ON THE TOPOLOGICAL PERIOD-INDEX PROBLEM OVER 8-MANIFOLDS

DIARMUID CROWLEY, XING GU, AND CHRISTIAN HAESEMEYER

Abstract. We establish upper bounds of the indices of topological Brauer classes over a closed orientable 8-manifolds. In particular, we verify the Topological Period-Index Conjecture (TPIC) for topological Brauer classes over closed orientable 8-manifolds of order not congruent to 2 (mod 4). In addition, we provide a counter-example which shows that the TPIC fails in general for closed orientable 8-manifolds.

1. Introduction

Let \( X \) be a topological space. An Azumaya algebra \( P \) over \( X \) of degree \( r \) is a principal \( \text{PU}_r \)-bundle over \( X \) (or equivalently, a sheaf of algebras over the continuous functions on \( X \) locally isomorphic to a matrix algebra). To such a principal bundle, one may associate a class \( \alpha \) in the topological Brauer group \( \text{Br}_\text{top}(X) := TH^3(X) \) (where we write \( TA \) for the torsion in an abelian group \( A \) and throughout \( H^*(X) \) denotes the integral cohomology groups of \( X \)). The order of \( \alpha \) in the topological Brauer group is traditionally called the period, denoted \( \text{per}(\alpha) \), and it divides the degree of \( P \). If \( X \) is a finite \( CW \)-complex, every class \( \alpha \in \text{Br}_\text{top}(X) \) arises in this fashion, and it is a natural question what the possible degrees of Azumaya algebras \( P \) with class \( \alpha \) are. Following Antieau and Williams in \([2]\), we call the greatest common divisors of these degrees the index of \( \alpha \), denoted \( \text{ind}(\alpha) \). As shown in loc. cit., the period and index of \( \alpha \) have the same prime divisors; it follows that the index divides some power of the period. This insight gives rise to the following problem:

**Question** (Topological Period-Index Problem). Let \( X \) be a topological space, homotopy equivalent to a finite \( CW \)-complex. Is there a bound \( e = e(X) \), computable in terms of “easy” topological invariants of \( X \), such that for every class \( \alpha \in \text{Br}_\text{top}(X) \) we have \( \text{ind}(\alpha)|\text{per}(\alpha)^e \)?

**Remark** 1.1. It follows from our hypotheses that the Brauer group of \( X \) is finite, and thus there is some bound \( e \) depending on \( X \). The problem is to describe it using other topological invariants of \( X \).

As explained in \([1]\), analogy with a major conjecture (known as the “Period-Index Conjecture”, see \([7]\)) in the study of central simple algebras over function fields leads to a naive guess, namely that for \( X \) of even dimension \( 2d \), one can take \( e(X) = d - 1 \). Antieau and Williams give an algebraic-topological formula for the index of a Brauer class on \( CW \) complexes of dimension at most 6, and use it to prove that the naive guess fails for \( d \geq 3 \). On the other hand, the first author and Grant show in \([8]\) that the naive guess is true for compact spin manifolds of

**Key words and phrases.** Brauer groups, twisted K-theory, period-index problems.
dimension 6. With this in mind, we state the following not as a conjecture to be proved, but rather as a hypothesis to be considered for certain classes of spaces such as closed orientable manifolds, spin$^c$ manifolds, complex projective manifolds, etc.

We will refer to this hypothesis as the Topological Period-Index Conjecture (TPIC) for finite CW complexes, closed orientable manifolds, spin$^c$ manifolds, complex projective manifolds, etc.

**Conjecture (The Topological Period-Index Conjecture).** Let $X$ be a topological space homotopy equivalent to a finite CW complex of dimension $2d$, and let $\alpha \in \text{Br}_{\text{top}}(X)$, then

$$\text{ind}(\alpha) | \text{per}(\alpha)^{d-1}.$$ 

In this paper we establish upper bounds of the indices of topological Brauer classes over closed orientable 8-manifolds, and in particular verify the TPIC for topological Brauer classes over closed orientable 8-manifolds of order not congruent to 2 (mod 4).

**Theorem 1.2.** Let $M$ be a closed orientable manifold of dimension 8 and $\alpha \in TH^3(M)$ a topological Brauer class. Then we have

$$\begin{cases} 
\text{ind}(\alpha) | 2 \text{per}(\alpha)^3, & \text{if } \text{per}(\alpha) \equiv 2 \pmod{4}, \\
\text{ind}(\alpha) | \text{per}(\alpha)^3, & \text{otherwise}.
\end{cases}$$

In particular, the TPIC holds if $\text{per}(\alpha) \not\equiv 2 \pmod{4}$.

Classes $\alpha$ in the Brauer group of a space $X$ give rise to a notion of $\alpha$-twisted $K$-theory on $X$, see [9] and [5], and this twisted $K$-theory is computed by a twisted Atiyah-Hirzebruch spectral sequence, see [5]. In [2], Antieau and Williams show that (for a connected compact space $X$) the index of the class $\alpha$ can be computed as the index of the subgroup of permanent cycles for the $\alpha$-twisted spectral sequence in $H^0(X) = \mathbb{Z}$. It follows that we may decompose ind($\alpha$) as the product of orders of $G_i(\alpha)$ where $G_i$’s are certain (higher) cohomology operations obtained from the differentials of the spectral sequence, with $G_0$ the identity. Thus we obtain the “period vector” of $\alpha$

$$\text{per}(\alpha) := (\text{ord}(G_0(\alpha)), \text{ord}(G_1(\alpha)), \cdots, \text{ord}(G_{m-2}(\alpha)))$$

where $2m$ is the dimension of the ambient CW complex $X$. In other words, we decompose ind($\alpha$) as the product of all entries of per($\alpha$). A more detailed discussion on period vectors will be presented in Section 2. The proof of Theorem 1.2 proceeds via a careful study of these higher cohomology operations. In the universal case (where the space $X$ is a (skeleton of) an appropriate Eilenberg-MacLane space) the operations $G_1$ and $G_2$ are described in Section 2, recalling results from [1] and [11].

Further consideration leads to additional restrictions on the entries of the period vectors which are not visible from previous results such as Theorem 2.1. For instance, we have the following

**Theorem 1.3.** Let $X$ be a finite connected CW complex with $\alpha \in TH^3(X)$ of period 2. Furthermore, suppose $\text{ord}(G_1(\alpha)) = 2$. Then we have $\text{ord}(G_2(\alpha)) | 2$.

In particular, the theorem implies that for a finite connected 8-complex $X$ and a Brauer class $\alpha \in TH^3(X)$ with $\text{per}(\alpha) = 2$, it is not possible to have $\text{per}(\alpha) = (2, 2, 4)$, although such a period vector would not violate Theorem 2.1. The main result on the TPIC for 8-complexes.
As a partial complement of Theorem 1.2, we have the following consequence of Theorem 1.3:

**Theorem 1.4.** Let $X$ be a finite connected CW-complex and let $\alpha \in TH^3(X)$ be of period 2 (mod 4), such that $4 \nmid \text{ord}(G_1(\alpha))$. Then we have

\[
\begin{cases}
\text{ind}(\alpha) | 3 \text{per}(\alpha)^3, & 3 \nmid \text{per}(\alpha), \\
\text{ind}(\alpha) \not| \text{per}(\alpha)^3, & 3 \mid \text{per}(\alpha).
\end{cases}
\]

In particular, if in addition we have $3 \nmid n$, then the TPIC holds for the pair $(X, \alpha)$.

Indeed, it follows from Theorem 1.3 of [3] that it suffices to consider the cases $\text{per}(\alpha) = 2$ and that $\text{per}(\alpha)$ is odd, for which we apply Theorem 1.3 and Theorem 1.2, respectively. Taken together, Theorems 1.2 and 1.4 imply that the TPIC will hold for Brauer classes on closed orientable 8-manifolds, except possibly for classes with 2-primary period vector $\text{per}(\alpha) = (2, 4, 2)$ and here we state our final main result.

**Theorem 1.5.**

1. There is a closed orientable non-spin $^c$ 8-manifold $M$ with $\alpha \in TH^3(M)$ such that $\text{per}(\alpha) = (2, 4, 2)$.
2. There is a closed parallelisable (hence almost complex) 8-manifold $M$ with $\alpha \in TH^3(M)$ such that $\text{per}(\alpha) = (2, 4, 1)$.

