A RIEMANN–HILBERT APPROACH TO THE MODIFIED CAMASSA–HOLM EQUATION WITH NONZERO BOUNDARY CONDITIONS

ANNA BOUTET DE MONVEL¹, DMITRY SHEPELSKY², AND IRYNA KARPENKO³

ABSTRACT. The paper aims at developing the Riemann–Hilbert problem approach to the modified Camassa–Holm (mCH) equation in the case when the solution is assumed to approach a non-zero constant at the both infinities of the space variable. In this case, the spectral problem for the associated Lax pair equation has a continuous spectrum, which allows formulating the inverse spectral problem as a Riemann–Hilbert factorization problem with jump conditions across the real axis. We obtain a representation for the solution of the Cauchy problem for the mCH equation and also a description of certain soliton-type solutions, both regular and non-regular.

1. Introduction

The Camassa–Holm (CH) equation [8, 9]

\[ u_t - uu_x + 3uu_{xx} - 2u_x u_{xx} - uu_{xxx} = 0, \]

which can also be written in terms of the momentum variable

\[ m_t + (um)_x = 0, \quad m := u - u_{xx}, \]

has been studied intensively over the last 25 years, due to its rich mathematical structure. It is a model for the unidirectional propagation of shallow water waves over a flat bottom [15, 26], is bi-Hamiltonian [8], and is completely integrable with algebro-geometric solutions [31]. The local and global well-posedness of the Cauchy problem for the CH equation have been studied extensively [12, 13, 18]. In particular, it has both globally strong solutions and blow-up solutions at finite time [10, 12–14], and also it has globally weak solutions in \( H^1(\mathbb{R}) \) [7, 16, 33].

The soliton-type solutions of the CH equation vanishing at infinity [9] are weak solutions, having the form of peaked waves \( u(x, t) \) and \( u_x(x, t) \) are bounded but \( u_x(x, t) \) is discontinuous), which are orbitally stable [17].

Key words and phrases. Riemann–Hilbert problem, Camassa–Holm equation.
On the other hand, adding to (1.1) a linear dispersion term $bu_x$ with $b > 0$ leads to a form of the CH equation
\[ u_t - u_{xxx} + bu_x + 3u_x - 2u_uxx - uu_xxx = 0, \] (1.3)
which supports conventional smooth solitons [2, 3, 11].

Over the last few years various modifications and generalizations of the CH equation have been introduced, see, e.g., [34] and references therein. Novikov [29] applied the perturbative symmetry approach in order to classify integrable equations of the form
\[ (1 - \partial^2_x) u_t = F(u, u_x, u_xx, u_xxx, \ldots), \quad u = u(x, t), \quad \partial_x = \partial/\partial x, \]
assuming that $F$ is a homogeneous differential polynomial over $\mathbb{C}$, quadratic or cubic in $u$ and its $x$-derivatives (see also [28]). In the list of equations presented in [29], equation (32), which was the second equation with cubic nonlinearity, had the form
\[ m_t + (u^2 - u_x^2)m_x = 0, \quad m := u - u_x. \] (1.4)
In an equivalent form, this equation was given by Fokas in [20] (see also [30] and [21]) and has attracted considerable interest since it was re-derived by Qiao [32]. So it is sometimes referred to as the Fokas–Olver–Rosenau–Qiao equation [24], but is also known as the modified Camassa–Holm (mCH) equation. Equation (1.4) has a bi-Hamiltonian structure [23, 30] and possesses a Lax pair [32]. Its algebro-geometric quasiperiodic solutions are studied in [24]. The local well-posedness for classical solutions and global weak solutions to (1.4) in Lagrangian coordinates are discussed in [22]. It also has solitary wave solutions [23]
\[ u(x, t) = \frac{p}{2} e^{-|x-x(t)|}, \quad m(x, t) = p\delta(x - x(t)) \quad \text{with} \quad x(t) = \frac{1}{6}p^2 t. \]

Notice that considering the initial value problem for the Camassa–Holm equation with a linear dispersion term (1.3) and with initial data decaying to 0 as $x \to \pm \infty$ is equivalent to considering the CH equation in the form (1.1) on a nonzero background, i.e., with initial data approaching a nonzero constant as $x \to \pm \infty$. A similar situation takes place, for example, for the Degasperis–Procesi equation
\[ m_t + (um)_x + 2uxm = 0, \quad m := u - u_x, \] (1.5)
which is also an integrable, CH-type equation with quadratic nonlinearity. On the other hand, for other CH-type equations, in particular, for those with cubic nonlinearity, the situation is different: while considering the equation on a nonzero background again leads to problems supporting smooth solitons, changing variables (leading to zero background) results in an equation having different form, which is not equivalent to adding just a linear dispersion term; see, e.g., the case of the Novikov equation [6].

In the present paper, we consider the initial value problem for the mCH equation (1.4):
\[ \begin{align*}
  m_t + (u^2 - u_x^2)m_x &= 0, \quad m := u - u_x, \quad t > 0, \quad -\infty < x < +\infty, \\
  u(x, 0) &= u_0(x), \quad -\infty < x < +\infty,
\end{align*} \] (1.6a)
\[ \begin{align*}
  u(x, 0) &= u_0(x), \quad -\infty < x < +\infty.
\end{align*} \] (1.6b)
assuming that $u_0(x) \to 1$ as $x \to \pm \infty$, and we search for a solution that preserves this behavior: $u(x, t) \to 1$ as $x \to \pm \infty$ for all $t > 0$. Then, in analogy with the CH equation and other CH-type equations, one can expect that the Cauchy problem (1.6) supports smooth soliton solutions.

Introducing a new function $\tilde{u}$ by
\[ u(x, t) = \tilde{u}(x - t, t) + 1, \] (1.7)
the mCH equation reduces to
\[\ddot{m}_t + (\ddot{\omega} \dot{m})_x = 0,\]  
\[\dot{m} := \ddot{u} - \dddot{u}_{xx} + 1,\]  
\[\ddot{\omega} := \ddot{u}^2 - \ddot{u}_{xx}^2 + 2\dddot{u}.\] (1.8a) (1.8b) (1.8c)

In what follows we will study equation (1.8) on zero background: \(\ddot{u} \to 0\) as \(x \to \pm \infty\). More precisely, we develop the Riemann–Hilbert (RH) problem approach to equation (1.8a) on zero background, aiming at obtaining a representation of the solution of the Cauchy problem for (1.8) in terms of the solution of an associated RH problem formulated in the complex plane of a spectral parameter.

The paper is organized as follows. In Section 2 we introduce the Jost solutions of the Lax pair equations written in a form appropriate for controlling their analytical properties as function of the spectral parameter. In Section 3 we formulate the Riemann–Hilbert problem in two settings: (i) in the original setting, it (implicitly) depends on the physical variables \((x, t)\) as parameters and (ii) in a transformed setting, introducing new variables \((y, t)\) in terms of which the RH problem has an explicit parameter dependence. The data for the later RH problem are uniquely determined by the initial data for the mCH equation, which gives rise to a procedure for solving the Cauchy problem (1.6). In Section 4 we show that starting with the solution of a RH problem with appropriate dependence on the parameters, we always arrive at a solution to the mCH equation, even if the data for this RH problem are not associated with some particular initial data for the mCH equation. Finally, in Section 5, using the RH problem formalism, we construct smooth as well as non-smooth soliton solutions to the mCH equation. Throughout the text, we emphasize the differences in the implementation of the RH approach to the CH and mCH equations.

Notations. Furthermore, \(\sigma_1 := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\), \(\sigma_2 := \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}\), and \(\sigma_3 := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\) denote the standard Pauli matrices. We also let \(f^*(k) := f(\overline{k})\) denote the Schwarz conjugate of a function \(f(k)\), \(k \in \mathbb{C}\).

2. LAX PAIRS AND EIGENFUNCTIONS

2.1. Lax pairs. In order to deduce the Lax pair for equation (1.8a), we take as starting point the Lax pair for the mCH equation (1.4) [32]
\[\Phi_x = U \Phi, \quad \Phi_t = V \Phi\]
where \(\Phi \equiv \Phi(x, t, \lambda)\), \(U \equiv U(x, t, \lambda)\), and \(V \equiv V(x, t, \lambda)\), the coefficients \(U\) and \(V\) being defined by
\[U = \frac{1}{2} \begin{pmatrix} -1 & \lambda m \\ -\lambda m & 1 \end{pmatrix},\]
\[V = \begin{pmatrix} \lambda^{-2} + \frac{u^2 - u_{xx}^2}{2} & -\lambda^{-1}(u - u_{xx}) - \frac{\lambda(u^2 - u_{xx}^2)m}{2} \\ \lambda^{-1}(u + u_{xx}) + \frac{\lambda(u^2 - u_{xx}^2)m}{2} & -\lambda^{-2} - \frac{\lambda(u^2 - u_{xx}^2)^2}{2} \end{pmatrix},\]
with \(m := u - u_{xx}\). This leads us to the pair of equations
\[\Phi_x = U \Phi,\]  
\[\Phi_t = V \Phi,\] (2.1a) (2.1b)
where the coefficients $U \equiv U(x,t,\lambda)$ and $V \equiv V(x,t,\lambda)$ are now defined by
\begin{equation}
U = \frac{1}{2} \begin{pmatrix}
-1 & \lambda \tilde{m} \\
-\lambda \tilde{m} & 1
\end{pmatrix},
\end{equation}
\begin{equation}
V = \begin{pmatrix}
\lambda^{-2} + \frac{\tilde{\omega}}{2} & -\lambda^{-1}(\tilde{u} - \tilde{u}_x + 1) - \frac{\lambda \tilde{m}}{2} \\
-\lambda^{-2} - \frac{\tilde{\omega}}{2} & -\lambda^{-1}(\tilde{u} + \tilde{u}_x + 1) + \frac{\lambda \tilde{m}}{2}
\end{pmatrix}.
\end{equation}

Here, $\tilde{m} := \tilde{u} - \tilde{u}_x + 1$ and $\tilde{\omega} := \tilde{u}^2 - \tilde{u}_x^2 + 2\tilde{u}$ as in (1.8b) and (1.8c), with $\tilde{u}$ as in (1.7). It can be directly verified that (1.8a) is the compatibility condition for the system (2.1)-(2.2). Thus, this system (2.1)-(2.2) constitutes a Lax pair for (1.8a).

The RH formalism for integrable nonlinear equations is based on using appropriately defined eigenfunctions, i.e., solutions of the Lax pair, whose behavior as functions of the spectral parameter is well-controlled in the extended complex plane. Notice that the coefficient matrices $U$ and $V$ are traceless, which provides that the determinant of a matrix solution to (2.1) (composed from two vector solutions) is independent of $x$ and $t$.

Also notice that $U$ and $V$ have singularities (in the extended complex $\lambda$-plane) at $\lambda = 0$ and $\lambda = \infty$. In order to control the behavior of solutions to (2.1) as functions of the spectral parameter $\lambda$ (which is crucial for the Riemann–Hilbert method), we follow a strategy similar to that adopted for the CH equation [2,3].

Namely, in order to control the large $\lambda$ behavior of solutions of (2.1), we will transform this Lax pair into an appropriate form (see [1–3]).

**Proposition 2.1.** Equation (1.8a) admits a Lax pair of the form
\begin{align}
\hat{\Phi}_x + Q_\lambda \hat{\Phi} &= \hat{U} \hat{\Phi}, \\
\hat{\Phi}_t + Q_\lambda \hat{\Phi} &= \hat{V} \hat{\Phi},
\end{align}
whose coefficients $Q \equiv Q(x,t,\lambda)$, $\hat{U} \equiv \hat{U}(x,t,\lambda)$, and $\hat{V} \equiv \hat{V}(x,t,\lambda)$ are $2 \times 2$ matrices having the following properties:

(i) $Q$ is diagonal and is unbounded as $\lambda \to \infty$.
(ii) $\hat{U} = O(1)$ and $\hat{V} = O(1)$ as $\lambda \to \infty$.
(iii) The diagonal parts of $\hat{U}$ and $\hat{V}$ decay as $\lambda \to \infty$.
(iv) $\hat{U} \to 0$ and $\hat{V} \to 0$ as $x \to \pm \infty$.

**Proof.** We first note that $U$ in (2.2a) can be written as
\begin{equation}
U(x,t,\lambda) = \frac{\tilde{m}(x,t)}{2} \begin{pmatrix}
-1 & \lambda \\
-\lambda & 1
\end{pmatrix} + \frac{\tilde{m}(x,t) - 1}{2} \begin{pmatrix}
1 & 0 \\
0 & -1
\end{pmatrix},
\end{equation}
where $\tilde{m}(x,t) - 1 \to 0$ as $x \to \pm \infty$. The first (non-decaying, as $x \to \pm \infty$) term in (2.4) can be diagonalized by introducing
\begin{equation}
\hat{\Phi}(x,t,\lambda) := D(\lambda)\Phi(x,t,\lambda),
\end{equation}
where
\begin{equation}
D(\lambda) := \begin{pmatrix}
1 & -\lambda \\
\frac{\lambda}{1+i\sqrt{1-\lambda^2}} & 1
\end{pmatrix},
\end{equation}
where the square root is chosen so that $\sqrt{1-\lambda^2} \sim i\lambda$ as $\lambda \to \infty$. This transforms (2.1a) into
\begin{equation}
\hat{\Phi}_x + \frac{\tilde{m}(x,t)}{2\sqrt{1-\lambda^2}} \sigma_3 \hat{\Phi} = \hat{U} \hat{\Phi},
\end{equation}
where $\hat{U} \equiv \hat{U}(x,t,\lambda)$ is given by
\begin{equation}
\hat{U} = \frac{\lambda(\tilde{m} - 1)}{2\sqrt{1-\lambda^2}} \begin{pmatrix}
0 & 1 \\
-1 & 0
\end{pmatrix} + \frac{\tilde{m} - 1}{2\sqrt{1-\lambda^2}} \sigma_3.
\end{equation}
Similarly, the \( t \)-equation (2.1b) of the Lax pair is transformed into

\[
\dot{\Phi}_t + \sqrt{1 - \lambda^2} \left( -\frac{1}{2} \tilde{m} \tilde{\omega} - \frac{1}{\lambda^2} \right) \sigma_3 \dot{\Phi} = \dot{V} \Phi,
\]

where \( \dot{V} \equiv \dot{V}(x, t, \lambda) \) is given by

\[
\dot{V} = \frac{1}{2\sqrt{1 - \lambda^2}} \left( \lambda \tilde{\omega}(\tilde{m} - 1) + \frac{2\tilde{u}}{\lambda} \right) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} + \frac{\tilde{u}_x}{\lambda} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.
\]

Now notice that equations (2.5a) and (2.5c) have the desired form (2.3), if we define \( Q \) by

\[
Q(x, t, \lambda) := p(x, t, \lambda) \sigma_3,
\]

with

\[
p(x, t, \lambda) := -\frac{1}{2} \sqrt{1 - \lambda^2} \int_x^{+\infty} (\tilde{m}(\xi, t) - 1) d\xi + \sqrt{1 - \lambda^2} - \frac{1}{2} \sqrt{1 - \lambda^2} t.
\]

Indeed, \( p \) has derivatives

\[
p_x = \frac{\tilde{m} \sqrt{1 - \lambda^2}}{2},
\]

\[
p_t = \sqrt{1 - \lambda^2} \left( -\frac{1}{2} \tilde{m} \tilde{\omega} - \frac{1}{\lambda^2} \right).
\]

The first formula is clear, while the second follows from (1.8a).

