathbf{p}^T}.
\]

For any norm on \( \mathbb{R}^{m+1} \) we have \( \Psi(p, \gamma) - \hat{\mathbf{p}} = \nabla \Psi(\hat{\mathbf{p}}, \gamma)(\mathbf{p} - \hat{\mathbf{p}}) + \mathcal{O}(\|\mathbf{p} - \hat{\mathbf{p}}\|^2) \). Consider \( \nabla \Psi(\hat{\mathbf{p}}, \gamma) \) as an operator on subspace \( \mathcal{Z}_m = \{z \in \mathbb{R}^{m+1} : 1^T z = 0\} \). If all components of \( \hat{\mathbf{p}} \) are positive then \( n^{-1} \nabla \ell_m(\gamma, \hat{\mathbf{p}}) = 1 \), and \( \nabla \Psi(\hat{\mathbf{p}}, \gamma) = I_{m+1} - \mathbf{Q} \), where \( \mathbf{Q} = -n^{-1} \Pi \partial^2 \ell_m(\gamma, \hat{\mathbf{p}}) / \partial \mathbf{p} \partial \mathbf{p}^T \). From (7) and (8) it follows that \( \mathbf{Q} \) is a left stochastic matrix and \( \hat{\mathbf{p}}^T \partial^2 \ell_m(\gamma, \hat{\mathbf{p}}) / \partial \mathbf{p} \partial \mathbf{p}^T = -n^{-1} \partial \ell_m(\gamma, \hat{\mathbf{p}}) / \partial \mathbf{p}^T = -1^T \). So \( \mathcal{Z}_m \) is invariant under \( \mathbf{Q} \).

Define an inner product \( \langle \cdot, \cdot \rangle \) by \( \langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{u}^T \Pi^{-1} \mathbf{v} \) for \( \mathbf{u}, \mathbf{v} \) in \( \mathcal{Z}_m \). It can be easily shown that, with respect to this inner product, \( \mathbf{Q} \) is symmetric and positive semidefinite on \( \mathcal{Z}_m \):

\[
\langle \mathbf{u}, \mathbf{Q} \mathbf{v} \rangle = \mathbf{u}^T \Pi^{-1} \mathbf{Q} \mathbf{v} = -\frac{1}{n} \mathbf{u}^T \frac{\partial^2 \ell_m(\gamma, \hat{\mathbf{p}})}{\partial \mathbf{p} \partial \mathbf{p}^T} \mathbf{v},
\]

14
\[ \langle Q u, v \rangle = u^T Q^T \Pi^{-1} v = -\frac{1}{n} u^T \frac{\partial^2 \ell_m(\gamma, \tilde{p})}{\partial \mathbf{p} \partial \mathbf{p}^T} v, \]

\[ \langle u, Q u \rangle = -\frac{1}{n} u^T \frac{\partial^2 \ell_m(\gamma, \tilde{p})}{\partial \mathbf{p} \partial \mathbf{p}^T} u \geq 0. \]

Let \( \lambda_0 \) and \( \lambda_m \) be the smallest and largest eigenvalues of \( Q \) associated with eigenvectors in \( \mathbb{Z}_m \). Then the operator norm of \( \nabla_p \Psi(\mathbf{p}, \gamma) \) on \( \mathbb{Z}_m \) w.r.t. this inner product equals \( \max\{|1 - \lambda_0|, |1 - \lambda_m|\} \). It is clear that \( 0 \leq \lambda_0 \leq \lambda_m \leq 1 \) because \( Q \) is a left stochastic matrix. Because \( \frac{\partial^2 \ell_m(\gamma, \tilde{p})}{\partial \mathbf{p} \partial \mathbf{p}^T} < 0 \) we have \( \lambda_0 > 0 \). Similar to the proof of Theorem 2 of Peters, Jr. & Walker (1978) the assertion of theorem follows. If \( \mathbf{p} \) contains zero component(s), say \( p_j = 0 \), \( j \in J_0 \), deleting the \( j \)-th row and \( j \)-th column of the vectors and matrices in the above proof for all \( j \in J_0 \) we can show that the iterates \( \tilde{p}_j^{(s)} \), \( s \in \mathbb{N}_0 \), converge to \( \tilde{p}_j \) as \( s \to \infty \) for all \( j \not\in J_0 \). Because \( \sum_{j=0}^m p_j^{(s)} = 1 \) and \( p_j^{(s)} \geq 0 \), \( j \in \mathbb{N}_0 \), for those \( j \in J_0 \), \( p_j^{(s)} \) converges to zero as \( s \to \infty \). The proof of Theorem 2 is complete.

