LOCALLY RECOVERABLE J-AFFINE VARIETY CODES

CARLOS GALINDO, FERNANDO HERNANDO AND CARLOS MUNUERA

ABSTRACT. We prove that subfield-subcodes over finite fields \( F_q \) of some \( J \)-affine variety codes provide locally recoverable codes correcting more than one erasure. We compute their \((r, \delta)\)-localities and show that some of these codes with lengths \( n \gg q \) are \((\delta - 1)\)-optimal.

INTRODUCTION

The growth of the amount of stored information in large scale distributed and cloud storage systems makes the loss of data due to node failures a major problem. To obtain a reliable storage, when a node fails, we want to recover the data it contains by using information from other nodes. This is the repair problem. A naive solving method consists of the replication of information across several nodes. A more clever method is to protect the data using error-correcting codes, what has led to the introduction of locally recoverable (LRC) codes \cite{9}. As typical examples of this solution we can mention Google and Facebook storage systems that use Reed-Solomon (RS) codes to protect the information.

The procedure is as follows: the information to be stored is a long sequence \( b \) of elements in a finite field \( F_m \). This sequence is divided into blocks, \( b = b_1, b_2, \ldots \), of the same length \( l \). According to the isomorphism \( F_m \cong F_m^l \), each of these blocks can be seen as an element of the finite field \( F_q \), \( q = m^l = p^s \), \( p \) being a prime number and \( s \) a positive integer. Fix an integer \( k < q \). The vector \( x = (b_1, b_2, \ldots, b_k) \in F_q^k \) is encoded by using a Reed-Solomon code of dimension \( k \) over \( F_q \), whose length \( n \), \( k < n \leq q \), is equal to the number of nodes that will be used in its storage. We choose \( \alpha_1, \alpha_2, \ldots, \alpha_n \in F_q \) and send \( f(\alpha_i) = b_1 + b_2 \alpha_i + \cdots + b_k \alpha_i^{k-1} \) to the \( i \)th node. Even if a node fails, we may recover the stored data \( (b_1, b_2, \ldots, b_k) \) by using Lagrangian interpolation from any other \( k \) available nodes.

Note that this method is wasteful, since \( k \) symbols over \( n \) nodes must be used to recover just one erasure. Of course other error-correcting codes, apart from RS codes, can be used to deal more efficiently with the repair problem. Thus in terms of coding theory the repair problem can be stated as follows: Let \( C \) be a linear code of length \( n \) and dimension \( k \) over \( F_q \). A coordinate \( i \in \{1, 2, \ldots, n\} \) is locally recoverable with locality \( r \) if there is a recovery set \( R \subset \{1, 2, \ldots, n\} \) with \( i \notin R \) and \( |R| = r \), such that for any codeword \( x \in C \), an erasure at position \( i \) of \( x \) can be recovered by using the information given by the coordinates of \( x \) with indices in \( R \). The code \( C \) is called to be locally recoverable (LRC) with locality \( \leq r \) if each coordinate is so, and the locality of \( C \) is the smallest \( r \) satisfying this condition. For example, MDS codes (RS codes in particular) of dimension \( k \) have locality \( k \). In Section \[1\] we will specify these definitions.

Key words and phrases. LRC codes; subfield subcodes; \( J \)-affine variety codes.

Supported by the Spanish Government, Ministerio de Ciencia, Innovación y Universidades (MICINN) (grants PGC2018-096446-B-C21 and PGC2018-096446-B-C22), Generalitat Valenciana (grant AICO-2019-223) and University Jaume I (grant PB1-1B2018-10).
Among the different classes of codes used as good candidates for local recovering, cyclic codes and subfield-subcodes of cyclic codes play an important role, as the cyclic shifts of a recovery set provide again recovery sets \([1, 10, 12, 17]\). In this article we continue this line of research by using the very general language of affine variety codes. We consider specific \(J\)-affine variety codes, which were introduced in \([7]\), whose subfield-subcodes provide LRC codes. These subfield-subcodes admit large lengths over fields \(\mathbb{F}_q, q = p^s\), and according to Theorems \([2, 6]\) and \([2, 7]\) have localities \(r \leq q - 2\) or \(r \leq q - 1\).