Part (1) of Theorem 1.5 shows that the TPIC fails in general for closed orientable 8-manifolds. To the best of our knowledge, the TPIC remains open for spin $^c$-manifolds and in particular for the analytic spaces underlying smooth complex varieties of (complex) dimension 4. Part (2) of Theorem 1.5 does show that spin $^c$-manifolds can have interesting period vectors and that if the TPIC holds for such manifolds, it is sharp in general.

The rest of this paper is organised as follows: In Section 2 we develop some necessary preliminaries. We prove Theorem 1.2 and in Section 3 and Theorem 1.3 in Section 4. In Section 5 prove the existence of the examples in Theorem 5.

**Acknowledgements:** We would like thank Mark Grant for numerous helpful comments and conversations.

2. **Preliminaries**

2.1. **The topological period-index problem over 8-complexes.** In [11] and [10], the third author considered the topological period-index problem for finite connected CW-complexes of dimension 8. Before stating the main result, we introduce the notation, which we use throughout the paper.

**Notation.** Throughout this paper $n$ is a positive integer, $K_n$ denotes the Eilenberg-MacLane space $K(\mathbb{Z}/n, 2)$, $\zeta'_n$ the fundamental class of $H^2(K_n; \mathbb{Z}/n)$, $\beta^{2/n}$ the Bockstein homomorphism $H^*(\cdot; \mathbb{Z}/n) \to H^{*+1}(\cdot; \mathbb{Z})$, and $\zeta_n := \beta^{2/n}(\zeta'_n)$. In addition $\epsilon_p(n)$ denotes the greatest common divisor of a prime number $p$ and $n$. 

Theorem 2.1 (Theorem 1.3, [10]). Let \( X \) be a topological space with the homotopy type of a finite connected 8-dimensional CW-complex, and let \( \alpha \in \text{TH}^3(X) \) be a topological Brauer class of period \( n \). Then
\[
\text{ind}(\alpha)|\varepsilon_3(n)n^3, \quad \text{if } 4|n,
\varepsilon_2(n)\varepsilon_3(n)n^3, \quad \text{otherwise}.
\]
(2.2)

In addition, if \( X \) is the 8-skeleton of \( K_n \) and \( \alpha = \zeta_n \), then
\[
\text{ind}(\zeta_n) = \varepsilon_3(n)n^3, \quad \text{if } 4|n,
\varepsilon_2(n)\varepsilon_3(n)n^3, \quad \text{otherwise}.
\]

In particular, the sharp lower bound of \( c \) such that \( \text{ind}(\alpha)|n^c \) for all \( X \) and \( \alpha \) is 4.

2.2. The Atiyah-Hirzebruch Spectral Sequence for twisted K-theory. For a connected topological space \( X \) and a class \( \alpha \in \text{TH}^3(X) \), Donovan and Karoubi ([9]) and also Atiyah and Segal ([4], [5]) considered the twisted versions of complex K-theory of \( X \) with respect to \( \alpha \), which we denote by \( KU(X)_\alpha \), following the convention in [2]. This generalizes the usual complex topological K-theory \( KU(X) \) in the sense that when \( \alpha = 0 \), we have \( KU(X)_\alpha \cong KU(X) \).

Similarly to untwisted K-theory, there is a twisted Atiyah-Hirzebruch spectral sequence for twisted K-theory, \( \tilde{E}_r^{s,t} \), which converges to \( KU(X)_\alpha \) when \( X \) is homotopy equivalent a finite CW complex and whose \( E_2 \)-terms,
\[
\tilde{E}_2^{s,t} \cong \begin{cases} H^3(X), & \text{if } t \text{ is even}, \\ 0, & \text{if } t \text{ is odd}, \end{cases}
\]
do not depend on the twist. For more details, see [1], [2] and [9]. The spectral sequence is closely related to the index of \( \alpha \), as shown in the following

Theorem 2.3 (Theorem 3.1, [11]). Let \( X \) be a connected finite CW-complex and let \( \alpha \in \text{Br}_{\text{top}}(X) \). Consider \( \tilde{E}_r^{s,t} \), the twisted Atiyah-Hirzebruch spectral sequence (AHSS) with respect to \( \alpha \) with differentials \( d_r^{s,t} \) with bi-degree \( (r,-r+1) \). In particular, \( \tilde{E}_2^{2,0} \cong \mathbb{Z} \), and any \( \tilde{E}_2^{0,0} \) with \( r > 2 \) is a subgroup of \( \tilde{E}_2^{2,0} \) and therefore generated by a positive integer. The subgroups \( \tilde{E}_3^{0,0} \) and \( \tilde{E}_\infty^{0,0} \) are generated respectively by \( \text{per}(\alpha) \) and \( \text{ind}(\alpha) \).

We call this spectral sequence the twisted AHSS for the pair \((X,\alpha)\).

Theorem 2.3 is the background result used in the proof of Theorem 2.1 and shows why understanding the differentials in the twisted AHSS is the key to computing \( \text{ind}(\alpha) \). To begin, we consider the case where \( X \) is the universal space \( K_n \). The cohomology of \( K_n \) can be deduced from [13], the standard reference for (co)homology of Eilenberg-MacLane spaces. Alternatively, all material in this section can be found in [11] and [11].

Recall that for any integer \( r > 1 \) we have
\[
H^5(K_n) \cong \mathbb{Z}/\varepsilon_2(n)n,
\]
and
\[
H^7(K_n) \cong \mathbb{Z}/\varepsilon_3(n)n.
\]

Recall also that the canonical generators \( Q_n \) of \( H^5(K_n) \) and \( R_n \) of \( H^7(K_n) \) satisfy
\[
\varepsilon_2(n)Q_n = \beta^{2/n}((\zeta_n^3)^2),
\varepsilon_3(n)R_n = \beta^{2/n}((\zeta_n^3)^3).
\]

(2.4)
Theorem 2.5. Let $\zeta_n \in TH^3(K_n)$ be the canonical generator of $H^3(K_n)$. Then the twisted Atiyah-Hirzebruch spectral sequence for $(K_n, \zeta_n)$ satisfies

\begin{equation}
\tilde{d}_5^{0,0}(n) = \lambda_1 Q_n
\end{equation}

and

\begin{equation}
\tilde{d}_7^{0,0}(\varepsilon_2(n)n^2) = \begin{cases} 
\frac{\lambda_2}{2} R_n & 4|n, \\
\lambda_2 R_n & \text{otherwise}, 
\end{cases}
\end{equation}

where $\lambda_1$ and $\lambda_2$ are integers co-prime to $n$.

Proof. Equation (2.7) is Theorem B of [1]. One then readily deduces (2.7) from Theorem 2.1 and Theorem 2.3. \hfill \Box

2.3. Period Vectors. As mentioned in the introduction, the finiteness of $X$ indicates that we may obtain $\text{ind}(\alpha)$ by computing the differentials $\tilde{d}_r^{0,0}$ for successive $r$'s. By doing so we obtain a stable chain of subgroups of $Z$

$$
\tilde{E}_{0,0}^2 = Z \supset \text{per}(\alpha)Z = \text{Ker} \tilde{d}_3^{0,0} \supset \text{Ker} \tilde{d}_5^{0,0} \supset \cdots \supset \text{Ker} \tilde{d}_{2r+1}^{0,0} \supset \cdots.
$$

Notice that, by Bott periodicity, the differentials $\tilde{d}_r^{0,0}$ for even $r$ are trivial. If we let $a'_r$ ($r \geq 0$) be the unique positive integer generating $\text{Ker} \tilde{d}_{2r+3}^{0,0}$, then, in particular, we have $a'_0 = \text{per}(\alpha)$. We also fix the notation $a'_{-1} = 1$. Consequently, we have $a'_r | a'_{r-1}$. The element $\tilde{d}_{2r+3}^{0,0}(a'_{r-1})$ is then a torsion element of order $a_r := a'_r/a'_{r-1}$. Therefore, if $X$ is of even dimension $2m$, then we have

\begin{equation}
\text{ind}(\alpha) = a_0 a_1 \cdots a_{m-2}.
\end{equation}

It is both conceptually illuminating and practically helpful to consider the higher cohomology operations $G_r$ defined on $TH^3(X)$ by

\begin{equation}
G_r(\alpha) = \tilde{d}_{0,0}^{2r+3}(\text{per}(a'_r)).
\end{equation}

By definition, $G_0$ is the identity on $TH^3(X)$. Antieau and Williams [1] determined the secondary operation $G_1$ (which they denote by $G$). Specifically, if $\text{per}(\alpha) = n$ and $\alpha = \beta^{2/n}(\xi)$ for $\xi \in H^2(X; Z/n)$, then [1] Theorem 5.2 states that

\begin{equation}
G_1(\alpha) = [\lambda \beta^{2/n}(\xi)]^n \in H^3(X)/\alpha H^3(X),
\end{equation}

where $P_2(\xi) = \xi^2$ if $n$ is odd, $P_2(\xi)$ is the Pontrjagin square of $\xi$ if $n$ is even and $\lambda$ is an integer prime to $n$. In general the computation of $G_2(\alpha)$ is more difficult than that of $G_1(\alpha)$. This because the definition of $G_2(\alpha)$ depends on the value of $G_1(\alpha)$ and because $G_2(\alpha)$ lies in a more complicated quotient than $G_1(\alpha)$. However, for $\alpha \in H^3(K_n)$, the canonical generator, Theorem 2.5 computes $G_2(\alpha)$.