### 7.3 Proof of Proposition 3

**Proof.** The derivatives of \( \ell(\gamma, f_0; z) \) w.r.t. \( \gamma \) are

\[
\frac{\partial \ell(\gamma, f_0; z)}{\partial \gamma} = -(1 - \delta) \left\{ 1 + \frac{ye^{-\gamma^T z} f_0(ye^{-\gamma^T z})}{f_0(ye^{-\gamma^T z})} \right\} x \\
+ \delta e^{-\gamma^T x} y_1 f_0(y_1 e^{-\gamma^T x}) - y_2 f_0(y_2 e^{-\gamma^T x}) \\
S_0(y_1 e^{-\gamma^T x}) - S_0(y_2 e^{-\gamma^T x}) \right\} x, \tag{18}
\]

\[
\frac{\partial^2 \ell(\gamma, f_0; z)}{\partial \gamma \partial \gamma^T} = (1 - \delta) \left\{ \frac{ye^{-\gamma^T x} f_0(ye^{-\gamma^T x})}{f_0(ye^{-\gamma^T x})} \\
+ \frac{y^2 e^{-2\gamma^T x} [f_0(ye^{-\gamma^T x}) f_0'(ye^{-\gamma^T x}) - \{f_0'(ye^{-\gamma^T x})\}]^2}{f_0^2(ye^{-\gamma^T x})} \right\} x x^T \\
- \delta e^{-\gamma^T x} \left[ \frac{y_1 f_0(y_1 e^{-\gamma^T x}) - y_2 f_0(y_2 e^{-\gamma^T x})}{S_0(y_1 e^{-\gamma^T x}) - S_0(y_2 e^{-\gamma^T x})} \right. \\
+ e^{-\gamma^T x} \left\{ \frac{y_1 f_0(y_1 e^{-\gamma^T x}) - y_2 f_0(y_2 e^{-\gamma^T x})}{S_0(y_1 e^{-\gamma^T x}) - S_0(y_2 e^{-\gamma^T x})} \right\} \\
+ e^{-\gamma^T x} \frac{y_1^2 f_0(y_1 e^{-\gamma^T x}) - y_2^2 f_0(y_2 e^{-\gamma^T x})}{S_0(y_1 e^{-\gamma^T x}) - S_0(y_2 e^{-\gamma^T x})} \right\} x x^T. \tag{19}
\]

If \( \tau_0 = \infty \), then \( \text{E}(T \mid X = x) = \int_0^\infty e^{-\gamma^T x} f_0(t e^{-\gamma^T x}) dt < \infty \) implies \( \lim_{y \to \infty} y f_0(y) = 0 \). Similarly, \( \text{E}(T^2 \mid X = x) < \infty \) implies \( \lim_{y \to \infty} y^2 f_0(y) = 0 \).
and thus \( \int_0^\infty t^2 e^{-2\gamma^T x} f_0(t e^{-\gamma^T x}) \, dt = -2E(T \mid X = x) \). The latter ensures \( \lim_{y \to \infty} y^k f_0(y) = 0 \). Therefore we have

\[
\lim_{y \to \infty} y^{k+1} f_0^{(k)}(y) = 0, \quad k = 0, 1. \tag{20}
\]

By (19) and the SLLN we have, as \( n \to \infty \),

\[
\frac{1}{n} \frac{\partial^2 \ell(\gamma, f_0)}{\partial \gamma \partial \gamma^T} \to H(\gamma, f_0) = -\sum_{k=0}^2 \rho_k \int_X I_k(x) e^{-2\gamma^T x} xx^T dH(x), \quad \text{a.s.,}
\]

where \( \rho_k \) is the probability that \( T \) is Case \( k \) censored so that \( \rho_0 + \rho_1 + \rho_2 = 1 \), and \( I_k(x) \) \((k = 0, 1, 2)\) are given below.