**2.2. Eigenfunctions.** The Lax pair in the form (2.5) allows us to determine dedicated solutions having a well-controlled behavior as functions of the spectral parameter \( \lambda \) for large values of \( \lambda \) via associated integral equations. Indeed, introducing

\[
\tilde{\Phi} = \Phi e^Q
\]

(understanding \( \tilde{\Phi} \) as a \( 2 \times 2 \) matrix), equations (2.5a) and (2.5c) can be rewritten as

\[
\begin{align*}
\dot{\Phi}_x + [Q_x, \Phi] &= \dot{U} \Phi, \\
\dot{\Phi}_t + [Q_t, \tilde{\Phi}] &= \dot{V} \Phi,
\end{align*}
\]

where \([ \cdot, \cdot ]\) stands for the commutator. We now determine particular (Jost) solutions \( \tilde{\Phi}_\pm \equiv \tilde{\Phi}_\pm(x, t, \lambda) \) of (2.8) as solutions of the associated Volterra integral equations:

\[
\tilde{\Phi}_\pm(x, t, \lambda) = I + \int_{\pm\infty}^x e^{\int_{\xi}^{\pm\infty} [Q, \Phi(t, \lambda)] d\eta} \tilde{U}(\xi, t, \lambda) \tilde{\Phi}_\pm(\xi, t, \lambda) e^{-\int_{\xi}^{\pm\infty} [Q, \Phi(t, \lambda)] d\eta} d\xi,
\]

that is, taking into account the definition (2.6) of \( Q \),

\[
\begin{align*}
\tilde{\Phi}_+(x, t, \lambda) &= I - \int_x^{+\infty} e^{\sqrt{1 - \lambda^2} \int_{\eta}^{+\infty} \tilde{m}(\eta, t) d\eta} \tilde{U}(\xi, t, \lambda) \tilde{\Phi}_+(\xi, t, \lambda) e^{-\sqrt{1 - \lambda^2} \int_{\eta}^{+\infty} \tilde{m}(\eta, t) d\eta} d\xi, \\
\tilde{\Phi}_-(x, t, \lambda) &= I + \int_{-\infty}^x e^{\sqrt{1 - \lambda^2} \int_{\eta}^{x} \tilde{m}(\eta, t) d\eta} \tilde{U}(\xi, t, \lambda) \tilde{\Phi}_-(\xi, t, \lambda) e^{-\sqrt{1 - \lambda^2} \int_{\eta}^{x} \tilde{m}(\eta, t) d\eta} d\xi
\end{align*}
\]

(\( I \) is the identity matrix). Hereafter, let \( \tilde{\Phi}_\pm := \tilde{\Phi}_\pm e^{-Q} \) denote the corresponding Jost solutions of (2.5).

Introducing a new spectral parameter \( k \) by

\[
\lambda^2 = 4k^2 + 1,
\]
the exponentials in (2.10) become $e^{\pm ikf^*_e} \tilde{m}(\xi,t) d\xi \sigma_3$. Moreover, introducing the new space variable
\[ y(x,t) := x - \int_{-\infty}^{+\infty} (\tilde{m}(\xi,t) - 1) d\xi, \tag{2.11} \]

$Q$ takes (by a slight abuse of notations) the form $Q(y,t,\mu) = -ik \left(y - \frac{2y}{\mu^2 + 1}\right) \sigma_3$, which coincides with that in the case of the Camassa–Holm equation [2,3].

**Remark 2.2.** Recall that the pair of renowned integrable equations — the Korteweg–de Vries (KdV) equation and the modified Korteweg–de Vries (mKdV) equation — shares the same $Q$, which, in those cases, has the form $Q(x,t,\mu) = (ikx + 4ik^2t)\sigma_3$. Therefore, the above consideration gives an additional reason to naming equation (1.4) as the *modified* Camassa–Holm (mCH) equation.

However, an important difference between the Lax pairs for the CH equation and the mCH equation is that in the latter case, the dependence of the associated coefficient matrix $\hat{U}(x,t,\mu)$ (by a slight abuse of notations we keep the same notation $\hat{U}$) on the spectral parameter $\mu$ is not rational (because of $\lambda(\mu)$):
\[ \hat{U}(x,t,\mu) = \tilde{m} - \frac{1}{2} \left( \frac{1}{2ik} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} + \frac{\lambda(\mu)}{2ik} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \right), \]

which would complicate the construction of the RH problem, requiring either the introduction of a branch cut in the $k$ plane or the formulation of the RH problem on the Riemann sphere associated with $\lambda^2 = 4k^2 + 1$.

In order to avoid these complications, we introduce a new (uniformizing) spectral parameter $\mu$ such that both $\lambda$ and $\mu$ are rational w.r.t. $\mu$:
\[ \lambda = -\frac{1}{2} \left( \mu + \frac{1}{\mu} \right), \quad \mu = \frac{1}{4} \left( \mu - \frac{1}{\mu} \right). \tag{2.12} \]

More precisely, we define $\mu = -\lambda - i\sqrt{1 - \lambda^2}$, so that $k = -\frac{i}{2} \sqrt{1 - \lambda^2}$ and $\sqrt{1 - \lambda^2} = \frac{i}{2} \mu^2 - 1 = 2ik$. In terms of $\mu$ we have
\[ p(x,t,\mu) = \frac{-i(\mu^2 - 1)}{4\mu} \left( \int_{-\infty}^{+\infty} (\tilde{m}(\xi,t) - 1) d\xi - x + \frac{8\mu^2}{(\mu^2 + 1)^2} \right), \tag{2.13} \]
\[ \hat{U}(x,t,\mu) = \frac{i(\mu^2 + 1)(\tilde{m} - 1)}{2(\mu^2 - 1)} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} - \frac{i\mu(\tilde{m} - 1)}{\mu^2 - 1} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{2.14} \]

and, accordingly, equations (2.10) become
\[ \tilde{\Phi}_\pm(x,t,\mu) = I + \int_{-\infty}^{\infty} e^{\frac{i\mu^2 - 1}{4\mu} f^*_e} \tilde{m}(\eta,t) d\eta \sigma_2 \hat{U}(\xi,t,\mu) e^{-\frac{i\mu^2 - 1}{4\mu} f^*_e} \tilde{m}(\eta,t) d\eta \sigma_2 d\xi. \tag{2.15} \]

We are now able, by analogy with the case of the CH equation [2,3], to analyze the analytic and asymptotic properties of the solutions $\tilde{\Phi}_\pm$ of (2.15) as functions of $\mu$, using Neumann series expansions. Let $A^{(1)}$ and $A^{(2)}$ denote the columns of a $2 \times 2$ matrix $A = (A^{(1)} \ A^{(2)})$. Using these notations we have the following properties:

- $\tilde{\Phi}_-(^{(1)})$ and $\tilde{\Phi}_+^{(2)}$ are analytic in $\mathbb{C}^+ = \{ \mu \in \mathbb{C} \mid \text{Im} \mu > 0 \}$;
- $\tilde{\Phi}_+(^{(1)})$ and $\tilde{\Phi}_-^{(2)}$ are analytic in $\mathbb{C}^- = \{ \mu \in \mathbb{C} \mid \text{Im} \mu < 0 \}$;
- $\tilde{\Phi}_-(^{(1)}), \tilde{\Phi}_+^{(2)}, \tilde{\Phi}_+^{(1)}$, and $\tilde{\Phi}_+^{(2)}$ are continuous up to the real line except at $\mu = \pm 1$. 
Further, we first observe that \( \tilde{U}(\mu) \equiv \tilde{U}(x,t,\mu) \), \( \tilde{V}(\mu) \equiv \tilde{V}(x,t,\mu) \) satisfy the same symmetries:

\[
\begin{align*}
\tilde{U}(\mu) &= \sigma_1 \tilde{U}(\mu) \sigma_1, & \tilde{U}(-\mu) &= \sigma_2 \tilde{U}(\mu) \sigma_2, & \tilde{U}(\mu^{-1}) &= \sigma_1 \tilde{U}(\mu) \sigma_1, \\
\tilde{V}(\mu) &= \sigma_1 \tilde{V}(\mu) \sigma_1, & \tilde{V}(-\mu) &= \sigma_2 \tilde{V}(\mu) \sigma_2, & \tilde{V}(\mu^{-1}) &= \sigma_1 \tilde{V}(\mu) \sigma_1,
\end{align*}
\]  
(2.16a)
\[
(2.16b)
\]

with \( \mu \neq \pm 1 \), and also \( \mu \neq 0 \) for the symmetry \( \mu \mapsto \mu^{-1} \). Moreover, \( p(\mu) \equiv p(x,t,\mu) \) satisfies the following symmetries:

\[
p^*(\mu) = -p(\mu) = p(-\mu) = p(\mu^{-1}).
\]  
(2.17)

It follows that

- \( \tilde{\Phi}_\pm \) also satisfy the same symmetries as in (2.16a):

\[
\tilde{\Phi}_\pm(\mu) = \sigma_1 \tilde{\Phi}_\pm(\mu) \sigma_1, & \quad \tilde{\Phi}_\pm(-\mu) = \sigma_2 \tilde{\Phi}_\pm(\mu) \sigma_2, & \quad \tilde{\Phi}_\pm(\mu^{-1}) = \sigma_1 \tilde{\Phi}_\pm(\mu) \sigma_1.
\]  
(2.18)

That means \( \tilde{\Phi}_\pm^{(1)}(\mu) = \sigma_1 \tilde{\Phi}_\pm^{(2)}(\mu) = \sigma_3 \tilde{\Phi}_\pm^{(2)}(-\mu) = \sigma_1 \tilde{\Phi}_\pm^{(2)}(\mu^{-1}) \) for \( \pm \text{Im} \mu \leq 0, \mu \neq \pm 1 \).

In (2.8) the coefficients are traceless matrices, from which it follows that

- \( \det \tilde{\Phi}_\pm \equiv 1 \).

Regarding the values of \( \tilde{\Phi}_\pm \) at particular points in the \( \mu \)-plane, (2.15) implies the following:

- \( (\tilde{\Phi}_\pm^{(1)}) \to I \) as \( \mu \to \infty \) with \( \text{Im} \mu \geq 0 \), and also for \( \mu = 0 \) (by the symmetry (2.18)).
- \( (\tilde{\Phi}_\pm^{(2)}) \to I \) as \( \mu \to \infty \) with \( \text{Im} \mu \leq 0 \), and also for \( \mu = 0 \).
- As \( \mu \to 1 \), \( \tilde{\Phi}_\pm(x,t,\mu) \to 1/(\mu - 1)(\mu \pm 1) + O(1) \) with \( \alpha_\pm(x,t) \in \mathbb{R} \) (understood column-wise, in the corresponding half-planes).
- As \( \mu \to -1 \), \( \tilde{\Phi}_\pm(x,t,\mu) \to -1/(\mu + 1)(\mu \pm 1) + O(1) \) with the same \( \alpha_\pm(x,t) \) as the previous ones (by symmetry (2.18)).

2.3. Spectral data. Introduce the scattering matrix \( s(\mu) \) as a matrix relating \( \tilde{\Phi}_+ \) and \( \tilde{\Phi}_- \) on the real line:

\[
\tilde{\Phi}_+(x,t,\mu) = \tilde{\Phi}_-(x,t,\mu) e^{-p(x,t,\mu)\sigma_3} s(\mu) e^{p(x,t,\mu)\sigma_3}, \quad \mu \in \mathbb{R}, \quad \mu \neq \pm 1.
\]  
(2.19)

By (2.18), \( s(\mu) \) can be written in terms of two scalar spectral functions, \( a(\mu) \) and \( b(\mu) \):

\[
s(\mu) = \begin{pmatrix} a(\mu) & b(\mu) \\ b(\mu) & a(\mu) \end{pmatrix}, \quad \mu \in \mathbb{R},
\]  
(2.20)

satisfying the symmetries \( \overline{a(\mu)} = a(-\mu) = a(\mu^{-1}) \) and \( \overline{b(\mu)} = -b(-\mu) = b(\mu^{-1}) \) for \( \mu \in \mathbb{R} \).