The element $G_r(\alpha)$ is defined so that equation (2.8) becomes

$$
\text{ind}(\alpha) = \text{ord}(G_0(\alpha)) \text{ord}(G_1(\alpha)) \cdots \text{ord}(G_{m-2}(\alpha)),
$$

where $\text{ord}(G_r(\alpha))$ is the order of $G_r(\alpha)$. Furthermore, we define the period vector of $\alpha$, denoted $\text{per}(\alpha)$, to be the ordered sequence of non-negative integers

$$
\text{per}(\alpha) := (\text{ord}(G_0(\alpha)), \text{ord}(G_1(\alpha)), \cdots, \text{ord}(G_{m-2}(\alpha)))
$$

and refer to $\text{ord}(G_r(\alpha))$ the $r$th period of $\alpha$. 

In terms of the period vector, what Antieau and Williams show is essentially the following: Let $X$ be the 6th skeleton of $K_n$ and $\alpha$ be the pull-back of $\zeta_n \in H^3(K_n)$, then we have

$$\text{per}(\alpha) = (n, \epsilon_2(n)n).$$

Similarly, what the third author shows in [11] and [10] is essentially the following: Let $X$ be the 8th skeleton of $K_n$ and $\alpha$ be the pull-back of $\zeta_n \in H^3(K_n)$, then we have

$$\text{per}(\alpha) = \begin{cases} (n, 2n, \epsilon_3(n)n), & n \equiv 2 \pmod{4}, \\ (n, n, \epsilon_3(n)n), & \text{otherwise}. \end{cases}$$

It follows from Theorem 2.3 and the functoriality of the twisted $K$-theory AHSS, that for a connected finite CW complex $X$ of dimension $2d$, and a class $\alpha \in TH^3(X)$ with period vector

$$\text{per}(\alpha) := (n, \text{ord}(G_1(\alpha)), \cdots, \text{ord}(G_{d-2}(\alpha))),$$

we have

$$\text{ind}(\alpha) = n \text{ord}(G_1(\alpha)) \cdots \text{ord}(G_{d-2}(\alpha)) | n \text{ord}(G_1(\zeta_n)) \cdots \text{ord}(G_{d-2}(\zeta_n)),$$

where $\zeta_n$ is the canonical generator of $H^3(K_n)$. However, in general, a period vector needs to satisfy more than (2.13), as illustrated in Theorem 1.3, which we prove in Section 3.

2.4. The linking pairing of a manifold. In this subsection we recall the linking pairing of a closed, oriented, connected $m$-manifold $M$. For $m = 8$ and $x \in H^2(M; \mathbb{Z}/3)$ we use the linking pairing of $M$ to define a symmetric cubic form on $V := TH^2(M; \mathbb{Z}) \otimes \mathbb{Z}/3$. The material in this subsection is a cubic version of parts of [8, §3].

Recall that for a finite abelian group $G$, its torsion dual is defined as $G^\wedge := \text{Hom}(G, \mathbb{Q}/\mathbb{Z})$.

If $H$ is another finite abelian group, then then a bilinear pairing

$$\lambda : G \times H \to \mathbb{Q}/\mathbb{Z}$$

gives rise to the adjoint homomorphisms

$$\hat{\lambda}_l : G \to H^\wedge, \quad g \mapsto \lambda(g, -) \quad \text{and} \quad \hat{\lambda}_r : H \to G^\wedge, \quad h \mapsto \lambda(-, h).$$

Given a topological space $X$, let

$$\beta^{\mathbb{Q}/\mathbb{Z}} : H^*(X; \mathbb{Q}/\mathbb{Z}) \to TH^{*+1}(X; \mathbb{Z})$$

be the Bockstein homomorphism. For $M$ as above, the linking pairing of $M$ is the bilinear map

$$b^k_M : TH^k(M) \times TH^{m-k+1}(M) \to \mathbb{Q}/\mathbb{Z}, \quad (x, y) \mapsto \langle \bar{x}y, [M] \rangle,$$

where $\bar{x} \in H^{k-1}(M; \mathbb{Q}/\mathbb{Z})$ is such that $\beta^{\mathbb{Q}/\mathbb{Z}}(\bar{x}) = x$. It is well-known that $b_M$ is perfect, meaning that $(\hat{b}^k_M)_l$ and $(\hat{b}^k_M)_r$ are both isomorphisms; see [8, §3]. For any
positive integer $l$, the commutative diagram of short exact coefficient sequences

\[
\begin{array}{ccc}
\mathbb{Z} & \rightarrow & \mathbb{Z} \\
\downarrow & & \downarrow \\
\mathbb{Z} & \rightarrow & \mathbb{Q}/\mathbb{Z},
\end{array}
\]

where $u : \mathbb{Z}/l \to \mathbb{Q}/\mathbb{Z}$, $1 \mapsto \frac{1}{l}$, gives that for all classes $x \in H^{k-1}(M; \mathbb{Z}/l)$ and $y \in TH^{m-k+1}(M)$ we have

\begin{equation}
(2.14) \quad b^M_\lambda(\beta_{\mathbb{Z}/l}(x), y) = u(\lambda x, [M]).
\end{equation}

Assume now that $M$ is an 8-manifold. For $x \in H^2(M; \mathbb{Z}/3)$ we define the following trilinear homomorphism

\[
\lambda_x : TH^2(M) \times TH^2(M) \times TH^2(M) \to \mathbb{Q}/\mathbb{Z}, \quad (z_1, z_2, z_3) \mapsto \iota_3(\langle xz_1z_2z_3, [M] \rangle).
\]

By $(2.14)$

\[
\lambda_x(z_1, z_2, z_3) = b^M_\lambda(\beta_{\mathbb{Z}/3}(x), z_1z_2z_3).
\]

For $V := TH^2(M) \otimes \mathbb{Z}/3$ the symmetric trilinear homomorphism $\lambda_x$ induces the map

\[
\lambda^V_x : V \times V \times V \to \mathbb{Z}/3, \quad ([z_1], [z_2], [z_3]) \mapsto \iota_3^{-1}(\lambda_x(z_1, z_2, z_3),
\]

which is a symmetric trilinear function of $(\mathbb{Z}/3)$-vector spaces. In the next subsection, we will make some elementary remarks about symmetric trilinear forms such as $\lambda^V_x$.

### 2.5. **Some elementary cubic algebra.**

In this subsection we establish elementary algebraic facts about symmetric trilinear forms. This generalises analogous material from [8] on symmetric bilinear forms.

Let $F_3 = \mathbb{Z}/3$ be the field with three elements. A symmetric trilinear form on a finite dimensional $F_3$ vector space $V$ is a trilinear map

\[
\lambda : V \times V \times V \to F_3
\]

such that for any permutation $\sigma \in \Sigma_3$ we have

\[
\lambda(v_1, v_2, v_3) = \lambda(v_{\sigma(1)}, v_{\sigma(2)}, v_{\sigma(3)}).
\]

Given trilinear forms $(V, \lambda_1)$ and $(W, \lambda_2)$, their orthogonal sum is the trilinear form

\[
\lambda : (V \oplus W) \times (V \oplus W) \times (V \oplus W) \to F_3
\]

define by

\[
(\lambda_1 \oplus \lambda_2)((v_1, v_2, v_3), (w_1, w_2, w_3)) = \lambda_1(v_1, v_2, v_3) + \lambda_2(w_1, w_2, w_3).
\]

Let $V^* = \text{Hom}(V, F_3)$ denote the dual of $V$. We consider two adjoint maps associated to a symmetric trilinear form $(V, \lambda)$. The first of these is the homomorphism

\[
\tilde{\lambda}^1 : V \to V^* \times V^*, \quad u \mapsto ((v, w) \mapsto \lambda(u, v, w)).
\]

We call the kernel of $\lambda^1$ the **radical** of $\lambda$ and denote it by $R$, since it is the subspace of $V$ which combines trivially with every pair in $V \times V$. Writing $V = R \oplus V/R$, we notice that $\lambda$ induces a symmetric trilinear form $\tilde{\lambda}$ on $V/R$ and that $\lambda$ is isomorphic to the orthogonal sum of the zero form on $R$ and $\lambda_R$:

\begin{equation}
(2.15) \quad \lambda \cong (R, 0) \oplus (V/R, \tilde{\lambda})
\end{equation}

If $\lambda^1$ is injective, we call $\lambda$ **nondegenerate.** In particular, $\tilde{\lambda}$ is nondegenerate.
The second adjoint of \((V, \lambda)\) is the homomorphism
\[
\hat{\lambda}^2 : V \times V \to V^*, \quad (u, v) \mapsto (w \mapsto \lambda(u, v, w)).
\]
Notice that the dual of \(\hat{\lambda}^2\) is precisely \(\hat{\lambda}_1 : (\hat{\lambda}^2)^* = \hat{\lambda}^1\). It follows that \(\hat{\lambda}^2\) is onto if and only if \(\hat{\lambda}^1\) is injective; i.e. \(\lambda\) is nondegenerate.