For Case 0 data, using substitution \( t = ye^{-\gamma^T x} \) we have

\[
I_0(x) = e^{2\gamma^T x} \int_0^{\tau_0} \left[ \frac{f_0'(t)}{f_0(t)} - f_0'(t) - tf_0''(t) \right] dt = e^{2\gamma^T x} \int_0^{\tau_0} \left\{ \frac{f_0'(t)}{f_0(t)} + 1 \right\}^2 f_0(t) dt - e^{2\gamma^T x} \{ \tau_0^2 f_0'(\tau_0) + \tau_0 f_0(\tau_0) \}.
\]

It follows from (20) if \( \tau_0 = \infty \) and the assumption \( \tau_0^2 f_0'(\tau_0) + \tau_0 f_0(\tau_0) \leq 0 \) if \( \tau_0 < \infty \) that

\[
I_0(x) \geq e^{2\gamma^T x} \int_0^{\tau_0} \left\{ \frac{f_0'(t)}{f_0(t)} + 1 \right\}^2 f_0(t) dt
\]

for all \( x \in X \). Therefore \( \Pr\{ f_0(T) = c_0/T \mid X = 0 \} < 1 \), for all \( c_0 > 0 \), implies that \( I_0(x) > 0 \) for all \( x \in X \).

For Case 1 data,

\[
I_1(x) = E \left( e^{\gamma^T X} \left[ \frac{-Uf_0(U^{-\gamma^T x})}{1 - S_0(U^{-\gamma^T x})} + e^{-\gamma^T x} \frac{\{Uf_0(U^{-\gamma^T x})\}^2}{\{1 - S_0(U^{-\gamma^T x})\}^2} \right] I(0 < T < U) \mid X = x \right)
\]

\[
+ E \left( e^{\gamma^T X} \left[ \frac{Uf_0(U^{-\gamma^T x})}{S_0(U^{-\gamma^T x})} + e^{-\gamma^T x} \frac{\{Uf_0(U^{-\gamma^T x})\}^2}{\{S_0(U^{-\gamma^T x})\}^2} \right] I(U < T < \infty) \mid X = x \right)
\]

\[
+ e^{-\gamma^T x} Uf_0'(U^{-\gamma^T x}) \frac{\{Uf_0(U^{-\gamma^T x})\}^2}{S_0(U^{-\gamma^T x})} I(U < T < \infty) \mid X = x \right)
\]

\[
= E \left( \left[ \frac{\{Uf_0(U^{-\gamma^T x})\}^2}{1 - S_0(U^{-\gamma^T x})} + \frac{\{Uf_0(U^{-\gamma^T x})\}^2}{\{S_0(U^{-\gamma^T x})\}^2} \right] \mid X = x \right)
\]

\[
= \int_0^{\infty} \frac{uf_0(ue^{-\gamma^T x})^2}{\{1 - S_0(ue^{-\gamma^T x})\}S_0(ue^{-\gamma^T x})} dG(u \mid x).
\]
Similarly, for Case 2 data, we have

\[
I_2(x) = \int \int_{u_1 < u_2} \left[ \frac{(u_1 f_0(u_1 e^{-\gamma^T x}))^2}{1 - S_0(u_1 e^{-\gamma^T x})} + \frac{(u_2 f_0(u_2 e^{-\gamma^T x}))^2}{S_0(u_2 e^{-\gamma^T x})} \right] dG(u_1, u_2 | x)
\]

\[
= \int \int_{u_1 < u_2} \left[ \psi(u, x; \gamma)^T A(u, x) \psi(u, x; \gamma) \right] \frac{dG(u | x)}{S_0(u_1 e^{-\gamma^T x}) - S_0(u_2 e^{-\gamma^T x})}
\]

where \( \psi(u, x; \gamma) = (u_1 f_0(u_1 e^{-\gamma^T x}), u_2 f_0(u_2 e^{-\gamma^T x}))^T \) and \( A(u, x) \) is the same as in (15). Clearly \( I_k(x) > 0 \) for \( k = 1, 2 \) and all \( x \in X \). The negative-definiteness of \( H(\gamma, f_0) \) follows. The proof is complete. \( \square \)