The spectral functions \( a(\mu) \) and \( b(\mu) \) are uniquely determined by \( u(x,0) \) through the solutions \( \tilde{\Phi}_\pm(x,0,\mu) \) of equations (2.15). On the other hand, using the representations

\[
a(\mu) = \det \begin{pmatrix} \tilde{\Phi}_\pm^{(1)} & \tilde{\Phi}_\pm^{(2)} \\ \tilde{\Phi}_\pm^{(2)} & \tilde{\Phi}_\pm^{(1)} \end{pmatrix}, \quad b(\mu) = e^{2p} \det \begin{pmatrix} \tilde{\Phi}_+^{(2)} & \tilde{\Phi}_-^{(2)} \\ \tilde{\Phi}_+^{(1)} & \tilde{\Phi}_-^{(1)} \end{pmatrix},
\]

the analytic properties of \( \tilde{\Phi}_\pm \) stated above imply corresponding properties of \( a(\mu) \) and \( b(\mu) \):

- \( a(\mu) \) can be analytically continued into \( \mathbb{C}^+ \), being continuous up to the real line, except at \( \mu = \pm 1 \). Moreover, \( a(0) = 1 \), \( a(\mu) \to 1 \) as \( \mu \to \infty \), and \( a(\mu) \) satisfies the symmetries

\[a(\mu) = a(-\mu) = a(\mu^{-1}) \quad \text{for} \quad \text{Im} \mu \geq 0.
\]

- \( b(\mu) \) is continuous for \( \mu \in \mathbb{R} \setminus \{-1,1\} \). Moreover, \( b(0) = 0 \) and \( b(\mu) \to 0 \) as \( \mu \to \pm \infty \).

- As \( \mu \to 1 \), \( a(\mu) = \gamma \frac{1}{2(\mu - 1)} + O(1) \) and \( b(\mu) = \gamma \frac{1}{2(\mu - 1)} + O(1) \) with the same \( \gamma \in \mathbb{R} \), as follows from (2.19).

- As \( \mu \to -1 \), \( a(\mu) = -\gamma \frac{1}{2(\mu + 1)} + O(1) \) and \( b(\mu) = -\gamma \frac{1}{2(\mu + 1)} + O(1) \) with the same \( \gamma \) as the previous one, by symmetry.

- \( |a(\mu)|^2 - |b(\mu)|^2 = 1 \) for \( \mu \in \mathbb{R}, \mu \neq \pm 1 \).
Remark 2.3. The case $\gamma \neq 0$ is generic. On the other hand, in the non-generic case $\gamma = 0$, we then have $a(\pm 1) = a_1$ and $b(\pm 1) = \pm b_1$ with some $a_1 \in \mathbb{R}$ and $b_1 \in \mathbb{R}$ such that $a_1^2 = 1 + b_1^2$. It then follows from (2.19) that the coefficients $\alpha_+(x, t)$ and $\alpha_-(x, t)$ appearing in the expansions of $\hat{\Phi}$ at $\mu = \pm 1$ are related by

$$\alpha_+(x, t) = (a_1 - b_1)\alpha_-(x, t).$$

(2.21)

3. Riemann–Hilbert problem

3.1. RH problem parametrized by $(x, t)$. The analytic properties of $\hat{\Phi}_{\pm}$ stated above allow rewriting the scattering relation (2.19) as a jump relation for a piece-wise meromorphic (w.r.t. $\mu$), $2 \times 2$-matrix valued function (depending on $x$ and $t$ as parameters). Indeed, define $M \equiv M(x, t, \mu)$ by

$$M(x, t, \mu) = \begin{cases} \left( \frac{\hat{\Phi}^{(1)}_+(x, t, \mu)}{a(\mu)} \cdot \hat{\Phi}^{(2)}_+(x, t, \mu), \quad \text{Im} \mu > 0, \right. \\ \left. \frac{\hat{\Phi}^{(1)}_+(x, t, \mu)}{a(\mu)} \cdot \hat{\Phi}^{(2)}_+(x, t, \mu), \quad \text{Im} \mu < 0. \right) \end{cases}$$

(3.1)

Define also

$$r(\mu) := \frac{b(\mu)}{a^*(\mu)}, \quad \mu \in \mathbb{R}. \quad (3.2)$$

Then the limiting values $M_{\pm}(x, t, \mu), \mu \in \mathbb{R}$ of $M$ as $\mu$ is approached from $\mathbb{C}^\pm$ are related by

$$M_-(x, t, \mu) = M_+(x, t, \mu)J(x, t, \mu), \quad \mu \in \mathbb{R}, \quad \mu \neq \pm 1,$$

(3.3a)

where

$$J(x, t, \mu) = e^{-\rho(x, t, \mu)\sigma_3}J_0(\mu)e^{\rho(x, t, \mu)\sigma_3}, \quad \text{with}$$

$$J_0(\mu) = \begin{pmatrix} 1 & -r(\mu) \\ r^*(\mu) & 1 - r(\mu)r^*(\mu) \end{pmatrix}. \quad (3.3b)$$

(3.3c)

Taking into account the properties of $\hat{\Phi}_{\pm}$ and $s(\mu)$ we check that $M(x, t, \mu)$ satisfies the following conditions:

- The jump condition (3.3) across $\mathbb{R}$.
- The determinant condition $\det M \equiv 1$.
- The normalization condition:

$$M \to I \quad \text{as} \quad \mu \to \infty \quad (3.4)$$

(and also $M(0) = I$ by symmetry, see (3.7)).

- Singularity conditions:

$$M(x, t, \mu) = \begin{cases} \left( \frac{i\alpha_+(x, t)}{2(\mu + 1)} \begin{pmatrix} -c & 1 \\ -c & 1 \end{pmatrix} + O(1), \quad \mu \to 1, \quad \text{Im} \mu > 0, \right. \\ \left. \frac{i\alpha_+(x, t)}{2(\mu - 1)} \begin{pmatrix} c & 1 \\ -c & -1 \end{pmatrix} + O(1), \quad \mu \to -1, \quad \text{Im} \mu > 0, \right) \end{cases}$$

(3.5)

with some $\alpha_+(x, t) \in \mathbb{R}$ and (see Remark 2.3)

$$c := \begin{cases} 0, \quad \text{if} \quad \gamma \neq 0, \\ \frac{a_1 + b_1}{a_1^2}, \quad \text{if} \quad \gamma = 0, \end{cases} \quad (3.6a)$$

where $a_1 = a(1), b_1 = b(1)$, and $\gamma := -2i \lim_{\mu \to 1} (\mu - 1)a(\mu)$.

Notice that in terms of $r(\pm 1)$, the generic case $\gamma \neq 0$ corresponds to $r(1) = -r(-1) = -1$ whereas in the non-generic case,
\(|r(\pm 1)| < 1\) (see the case of the one-dimensional Schrödinger operator \([19]\), which constitutes the spectral problem for the Korteweg–de Vries equation). Therefore, \((3.6a)\) can be written as

\[
c := \begin{cases} 
0, & \text{if } r(1) = -1, \\
1 + r(1) = 1 - r(-1), & \text{if } |r(1)| < 1.
\end{cases}
\]  

(3.6b)

Both conditions in \((3.5)\) are actually equivalent by the symmetries \((3.7)\).

- **Symmetries** (which result from \((2.18)\)):

\[
M(\bar{\mu}) = \sigma_1 M(\mu)\sigma_1, \quad M(-\mu) = \sigma_2 M(\mu)\sigma_2, \quad M(\mu^{-1}) = \sigma_1 M(\mu)\sigma_1, \quad (3.7)
\]

where \(M(\mu) \equiv M(x,t,\mu)\). The first symmetry can also be written as \(\sigma_1 M^{(1)*} = M^{(2)}\). Moreover, \((3.7)\) implies the symmetries \(M(-\mu) = M(-\mu)^{-1} = \sigma_3 M(\mu)\sigma_3\).

If \(a(\mu)\) is allowed to have zeros in \(\mathbb{C}^+\), the above conditions must be supplemented by residue conditions at these zeros. Assume that \(a(\mu)\) has a finite number of simple zeros \({\mu_j}\) in \(\mathbb{C}^+\). Symmetries \(a(\mu) = a(-\bar{\mu}) = a(-\mu^{-1})\) imply that this set of zeros is invariant under the transformations \(\mu \mapsto -\bar{\mu}\) and \(\mu \mapsto -\mu^{-1}\): for each \(j\) there exist \(j'\) and \(j''\) such that \(-\bar{\mu}_j = \mu_{j'}\) and \(-\mu_j^{-1} = \mu_{j''}\).

- **Residue conditions**: \(M^{(1)}(x,t,\mu)\) has simple poles at \({\mu_j}\) and \(M^{(2)}(x,t,\mu)\) has simple poles at \({\bar{\mu}_j}\). Moreover

\[
\text{Res}_{\mu_j} M^{(1)}(x,t,\mu) = \frac{1}{\zeta_j(x,t)} M^{(2)}(x,t,\bar{\mu}_j), \quad (3.8a)
\]

\[
\text{Res}_{\bar{\mu}_j} M^{(2)}(x,t,\mu) = \frac{1}{\zeta_j(x,t)} M^{(1)}(x,t,\mu_j). \quad (3.8b)
\]

Here \(\zeta_j(x,t) = \hat{a}(\mu_j)\delta_j e^{-2p(x,t,\mu_j)}\) with some constants \(\delta_j \neq 0\). By symmetries \((3.7)\) both conditions in \((3.8)\) are equivalent. Note also how the residue changes under the transformations \(\mu \mapsto -\bar{\mu}\) and \(\mu \mapsto -\mu^{-1}\): if \(-\bar{\mu}_j = \mu_{j'}\) and \(-\mu_j^{-1} = \mu_{j''}\) then \(\zeta_j = \zeta_{j'} = -\mu_j^{-2} \zeta_{j''}\).

**Proof of \((3.8)\)**. Indeed, let \(\mu_j\) be a simple root of \(a(\mu)\), that is, \(a(\mu_j) = 0\) with \(\hat{a}(\mu_j) \neq 0\). Then, using \(a(\mu) = \det \left( \Phi^1 \right) \Phi^2 \right)\), we have

\[
\hat{\Phi}^1_+(x,t,\mu_j) = \delta_j \hat{\Phi}^1_-(x,t,\mu_j), \quad (3.9a)
\]

\[
\hat{\Phi}^2_+(x,t,\mu_j) = \delta_j e^{-2p(x,t,\mu_j)} \hat{\Phi}^1_+(x,t,\mu_j). \quad (3.9b)
\]

with some constant \(\delta_j \neq 0\). Hence,

\[
\text{Res}_{\mu_j} M^{(1)}(x,t,\mu) = \text{Res}_{\mu_j} \frac{\hat{\Phi}^1_+(x,t,\mu)}{a(\mu)} = \hat{\Phi}^1_+(x,t,\mu_j) = \frac{\hat{\Phi}^2_+(x,t,\mu_j)}{\hat{a}(\mu_j)} e^{-2p(x,t,\mu_j)}.
\]

Denoting \(\zeta_j(x,t) := \hat{a}(\mu_j)\delta_j e^{-2p(x,t,\mu_j)}\) we get \((3.8a)\). The residue relation \((3.8b)\) then follows by the symmetry \(\mu \mapsto \mu^* = \bar{\mu}\). Indeed, applying this symmetry to \((3.8a)\) and multiplying by \(\sigma_1\) we get

\[
\text{Res}_{\bar{\mu}_j} \sigma_1 M^{(1)*}(x,t,\mu) = \frac{1}{\zeta_j(x,t)} \sigma_1 M^{(2)*}(x,t,\mu_j),
\]

which reduces to \((3.8b)\) in view of the relation \(\sigma_1 M^{(1)*} = M^{(2)}\) (see \((3.7)\)).

In the framework of the Riemann–Hilbert approach to nonlinear evolution equations, we interpret the jump relation \((3.3a)\), normalization condition \((3.4)\), singularity conditions \((3.5)\), and residue conditions \((3.8)\) as a Riemann–Hilbert problem, with the jump matrix and residue parameters determined by the initial data for the nonlinear problem. We proceed as in the case of the Camassa–Holm equation:
1) In order to have the data for the RH problem to depend explicitly on the parameters, we use the space variable \( y(x, t) := x - \int_x^\infty (\hat{m}(\xi, t) - 1) d\xi \) we have introduced in (2.11).

2) In order to determine an efficient way for retrieving the solution of the mCH equation from the solution of the RH problem, we pay a special attention to the behavior of the Jost solutions at dedicated points in the complex plane of the spectral parameter

\[
\text{Eigenfunction near } \mu = i. \text{ In the case of the Camassa–Holm equation [3] as well as other CH-type nonlinear integrable equations studied so far, see, e.g., [4,5], the analysis of the behavior of the respective Jost solutions at dedicated points in the complex plane of the spectral parameter (see Item 2) above requires a dedicated gauge transformation of the Lax pair equations.}
\]

It is remarkable that in the case of the mCH equation, we don’t need to use such a transformation; all we need is to regroup the terms in the Lax pair (2.5a, 2.5c).