We define the characteristic element of \((V, \lambda)\) to be the map
\[
\gamma(\lambda) : V \to \mathbb{F}_3, \quad v \mapsto \lambda(v, v, v).
\]
The symmetry of \(\lambda\) ensures that \(\gamma(\lambda)\) is linear; i.e. we have the following equations:
For all \(v, w \in V\)
\[
\gamma(\lambda)(v + w) = \lambda(v + w, v + w, v + w) \]
\[
= \lambda(v, v, v) + \lambda(v, v, w) + \lambda(v, w, v) + \lambda(w, v, v) + \lambda(w, w, v) + \lambda(v, v, v) + \lambda(v, v, w) + \lambda(v, w, w) + \lambda(w, w, v) + \lambda(w, v, w) + \lambda(w, w, w) 
\]
\[
= \lambda(v, v, v) + 3\lambda(v, v, w) + 3\lambda(w, w, v) + \lambda(w, w, w) 
\]
\[
= \lambda(v, v, v) + \lambda(w, w, w) 
\]
\[
= \gamma(\lambda)(v) + \gamma(\lambda)(w),
\]
and for all \(a \in \mathbb{F}_3\)
\[
\gamma(\lambda)(av) = \lambda(av, av, av) = a^3\lambda(v, v, v) = a\lambda(v, v, v) = a\gamma(\lambda)(v).
\]
Hence \(\gamma(\lambda) \in V^*\). Moreover, it is clear that the characteristic element of the orthogonal sum of trilinear forms, \((V_1, \lambda_1)\) and \((V_2, \lambda_2)\) is given by
\[
(2.16) \quad \gamma(\lambda_1 \oplus \lambda_2) = (\gamma(\lambda_1), \gamma(\lambda_2)) \in V_1^* \oplus V_2^*
\]
The following lemma relates \(\gamma(\lambda)\) to the second adjoint of \((V, \lambda)\).

**Lemma 2.17.** For all trilinear forms \((V, \lambda)\), we have \(\gamma(\lambda) \in \text{im}(\hat{\lambda}^2)\).

**Proof.** By \((2.16)\), we have that \((V, \lambda) = (R, 0) \oplus (V/R, \hat{\lambda})\) is the the sum of a zero form and the nondegenerate form \((V, \lambda)\). Hence \(\gamma(\lambda) = (0, \gamma(\hat{\lambda}))\) by \((2.16)\). But nondegenerate trilinear forms are precisely those for which the second adjoint is onto. Hence \(\gamma(\hat{\lambda}) \in \text{im}(\hat{\lambda})\) and so \(\gamma(\lambda) \in \text{im}(\hat{\lambda}^2)\). \(\square\)

2.6. The Pontrjagin cube. The purpose of this section is to prove Lemma 2.21

Let \(\alpha \in TH^3(X)\) with period \(n\) and let
\[
\beta^{2/n} : H^*(X; \mathbb{Z}/n) \to H^{*+1}(X)
\]
be the mod \(n\) Bockstein, which lies is the exact sequence
\[
H^*(X; \mathbb{Z}/n) \xrightarrow{\beta^{2/n}} H^{*+1}(X) \xrightarrow{\times n} H^{*+1}(X).
\]
As \(\alpha\) has period \(n\) we see that \(\alpha = \beta^{2/n}(\xi)\) for some \(\xi \in H^2(X; \mathbb{Z}/n)\). In the case where \(n = 3k\), where we have the Pontrjagin Cube
\[
P_3 : H^2(X; \mathbb{Z}/3k) \to H^6(X; \mathbb{Z}/9k),
\]
which satisfies
\[
(2.18) \quad \rho_3(\xi^3) = \rho_3(P_3(\xi)),
\]
where $\rho_3$ denotes reduction modulo 3. Recall that in Subsection 2.2 we defined classes $R_n \in H^2(K_n)$. We use $R_n$ to denote the cohomology operation defined by $R_n$ and this cohomology operation satisfies
\[
R_n(\xi) := \begin{cases} 
[\beta^{2/n}(\xi^3)] & 3 \nmid n, \\
[\beta^{2/3n}(\rho_3(\xi))] & 3 \mid n.
\end{cases}
\]
Next we consider the following commutative diagram
\[
\begin{array}{ccc}
H^*(X; \mathbb{Z}/3k) & \xrightarrow{\beta^{2/3k}} & H^{*+1}(X) \\
\downarrow{\rho_3} & & \downarrow{x} \\
H^*(X; \mathbb{Z}/3) & \xrightarrow{\beta^{2/3}} & H^{*+1}(X),
\end{array}
\]
whose commutativity follows from the following commutative diagram of coefficient short exact sequences:
\[
\begin{array}{ccc}
\mathbb{Z} & \xrightarrow{x^{3k}} & \mathbb{Z} \\
\downarrow{x} & & \downarrow{\rho_3} \\
\mathbb{Z} & \xrightarrow{\rho_3} & \mathbb{Z}/3k \\
\end{array}
\]
Hence for all $x \in H^*(X; \mathbb{Z}/3k)$ we have the equation
\[
\beta^{2/3}(\rho_3(x)) = k\beta^{2/3k}(x),
\]
from which we obtain the following
\begin{lemma}
For any space $X$ and $\xi \in H^2(X; \mathbb{Z}/3k)$, the cohomology operation $R_{3k}$ satisfies
\[
3kR_{3k}(\xi) = \beta^{2/3}(\rho_3(\xi^3)).
\]
\end{lemma}
\begin{proof}
This follows by direct computation, taking $k = 3m$ in (2.19):
\[
\begin{align*}
3mR_{3m}(\xi) &= 3m\beta^{2/3k}(\rho_3(\xi)) \\
&= \beta^{2/3}\rho_3(\rho_3(\xi)) \\
&= \beta^{2/3}(\rho_3(\xi^3)).
\end{align*}
\]
The last step follows from (2.18).
\end{proof}

2.7. Mod 3 Wu classes. Let $p$ be a prime number and $M$ a closed (and oriented if $p > 2$) manifold of dimension $n$. One readily verifies that the functions
\[
\begin{cases}
H^{n-r}(M; \mathbb{Z}/2) \to \mathbb{Z}/2, & u \mapsto \text{Sq}^r(u) \cap [M], \text{ if } p = 2, \\
H^{n-2r(p-1)}(M; \mathbb{Z}/p) \to \mathbb{Z}/p, & u \mapsto \text{Sq}^r(u) \cap [M], \text{ if } p > 2,
\end{cases}
\]
are $\mathbb{Z}/p$-linear, where $\text{Sq}^r$ and $\text{Sq}^r$ are the Steenrod reduced power operations. By Poincaré duality, there are “mod $p$ Wu classes” $v_r \in H^r(M; \mathbb{Z}/2)$ and $v_r \in H^{2r(p-1)}(M; \mathbb{Z}/p)$ for $p > 2$, such that
\[
\begin{align*}
\text{Sq}^r(u) &= v_r u, \text{ if } p = 2, \ u \in H^{n-r}(M; \mathbb{Z}/2), \\
\text{Sq}^r(u) &= v_r u, \text{ if } p > 2, \ u \in H^{n-2r(p-1)}(M; \mathbb{Z}/p).
\end{align*}
\]
In [15], Wu expressed the mod $2$ Wu classes as polynomials in Stiefel-Whitney classes of $M$. For $p > 2$, Hirzebruch determined the mod $p$ Wu classes as polynomials in the Pontrjagin classes (Theorem 1, [12]). In particular, his work yields

**Proposition 2.24.** When $p = 3$, we have

$$v_1 = \rho_3(p_1),$$

where $p_1$ is the first Pontrjagin class of $M$.