### 7.4 Proof of Theorem 4

**Proof.** Assume that the data are arranged so that \( \delta_i = k \) for \( i = n_{k-1} + 1, \ldots, n_k \), \( k = 0, 1, 2 \), where \( n_{-1} = 0 \). Let \( \gamma_0 \) be the true value of \( \gamma \). Define \( \tilde{\mathcal{R}}(\gamma, p) = \{ \ell(\gamma_0, f_0) - \ell_m(\gamma, p) \} / n \). By (10) and Taylor expansion we obtain

\[
\tilde{\mathcal{R}}(\gamma, p) = - \sum_{0 \leq i < j \leq 1} \tilde{R}_{ij}(\gamma, p) + \frac{1}{2} \sum_{i=0}^{1} \tilde{R}_{i2}(\gamma, p) + \sum_{i=0}^{1} o(\tilde{R}_{i2}(\gamma, p)), \quad (21)
\]

where \( \tilde{R}_{00}(\gamma, p) = -n^{-1} \sum_{i=0}^{n} (\gamma - \gamma_0)^T x_i \),

\[
\tilde{R}_{0k}(\gamma, p) = \frac{1}{n} \sum_{i=0}^{n} \left( \frac{f_m(y_i e^{-\gamma^T x_i}; p)}{f_0(y_i e^{-\gamma_0^T x_i})} - 1 \right), \quad k = 1, 2,
\]

\[
\tilde{R}_{1k}(\gamma, p) = \frac{1}{n} \sum_{i=n_0+1}^{n} \left( \frac{S_m(y_{i1} e^{-\gamma^T x_i}; p) - S_m(y_{i2} e^{-\gamma^T x_i}; p)}{S_0(y_{i1} e^{-\gamma_0^T x_i}) - S_0(y_{i2} e^{-\gamma_0^T x_i})} - 1 \right), \quad k = 1, 2.
\]

By Stirling formula, for all real \( x \),

\[
\left| e^x - \sum_{j=0}^{j} \frac{1}{j!} x^j \right| \leq \frac{e^{2\sqrt{j+1}|x|}|j+1|^j}{\sqrt{2\pi}(j+1)!}, \quad j = 0, 1, 2, \ldots, \quad (22)
\]

All the large sample statements in the following proofs are almost sure.
If $\rho_0 > 0$, under Condition [0] by the LIL and Kolmogorov’s SLLN we have

\[
\hat{R}_{00}(\gamma, \rho) = -\rho_0 (\gamma - \gamma_0)^T E(X) + \mathcal{O} \{|(\gamma - \gamma_0)^T \text{Var}(X)(\gamma - \gamma_0)|\}^{1/2} + (\log \log n/n)^{1/2},
\]

(23)

\[
\hat{R}_{02}(\gamma, \rho) = \rho_0 \int \int_{\gamma_0 e^\gamma d\gamma} \int_{0}^{\gamma_0 e^\gamma} e^{-\gamma_0 x} \left\{ \frac{f_m(ye^{-\gamma_0 x}; \rho)}{f_0(ye^{-\gamma_0 x})} - 1 \right\}^2 f_0(ye^{-\gamma_0 x}) dymdH(x)
\]

\[
+ o \left\{ \chi_0(\gamma, \rho) \right\}
\]

\[
= \rho_0 \chi_0(\gamma, \rho) + o \left\{ \chi_0(\gamma, \rho) \right\},
\]

(24)

where

\[
\chi_0(\gamma, \rho) = \int \int_{\gamma_0 e^\gamma d\gamma} \int_{0}^{\gamma_0 e^\gamma} e^{-\gamma_0 x} \left\{ \frac{f_m(ye^{-\gamma_0 x}; \rho)}{f_0(ye^{-\gamma_0 x})} - 1 \right\}^2 f_0(ye^{-\gamma_0 x}) dymdH(x)
\]

\[
= \int \int_{\gamma_0 e^\gamma d\gamma} \left\{ \frac{f_m(t(e^{-\gamma_0 x}; \rho))}{f_0(t)} - 1 \right\}^2 f_0(t) dtdH(x).
\]

By the LIL we have

\[
\hat{R}_{01}(\gamma, \rho) = \rho_0 \int \int_{\gamma_0 e^\gamma d\gamma} \int_{0}^{\gamma_0 e^\gamma} e^{-\gamma_0 x} \left\{ \frac{f_m(ye^{-\gamma_0 x}; \rho)}{f_0(ye^{-\gamma_0 x})} - 1 \right\}^2 f_0(ye^{-\gamma_0 x}) dymdH(x)
\]

\[
+ \mathcal{O} \left\{ \chi_0(\gamma, \rho)(\log \log n/n)^{1/2} \right\}
\]

\[
= \rho_0 E\{e^{(\gamma - \gamma_0)^T X} - 1\} + \mathcal{O} \left\{ \chi_0(\gamma, \rho)(\log \log n/n)^{1/2} \right\}.
\]

(25)