Namely, let us rewrite (2.5a) in terms of \( \mu \) (keeping the same notation \( \hat{\Phi} \) for the solution):

\[
\hat{\Phi}_x + \frac{i(\mu^2 - 1)}{4\mu} \sigma_3 \hat{\Phi} = \hat{U}_0 \hat{\Phi},
\]

where

\[
\hat{U}_0(x, t, \mu) := \frac{i(\mu^2 + 1)(\hat{m} - 1)}{2(\mu^2 - 1)} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} + \begin{pmatrix} i\mu(\hat{m} - 1) \mu^2 - 1 & i(\mu^2 - 1)\hat{m} - i(\mu^2 - 1) \mu^2 - 1 \end{pmatrix} \sigma_3,
\]

so that \( \hat{U}_0(x, t, \pm i) \equiv 0 \). Accordingly, rewrite (2.5c) as

\[
\hat{\Phi}_t - \frac{2i(\mu^2 - 1)\mu}{(\mu^2 + 1)^2} \sigma_3 \hat{\Phi} = \hat{V}_0 \hat{\Phi},
\]

where

\[
\hat{V}_0(x, t, \mu) := \frac{i(\mu^2 - 1)}{4\mu} (\hat{u}^2 - \hat{u}_-^2 + 2\hat{u})\hat{m}\sigma_3 + \hat{V}(x, t, \mu).
\]

Further, introduce (compare with (2.13))

\[
p_0(x, t, \mu) := \frac{i(\mu^2 - 1)}{4\mu} x - \frac{2i(\mu^2 - 1)\mu}{(\mu^2 + 1)^2} t,
\]

then \( Q_0 := p_0\sigma_3 \), and \( \tilde{\Phi}_0 := \hat{\Phi}_0Q_0 \) so that equations (3.10a) and (3.10c) become

\[
\begin{cases}
\hat{\Phi}_{0x} + [Q_{0x}, \hat{\Phi}_0] = \hat{U}_0 \hat{\Phi}_0, \\
\hat{\Phi}_{0t} + [Q_{0t}, \hat{\Phi}_0] = \hat{V}_0 \hat{\Phi}_0.
\end{cases}
\]

Define the Jost solutions \( \tilde{\Phi}_{0\pm} \) of (3.12) as the solutions of the integral equations

\[
\tilde{\Phi}_{0\pm}(x, t, \mu) = I + \int_{\pm\infty} e^{\frac{i(\mu^2 - 1)}{4\mu}(x-\xi)\sigma_3} \hat{U}_0(\xi, t, \mu) \tilde{\Phi}_{0\pm}(\xi, t, \mu) e^{\frac{i(\mu^2 - 1)}{4\mu}(x-\xi)\sigma_3} d\xi.
\]

If \( \tilde{\Phi}_{0\pm} := \tilde{\Phi}_{0\pm} e^{-p_0\sigma_3} \) we observe that \( \tilde{\Phi}_{0\pm}(x, t, \mu) \) and \( \tilde{\Phi}_{\pm}(x, t, \mu) \) satisfy the same differential equations (3.10) and thus they are related by matrices \( C_{\pm}(\mu) \) independent of \( x \) and \( t \):

\[
\tilde{\Phi}_{\pm} = \tilde{\Phi}_{0\pm} C_{\pm}(\mu).
\]

It follows that

\[
\tilde{\Phi}_{\pm}(x, t, \mu) = \tilde{\Phi}_{0\pm}(x, t, \mu) e^{-p_0(x,t,\mu)\sigma_3} C_{\pm}(\mu) e^{p(x,t,\mu)\sigma_3}.
\]

Thus, \( C_{\pm}(\mu) = e^{p_0(\pm\infty, t, \mu) - p_0(\pm\infty, t, \mu)\sigma_3} \). Since \( p(x, t, \mu) - p_0(x, t, \mu) = -\frac{i(\mu^2 - 1)}{4\mu} \int_x^{\pm\infty} (\hat{m}(\xi, t) - 1) d\xi \) we find that \( C_-(\mu) \equiv I \) whereas \( C_+(\mu) = e^{\frac{i(\mu^2 - 1)}{4\mu} \int_x^{\pm\infty} (\hat{m}(\xi, t) - 1) d\xi} \) \( \sigma_3 \).
Since $\tilde{U}_0(x, t, i) \equiv 0$, it follows from (3.13) that $\tilde{\Phi}_{0\pm}(x, t, i) \equiv I$ and thus
\[
\tilde{\Phi}_+(x, t, i) = e^{\frac{i}{2} \int_{x}^{\infty} (\tilde{m}(\xi, t) - 1) d\xi} \sigma_3 \quad \text{and} \quad \tilde{\Phi}_-(x, t, i) = e^{-\frac{i}{2} \int_{x}^{\infty} (\tilde{m}(\xi, t) - 1) d\xi} \sigma_3.
\]
Consequently,
\[
a(i) = e^{-\frac{i}{2} \int_{x}^{\infty} (\tilde{m}(\xi, t) - 1) d\xi}
\]
and
\[
M(x, t, i) = \begin{pmatrix}
e^{\frac{i}{2} \int_{x}^{\infty} (\tilde{m}(\xi, t) - 1) d\xi} & 0 \\
0 & e^{-\frac{i}{2} \int_{x}^{\infty} (\tilde{m}(\xi, t) - 1) d\xi}
\end{pmatrix}.
\]
(3.15a)

Then, by symmetry,
\[
M(x, t, -i) = \begin{pmatrix}
e^{-\frac{i}{2} \int_{x}^{\infty} (\tilde{m}(\xi, t) - 1) d\xi} & 0 \\
0 & e^{\frac{i}{2} \int_{x}^{\infty} (\tilde{m}(\xi, t) - 1) d\xi}
\end{pmatrix}.
\]
(3.15b)

Remark 3.1. The symmetries (3.7) imply that $M(i) = M(i) = \sigma_3 M(i) \sigma_3$ where $M(i) \equiv M(x, t, i)$, and thus $M(i)$ is a diagonal matrix with real entries which, due to the determinant equality $\det M \equiv 1$, has the form
\[
M(x, t, i) = \begin{pmatrix}
\varphi(x, t) & 0 \\
0 & \varphi^{-1}(x, t)
\end{pmatrix}
\]
(3.16a)

with some $\varphi(x, t) \in \mathbb{R}$. Then, referring again to (3.7), it follows that
\[
M(x, t, -i) = \begin{pmatrix}
\varphi^{-1}(x, t) & 0 \\
0 & \varphi(x, t)
\end{pmatrix}
\]
(3.16b)

with the same $\varphi(x, t)$. Therefore, the matrix structure of $M(x, t, \pm i)$ as in (3.15) follows from the general properties of the solution of a Riemann–Hilbert problem (specified by jump, normalization, residue, singularity, and symmetry conditions). This is in contrast with the case of the Camassa–Holm equation [2,3], where a specific matrix structure of the solution of the associated RH problem, evaluated at a dedicated point ($k = \frac{1}{2}$ for the CH equation), constitutes an additional requirement for the solution. In that case, the proof of the uniqueness of the solution of the RH problem relies essentially on this additional property.

In what follows we will use (3.15) in order to extract the solution of the mCH equation from the solution of the associated RH problem.

3.3. RH problem in the $(y, t)$ scale. Introducing the new space variable $y(x, t)$ by (2.11), $M(y, t, \mu)$ so that $M(x, t, \mu) = M(y(x, t), t, \mu)$, the jump condition (3.3a) becomes
\[
\hat{M}_-(y, t, \mu) = \hat{M}_+(y, t, \mu) \hat{J}(y, t, \mu), \quad \mu \in \mathbb{R}, \quad \mu \neq \pm 1,
\]
(3.17a)

where
\[
\hat{J}(y, t, \mu) := e^{-\hat{\phi}(y, t, \mu)^\sigma_3} J_0(\mu) e^{\hat{\phi}(y, t, \mu)^\sigma_3}
\]
(3.17b)

with $J_0(\mu)$ defined by (3.3c) and
\[
\hat{\phi}(y, t, \mu) := -\frac{i(\mu^2 - 1)}{4\mu} \left(-y + \frac{8\mu^2}{(\mu^2 + 1)^2} t\right).
\]
(3.17c)

so that $J(x, t, \mu) = \hat{J}(y(x, t), t, \mu)$ and $p(x, t, \mu) = \hat{p}(y(x, t), t, \mu)$, where the jump $J(x, t, \mu)$ and the phase $p(x, t, \mu)$ are defined in (3.3b) and (2.13), respectively.

Accordingly, in this scale, the residue conditions (3.8) become explicit as well:
\[
\text{Res}_{\mu_j} \hat{M}^{(1)}(y, t, \mu) = \frac{1}{\lambda_j(y, t)} \hat{M}^{(2)}(y, t, \mu_j),
\]
\[
\text{Res}_{\mu_j} \hat{M}^{(2)}(y, t, \mu) = \frac{1}{\lambda_j(y, t)} \hat{M}^{(1)}(y, t, \mu_j),
\]
(3.18)
with \( \hat{\tau}_j(y, t) = \hat{a}(\mu_j)\delta_j e^{-2\hat{\rho}(\hat{y}, t, \mu_j)} \). Further we denote \( \rho_j := \hat{a}(\mu_j)\delta_j \).

Noticing that the normalization condition (3.4), the symmetries (3.7), and the singularity conditions (3.5) at \( \mu = \pm 1 \) hold when using the new scale \((y, t)\), we arrive at the basic RH problem.

**Basic RH problem.** Given \( r(\mu) \) for \( \mu \in \mathbb{R} \), \( c \in \mathbb{R} \), and \( \{\mu_j, \rho_j\}_1^N \) a set of points \( \mu_j \in \mathbb{C}^+ \) and complex numbers \( \rho_j \neq 0 \) invariant by \( \mu \to -\mu \) and \( \mu \to -\mu^{-1} \) (that is, \( -\mu_j = \mu_j \) and \( -\mu_j^{-1} = \mu_j^{-\nu} \) with \( \rho_j = \frac{\rho_j}{\mu_j^{-\nu}} = -\mu_j^{-2\nu} \), find a piece-wise (w.r.t. \( \mathbb{R} \)) meromorphic, \( 2 \times 2 \)-matrix valued function \( \hat{M}(y, t, \mu) \) satisfying the following conditions:

- The jump condition (3.17) across \( \mathbb{R} \) (with \( J_0(\mu) \) defined by (3.3c)).
- The residue conditions (3.18) with \( \hat{\tau}_j(y, t) = \rho_j e^{-2\hat{\rho}(\hat{y}, \hat{\mu}_j)} \).
- The normalization condition \( \hat{M}(y, t, \mu) \to I \) as \( \mu \to \infty \).
- The symmetries

\[
\hat{M}(\bar{\mu}) = \sigma_1 \hat{M}(\mu)\sigma_1, \quad \hat{M}(-\mu) = \sigma_2 \hat{M}(\mu)\sigma_2, \quad \hat{M}(\mu^{-1}) = \sigma_1 \hat{M}(\mu)\sigma_1
\]

where \( \hat{M}(\mu) \equiv \hat{M}(y, t, \mu) \). These symmetries imply that \( \hat{M}(-\mu^{-1}) = \sigma_3 \hat{M}(\mu)\sigma_3 = \hat{M}(\bar{\mu}) \).

- The singularity conditions

\[
\hat{M}(y, t, \mu) = \frac{i\hat{\alpha}_+(y, t)}{2(\mu - 1)} \left( \begin{array}{cc}
-c & 1 \\
-c & 1
\end{array} \right) + O(1) \quad \text{as} \quad \mu \to 1, \quad \text{Im} \mu > 0,
\]

\[
\hat{M}(y, t, \mu) = \frac{-i\hat{\alpha}_+(y, t)}{2(\mu - 1)} \left( \begin{array}{cc}
-c & 1 \\
-c & -1
\end{array} \right) + O(1) \quad \text{as} \quad \mu \to -1, \quad \text{Im} \mu > 0,
\]

where \( \hat{\alpha}_+(y, t) \in \mathbb{R} \) is not specified. These two singularity conditions are actually equivalent by symmetries (3.19).

**Data of this RH problem associated with \( u_0(x) \).** Specific data for this RH problem can be derived from initial data of the Cauchy problem (1.6) satisfying \( u_0(x) \to 1 \) as \( x \to \pm \infty \).

- We first get \( s(\mu) \) through (2.19) at \( t = 0 \) (using the solutions of (2.15) taken at \( t = 0 \)).
- Spectral data \( a(\mu), b(\mu), \) and \( r(\mu) \) follow through (2.20) and (3.2).
- Then \( \{\mu_j\}_1^N \) are the zeros of \( a(\mu) \in \mathbb{C}^+ \).
- The real constant \( c \) is defined through (3.6).
- The constants \( \{\delta_j\}_1^N \) are defined by (3.9b) at \( t = 0 \) (using the solutions of (2.9) at \( t = 0 \)).
- Finally, the \( \{\rho_j\}_1^N \) are defined by \( \rho_j = \hat{a}(\mu_j)\delta_j \).

Further, the basic RH problem associated with the Cauchy problem (1.6) for the mCH equation is the basic RH problem with data associated with initial data satisfying \( u_0(x) \to 1 \) as \( x \) just specified.

**Remark 3.2.** An important difference between the cases of the CH and mCH equations is that in the former case, there is a possibility to reduce the matrix RH problems to vector ones which have no singularity at a point on the contour: this can be done by multiplying the respective \( \hat{M} \) by the vector \((1, 1)\) from the left. This trick will obviously not work in our current case, since the matrix structure (see (2.20)) of the singularity at \( \mu = 1 \) is different from that at \( \mu = -1 \).

3.4. **Uniqueness of the solution of the basic RH problem.** Assume that the RH problem (3.17)–(3.20) has a solution \( \hat{M} \). In order to prove that this solution is unique, we first observe that \( \det \hat{M} \equiv 1 \).

Indeed, the conditions for \( \hat{M} \) imply that \( \det \hat{M} \) has neither a jump across \( \mathbb{R} \) no singularities at \( \mu_j \). Moreover, \( \det \hat{M} \) tends to 1 as \( \mu \to \infty \), and the only possible singularities of \( \det \hat{M} \) are simple poles at \( \mu = \pm 1 \). Then, by Liouville’s theorem, \( \det \hat{M} \equiv 1 + \frac{\phi_1}{\mu + 1} + \frac{\phi_2}{\mu + 1} \) with some \( \phi_j \).
But then, the symmetry \( \hat{M}(\mu^{-1}) = \sigma_1 \hat{M}(\mu) \sigma_1 \) from (3.19) implies that \( \phi_1 = \phi_2 = 0 \) and thus \( \det \hat{M} = 1 \).

Now suppose that \( \hat{M}_1 \) and \( \hat{M}_2 \) are two solutions of the RH problem, and consider \( P := \hat{M}_1(\hat{M}_2)^{-1} \). Obviously, \( P \) has neither a jump across \( \mathbb{R} \) nor singularities at \( \mu_j \). Moreover, \( P \) tends to \( I \) as \( \mu \to \infty \), and the only possible singularities of \( P \) are simple poles at \( \mu = \pm 1 \).