3. **Proof of Theorem 1.2**

In this section we prove Theorem 1.2. Recall that $M$ is a closed, connected, oriented manifold of dimension $8$ with first Pontrjagin class $p_1 \in H^4(M)$ and that $V$ is the $\mathbb{Z}/3$-vector space $V := TH^2(M)/3TH^2(M)$. For any cohomology class $x \in H^2(M; \mathbb{Z}/3)$, we have the symmetric trilinear function

$$\lambda^V: V \times V \times V \to \mathbb{Z}/3, \quad ([z_1], [z_2], [z_3]) \mapsto (x z_1 z_2 z_3, [M]) = b^3_M(\beta^{2/3}(x), z_1 z_2 z_3).$$

For $3TH^2(M)^\wedge \subseteq TH^2(M)^\wedge$ the subgroup of $3$-torsion elements, we have the isomorphism

$$\iota_3: V^* \to 3TH^2(M)^\wedge, \quad f \mapsto (z \mapsto f(z)).$$

We also recall the following adjoint of the linking pairing of $M$, which is the isomorphism

$$\tilde{b}^3_M: TH^7(M) \to TH^2(M)^\wedge, \quad w \mapsto (z \mapsto b^3_M(w, z)).$$

**Lemma 3.1.** Let $M$ be a closed oriented manifold of dimension $8$ and $x \in H^2(M; \mathbb{Z}/3)$. Then

$$\iota_3(\gamma(\lambda^V_x)) = (\tilde{b}^3_M)l(\beta^{2/3}(x)p_1 - \beta^{2/3}(x^3)).$$

**Proof.** Fix the prime number $3$ and let $\mathcal{P}^r$ be the $r$th Steenrod reduced power operation. For $z \in TH^2(M)$ the Cartan formula gives

$$\mathcal{P}^1(xz) = x^3 z + xz^3.$$

On the other hand, by Proposition 2.24 we have

$$\mathcal{P}^1(xz) = xp_1 z.$$

Therefore, we have

$$xz^3 = xp_1 z - x^3 z. \quad (3.2)$$

Now we have

$$\iota_3(\gamma(\lambda^V_x)([z])) = \iota_3([xz^3, [M]]) = \iota_3(([xp_1 z - x^3 z, [M]])) \quad \text{(using (3.2))}$$

$$= \tilde{b}^3_M(\beta^{2/3}(x)p_1 - \beta^{2/3}(x^3), z)$$

$$= (\tilde{b}^3_M)l(\beta^{2/3}(x)p_1 - \beta^{2/3}(x^3))(z).$$

Since $[z] \in V$ is arbitrary, the required equation holds.

**Lemma 3.3.** Let $M$ be a closed oriented manifold of dimension $8$, and $x \in H^2(M; \mathbb{Z}/3)$. Then there are $z_1, z_2 \in H^2(M)$ such that

$$\beta^{2/3}(x^3) = \beta^{2/3}(x)(p_1 - z_1 z_2).$$
Proof. By Lemma 2.17 we have $z_1, z_2 \in TH^2(M)$ satisfying
$$\gamma(\lambda^x_k) = (\tilde{\lambda}^x_k)_2([z_1], [z_2])$$
and by definition, this means that
$$\iota_3(\gamma(\lambda^x_k)) = (\tilde{\sigma}_M^x)(\beta^{2/3}(x)z_1z_2).$$
Now by Lemma 3.1 we have
$$\iota_3(\gamma(\lambda^x_k)) = (\tilde{\sigma}_M^x)(\beta^{2/3}(x)p_1 - \beta^{2/3}(x^3)).$$
Since $\iota_3: V^* \to 3TH^2(M)$ are isomorphisms, we conclude that
$$\beta^{2/3}(x)z_1z_2 = \beta^{2/3}(x)p_1 - \beta^{2/3}(x^3)$$
and so
$$\beta^{2/3}(x^3) = \beta^{2/3}(x)(p_1 - z_1z_2). \quad \square$$

Before stating Proposition 3.4 we recall the AHSS of the twisted $K$-theory of
a pair $(X, \alpha)$, which we denote by $(\tilde{E}^*_x, \tilde{d}_x^*)$. We denote the untwisted one by
$(E^*_x, d^*_x)$. Then it follows from Bott periodicity theorem that we have
$$E^s_{2.t} = \tilde{E}^s_{2.t} \cong \begin{cases} H^s(X), & \text{if } t \text{ is even,} \\ 0, & \text{if } t \text{ is odd.} \end{cases}$$
In view of the above identification we do not distinguish $H^s(X)$, $E^s_{2.t}$ and $\tilde{E}^s_{2.t}$ for
even $t$. We also recall the cohomology operation $R_n \in H^7(K_n)$ of order $e_3(n)n$.

Proposition 3.4. Let $M$ be a closed oriented 8-manifold, $\alpha \in TH^3(M)$ with
period $n$, $\xi \in H^2(M; \mathbb{Z}/n)$ such that $\beta^{2/n}(\xi) = \alpha$ and $(\tilde{E}^*_x, \tilde{d}_x^*)$ be the AHSS for
the twisted $K$-theory of the pair $(M, \alpha)$. Identifying $H^7(M)$ with $\tilde{E}^7_{2,-6}$, we have
$$nR_n(\xi) \in \mathrm{im}(\tilde{d}^3_3).$$

Proof. If $3 \nmid n$, then we have $nR_n = 0$ and there is nothing to show. Therefore we
assume $n = 3k$.

First we recall some general facts on the Atiyah-Hirzebruch spectral sequences of
both the twisted and untwisted $K$-theories. Then $(\tilde{E}^*_x, \tilde{d}_x^*)$ is a bi-graded module
over $(E^*_x, d^*_x)$. More precisely, suppose $u \in E^s_{2.t}$ and $v \in \tilde{E}^s_{2.t'}$. Then the module
structure yields $uv \in \tilde{E}^{s+t,s+t'}$ and furthermore,
$$\tilde{d}_r(uv) = d_r(u)v + (-1)^{s+t}ud_r(v).$$
It follows from Bott periodicity that $E^s_{2i} = E^s_{2i+1}$ for all $i > 0$. For $u \in E^s_{2i} = E^s_{2i+1}$,
by the discussion in 2.3 of [6], we have $d_3(u) = \mathrm{Sq}^3_2(u)$, where $\mathrm{Sq}^3_2$ be the 3rd integral
Steenrod square operation. On the other hand, by Proposition 2.4 of [2], we have
$$\tilde{d}_3(1) = \alpha.$$ Therefore, for $y \in \tilde{E}^s_{2.t}$, we have
$$\tilde{d}_3(y) = \tilde{d}_3(y \cdot 1)$$
$$= \mathrm{Sq}^3_2(y) + (-1)^{s+t}y\tilde{d}_3(1)$$
$$= \mathrm{Sq}^3_2(y) + (-1)^{s+t}y\alpha.$$

It follows from Lemma 3.3 that we may take $z_1, z_2 \in H^2(M)$ such that
$$\beta^{2/3}(\rho_3(\xi)) = (p_1 - z_1z_2)\beta^{2/3}(\rho_3(\xi)).$$
By Lemma (2.21) we have
\[(3.6) \quad nR_{\eta}(\xi) = \beta^{2\zeta}(\rho_5(\xi)) = (p_1 - z_1z_2)\beta^{2\zeta}(\rho_3(\xi)) = m(p_1 - z_1z_2)\alpha,\]
where the last equation follows from (2.20).

On the other hand, we have \(\text{Sq}_3^3(p_1) = 0\) since by definition \(p_1\) is the Chern class of some vector bundle over \(M\), and \(H^*(BU)\) concentrates in even degrees. Similarly we have \(\text{Sq}_3^3(z_1z_2) = 0\) since \(H^*(K(\mathbb{Z}, 2)^{\times 2})\) concentrates in even degrees. Therefore we have
\[(3.7) \quad \text{Sq}_3^3(p_1 - z_1z_2) = 0.\]

Finally, it follows from (3.6), (3.7) and (3.8) that we have
\[\tilde{d}_3(m(p_1 - z_1z_2)) = nR_{\eta}(\xi),\]
and we conclude. \(\square\)

Proof of Theorem 1.2. We can work in each connected component of \(M\) individually, so we assume that \(M\) is connected. If \(3 \nmid n\), the theorem follows from Theorem 2.1 formally. So we assume \(3\nmid n\).