A variation of LRC codes was introduced in \([10]\). As multiple device failures may occur simultaneously, it is of interest to consider LRC codes correcting more than one erasure. This idea leads to the concept of \((r, \delta)\)-locality (see Section \([1]\) and Theorem \([2, 9]\)). Codes of this type have been subsequently studied in \([1, 3]\). The codes we present in this work belong to this category. Using affine variety constructions we are able to provide examples of good LRC codes correcting several erasures, and also to compute its \((r, \delta)\)-locality. In some cases these codes are optimal for the Singleton-like bound \([2]\). Compared with the codes obtained in \([1]\), our codes are considerably longer, although they are not optimal in general. Let us recall here that most good currently known LRC codes have small lengths \(n\), in comparison with the cardinality of the ground field \(q\): usually \(n < q, \quad [11]\) (or \(n = q + 1\) for the codes in \([1]\)). For the opposite, our codes (as is the case with those in \([3]\)) have lengths \(n \gg q\).

Section \([1]\) recalls some basic facts on LRC codes. In Subsection \([2, 1]\) we introduce \(J\)-affine variety codes which also gave rise to good quantum error-correcting codes \([6, 7, 4]\). Subsections \([2, 2]\) and \([2, 3]\) show \(J\)-affine variety codes for which locality and \((r, \delta)\)-locality of their subfield-subcodes can be determined. Finally in Section \([3]\) we provide examples of parameters of good LRC codes obtained with our procedure.

1. LRC codes

In this section we state some definitions and facts concerning LRC codes that will be necessary for the rest of the work. We mostly follow the usual conventions and definitions of locally recoverable codes. As a notation, given a fixed coordinate \(i\) and a set \(R\) such that \(i \notin R\), we write \(\bar{R} = R \cup \{i\}\). Let \(\mathcal{C}\) be an \([n, k, d]\) code over \(\mathbb{F}_q\). Let \(G\) be a generator matrix of \(\mathcal{C}\) with columns \(c_1, c_2, \ldots, c_n\). A set \(R \subseteq \{1, 2, \ldots, n\}\) is a recovery set for a coordinate \(i \notin R\) if \(c_i \in \langle c_j : j \in R\rangle\), the linear space spanned by \(\{c_j : j \in R\}\). In this case, for any codeword \(x \in \mathcal{C}\), \(x_i\) can be obtained from \((x_j : j \in R)\) just by solving the linear system whose augmented matrix is \((c_j, j \in R | c_i)\).

Let \(\pi_R : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^r, r = \#R\), be the projection on the coordinates in \(R\). For \(x \in \mathbb{F}_q^n\) we write \(x_R = \pi_R(x)\). Often we will consider the punctured and shortened codes: \(\mathcal{C}[R] = \{x_R : x \in \mathcal{C}\}\) and \(\mathcal{C}[[R]] = \{x_R : x \in \mathcal{C}, \text{supp}(x) \subseteq R\}\), respectively, where \(\text{supp}(x)\) denotes the support of \(x\), \(\text{supp}(x) = \{i : x_i \neq 0\}\). Note that \(c_i \in \langle c_j : j \in R\rangle\) if and only if \(\dim(\mathcal{C}[R]) = \dim(\mathcal{C}[\bar{R}])\). So the notion of recovery set does not depend on the generator matrix chosen. In this case, there exist \(w_1, w_2, \ldots, w_n \in \mathbb{F}_q\) such that \(\sum_{j=1}^n w_j c_j = 0\) with \(w_i \neq 0\) and \(w_j = 0\) if \(j \notin R\). Then \(w = (w_1, w_2, \ldots, w_n) \in \mathcal{C}^\perp\), the dual of \(\mathcal{C}\), and \(w_R \in \mathcal{C}^{\perp}[R]\). Thus \(R\) is a recovery set for a coordinate \(i\) if and only if there exists a word \(w_R \in \mathcal{C}^{\perp}[R]\) with \(w_i \neq 0\). In this case \(\#R \geq d(\mathcal{C}^\perp) - 1\).

The smallest cardinality of a recovery set \(R\) for a coordinate \(i\) is the locality of \(i\). The locality of \(\mathcal{C}\), often denoted by \(r = r(\mathcal{C})\), is the largest locality of any of its coordinates. Thus, we have proved the following result.

**Proposition 1.1.** The locality \(r\) of an LRC code \(\mathcal{C}\) satisfies \(r \geq d(\mathcal{C}^\perp) - 1\).
A code \( C \) reaching equality in the bound given by Proposition 1.1 will be called *sharp*. Note that all cyclic codes are sharp. Apart from Proposition 1.1, perhaps the most important bound on the locality \( r \) of an \([n, k, d]\) code is given by the following Singleton-like inequality, see [9].