Consider, for example, the development of \( \hat{M}_j, \ j = 1, 2 \) as \( \mu \to -1 \) with \( \Im \mu > 0 \):

\[
\hat{M}_j(y, t, \mu) = -\frac{i\beta_j(y, t)}{2(\mu + 1)} \begin{pmatrix} c & 1 \\ -c & -1 \end{pmatrix} + \begin{pmatrix} n_j(y, t) & m_j(y, t) \\ f_j(y, t) & g_j(y, t) \end{pmatrix} + O(\mu + 1) \text{ as } \mu \to -1, \ \mu \in \mathbb{C}^+.
\]

By \( \det \hat{M}_j \equiv 1 \) it follows that

\[
(\hat{M}_j(y, t, \mu))^{-1} = -\frac{i\beta_j(y, t)}{2(\mu - 1)} \begin{pmatrix} -1 & 1 \\ c & -1 \end{pmatrix} + \begin{pmatrix} g_j(y, t) & -m_j(y, t) \\ f_j(y, t) & n_j(y, t) \end{pmatrix} + O(\mu + 1) \text{ as } \mu \to -1, \ \mu \in \mathbb{C}^+.
\]

Moreover, using these expressions to calculate the expansion of \( \hat{M}_j \hat{M}_j^{-1} \) as \( \mu \to -1 \) the vanishing of the term of order \((\mu + 1)^{-1}\) reads as

\[
n_j(y, t) + f_j(y, t) = c(m_j(y, t) + g_j(y, t)), \quad j = 1, 2. \tag{3.21}
\]

Hence, (3.21) implies that

\[
P(y, t, \mu) = -\frac{i\psi(y, t)}{2(\mu + 1)} \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} + O(1) \text{ as } \mu \to -1, \ \mu \in \mathbb{C}^+,
\]

for some \( \psi(y, t) \). Then, by the symmetry \( P(\mu^{-1}) = \sigma_3 P(\mu) \sigma_3 \), we have

\[
P(y, t, \mu) = -\frac{i\psi(y, t)}{2(\mu - 1)} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} + O(1) \text{ as } \mu \to 1, \ \mu \in \mathbb{C}^+,
\]

and, according to the Liouville theorem and the normalization condition,

\[
P = \frac{1}{2} \psi(y, t) \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} + \frac{1}{\mu + 1} \left( \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \right)^{-1} + I.
\]

Evaluating this at \( \mu = i \) we have

\[
P(y, t, i) = \frac{1}{2} \psi(y, t) \begin{pmatrix} -i & 1 \\ 1 & i \end{pmatrix} + I. \tag{3.22}
\]

But, according to (3.16a), both matrices \( \hat{M}_1(i) \) and \( \hat{M}_2(i) \) are diagonal. Hence \( P(y, t, i) \) is also diagonal and (3.22) implies that \( \psi(y, t) \equiv 0 \). Consequently, \( P(y, t, \mu) \equiv I \) so that \( \hat{M}_1 \equiv \hat{M}_2 \).

3.5. Recovering \( \mathbf{u}(x, t) \) from the solution of the RH problem. We will show how to recover the solution of the Cauchy problem (1.6) from the solution of the basic RH problem whose data are associated with the initial data \( u_0(x) \). We begin with some preliminary observations.

Going back to the construction of \( M(x, t, \mu) \) from the Jost solutions, see Section 3.2, we can use (3.15a) in order to express the solution \( \mathbf{u}(x, t) \) of the mCH equation in terms of \( M(x, t, \mu) \) evaluated at \( \mu = 1 \). Indeed, introduce (compare with the case of the CH equation [3])

\[
\tilde{\mu}_1(x, t) := M_{11}(x, t, i) + M_{21}(x, t, i) = e^{\int_x^{\infty} \tilde{m}(\xi, t) \, d\xi},
\]

\[
\tilde{\mu}_2(x, t) := M_{12}(x, t, i) + M_{22}(x, t, i) = e^{\int_x^{\infty} \tilde{m}(-\xi, t) \, d\xi}.
\]

Using the new space variable \( y(x, t) := x - \int_x^{\infty} \tilde{m}(\xi, t) - 1 \, d\xi \) we have introduced in (2.11), the above equations yield

\[
\frac{\tilde{\mu}_1(x, t)}{\tilde{\mu}_2(x, t)} = e^{\int_x^{\infty} \tilde{m}(\xi, t) - 1 \, d\xi} = e^{x - y(x, t)} \tag{3.23}
\]
From \( \frac{\partial}{\partial x} \) the parametric representation
\[
\tilde{x}(x, t) = \tilde{y}(x, t) := \tilde{u}(x, y, t),
\]
and thus
\[
x = y(x, t) + \ln \frac{\tilde{\mu}_1(x, t)}{\tilde{\mu}_2(x, t)}. \tag{3.24}
\]
Also notice that
\[
\tilde{\mu}_1(x, t)\tilde{\mu}_2(x, t) = 1. \tag{3.25}
\]

**Proposition 3.3.** Let \( \tilde{M}(y, t, \mu) \) be the solution of the RH problem (3.17)–(3.20) whose data are associated with the initial data \( u_0(x) \). Define \( \tilde{\mu}_1(y, t) := \tilde{M}_{11}(y, t, i) + \tilde{M}_{21}(y, t, i) \) and \( \tilde{\mu}_2(y, t) := \tilde{M}_{12}(y, t, i) + \tilde{M}_{22}(y, t, i) \). The solution \( u(x, t) \) of the Cauchy problem (1.6) has \( x \)-derivative given by the parametric representation
\[
u_x(x + t, t) = \frac{1}{2} \partial_t \ln \frac{\tilde{\mu}_1(y, t)}{\tilde{\mu}_2(y, t)}, \tag{3.26a}
\]
\[
x(y, t) = y + \ln \frac{\tilde{\mu}_1(y, t)}{\tilde{\mu}_2(y, t)}. \tag{3.26b}
\]

**Proof.** In what follows we will express \( \tilde{u}_x \) in the variables \((y, t)\). To express a function \( \tilde{f}(x, t) \) in \((y, t)\) we will use the notation \( \tilde{f}(y, t) := f(x(y, t), t) \), e.g.,
\[
\tilde{u}(y, t) := \tilde{u}(x(y, t), t), \quad \tilde{u}_x(y, t) := \tilde{u}_x(x(y, t), t), \quad \tilde{\mu}(y, t) := \tilde{\mu}(x(y, t), t), \quad \tilde{\omega}(y, t) := \tilde{\omega}(x(y, t), t).
\]

Differentiation of the identity \( x(y(x, t), t) = x \) w.r.t. \( t \) gives
\[
\partial_t (x(y(x, t), t)) = x_y(y, t)g_t(x, t) + x_t(y, t) = 0. \tag{3.27}
\]
From (2.11) it follows that
\[
x_y(y, t) = \frac{1}{\tilde{m}(y, t)} \tag{3.28}
\]
and \( y_t(x, t) = -\int_x^{+\infty} \tilde{m}_t(\xi, t)d\xi \). By (1.8a), the latter equality becomes
\[
y_t(x, t) = \int_x^{+\infty} (\tilde{\omega}\tilde{m})(\xi, t)d\xi = -\tilde{\omega}\tilde{m}(x, t).
\]
Substituting this and (3.28) into (3.27) we obtain
\[
x_t(y, t) = \tilde{\omega}(y, t). \tag{3.29}
\]
Further, differentiating (3.29) w.r.t. \( y \) we get
\[
x_{ty}(y, t) = \tilde{\omega}_x x_y(y, t) = 2\tilde{u}_x(\tilde{u}_x - \tilde{u}_{xx} + 1)\frac{1}{\tilde{m}}(y, t) = 2\tilde{u}_x(y, t). \tag{3.30}
\]
Therefore, we arrive at a parametric representation of \( \tilde{u}_x(x, t) \):
\[
\tilde{u}_x(x(y, t), t) \equiv \tilde{u}_x(y, t) = \frac{1}{2} \partial_t x(y, t),
\]
\[
x(y, t) = y + \ln \frac{\tilde{\mu}_1(y, t)}{\tilde{\mu}_2(y, t)},
\]
which yields (3.26). For the direct determination of \( u \) from the solution of the RH problem, see Remark 4.8 below. \[\square\]

**Remark 3.4.** In the case of the Camassa–Holm equation, the relation between the new and original space variables (3.24) is the same whereas the derivative (3.29) gives directly the solution \( u \) of the nonlinear equation (in the \((y, t)\) variables) in question.
4. FROM A SOLUTION OF THE RH PROBLEM TO A SOLUTION OF THE MCH EQUATION

Henceforth we consider a RH problem (3.17)–(3.20) with data not necessarily related to initial data for the mCH equation. This section aims to show that starting from the solution $\hat{M}(y,t,\mu)$ of such a RH problem one can construct a solution (at least, locally) of the mCH equation by manipulations similar to those of Section 3.5. For this purpose, we will show that starting from $\hat{M}(y,t,\mu)$ one can define $2 \times 2$-matrix valued functions $\hat{\Psi}(y,t,\mu)$ satisfying Lax pair equations

$$\dot{\hat{\Psi}}_y = \hat{U}\hat{\Psi},$$
$$\dot{\hat{\Psi}}_t = \hat{V}\hat{\Psi},$$

whose coefficients $\hat{U}$ and $\hat{V}$ are obtained from $\hat{M}(y,t,\mu)$, and whose compatibility condition is the mCH equation (written in the $(y,t)$ variables).

First, let us reformulate the original Lax pair equations (2.5) in the $(y,t)$ variables. Introducing $\hat{\Psi}(y,t) = \hat{\Phi}(x(y,t),t)$ and taking into account (3.29) and (3.28), the Lax pair (2.5) in the variables $(y,t)$ takes the form:

$$\dot{\hat{\Psi}}_y + 2i\kappa \mu \sigma_3 \hat{\Psi} = \frac{\tilde{m} - 1}{\tilde{m}} \frac{\lambda}{4i\kappa} \left( \begin{array}{cc} \lambda & 1 \\ -1 & \frac{1}{\lambda} \end{array} \right) \hat{\Psi},$$
$$\dot{\hat{\Psi}}_t = 2i\mu (\mu^2 + 1)^2 \kappa \sigma_3 \hat{\Psi} = \left( \frac{\tilde{u}}{2i\kappa} \left( \begin{array}{cc} -1 & -\frac{1}{\lambda} \\ \frac{1}{\lambda} & 1 \end{array} \right) + \frac{\tilde{u}^2}{\lambda} \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right) \right) \hat{\Psi},$$

where $\kappa := -\frac{1}{\lambda} \sqrt{1 - \lambda^2}$.

Consequently, using $\mu$ as spectral parameter (see (2.12)), we have

**Proposition 4.1.** The Lax pair (2.5) has the following form in the variables $(y,t,\mu)$:

$$\dot{\hat{\Psi}}_y + \frac{i(\mu^2 - 1)}{4\mu} \sigma_3 \hat{\Psi} = \hat{U}\hat{\Psi},$$
$$\dot{\hat{\Psi}}_t - \frac{2i(\mu^2 - 1)}{(\mu^2 + 1)^2} \mu \sigma_3 \hat{\Psi} = \hat{V}\hat{\Psi},$$

where

$$\hat{U}(y,t,\mu) = \frac{f(y,t)}{\mu - 1} \left( \begin{array}{cc} 1 & -1 \\ 1 & -1 \end{array} \right) + \frac{i\hat{g}(y,t)}{\mu + 1} \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) + \frac{i\hat{g}(y,t)}{\mu + 1},$$
$$\hat{V}(y,t,\mu) = \frac{q(y,t)}{\mu - 1} \left( \begin{array}{cc} 1 & -1 \\ 1 & -1 \end{array} \right) + \frac{iq(y,t)}{\mu + 1} \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) + \frac{1}{\mu - i} \left( \begin{array}{cc} 0 & \hat{g}_2(y,t) \\ \hat{g}_1(y,t) & 0 \end{array} \right) + \frac{1}{\mu + i} \left( \begin{array}{cc} 0 & \hat{g}_2(y,t) \\ \hat{g}_1(y,t) & 0 \end{array} \right),$$

with $f, q, g_1, \text{ and } g_2$ as follows:

$$f = \frac{\tilde{m} - 1}{2\tilde{m}}, \quad q = \tilde{u}, \quad g_1 = -\tilde{u} - \tilde{u}_x, \quad g_2 = \tilde{u} - \tilde{u}_x.$$

Our goal in this section is to show that giving a solution $\hat{M}(y,t,\mu)$ to the RH problem (3.17)–(3.20), where the data $r(\mu)$ for $\mu \in \mathbb{R}$, $c \in \mathbb{R}$, and $(\mu_j, \rho_j) \in \mathbb{C}$ are not a priori associated with some initial data $u_0(x)$, one can “extract” from $\hat{M}(y,t,\mu)$ a solution to the mCH equation. The idea is as follows:
(a) Starting from \( \hat{M}(y, t, \mu) \), define \( \hat{\Psi}(y, t, \mu) = \hat{M}(y, t, \mu)e^{-\hat{\rho}(y, t, \mu)\sigma_3} \) and show that \( \hat{\Psi}(y, t, \mu) \) satisfies the system of differential equations:

\[
\begin{align*}
\hat{\Psi}_y &= \hat{U}\hat{\Psi}, \\
\hat{\Psi}_t &= \hat{V}\hat{\Psi},
\end{align*}
\]  

(4.4)

where \( \hat{U} \) and \( \hat{V} \) have the same (rational) dependence on \( \mu \) as in (4.1) and (4.2), with coefficients given in terms of \( \hat{M}(y, t, \mu) \) evaluated at appropriate values of \( \mu \).

(b) Show that the compatibility condition for (4.4), which is the equality \( \hat{U}_t - \hat{V}_y + [\hat{U}, \hat{V}] = 0 \), reduces to the mCH equation.