Let \((\tilde{E}_n^{*,*}, \tilde{d}_n^{*,*})\) be the AHSS of the twisted \(K\)-theory of the pair \((X, \alpha)\), where \(\text{per}(\alpha) = n\). Let \(\xi \in H^2(M; \mathbb{Z}/n)\) such that \(\beta^{2\zeta}(\xi) = \alpha\). By construction we have \(\tilde{E}_2^0, 0 \cong \mathbb{Z}\). For degree reasons there is no nontrivial differential into \(\tilde{E}_r^{0, 0}\) for any \(r \geq 2\). We therefore identify \(\tilde{E}_r^{0, 0} (r \geq 2)\) as subgroups of \(\tilde{E}_2^0, 0 \cong \mathbb{Z}\), as in the setting of Theorem 2.3.

It follows from (2.0) of Theorem 2.5 that we have \(c_2(n)n^2 \in \tilde{E}_7^0, 0\). Furthermore, it follows from Proposition 3.4 that the order of \([R_{\eta}(\xi)]\in \tilde{E}_7^0, 0\) divides \(n\). Therefore, by (2.7) of Theorem 2.5 the order of \(\tilde{d}_7^0(c_2(n)n^2)\) divides \(\frac{n}{2}\) if \(4\nmid n\) and divides \(n\) otherwise. Hence we have
\[
\begin{cases} 
\tilde{E}_8^0, 0 \supseteq 2n^3\tilde{E}_2^0, 0 & \text{if } n \equiv 2 \pmod{4}, \\
\tilde{E}_8^0, 0 \supseteq n^3\tilde{E}_2^0, 0 & \text{otherwise}.
\end{cases}
\]

The theorem then follows from Theorem 2.3. \(\square\)

4. Proof of Theorem 1.3

Recall that the cohomology group \(H^3(K_2)\) is generated by an element \(Q_2\) of order 4. On the other hand, recall that the cohomology ring of \(H^*(K(\mathbb{Z}, 2))\) is isomorphic to the polynomial ring \(\mathbb{Z}[\zeta_2]\) with one generator \(\zeta_2\) of degree 2.

Let “\(\times\)” denote the exterior cup product operation, then we have a class \(2Q_2 \times 1 - \zeta_2 \times \zeta_2 \in H^3(K_2 \times K(\mathbb{Z}, 2))\), which is represented by a homotopy class
\[2Q_2 \times 1 - \zeta_2 \times \zeta_2 : K_2 \times K(\mathbb{Z}, 2) \to K(\mathbb{Z}, 5).\]

Let \(Y\) be the homotopy fiber of the above map and we have the following fiber sequence
\[(4.1) \quad Y \xrightarrow{h} K_2 \times K(\mathbb{Z}, 2) \xrightarrow{2Q_2 \times 1 - \zeta_2 \times \zeta_2} K(\mathbb{Z}, 5).\]

It then follows that
\[h^* : H^3(K_2 \times K(\mathbb{Z}, 2)) \to Y\]
is an isomorphism of abelian groups. We take \(\alpha_Y := h^*(\zeta_2 \times 1)\) a generator of \(H^3(Y)\). Then we have the following
Lemma 4.2. Suppose $X$ is a connected finite CW complex and $\alpha \in H^3(X)$ satisfying $\text{per}(\alpha) = 2$ and $\text{ord}(G_i(\alpha)) = 2$. Then there is a map $f : X \to Y$ satisfying $f^*(G_i(\alpha_Y)) = G_i(\alpha)$, for $i = 0, 1, 2$.

Proof. We take $f$ to be a map representing a cohomology class $\alpha' \in H^2(K_2, \mathbb{Z}/2)$ such that $\beta^2/2(\alpha') = \alpha$. The lemma then follows from (2.9). □

We verify some useful properties of $Y$ in the following

Lemma 4.3. (1) The map $h^* : H^i(K_2 \times K(\mathbb{Z}, 2)) \to H^i(Y)$ is an isomorphism for $0 \leq i \leq 3$. For $i = 4$, we have the following split short exact sequence

$$0 \to H^4(K_2 \times K(\mathbb{Z}, 2)) \xrightarrow{h^*} H^4(Y) \to \mathbb{Z} \to 0.$$  

In particular, the image of $h^*$ contains all torsion elements of $H^4(Y)$.

(2) Let $\zeta_2^4 \in H^2(K_2; \mathbb{Z}/2)$ be the fundamental class, and let $\rho_2 : H^*(--; \mathbb{Z}) \to H^*(-; \mathbb{Z}/2)$ be the $(\text{mod } 2)$ reduction map. Then the class $h^*((\zeta_2^4)^2 \times 1 - \zeta_2' \times \rho_2(\nu_2)) \in H^4(Y; \mathbb{Z}/2)$ has an integral lift $\nu \in H^4(Y)$, i.e., we have $\rho_2(\nu) = h^*((\zeta_2^4)^2 \times 1 - \zeta_2' \times \rho_2(\nu_2)).$

(3) $\text{Sq}_3^3 \cdot \rho_2(\nu) = 0.$

Proof. By definition we have a homotopy fiber sequence

$$K(\mathbb{Z}, 4) \to Y \xrightarrow{h} K_2 \times K(\mathbb{Z}, 2).$$

We denote by $E^{*+}_{\mathbb{Z}}(Y)$ the associated cohomological integral Serre spectral sequence. The statement (1) then follows immediately from $E^{*+}_{\mathbb{Z}}(Y)$.

For the statement (2), notice that by the definition of $Y$ we have

$$h^*\beta^{2/2}((\zeta_2')^2 \times 1 - \zeta_2' \times \rho_2(\nu_2)) = h^*(2Q_2(\zeta_2') \times 1 - \zeta_2' \times \nu_2) = 0,$$

and the statement (2) follows from the long exact sequence of cohomology groups induced from the short exact sequence of coefficients groups

$$0 \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \to \mathbb{Z}/2 \to 0.$$

Statement (3) follows from direct computation

$$\text{Sq}_3^3 \cdot \rho_2(\nu) = \beta^{2/2} \cdot \text{Sq}_2 \cdot h^*((\zeta_2^4)^2 \times 1 - \zeta_2' \times \rho_2(\nu_2)) = \beta^{2/2} \cdot h^*(\zeta_2^4 \times 1 - (\zeta_2')^2 \times \rho_2(\nu_2) - \zeta_2' \times \rho_2(\nu_2)^2) = h^*(2Q_2 \times \nu_2 - \zeta_2 \times \zeta_2^2) = h^*[(2Q_2 \times 1 - \zeta_2 \times \nu_2)(1 \times \nu_2)] = 0.$$

□
Proof of Theorem 1.3. First we recall some general facts on the Atiyah-Hirzebruch spectral sequences of both the twisted and untwisted $K$-theories. Let $(\tilde{E}_s^*, d_s^*)$ be the twisted Atiyah-Hirzebruch spectral sequence for a CW complex $X$ and a class $\alpha \in TH^3(X)$ of period $n$. Then $(\tilde{E}_s^*, d_s^*)$ is a bi-graded module over $(E_s^*, d_s^*)$. More precisely, suppose $u \in \tilde{E}_s^{s,t}$ and $v \in \tilde{E}_t^{s,t'}$. Then the module structure yields $uv \in \tilde{E}_r^{s+t,s+t'}$ and furthermore,

$$
\tilde{d}_r(uv) = d_r(u)v + (-1)^{s+t}ud_r(v).
$$

It follows from the Bott periodicity theorem that $E_{2i+1} = E_{2i+1}$ for all $i > 0$. The Bott periodicity theorem also indicates

$$
\tilde{E}_s^{s,t} \simeq \begin{cases} H^s(X) & t \text{ even}, \\ 0 & t \text{ odd}. \end{cases}
$$

In view of the above, we identify the group $\tilde{E}_s^{s,2t}$ with the corresponding subquotient of $H^s(X)$. For $u \in \tilde{E}_2^{s,*} = E_3^{s,*}$, by the discussion in 2.3 of [9], we have $d_3(u) = Sq_2^3(u)$, where $\frac{1}{2}d_3$ be the 3rd integral Steenrod square operation. On the other hand, by Proposition 2.4 of [2], we have $\tilde{d}_3(1) = \alpha$. Therefore, for $y \in \tilde{E}_2^{s,t}$, we have

$$
\tilde{d}_3(y) = \tilde{d}_3(y \cdot 1) = Sq_3^3(y) + (-1)^{s+t}y\tilde{d}_3(1) = Sq_3^3(y) + (-1)^{s+t}\alpha.
$$

It is considerably harder to obtain a similar formula for $\tilde{d}_5$ since it involves unstable cohomology operations. Nonetheless we may compute $\tilde{d}_5$ for

$$
n \times 2 \in H^2(K_n \times K(\mathbb{Z}, 2)).
$$

Indeed, by [15] we have $\tilde{d}_3(n \times 2) = 0$, and since $K(\mathbb{Z}, 2)$ has trivial cohomology in odd degrees, we have $\tilde{d}_3(1 \times 2) = 0$ and $\tilde{d}_5(1 \times 2) = 0$. Now it follows from (4.4) that we have

$$
\tilde{d}_5(n \times 2) = \tilde{d}_5(n \times 1) + nd_5(1 \times 2) = Q_n \times 2.
$$

By Lemma 4.2 it suffices to verify the proposition in the case $X = Y$ and $\alpha = \alpha_Y := h^*(\zeta_2 \times 1)$.