By [22] we get

\[
\hat{R}_0(\gamma, \rho) = -\sum_{i=0}^{1} \hat{R}_0_i(\gamma, \rho) + \frac{1}{2} \hat{R}_{02}(\gamma, \rho) + o(\hat{R}_{02}(\gamma, \rho))
\]

\[
= E\{e^{(\gamma - \gamma_0)^T X} - 1\} - (\gamma - \gamma_0)^T X + \frac{1}{2} \chi_0(\gamma, \rho)
\]

\[
+ \mathcal{O} \left\{ \chi_0(\gamma, \rho)(\log \log n/n)^{1/2} \right\}
\]

\[
+ \mathcal{O} \left\{ \{(\gamma - \gamma_0)^T \text{Var}(X)(\gamma - \gamma_0)\}^{1/2}(\log \log n/n)^{1/2} \right\}
\]

\[
+ o \left\{ \chi_0(\gamma, \rho) \right\}
\]

\[
= \frac{1}{2} D_0^2(\gamma, \rho) + \mathcal{O} \left\{ \chi_0(\gamma, \rho)(\log \log n/n)^{1/2} \right\}
\]

\[
+ \mathcal{O} \left\{ \{(\gamma - \gamma_0)^T \text{Var}(X)(\gamma - \gamma_0)\}^{1/2}(\log \log n/n)^{1/2} \right\}
\]

\[
+ \frac{1}{6} \mathcal{O} \left\{ E\{o((\gamma - \gamma_0)^T X)^3\} ||(\gamma - \gamma_0)^T X||^3 \right\} + o \left\{ \chi_0(\gamma, \rho) \right\}.
\]

(26)

Under Conditions [1] and [2] if $\rho_k > 0$, $k = 1, 2$, similar to the proof of Proposition [3] we have $\hat{R}_{11}(\gamma, \rho) = \mathcal{O} \left\{ \sum_{k=1}^{2} \rho_k D_k(\gamma, \rho)(\log \log n/n)^{1/2} \right\}$ by LIL
\[ \hat{R}_{12}(\gamma, p) = \sum_{k=1}^{2} \rho_k D_k^2(\gamma, p) + o(\sum_{k=1}^{2} \rho_k D_k^2(\gamma, p)) \] by Kolmogorov’s SLLN. Thus

\[ \hat{R}_1(\gamma, p) = -\hat{R}_{11}(\gamma, p) + \frac{1}{2} \hat{R}_{12}(\gamma, p) + o(\hat{R}_{12}(\gamma, p)) \]

\[ = \frac{1}{2} \sum_{k=1}^{2} \rho_k D_k^2(\gamma, p) + O \left( \sum_{k=1}^{2} \rho_k D_k(\gamma, p)(\log \log n/n)^{1/2} \right) \]

\[ + o \left( \sum_{k=1}^{2} \rho_k D_k^2(\gamma, p) \right). \] (27)

If \[ \sum_{k=0}^{2} \rho_k D_k^2(\gamma, p) = (\log \log n)^\alpha / n \] then

\[ \hat{R}(\gamma, p) = \frac{1}{2}(\log \log n)^\alpha / n + O \{(\log \log n)^{(\alpha + 1)/2} / n\} + o(\log \log n)^\alpha / n. \]

While at \((\gamma, p) = (\gamma_0, p_0)\), if \( m = Cn^{1/3} \) then, by \((A.2)\) \[ \sum_{k=0}^{2} \rho_k D_k^2(\gamma, p) = O(1/n) \] and \[ \hat{R}(\gamma, p) = O(1/n) + o(1/n). \] Thus \[ D_k^2(\gamma, \tilde{p}) \leq (\log \log n)^\alpha / n \] if \( \alpha > 1. \)

### 7.5 Proof of Theorem 5

Proof. Theorem 4 implies that \[ \| \hat{\gamma} - \gamma_0 \|^2 = O\{(\log \log n)^\alpha / n\} \] under Assumption \((A.1)\) and Condition 0. By the reverse triangular inequality we have

\[ \chi_0^2(\gamma, p) \geq \{ \chi_0(\gamma_0, p) - \hat{\chi}_0(\gamma, p) \}^2. \] (28)

where

\[ \hat{\chi}_0^2(\gamma, p) = \int_{\mathcal{X}} \int_0^\infty e^{-\gamma_0 x} \frac{f_m(ye^{-\gamma_0 x}; p) - f_m(ye^{-\gamma_0 x}; p)}{f_0(ye^{-\gamma_0 x})}^2 dydH(x). \]