**Proposition 4.2.** Let \( \hat{M}(y, t, \mu) \) be the solution of the RH problem (3.17)–(3.20). Define

\[
\hat{\Psi}(y, t, \mu) = \hat{M}(y, t, \mu)e^{-\hat{\rho}(y, t, \mu)\sigma_3},
\]

(4.5)

where \( \hat{\rho}(y, t, \mu) := -\frac{(\mu^2 - 1)}{4\mu} \left( -y + \frac{8\mu^2}{(\mu^2 + 1)}t \right) \). Then \( \hat{\Psi}(y, t, \mu) \) satisfies the differential equation

\[
\hat{\Psi}_y = \hat{U}\hat{\Psi}
\]

with \( \hat{U} = -\frac{(\mu^2 - 1)}{4\mu} \sigma_3 + \tilde{U} \), where \( \tilde{U} \) is as in (4.2a) with \( f \) given by

\[
f(y, t) := -\frac{\eta(y, t)}{2},
\]

\( \eta(y, t) \) being extracted from the large \( \mu \) expansion of \( \hat{M}(y, t, \mu) \):

\[
\hat{M}(y, t, \mu) = I + \frac{1}{\mu} \begin{pmatrix} \xi(y, t) & \eta(y, t) \\ \eta(y, t) & -\xi(y, t) \end{pmatrix} + \text{O}(\mu^{-2}), \quad \mu \to \infty.
\]

**Proof.** First, notice that \( \hat{\Psi}(y, t, \mu) \) satisfies the jump condition

\[
\hat{\Psi}_-(y, t, \mu) = \hat{\Psi}_+(y, t, \mu)J_0(\mu)
\]

with the jump matrix \( J_0 \) independent of \( y \). Hence, \( \hat{\Psi}(y, t, \mu) \) satisfies the same jump condition. Consequently, \( \hat{\Psi}_y\hat{\Psi}^{-1} = \hat{M}_y\hat{M}^{-1} - \hat{\rho}_y\hat{M}\sigma_3\hat{M}^{-1} \) has no jump and thus it is a meromorphic function, with possible singularities at \( \mu = \infty, \mu = 0 \), and \( \mu = \pm 1 \). Let us evaluate \( \hat{\Psi}_y\hat{\Psi}^{-1} \) near these points.

(i) As \( \mu \to \infty \), we have \( \hat{\rho}_y = \frac{i\mu}{4} + \text{O}(\mu^{-1}) \) and thus

\[
\hat{\Psi}_y\hat{\Psi}^{-1} = \frac{i\mu}{4} \sigma_3 - \frac{i}{4}[\hat{M}(\infty), \sigma_3] + \text{O}(\mu^{-1}),
\]

where \( \hat{M}(\infty) \equiv \hat{M}(\infty)(y, t) \) comes from the large \( \mu \) asymptotics of \( \hat{M} \):

\[
\hat{M} = I + \frac{\hat{M}(\infty)}{\mu} + \text{O}(\mu^{-2}), \quad \mu \to \infty.
\]

Symmetries (3.19) imply that \( \sigma_2\hat{M}(\infty)\sigma_2 = -\hat{M}(\infty) \) and \( \sigma_1\hat{M}(\infty)\sigma_1 = \hat{M}(\infty) \), so that

\[
\hat{M}(\infty) = \begin{pmatrix} \xi & \eta \\ \eta & -\xi \end{pmatrix}
\]

with some \( \xi(y, t) \in i\mathbb{R} \) and \( \eta(y, t) \in \mathbb{R} \). Consequently,

\[
\hat{\Psi}_y\hat{\Psi}^{-1} = \frac{i\mu}{4} \sigma_3 - \frac{i}{2} \begin{pmatrix} 0 & -\eta \\ \eta & 0 \end{pmatrix} + \text{O}(\mu^{-1}), \quad \mu \to \infty.
\]

(4.6)
Then, by symmetry,
\[ \hat{\Psi}_y \hat{\Psi}^{-1} = \frac{i}{4\mu} \sigma_3 + \frac{i}{2} \begin{pmatrix} 0 & -\eta \\ \eta & 0 \end{pmatrix} + O(\mu), \quad \mu \to 0. \] (4.7)

(ii) Pushing the expansion (3.20a) of \( \hat{M}(\mu) \) a step further, and proceeding as in Section 3.4 to get (3.21) we have
\[ \hat{\Psi}_y \hat{\Psi}^{-1} = \frac{i\beta_1}{\mu - 1} \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix} + O(1), \quad \mu \to 1, \] (4.8)
with some \( \beta_1(y, t) \in \mathbb{R} \). By symmetry,
\[ \hat{\Psi}_y \hat{\Psi}^{-1} = \frac{i\beta_1}{\mu + 1} \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} + O(1), \quad \mu \to -1. \] (4.9)

Combining (4.6), (4.7), (4.8), and (4.9), we obtain that the function
\[ \hat{\Psi}_y \hat{\Psi}^{-1} = \frac{i(\mu^2 - 1)}{4\mu} \sigma_3 - \frac{i\beta_1}{\mu - 1} \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix} - \frac{i\beta_1}{\mu + 1} \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} + \frac{i}{2} \begin{pmatrix} 1 & -\eta \\ \eta & 0 \end{pmatrix} \]
is holomorphic in the whole complex \( \mu \)-plane and, moreover, vanishes as \( \mu \to \infty \). Then, by Liouville’s theorem, it vanishes identically.

Further, again by symmetry, \( \hat{M}(y, t, \mu) \) is diagonal (see Remark 3.1), which implies that the following sum is diagonal as well:
\[ \frac{i\beta_1}{1-1} \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix} + \frac{i\beta_1}{1+1} \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} - \frac{i}{2} \begin{pmatrix} 1 & -\eta \\ \eta & 0 \end{pmatrix}. \]

It follows that \( \frac{\eta}{2} = -\beta_1 \), and thus we arrive at the equality \( \hat{\Psi}_y = \hat{U} \hat{\Psi} \) with \( \hat{U} = -\frac{i(\mu^2 - 1)}{4\mu} \sigma_3 + \hat{\Upsilon} \), where \( \hat{U} \) is as in (4.2a) with \( f = \beta_1 \). \( \square \)

**Proposition 4.3.** The function \( \hat{\Psi}(y, t, \mu) \) defined by (4.5) satisfies the differential equation
\[ \hat{\Psi}_t = \hat{V} \hat{\Psi} \] (4.10)
with \( \hat{V} = \frac{2(\mu^2 - 1)}{(\mu^2 + 1)^2} \sigma_3 + \hat{\Upsilon} \), where \( \hat{\Upsilon} \) is as in (4.2b) with coefficients \( q, g_1, \) and \( g_2 \) determined by evaluating \( \hat{M}(y, t, \mu) \) as \( \mu \to 1 \) and \( \mu \to i \).

**Proof.** Similarly to Proposition 4.2, we notice that \( \hat{\Psi}_t \hat{\Psi}^{-1} = \hat{M}_t \hat{M}^{-1} - \hat{p}_t \hat{M} \sigma_3 \hat{M}^{-1} \) has no jump and thus it is a meromorphic function, with possible singularities at \( \mu = \infty \), \( \mu = 0 \), \( \mu = \pm 1 \), and \( \mu = \pm i \), the latter being due to the singularity of \( \hat{p}_t \) at \( \mu = \pm i \):
\[ \hat{p}_t(\mu) = \pm \frac{1}{(\mu + i)^2} - \frac{i}{\mu + 1} + O(1), \quad \mu \to \pm i. \] (4.11)

Evaluating \( \hat{\Psi}_t \hat{\Psi}^{-1} \) near these points, we have the following.
(i) As \( \mu \to \infty \), we have \( \hat{p}_t(\mu) = O(\mu^{-1}) \) and thus
\[ \hat{\Psi}_t \hat{\Psi}^{-1}(\mu) = O(\mu^{-1}), \quad \mu \to \infty. \] (4.12)

Then, by symmetry,
\[ \hat{\Psi}_t \hat{\Psi}^{-1}(\mu) = O(\mu), \quad \mu \to 0. \] (4.13)

(ii) Expanding \( \hat{M}(\mu) \) at \( \mu = 1 \), and proceeding as above to get (4.8), we have
\[ \hat{\Psi}_t \hat{\Psi}^{-1}(\mu) = \frac{i\beta_2}{\mu - 1} \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix} + O(1), \quad \mu \to 1, \] (4.14)
with some $\beta_2(y, t) \in \mathbb{R}$. By symmetry,

$$
\hat{\Psi}_t \hat{\Psi}^{-1}(\mu) = \frac{i\beta_2}{\mu + 1} \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} + O(1), \quad \mu \to -1.
$$

(4.15)

(iii) Evaluating $\hat{M}(\mu)$ as $\mu \to i$, we first notice that, due to symmetries,

$$
\hat{M}(\mu) = \left( a_1 \begin{pmatrix} 0 & 0 \\ 0 & a_1^{-1} \end{pmatrix} + \begin{pmatrix} 0 & a_2 \\ a_3 & 0 \end{pmatrix} (\mu - i) + O((\mu - i)^2), \quad \mu \to i,
$$

with some $a_j \equiv a_j(y, t), j = 1, 2, 3$. Taking into account (4.11), we have

$$
\hat{\Psi}_t \hat{\Psi}^{-1}(\mu) = -\frac{1}{(\mu - i)^2} \sigma_3 + \frac{1}{\mu - i} \left( i\sigma_3 + \begin{pmatrix} 0 & 2a_2a_1^{-1} \\ -2a_3a_1^{-1} & 0 \end{pmatrix} \right) + O(1), \quad \mu \to i.
$$

(4.17)

Then, by symmetry,

$$
\hat{\Psi}_t \hat{\Psi}^{-1}(\mu) = \frac{1}{(\mu + i)^2} \sigma_3 + \frac{1}{\mu + i} \left( i\sigma_3 + \begin{pmatrix} 0 & -2a_2a_1^{-1} \\ 2a_3a_1^{-1} & 0 \end{pmatrix} \right) + O(1), \quad \mu \to -i.
$$

(4.18)

Combining (4.12), (4.14), and (4.15), (4.17), and (4.18), we obtain that the function

$$
\hat{\Psi}_t \hat{\Psi}^{-1}(\mu) = \frac{2i(\mu^2 - 1)\mu}{(\mu^2 + 1)^2} \sigma_3 - \frac{1}{\mu - i} i\beta_2 \begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix} - \frac{1}{\mu + i} i\beta_2 \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}
$$

$$
- \frac{1}{\mu - i} \begin{pmatrix} 0 & \gamma_1 \\ \gamma_1 & 0 \end{pmatrix} - \frac{1}{\mu + i} \begin{pmatrix} 0 & \gamma_2 \\ \gamma_2 & 0 \end{pmatrix}
$$

with $\gamma_1 = 2a_2a_1$ and $\gamma_2 = -2a_3a_1^{-1}$ is holomorphic in the whole complex $\mu$-plane and, moreover, vanishes as $\mu \to \infty$. Then, by Liouville’s theorem, it vanishes identically. Thus we arrive at the equality $\hat{\Psi}_t = \hat{V}' \hat{\Psi}$ with $\hat{V}(\mu) = \frac{2i(\mu^2 - 1)\mu}{(\mu^2 + 1)^2} \sigma_3 + \hat{V}(\mu)$, where $\hat{V}(\mu)$ is as in (4.2b) with $q = \beta_2, g_1 = \gamma_1$, and $g_2 = \gamma_2$.

The next step is to demonstrate that the compatibility condition

$$
\hat{U}_t - \hat{V}_y + [\hat{U}, \hat{V}] = 0
$$

yields the mCH equation in the $(y, t)$ variables, which is as follows:

**Proposition 4.4.** The mCH equation (1.8a) in the $(y, t)$ variables reads as follows:

$$
(m^{-1})_t y(y, t) = 2\hat{u}_x(y, t), \quad m(y, t) = \hat{u}(y, t) - \hat{u}_{xx}(y, t) + 1,
$$

(4.20a)

(4.20b)

where $\hat{f}(y, t) := \hat{f}(x(y, t), t)$ for any function $\hat{f}(x, t)$ and $x_y(y, t) = m^{-1}(y, t)$.

**Proof.** Substituting $\hat{m}_t = -\hat{\omega} m$, from (1.8a) and $x_t = \hat{\omega}$ from (3.29) into the equality

$$
\hat{m}_t(y, t) = \hat{m}_x(x(y, t), t)x_t(y, t) + \hat{m}_t(x(y, t), t)
$$

and using that $\hat{\omega}_x = 2\hat{m} \hat{u}_x$ we get

$$
\hat{m}_t(y, t) = \hat{m}_x(x(y, t), t)\hat{\omega}(y, t) - \hat{m}_x(x(y, t), t)\hat{\omega}(y, t) - 2\hat{m}^2(x(y, t), t)\hat{u}_x(y, t) = -2\hat{u}_x\hat{u}_y(y, t)
$$

and thus (4.20a) follows.

**Remark 4.5.** Notice that (4.20b) can be written as

$$
\hat{m}(y, t) = \hat{u}(y, t) - (\hat{u}_x)_y(y, t)\hat{m}(y, t) + 1.
$$

(4.21)

Now, evaluating the compatibility equation (4.19) at the singular points for $\hat{U}$ and $\hat{V}$, we get algebraic and differential equations amongst the coefficients of $\hat{U}$ and $\hat{V}$, i.e., amongst $\beta_1, \beta_2, \gamma_1$, and $\gamma_2$, that can be reduced to (4.20a).
Proposition 4.6. Let $\beta_1(y,t), \beta_2(y,t), \gamma_1(y,t),$ and $\gamma_2(y,t)$ be the functions determined in terms of $\bar{M}(y,t,\mu)$ as in Propositions 4.2 and 4.3. Then they satisfy the following equations:

\begin{align*}
\beta_{1t} + \frac{\gamma_1 + \gamma_2}{2} &= 0; \tag{4.22a} \\
\beta_2 - \frac{\gamma_2 - \gamma_1}{2} &= 0; \tag{4.22b} \\
(\gamma_1 - \gamma_2)y - (1 + 2\beta_1)(\gamma_1 + \gamma_2) &= 0; \tag{4.22c} \\
(\gamma_2 + \gamma_1)y + 4\beta_1 - (1 + 2\beta_1)(\gamma_1 - \gamma_2) &= 0. \tag{4.22d}
\end{align*}

Proof. Recall $\beta_1$ and $\beta_2$ are given by (4.8) and (4.14), respectively. Moreover, $\gamma_1 := 2a_2a_1$ and $\gamma_2 := -2a_3a_1^{-1}$, where $a_1, a_2$, and $a_3$ are defined by (4.16).