Let $\xi_Y := h^*(\zeta_2' \times 1)$. It follows from Theorem 2.4 that we have $d_7^0(8) = [R_2(\xi_Y)]$, where $[R_2(\xi_Y)] \in E_7^{0,-6}$ denotes the equivalence class of $R_2(\xi_Y)$. Therefore, it suffices to show $[R_2(\xi_Y)] = 0 \in E_7^{0,-6}$.

By Lemma 4.3 we have a class $\nu \in H^4(Y)$ such that

$$
\rho_2(\nu) = h^*([\zeta_2'^2] \times 1 - [\zeta_2' \times \rho_2(\xi_2)]).
$$
By (2.4), we have
\[ R_2(\xi_Y) = \beta^{2/2}((\xi_Y)^3) \]
\[ = \beta^{2/2}[\xi_Y \rho_2(\nu) + h^*(\langle \xi_2^2 \rangle \times \rho_2(\nu))] \]
\[ = \alpha_Y \nu + h^*(2Q_2 \times \nu) \]
\[ = \alpha_Y \nu + Q_2(\alpha_Y')2h^*(1 \times \nu). \]
Applying (3) Lemma 4.3 to the above, we have
\[ R_2(\xi_Y) = \beta^{2/2}((\xi_Y)^3) \]
\[ = [\alpha_Y \nu + Sq^3_2(\nu)] + Q_2(\alpha_Y')2h^*(1 \times \nu). \]
Applying (4.5) and (4.6) to (4.7), we have
\[ R_2(\xi_Y) = \beta^{2/2}((\xi_Y)^3) \]
\[ = [\alpha_Y \nu + Sq^3_2(\nu)] + Q_2(\alpha_Y')2h^*(1 \times \nu) \]
\[ = \tilde{d}_3(\nu) + 2\tilde{d}_5(2h^*(1 \times \nu)), \]
which proves \( R_2(\alpha_Y') = 0, \) and we are done. \( \square \)

5. Examples

In this section we give examples of closed, connected, orientable 8-manifolds \( M \) with Brauer classes \( \alpha \in \text{TH}^3(M) \) having interesting period vectors, thereby proving Theorem 1.5.

**Proposition 5.1.** There is a closed, connected orientable, non-spin \( c \) 8-manifold \( M \) with Brauer class \( \alpha \in \text{TH}^3(M) \) such that \( \text{per}(\alpha) = (2, 4, 2) \). It follows that \( \text{ind}(\alpha) = \text{per}(\alpha)^4 \) and so \( \alpha \) violates the TPIC.

**Remark 5.2.** We currently do not know of any spin \( c \) counter examples to the TPIC.

**Proof.** We start with \( N \) an orientable but non-spin \( c \) 6-manifold and \( \beta \in \text{TH}^3(N) \) with \( \text{per}(\beta) = (2, 4) \). Such pairs \( (N, \beta) \) exist by By [8, Theorem 1.4(2)]. Set
\[ M_0 := S^2 \times N, \]
let \( \pi_N : M_0 \to N \) and \( \pi_S : S^2 \times N \to S^2 \) be the projections and \( \alpha_0 := \pi_N(\beta) \). We have \( \pi_2(M_0) \cong \pi_2(S^2) \times \pi_2(N) \cong \mathbb{Z} \oplus \pi_2(N) \). By general position, the homotopy class \( (2, 0) \) is represented by an embedding \( \phi : S^2 \to M_0 \), which is unique up to isotopy. Since the stable tangent bundle of \( M_0 \) restricted to \( S^2 \times * \) is trivial, it follows that the normal bundle of \( \phi \) is trivial. Hence there is an embedding
\[ \phi : D^6 \times S^2 \to M_0, \]
which represents \( (2, 0) \in \pi_2(M_0) \) and which is unique up to isotopy since \( \pi_2(SO(6)) = 0 \). We define \( M \) to be the outcome of surgery on \( \phi \). That is, the compact manifold
\[ W_\phi := (M_0 \times I) \cup_\phi (D^6 \times D^3), \]
has boundary \( M_0 \sqcup M \). Below we shall see that there is a canonical isomorphism
\[ \text{TH}^3(M) \cong \mathbb{Z}/2 \oplus \text{TH}^3(M_0). \]
We set \( \alpha := ([1], \alpha_0) \in \text{TH}^3(M) \) and we will show that \( \text{per}(\alpha) = (2, 4, 2) \) and that \( M \) is not spin \( c \).
The bordism $W$ has homotopy type given by

$$W \simeq M_0 \cup_\partial D^3 \simeq M \cup D^6.$$  

For $u \in H^2(M_0)$ the pull back of a generator of $H^2(S^2)$ along $\pi_{S^2}$, the Kunneth Theorem gives

$$H^i(M_0) = H^i(N) \oplus uH^{i-2}(N),$$

where we have dropped $\pi^*_N$ from the notation, identifying $H^*(N)$ with its image under $\pi^*_N$. If $i_0: M_0 \to W$ is the inclusion then an elementary calculation using the homotopy equivalence $W \simeq M_0 \cup_\partial D^3$ gives

$$(5.3) \quad i_0^*: H^*(W) \to H^*(M_0)$$

$\begin{cases}
\text{is a split injection onto } H^2(N) \subset H^2(M_0) & * = 2, \\
\text{is a split surjection with kernel } \mathbb{Z}/2 & * = 3, \\
\text{is an isomorphism} & * \neq 2, 3
\end{cases}$$

and

$$(5.4) \quad i_0^*: H^*(W; \mathbb{Z}/2) \to H^*(M_0; \mathbb{Z}/2)$$

$\begin{cases}
\text{is a split surjection with kernel } \mathbb{Z}/2 & * = 3, \\
\text{is an isomorphism} & * \neq 3.
\end{cases}$$

On the other hand, we have the homotopy equivalence $W \simeq M \cup D^6$, where rationally $H^0(W; \mathbb{Q}) \cong H^6(M; \mathbb{Q}) \oplus \mathbb{Q}$. It follows that for the inclusion $i: M \to W$ we have

$$(5.5) \quad i^*: H^*(W) \to H^*(M)$$

$\begin{cases}
\text{is a split surjection with kernel } \mathbb{Z} & * = 6, \\
\text{is an isomorphism} & * \neq 6.
\end{cases}$$

In particular, for $j \neq 2, 3$, we have the zig-zag of homomorphisms

$$H^j(M_0) \xleftarrow{i_0^*} H^j(W) \xrightarrow{i^*} H^j(M)$$

and for $j \neq 2, 3$ we define

$$\psi^j := i^* \circ (i_0^*)^{-1}: H^j(M_0) \to H^j(M),$$

which is an isomorphism if in addition $j \neq 6$.