Noting that \[ |f_m^i(t; p)| \leq C_2 m^2 \], Theorem 4 with \( i = 0 \), together with (28), imply that \[ \chi_0^2(\gamma_0, \tilde{p}) = O\{(\log \log n)^\alpha n^{-1+1/\rho}\}. \]

Under Condition 1, by triangular inequality

\[ D_1^2(\gamma, p) \leq 2D_1^2(\gamma_0, p) + 2\hat{D}_1^2(\gamma, p), \] (29)

where

\[ \hat{D}_1^2(\gamma, p) = \int_{\mathcal{X}} \int_{\mathcal{T}_0} \frac{\{S_m(ue^{-\gamma x}; p) - S_m(ue^{-\gamma_0 x}; p)\}^2}{S_0(ue^{-\gamma_0 x})\{1 - S_0(ue^{-\gamma_0 x})}\} dG(u | x)dH(x). \]

We also have

\[ D_1^2(\gamma, p) \geq \{D_1(\gamma_0, p) - \hat{D}_1(\gamma, p)\}^2. \] (30)
Noting that \( f_m(t; p) \leq (m + 1)/\tau_n \) we have,

\[
\tilde{D}_1^2(\gamma, p) \leq \frac{(m + 1)^2}{\tau_n^2} \int \int_{\tau_1} \frac{u^2(e^{-\gamma x} - e^{-\gamma^2 x})^2 dG(u | x)}{S_0(ue^{-\gamma x})(1 - S_0(ue^{-\gamma x}))} dH(x)
\]

\[
= \tau_n^{-2}(m + 1)^2 \mathcal{O}\left\{ (\gamma - \gamma_0)^T M_0 (\gamma - \gamma_0) \right\},
\]  

(31)

where

\[
M_0 = \int \int_{\tau_1} \frac{\gamma u^2 e^{-2\gamma x} x^2 dG(u | x)}{S_0(ue^{-\gamma x})(1 - S_0(ue^{-\gamma x}))} dH(x).
\]

Because \( \mathcal{X} \) is compact and \( 0 < \tau_1 < \tau_u < \infty \),

\[
\mathcal{O}\left\{ (\gamma - \gamma_0)^T M_0 (\gamma - \gamma_0) \right\} = \mathcal{O}(\|\gamma - \gamma_0\|^2).
\]

For any fixed \( \gamma \in \mathcal{B}_{n, \epsilon} \), if \( m = C n^{1/\rho} \) and \( D_1^2(\gamma_0, p) = n^{-1+\epsilon'+2/\rho} \) for any \( \epsilon' > \epsilon \),

we can show that there exists an \( \eta > 0 \) so that \( \mathcal{R}(\gamma, p) \geq \eta m^{-1+\epsilon'+2/\rho} \), a.s.. While at \( p = p_0 \) we have, by (29), \( \mathcal{R}(\gamma, p) = \mathcal{O}(n^{-1+\epsilon+2/\rho}) \), a.s.. Thus for any fixed \( \gamma \in \mathcal{B}_{n, \epsilon} \), the maximizer \( p(\gamma) \) of \( \ell_m(\gamma, p) \) satisfies \( D_1^2(\gamma_0, p(\gamma)) \leq n^{-1+\epsilon'+2/\rho} \) whenever \( \epsilon' > \epsilon \).

Under Condition 2, \( D_2^2(\gamma, p) \leq 2 \tilde{D}_2^2(\gamma, p) + 2 \tilde{D}_2^2(\gamma_0, p) \) and \( D_2^2(\gamma, p) \geq \{ D_2(\gamma_0, p) - \tilde{D}_2(\gamma, p) \}^2 \), where

\[
\tilde{D}_2^2(\gamma, p) = E\left\{ \tilde{W}(U, X; \theta)^T A(U, X) \tilde{W}(U, X; \theta) \right\}.
\]

\[
\tilde{W}(u, x; \theta) = \left\{ S_m \left( \frac{u_1}{e^{\gamma x}} ; p \right) - S_m \left( \frac{u_1}{e^{\gamma x}} ; p \right), S_m \left( \frac{u_2}{e^{\gamma x}} ; p \right) - S_m \left( \frac{u_2}{e^{\gamma x}} ; p \right) \right\}^T.
\]

The proof under Condition 2 is similar to that under Condition 1. □