(i) Evaluating the l.h.s. of (4.19) as $\mu \to \infty$, the main term (of order $O(1)$) is

$$
\left(\beta_{1t} + \frac{\gamma_1 + \gamma_2}{2}\right) \sigma_2,
$$

from which (4.22a) follows.

(ii) Evaluating the l.h.s. of (4.19) as $\mu \to 0$, the main term (of order $O(\mu^{-1})$) is

$$
-\frac{1}{\mu} \left(\beta_2 + \frac{\gamma_1 - \gamma_2}{2}\right) \sigma_1,
$$

from which (4.22b) follows.

(iii) Evaluating the l.h.s. of (4.19) as $\mu \to 1$, the diagonal part of the main term (of order $O((\mu - 1)^{-1})$) is

$$
\frac{i}{\mu - 1} (\beta_{1t} - \beta_{2y} - \beta_1(\gamma_1 + \gamma_2)) \sigma_3,
$$

from which (4.22c) follows, taking into account (4.22a) and (4.22b).

(iv) Evaluating the l.h.s. of (4.19) as $\mu \to i$, the main term (of order $O((\mu - i)^{-1})$) is

$$
\frac{1}{\mu - i} \left[ \begin{pmatrix} 0 & -\gamma_1 y \\ -\gamma_2 y & 0 \end{pmatrix} + (1 + 2\beta_1) \begin{pmatrix} 0 & \gamma_1 \\ -\gamma_2 & 0 \end{pmatrix} - 2\beta_1 \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \right],
$$

from which (4.22d) follows. \hfill \Box

Proposition 4.7. Let $\hat{m}(y,t), \hat{u}(y,t),$ and $x(y,t)$ be defined in terms of $\beta_1, \beta_2, \gamma_1,$ and $\gamma_2$ as follows:

$$
\hat{m} = (1 + 2\beta_1)^{-1}, \quad \hat{u} = \beta_2 = \frac{\gamma_2 - \gamma_1}{2}, \quad x = 1 + 2\beta_1. \tag{4.23}
$$

Then the four equations (4.22) reduce to (4.20a) and (4.21).

Proof. Indeed, defining $\hat{u}$ and $x(y,t)$ as prescribed in (4.23), equation (4.22c) implies that $\hat{u}_x = \hat{u}_y x^{-1}$ can be expressed as

$$
\hat{u}_x = -\frac{\gamma_1 + \gamma_2}{2}.
$$

Then, taking into account the definition of $\hat{m}$ in (4.23), equation (4.22a) takes the form of the equation (4.20a). Finally, using the notations introduced above, equation (4.21) can be written as

$$
\frac{1}{1 + 2\beta_1} = \frac{\gamma_2 - \gamma_1}{2} + \frac{(\gamma_1 + \gamma_2)y}{2} \frac{1}{1 + 2\beta_1} + 1,
$$

which is just equation (4.22d). \hfill \Box
Remark 4.8. Formulas $\hat{u} = \frac{-3\rho y}{2}$ and $\hat{u}_x = -\frac{3\rho y}{2}$ provide an alternative way to obtain $\hat{u}$ as well as $\hat{u}_x$ from the solution $\hat{M}$ of the RH problem. Indeed, according to Proposition 4.3, $\hat{u}$ and $\hat{u}_x$ (as functions of $(y, t)$) can be obtained using the coefficients $a_j(y, t)$ (see (4.16)) of the development of $\hat{M}(y, t, k)$ as $\mu \to i$ (thus avoiding the differentiations used in Section 3.5):

$$\hat{u}(y, t) = -a_2a_1 - a_3a_1^{-1}, \quad \hat{u}_x(y, t) = -a_2a_1 + a_3a_1^{-1},$$

(4.24)

where $a_j(y, t)$ are determined by (4.16). Recall also the representation for $\hat{m}$ in terms of $\hat{M}$ evaluated as $\mu \to \infty$, see Proposition 4.2:

$$\hat{m}(y, t) = \frac{1}{1 + 2\hat{\beta}_1(y, t)} = \frac{1}{1 - \eta(y, t)},$$

\eta(y, t) \equiv \lim_{\mu \to \infty} \mu \hat{M}_{12}(y, t, \mu).

(4.25)

Considered together with the expression for the change of variables (3.26b), which can be written as (we indeed have $\hat{\mu}_1 = a_1$ and $\hat{\mu}_2 = a_1^{-1}$)

$$x(y, t) = y + 2\ln a_1(y, t),$$

(4.26)

equations (4.24) and (4.25) give a parametric representation of the solution of the mCH equation (1.8a).

5. Solitons

In the Riemann–Hilbert variant of the inverse scattering transform method, pure soliton solutions can be obtained from the solutions of the RH problem assuming that the jump is trivial ($\hat{J} \equiv I$), which reduces the construction to solving a system of linear algebraic equations generated by the residue conditions.

In order to construct the simplest, one-soliton solution, we consider the RH problem (3.17)–(3.20) with specific data, in particular $r(\mu) \equiv 0$, so that $\hat{J} \equiv I$. Regarding the other data, we require that $\hat{M}^{(1)}$ has a simple pole on the unit circle, at $\mu_1 = e^{i\theta}$, $\theta \in (0, \frac{\pi}{2})$. It follows that $\hat{M}^{(1)}$ has also a simple pole at $\mu_2 = -e^{-i\theta} = -\mu_1^{-1}$. According to the symmetries (3.19) the coefficients $\hat{\xi}_j(y, t) = \rho_j e^{-2i\theta_1(y, t, \mu_j)}$, $j = 1, 2$ in the residue conditions (3.18) must satisfy the relations $\hat{\xi}_1 = \hat{\xi}_2 = -\mu_1^{-2} \hat{\xi}_2$, that is, $\rho_1 = \frac{\mu_2}{\mu_1^2} = -\mu_1^{-2} \rho_2$ which imply $\rho_1 = ie^{-i\theta} \hat{\delta}$ for some $\hat{\delta} \in \mathbb{R}$. Further we denote $\hat{\xi}(y, t) := \hat{\xi}_1(y, t)$ and $\rho := \rho_1 \in \mathbb{C}$. So $\rho$ satisfies

$$\hat{\rho} = -e^{2i\theta} \rho.$$

(5.1)

Thus we arrive at the following Riemann–Hilbert problem:

**Soliton RH problem.** Given $\theta \in (0, \frac{\pi}{2})$ and $\hat{\delta} \neq 0$ two real parameters, together with $c \in \mathbb{R}$, find a piece-wise (w.r.t. $\mathbb{R}$) meromorphic, $2 \times 2$-matrix valued function $\hat{M}(y, t, \mu)$ satisfying the following conditions:

- The jump condition $\hat{J} \equiv I$ across $\mathbb{R}$.
- The residue conditions (3.18) at $\mu_1 = e^{i\theta}$ and $\mu_2 = e^{-i\theta}$:

$$\text{Res}_{e^{i\theta}} \hat{M}^{(1)}(y, t, \mu) = -\frac{1}{\hat{\xi}(y, t)} \hat{M}^{(2)}(y, t, e^{i\theta}),$$

$$\text{Res}_{e^{-i\theta}} \hat{M}^{(2)}(y, t, \mu) = -\frac{1}{\hat{\xi}(y, t)} \hat{M}^{(1)}(y, t, e^{-i\theta}),$$

(5.2a)

(5.2b)

where $\hat{\xi}(y, t) = ie^{-i\theta} e^{-2i\rho(y, t, e^{i\theta})}$ with $\hat{\rho}(y, t, e^{i\theta}) = \frac{\sin \theta}{2} (-y + \frac{2}{\cos \theta} t)$, and $\hat{\xi} = -e^{2i\theta} \hat{\xi}$.

- The normalization condition $\hat{M}(y, t, \infty) = I$.
- The symmetries (3.19).
The singularity conditions (3.20) at $\mu = \pm 1$.

The residue conditions at $\mu_2$ and $\bar{\mu}_2$ follow from (5.2) using the symmetries (3.19):

$$\text{Res}_{-e^{i\vartheta}} \bar{M}^{(1)}(y,t,\mu) = \frac{1}{\bar{\varpi}(y,t)} \bar{M}^{(2)}(y,t, -e^{-i\vartheta}),$$  \hspace{1cm} (5.3a)

$$\text{Res}_{-e^{i\vartheta}} \bar{M}^{(2)}(y,t,\mu) = \frac{1}{\bar{\varpi}(y,t)} \bar{M}^{(1)}(y,t, -e^{i\vartheta}).$$  \hspace{1cm} (5.3b)

To summarize, the soliton RH problem of parameters $(\theta, \delta)$ is the RH problem (3.17)–(3.20) with trivial jump condition and residue conditions data $\{\mu_j, \rho_j\}_{1}^{2}$ where $\mu_1 = -\bar{\mu}_2 = e^{i\vartheta}$ and $\rho_1 = \bar{\rho}_2 = ie^{-i\vartheta} \delta$.

Remark 5.1. Assume that the data of the soliton RH problem are associated with the spectral data corresponding to some initial data $u_0(x)$, see Section 2.3. In particular, $b(\mu) \equiv 0$ and $a(\mu)$ has two zeros in $\mathbb{C}^+$, each of multiplicity one, $\mu_1 = e^{i\vartheta}$ and $\mu_2 = -e^{-i\vartheta}$, both on the unit circle. The function $\bar{\varpi}$ in the residue condition for $\bar{M}^{(1)}$ at $\mu_1$ is given by $\bar{\varpi} = \rho e^{-2\theta(y,t,e^{i\vartheta})}$ with $\rho = \hat{a}(e^{i\vartheta})\delta$, where the constant $\delta$ relates to two Jost functions: $\hat{\Phi}_0^{(2)}(x,t,\mu_1) = \delta \hat{\Phi}_0^{(1)}(x,t,\mu_1)$. Using the symmetries (2.18) and the relation $\bar{\mu}_1 = \mu_1^{-1}$ we find that $\sigma_1 \hat{\Phi}_0(e^{-i\vartheta})\sigma_1 = \Phi_{\pm}(e^{i\vartheta})\Phi_{\mp}(e^{i\vartheta})$ and thus $\delta$ is real. Moreover, from the symmetry relation $a(\mu^{-1}) = \bar{a}(\mu)$ it follows that $\bar{a}(e^{i\vartheta}) = -e^{2i\theta} \hat{a}(e^{i\vartheta})$, and thus $\rho = \hat{a}(e^{i\vartheta})\delta$ satisfies (5.1). To conclude, in that case, $\delta = -ie^{i\vartheta} \hat{a}(e^{i\vartheta})\delta$.

Proposition 5.2. Let $\theta \in (0, \frac{i}{\pi}\mathbb{Z})$ and $\delta \neq 0$ be two real parameters. Then, the soliton RH problem of parameters $(\theta, \delta)$ has a solution $\bar{M} \equiv \bar{M}_{\theta, \delta}$ provided that $c = 1$:

$$\bar{M}(y,t,\mu) = I + \frac{i}{2} \begin{pmatrix} \hat{\alpha}_+(y,t) & -1 & 1 \\ -1 & 1 & 1 \\ -1 & 1 & 1 \end{pmatrix} + \begin{pmatrix} i\tilde{\kappa}_2(y,t)e^{i\vartheta} & -i\tilde{\kappa}_2(y,t)e^{-i\vartheta} \\ -i\tilde{\kappa}_2(y,t)e^{i\vartheta} & i\tilde{\kappa}_2(y,t)e^{-i\vartheta} \\ \tilde{\kappa}_2(y,t)e^{i\vartheta} & \tilde{\kappa}_2(y,t)e^{-i\vartheta} \end{pmatrix},$$  \hspace{1cm} (5.4)

where

$$\tilde{\kappa}_2^{-1}(y,t) = -\frac{\cos^2 \theta}{4\varpi(y,t)\sin^2 \theta} - \frac{1}{\sin \theta},$$  \hspace{1cm} (5.5a)

$$\tilde{\kappa}_1(y,t) = -\frac{\cos \theta}{2\varpi(y,t)\sin \theta} \tilde{\kappa}_2(y,t),$$  \hspace{1cm} (5.5b)

$$\hat{\alpha}_+(y,t) = 2\tilde{\kappa}_2(y,t).$$  \hspace{1cm} (5.5c)

Here,

$$\varpi(y,t) := \delta e^{-2\rho(y,t,e^{i\vartheta})} \quad \text{with} \quad \rho(y,t,e^{i\vartheta}) = \frac{\sin \theta}{2} \left( -y + \frac{2}{\cos^2 \theta} \right).$$  \hspace{1cm} (5.5d)

Proof. Since $\bar{M}(\mu) \equiv \bar{M}(y,t,\mu)$ is solution of the soliton RH problem whose jump condition is trivial, it is a rational function, whose pole structure is specified by the singularity conditions (3.20) at $\mu = \pm 1$ and by the residue conditions (5.2) at $\mu = \pm e^{i\vartheta}$:

$$\bar{M}(\mu) = I + \frac{i}{2}\hat{\alpha}_+(y,t) \begin{pmatrix} -c & 1 \\ -c & 1 \end{pmatrix} - \frac{i}{2} \hat{\alpha}_+(y,t) \begin{pmatrix} c & 1 \\ -c & -1 \end{pmatrix} + \begin{pmatrix} c_1 \mu^{-e^{-i\vartheta}} + c_2 \mu^{e^{-i\vartheta}} + c_3 \mu^{e^{i\vartheta}} + c_4 \mu^{-e^{i\vartheta}} \\ c_1 \mu^{-e^{-i\vartheta}} + c_2 \mu^{e^{-i\vartheta}} + c_3 \mu^{e^{i\vartheta}} + c_4 \mu^{-e^{i\vartheta}} \end{pmatrix},$$  \hspace{1cm} (5.6)

with some $\hat{\alpha}_+(y,t), c_j(y,t), \tilde{c}_j(y,t)$, and $c$. We will specify the coefficients using the symmetries (3.19). The symmetry $\bar{M}^{(1)}(-\mu) = \sigma_3 \sigma_1 \bar{M}^{(2)}(\mu)$ shows that $c = 1, \tilde{c}_1 = c_4, \tilde{c}_2 = -c_3, \tilde{c}_3 = c_2,$
and \( \tilde{c}_4 = -c_1 \). On the other hand, the symmetry \( M^{(1)}(-\mu) = \sigma_3 M^{(1)}(\mu) \) shows that \( c_3 = -\tilde{c}_1 \) and \( c_4 = \tilde{c}_2 \). Thus (5.6) takes the form

\[
\dot{M}(\mu) = I + \frac{i}{2\mu - 1} \left( \begin{array}{cc} -1 & 1 \\ -1 & 1 \end{array} \right) - \frac{i}{2\mu + 1} \left( \begin{array}{cc} 1 & 1 \\ -1 & -1 \end{array} \right) \left( \begin{array}{cc} \frac{c_1}{\mu - e^{-\theta}} & \frac{-c_1}{\mu - e^{-\theta}} \\ \frac{\mu e^{-\theta}}{\mu - e^\theta} & \frac{\mu e^\theta}{\mu - e^\theta} \end{array} \right).
\]

The symmetry \( \dot{M}^{(1)}(-\mu^{-1}) = \sigma_3 \dot{M}^{(1)}(\mu) \) shows that \( c_3 = c_1 e^{-2i\theta} \) and \( c_4 = -c_2 e^{-2i\theta} \), so that \( \tilde{c}_4 = -c_2 e^{-2i\theta} \) for \( j = 1, 2 \), that is, \( c_j(y, t) = i e^{i\theta} \tilde{c}_j(y, t) \) with \( \tilde{c}_j(y, t) \in \mathbb{R} \). Thus we get (5.4).