Now $\alpha_0 = \beta^{\mathbb{Z}/2}(\xi_0)$ for some $\xi_0 \in H^2(N; \mathbb{Z}/2)$ and set

$$\xi_0 := (\rho_2(u), \xi_0) \in H^2(M_0; \mathbb{Z}/2) = \mathbb{Z}/2(\rho_2(u)) \oplus H^2(N; \mathbb{Z}/2),$$

where $\rho_2$ denotes reduction mod 2. By (5.3), there is a unique class $\xi_W \in H^2(W; \mathbb{Z}/2)$ such that $i_0^*(\xi_W) = \xi_0$ and we set $\alpha_W := \beta^{\mathbb{Z}/2}(\xi_W)$ and $\xi := i^*(\xi_W)$. Then it is easy check that under the isomorphisms

$$TH^3(M) \cong TH^3(W) \cong \mathbb{Z}/2 \oplus TH^3(M_0),$$

the element $\alpha = ([1], \alpha_0)$ satisfies $\alpha = \beta^{\mathbb{Z}/2}(\xi) \in TH^3(M)$. Of course, $\alpha_0 = i_0^*(\alpha_W)$ and $\alpha = i^*(\alpha_W)$.

It remains to compute $\text{ord}(G_1(\alpha))$ and $\text{ord}(G_2(\alpha))$. For $G_1(\alpha)$ we use the formula (2.10), which gives $G_1(\alpha) = \beta^{\mathbb{Z}/2}(\rho_2(\xi^2))$. Since $i^*: H^j(W) \to H^j(M)$ is an isomorphism for $j = 2, 5$, it follows that

$$\text{ord}(G_1(\alpha)) = \text{ord}(G_1(\alpha_W)).$$

Now can compute $G_1(\alpha_W)$ by restricting to $M_0$. Specifically,

$$i_0^*(G_1(\alpha_W)) = G_1(i_0^*(\alpha_W)) = [\beta^{\mathbb{Z}/2}(\rho_2(u) + \xi_0^2)] = [\beta^{\mathbb{Z}/2}(\xi_0^2)].$$
Since $H^2(M_0) \alpha \cap H^5(N) = H^4(N) \beta$, it follows that
$$\text{ord}(G_1(\alpha_W)) = \text{ord}(G_1(\alpha)) = \text{ord}(G_1(\beta)) = 4$$
and so $\text{ord}(G_1(\alpha)) = 4$.

To compute $G_2(\alpha)$ we need to compute $R_2(\xi)$. Now $R_2(\xi) = \psi^7(R_2(\xi_0))$ and

$$R_2(\xi_0) = \beta^2/\beta((\rho_2(u) + \xi_0')^3) = \beta^2/\beta(\rho_2(u)^3 + 3\rho_2(u)\xi_0' + 3\rho_2(u)(\xi_0')^2 + (\xi_0')^3) = \beta^2/\beta(\rho_2(u)(\xi_0')^2) = u\beta^2/\beta((\xi_0')^2) \neq 0.$$

Since $\psi^7$ is an isomorphism, $R_2(\xi) \neq 0$ and it remains to show that $R_2(\xi)$ does not lie in the indeterminacy of $G_2$, which for a space $X$ is the group

$$(5.7) \quad I_2(X) = (\text{Sq}_3^3 + \cup \alpha)H^4(X) + \text{Im} \delta_5^{-2}(H^2(X)) \subset H^7(X).$$

We note that $I_2(M) \subset \psi^3(\text{I}_2(M_0))$ and we can use naturality to compute $I_2(M)$ using $I_2(M_0)$. We have that

$$H^7(M_0) = H^7(N) \oplus uH^5(N) = uH^5(N)$$

and $H^4(M_0) = H^4(N) \oplus uH^2(N)$. Now $\text{Sq}_3^3(H^4(N)) = 0$ and $\text{Sq}_3^3(uH^2(N)) = 0$, since $\text{Sq}_3^3$ vanishes on any product of two degree two classes. Therefore we conclude

$$\text{Sq}_3^3(H^4(M_0)) = 0.$$ 

Now $[\beta^{2/2}((\xi_0')^2)] \neq 0 \in H^5(N)/\beta H^2(N)$ and by (5.8)

$$R_2(\xi_0) = u\beta^2/\beta((\xi_0')^2).$$

However, since $\alpha_0 = \pi_\alpha(\beta) \in H^3(M_0)$,

$$\alpha_0H^4(M) = \alpha_0(H^4(N) \oplus uH^2(N)) = u\beta H^2(N)$$

and so

$$R_2(\xi_0) \notin \alpha_0H^4(M_0).$$

This and (5.8) show that $R_2(\xi_0)$ does not lie in $(\text{Sq}_3^3 + \cup \alpha)(H^4(M_0))$ and hence $R_2(\xi_W)$ does not lie in $(\text{Sq}_3^3 + \cup \alpha_W)(H^4(W))$.

Now $i_5^*: H^2(W) \rightarrow H^2(M_0)$ is an isomorphism with $i_5^*(H^2(W)) = H^2(N)$ and $G_2(H^2(N)) = 0$ since $H^7(N) = 0$. By naturality, it follows that $\delta_5^{-2}(W) = 0$. Comparing the above to (5.7), it follows that $R_2(\xi_W)$ does not lie in $I_2(W)$ and so $R_2(\xi)$ does not lie in $I_2(M)$.

We must finally show that $M$ is not spin$^c$. Recall that a manifold $X$ is not spin$^c$ if and only if $W_3(X) \neq 0 \in H^3(X)$. By construction $M_0$ is not spin$^c$ and so $W_3(M_0) \neq 0$. Since $W_3$ is a stable characteristic class, $W_3(M_0) = i_5^*(W_3(W))$ and so $W_3(W) \neq 0$. Now $W_3(M) = i^*(W_3(W))$ and by (5.8), $i^*: H^3(W) \rightarrow H^3(M)$ is an isomorphism. Hence $W_3(M) \neq 0$ and $M$ is not spin$^c$.

**Proposition 5.9.** There is a closed, connected parallelisable (hence almost complex) 8-manifold $M$ with Brauer class $\alpha \in TH^3(M)$ such that $\text{per}(\alpha) = (2, 4, 1)$.

**Proof.** Choose a finite 5-skeleton $K \subset K_2$ for $K_2$. By a theorem of Wall [14] Embedding Theorem, there is a thickening of $K$ (i.e. a homotopy equivalence $\phi: K \rightarrow W$, where $W$ is compact smooth manifold with simply-connected boundary) such that $W \subset S^9$ is a co-dimension zero submanifold of the 9-sphere. We let $M_0 := \partial W$ be the boundary of $W$ and $C \subset S^9$ be the complement of the interior of $W$, so that $S^9 = W \cup M_0 C$. 

By Alexander duality, $C$ is 2-connected. The Mayer-Vietoris sequence for the decomposition $S^9 = W \cup_M C$ gives that the sum of the maps induced by the inclusions $i_W : M \to W$ and $i_C : M_0 \to C$

$$i_W \circ i_C : H_i(M_0) \to H_i(W) \oplus H_i(C)$$

is an isomorphism for $i = 1, \ldots, 7$. Applying the Universal Coefficient Theorem we deduce that we have isomorphisms

$$TH^3(M_0) \overset{i_W^*}{\to} TH^3(W) \cong TH^3(K) = TH^3(K_2) = \mathbb{Z}/2$$

and

$$H^2(M_0) \cong H^2(W) \cong H^2(K) = 0.$$  

We also deduce that $i_W^* : TH^5(M_0) \to TH^5(W) \cong TH_4(K) = TH_4(K_2) \cong \mathbb{Z}/4$ is a split surjection.

Let $\alpha_0 \in TH^3(M_0)$ be the generator. The above shows that $G_1(\alpha_0)$ generates a $\mathbb{Z}/4$-summand of $TH^5(M_0)/\alpha H^2(M_0) = TH^5(M_0)$. Since $\alpha_0$ pulls back from $W \cong K$ and $K$ is 5-dimensional, the higher periods of $\alpha_0$ are 1 by naturality and so $\text{per}(\alpha_0) = (2, 4, 1)$.

Since $M_0$ is a hyper-surface in $S^9$, $M_0$ is stably parallelisable. It follows that the tangent bundle of $M_0$ pulls back along the degree one collapse map $c : M_0 \to S^8$ and that there is a vector bundle isomorphism

$$TM_0 \cong c^*(k\tau_{S^8}),$$

where we regard $\tau_{S^8}$ as an element of $\pi_7(SO(8))$ and $k$ is some integer determined by the equation

$$\chi(M_0) = 2k.$$  

It follows that we may take the connected sum of $M_0$ and copies of either $S^4 \times S^4$ or $S^3 \times S^5$, to achieve a parallelisable manifold $M$ with $TH^3(M_0)$ identified with $TH^3(M)$. Moreover, if we take $\alpha \in TH^3(M)$ corresponding to $\alpha_0 \in TH^3(M_0)$ under this identification, then it is clear that $\text{per}(\alpha) = \text{per}(\alpha_0)$. This finishes the proof.