Then, using \( \dot{M}(0) = \sigma_1 \dot{M}(\infty) \sigma_1 = I \), it follows that \( \tilde{\alpha} = 2\mu \), that is, (5.5c).

Introducing \( \tilde{\kappa}(y, t) := \tilde{\delta} e^{-2i(y,t)\theta} \) so that \( \tilde{\kappa}(y, t) = i e^{-i\theta} \tilde{\kappa}(y, t) \) and substituting (5.4) into the residue condition (5.2a) at \( e^{i\theta} \), we find (5.5b) on the first row and then (5.5a) on the second one.

\( \square \)

\textbf{Remark 5.3.} Assume that the data of our soliton RH problem are derived from the spectral data corresponding to some initial data \( u_0(x) \), as in Remark 5.1. Then, it directly follows that \( c = 1 \). Since \( b(\mu) \equiv 0 \) we indeed have (see Remark 2.3 and (3.6)) \( \rho = 0, b_1 = 0 \), and \( a_1 = 1 \); thus \( c = 1 \).

According to Section 4, a solution of the soliton RH problem gives rise to a solution (at least, locally, in the \( (y, t) \) variables) of the mCH equation. Thus, Proposition 5.2 provides a family of one-soliton solutions parametrized by two real parameters \( \theta \in (0, \frac{\pi}{2}) \) and \( \delta \neq 0 \).

\textbf{Proposition 5.4.} The one-soliton solution \( \tilde{u} \equiv \tilde{u}_{\theta, \delta} \) of parameters \( (\theta, \delta) \) has the following form in the \( (y, t) \)-scale:

\[
\tilde{u}(y, t) = 4 \tan^2 \theta \frac{z^2(y, t) + 2 \cos^2 \theta \cdot z(y, t) + \cos^2 \theta}{(z^2(y, t) + 2 z(y, t) + \cos^2 \theta)^2} z(y, t), \tag{5.7a}
\]

where

\[
z(y, t) = 2\delta \sin \theta e^{\sin \theta (y - \frac{z}{\cos \theta})}. \tag{5.7b}
\]

\textbf{Proof.} Let \( z(y, t) \) be defined by

\[
z(y, t) := 2 \tilde{\kappa}(y, t) \sin \theta. \tag{5.8}
\]

Then, \( z(y, t) = 2 \delta \sin \theta e^{\sin \theta (y - \frac{z}{\cos \theta})} \). Thus, \( z \) is real-valued. Moreover, \( z(y, t) > 0 \) if \( \delta > 0 \) and \( z(y, t) < 0 \) if \( \delta < 0 \). Using (5.5a), (5.5b), and (5.8) we get the following expressions of \( \tilde{\kappa}_2 \) and \( \tilde{\kappa}_1 \):

\[
\tilde{\kappa}_2 = -\frac{2 \sin \theta}{z^2 + 2 z + \cos^2 \theta} \quad \text{and} \quad \tilde{\kappa}_1 = -\frac{\cos \theta}{z} \tilde{\kappa}_2 = \frac{2 \sin \theta \cos \theta}{z^2 + 2 z + \cos^2 \theta}. \tag{5.9}
\]

In order to obtain the formula for the soliton solution \( \tilde{u} \equiv \tilde{u}(y, t) \), we use the relation

\[
\tilde{u} = -a_2 a_1 - a_3 a_1^{-1} \tag{5.10}
\]

from (4.24). To compute \( a_1 \equiv a_1(y, t) \) we observe that \( a_1 = \dot{M}_{11}(i) \). We thus obtain

\[
a_1 = 1 - \frac{\tilde{\alpha} + 1}{2(1 - \sin \theta)} \frac{1 + e^{2i\theta}}{2(1 - \sin \theta)} = 1 - \dot{\kappa}_2 + \dot{\kappa}_1 \frac{\cos \theta}{1 - \sin \theta},
\]

using the relation \( \frac{\tilde{\alpha}}{2} = \dot{\kappa}_2 \) from (5.5c). Using the expressions of \( \dot{\kappa}_1 \) and \( \dot{\kappa}_2 \) from (5.9) we get

\[
a_1 = \frac{z + 1 + \sin \theta}{z + 1 - \sin \theta}. \tag{5.11a}
\]
To compute $a_2 \equiv a_2(y,t)$ and $a_3 \equiv a_3(y,t)$ we observe that $a_2 = \partial_y \hat{M}_{12}(i)$ and $a_3 = \partial_y \hat{M}_{21}(i)$. Using in addition the expression of $\hat{\kappa}_2$ from (5.9) we obtain

\begin{align}
\frac{a_2}{\sin \theta} = & \frac{1}{1 + \sin \theta} \hat{\kappa}_2 = -\frac{2z \sin^2 \theta}{(1 + \sin \theta)(z^2 + 2z + \cos^2 \theta)}, \\
\frac{a_3}{\sin \theta} = & \frac{1}{1 - \sin \theta} \hat{\kappa}_2 = -\frac{2z \sin^2 \theta}{(1 - \sin \theta)(z^2 + 2z + \cos^2 \theta)}. \tag{5.11b}
\end{align}

Then, substituting (5.11) into (5.10), we arrive at (5.7a).

It follows from (5.7a) that if $\delta > 0$, then for any $t \geq 0$, $\hat{u}(y,t)$ is a smooth function of $y$ having a single peak and (exponentially) approaching $0$ as $y \to \pm \infty$. On the other hand, if $\delta < 0$, then $\hat{u}$ has two singular points corresponding to $z = -1 \pm \sin \theta$.

Now let us discuss the change of variable $(y,t) \mapsto (x,t)$, which can be specified explicitly. This change of variable is associated with $\hat{u}_{\theta, \delta}$; that is, it is given by (3.26b) where $\hat{\mu}_1$ and $\hat{\mu}_2$ are defined in terms of $\hat{M} \equiv \hat{M}_{\theta, \delta}$.

**Proposition 5.5.** The change of variable $x(y,t)$ associated with the soliton $\hat{u}_{\theta, \delta}$ takes the following form:

\begin{equation}
x(y,t) = y + 2 \ln \frac{z(y,t) + 1 + \sin \theta}{z(y,t) + 1 - \sin \theta}. \tag{5.12}
\end{equation}

**Proof.** As we have shown in Section 4, $x(y,t)$ can be given by (4.26):

\begin{equation}
x(y,t) = y + 2 \ln a_1(y,t), \tag{5.13}
\end{equation}

where $a_1(y,t) = \hat{M}_{11}(y,t,i)$. Substituting (5.11a) into (5.13), we obtain (5.12).

**Corollary 5.6.** Let $x(y,t)$ be the change of variable associated with $\hat{u}_{\theta, \delta}$. Its regularity properties are as follows.

(a) If $\delta < 0$, then $x(\cdot, t)$ is singular: there exist values of $y$ at which $x(y,t)$ is infinite.

(b) If $\delta > 0$, then $x(\cdot, t) : \mathbb{R} \to \mathbb{R}$ is a regular map. Moreover, it has the following additional properties:

(i) If $\theta \in (0, \frac{\pi}{4})$, then $x(\cdot, t) : \mathbb{R} \to \mathbb{R}$ is a diffeomorphism for any $t \geq 0$.

(ii) If $\theta = \frac{\pi}{4}$, then $x(\cdot, t) : \mathbb{R} \to \mathbb{R}$ is a bijection, but the derivative of the inverse map has a singularity, and only one.

(iii) If $\theta \in (\frac{\pi}{2}, \frac{3\pi}{4})$, then $x(\cdot, t)$ is not monotonous. More precisely, there are three intervals of monotonicity.

The possible singularities of $x(y,t)$ are those for $\hat{u}(y,t)$: they correspond to $z = -1 \pm \sin \theta$. Therefore, if $\delta > 0$, then $z(y,t) > 0$ and thus there are no singularities, whereas if $\delta < 0$, then $x(y,t)$ is singular at those $y$ where $z = -1 \pm \sin \theta$.

We now consider the case $\delta > 0$ (and thus $z(y,t) > 0$). The derivative $\partial_y x(y,t)$ is given by

\[ \partial_y x(y,t) = R(z(y,t)), \]

where

\[ R(z) = \frac{z^2 + 2z \cos 2\theta + \cos^2 \theta}{z^2 + 2z + \cos^2 \theta}. \]

It follows that $R(0) = R(\infty) = 1$. Moreover, we have the following:

1) If $\theta \in (0, \frac{\pi}{4})$, then $R(z) > 0$ for all $z \geq 0$.

2) If $\theta = \frac{\pi}{4}$, then $z = \frac{1}{2}$ is a double zero of $R(z)$.

3) If $\theta \in (\frac{\pi}{2}, \frac{3\pi}{4})$, then

a) $R(z) > 0$ for $z \in [-\cos 2\theta - \sqrt{-\sin \theta \cdot \sin 3\theta}, -\cos 2\theta + \sqrt{-\sin \theta \cdot \sin 3\theta}]$, $+\infty$.

b) $R(z) < 0$ for $z \in (-\cos 2\theta - \sqrt{-\sin \theta \cdot \sin 3\theta}, -\cos 2\theta + \sqrt{-\sin \theta \cdot \sin 3\theta})$. 

In particular, for $\theta = \frac{\pi}{2}$ we have a cuspon solution $\tilde{u}(x,t) = \tilde{u}(y(x,t), t)$ (with $\tilde{u}_x(x,t) = \infty$ when $z(y(x,t), t) = \frac{1}{2}$) given in parametric form by

$$
\tilde{u}(y,t) = 48z(y,t) \frac{4z^2(y,t) + 2z(y,t) + 1}{(4z^2(y,t) + 8z(y,t) + 1)^2},
$$

(5.14a)

$$
z(y,t) = \delta \sqrt{3} e^{\frac{3}{2}y} e^{-4\sqrt{3}t},
$$

(5.14b)

$$
x(y,t) = y + 2\ln \frac{\delta \sqrt{3} e^{\frac{3}{2}y} e^{-4\sqrt{3}t} + 1 + \frac{\sqrt{3}}{y}}{\delta \sqrt{3} e^{\frac{3}{2}y} e^{-4\sqrt{3}t} + 1 - \frac{\sqrt{3}}{y}}.
$$

(5.14c)

Thus we arrive at

**Theorem 5.7.** The mCH equation in the form (1.8) has a family of one-soliton solutions, regular as well as non-regular, $\tilde{u}(x,t) \equiv \tilde{u}_{\delta, \theta}(x,t)$, parametrized by two parameters, $\delta > 0$ and $\theta \in (0, \frac{\pi}{2})$. These solitons $\tilde{u}(x,t) \equiv \tilde{u}(y(x,t), t)$ are given, in parametric form, by

$$
\tilde{u}(y,t) = 4 \tan^2 \theta \frac{z^2(y,t) + 2 \cos^2 \theta \cdot z(y,t) + \cos^2 \theta}{(z^2(y,t) + 2z(y,t) + \cos^2 \theta)^2} z(y,t),
$$

(5.15a)

$$
x(y,t) = y + 2\ln \frac{z(y,t) + 1 + \sin \theta}{z(y,t) + 1 - \sin \theta},
$$

(5.15b)

$$
z(y,t) = 2\delta \sin \theta e^{\theta \sin \theta} e^{-\frac{4\delta \sin \theta}{\cos \theta}}.
$$

(5.15c)

They have different properties depending on the value of the parameter $\theta$:

(i) For $\theta \in (0, \frac{\pi}{2})$, the one-soliton solution $\tilde{u}(x,t)$ is smooth in the $(x,t)$ variables.

(ii) For $\theta = \frac{\pi}{2}$, then $\tilde{u}(x,t)$ is given by (5.14) and has the form of a cuspon, with $\tilde{u}_x(x,t) = \infty$ when $z(y(x,t), t) = \frac{1}{2}$.

(iii) If $\theta \in (\frac{\pi}{2}, \frac{3\pi}{4})$, then $\tilde{u}(x,t) = \tilde{u}(y,t)$ is regular in $(y,t)$, multivalued in $(x,t)$, and loop-shaped.