**Theorem 1.2.** The locality of an LRC code \( C \) satisfies

\[
d + k + \left\lceil \frac{k}{r} \right\rceil \leq n + 2.
\]

The difference between the two terms in Theorem 1.2, \( D_1 = n + 2 - d - k - \left\lceil k/r \right\rceil \), is the LRC-Singleton defect of \( C \). Codes with \( D_1 = 0 \) are called *Singleton-optimal* (or simply *optimal*). While optimal LRC codes are known for all lengths \( n \leq q \), [13], the searching of these codes when \( n > q \) is a challenging problem [11].

The LRC codes that we have described above allow local recovery of the information stored in a failed node. However, concurrent failures of several nodes in a network are also possible and uncommon. Thus, it is also of interest to consider LRC codes that allow local recovery of failed nodes even in the presence of failures or errors in other nodes. This problem was first treated in [16].

**Definition 1.3.** A code \( C \) has *locality* \((r, \delta)\) if for any coordinate \( i \) there exists a set of positions \( \overline{R} \subset \{1, 2, \ldots, n\} \) such that

(a) \( i \in \overline{R} \) and \( \#\overline{R} \leq r + \delta - 1 \);

(b) \( d(C[\overline{R}]) \geq \delta \).

Notice that the original definition of locality of LRC codes corresponds to the case \( \delta = 2 \). Provided that \( \delta \geq 2 \), any subset \( i \notin R \subset \overline{R} \) of cardinal \( r \) satisfies that \( d(C[R]) \geq 2 \) and consequently \( R \) is a recovery set for \( i \); the locality of \( C \) is \( \leq r \) and the number of recovery sets of cardinality \( r \) is at least

\[
\binom{\#\overline{R} - 1}{r},
\]

which can be relevant to improve the availability of \( C \) for recovering erasures. In addition, the correction capability of \( C[R] \) can be used to correct the erasure \( i \) plus any other \( \delta - 2 \) erasures in \( \overline{R} \setminus \{i\} \). The sets \( R \) satisfying Conditions (a) and (b) above are called \((r, \delta)\)-sets. The following generalization of the Singleton-like bound of Theorem 1.2 was proved in [16].

**Proposition 1.4.** The \((r, \delta)\)-locality of an LRC code \( C \) satisfies the following inequality

\[
d + k + \left( \left\lceil \frac{k}{r} \right\rceil - 1 \right) (\delta - 1) \leq n + 1.
\]

Analogously to what was done for the locality \( r \), for \( t = 1, 2, \ldots, d(C) - 1 \), we define

\[
r_t = r_t(C) = \min \{ \rho : \text{for all } i = 1, 2, \ldots, n, \text{there is a set } \overline{R}_i \subset \{1, 2, \ldots, n\} \text{ with } i \in \overline{R}_i, \#\overline{R}_i \leq \rho \text{ and } d(C[\overline{R}_i]) \geq t + 1 \} - 1.
\]

The value \( r_t \) is the minimum number of positions, \( \#\overline{R} - 1 \), needed to recover a given coordinate \( i \in \overline{R} \) of any codeword \( x \), when at most \( t \) erasures occur in \( x[\overline{R}] \). Clearly \( r_1 = r \), the usual locality of \( C \). We refer to \( r_t \) as the \textit{t-locality} of \( C \). For example, since puncturing \(< d \) times an MDS code gives a new MDS code of the same dimension, for \( t < d \) the \textit{t-locality} of an \([n, k, d]\) MDS code is \( r_t = k + t - 1 \).
We can translate the bound given by Proposition 1.4 in terms of \( r_t \)'s, as
\[
d + k + \left\lfloor \frac{k}{r_t - t + 1} \right\rfloor t \leq n + t + 1
\]
which, in spirit, seems to be closer to (1) than (2). The difference between the two terms of Equation (3),
\[
D_t = n + t + 1 - d - k - \left\lfloor \frac{k}{r_t - t + 1} \right\rfloor t,
\]
is the \( t \)-th LRC-Singleton defect of \( C \). Codes with \( D_t = 0 \) will be called \( t \)-optimal. For example, MDS codes are \( t \)-optimal for all \( t = 1, 2, \ldots, d - 1 \).

We can extend to all \( r_t \)'s the bound for \( r_t \) given in Proposition 1.1. For it we use generalized Hamming weights (see [15] Section 4.5.1) for the definition and properties of these weights). Let us see that result.

**Proposition 1.5.** For \( t = 1, 2, \ldots, d - 1 \), the \( t \)-locality of an LRC \([n, k, d]\) code \( C \) satisfies
\[
r_t \geq d_t(C^\perp) - 1, \quad \text{where } d_t(C^\perp) \text{ is the } t \text{-th generalized Hamming weight of the dual code } C^\perp.
\]

**Proof.** Let \( \overline{R} \) be a set of coordinates such that \( \# \overline{R} \leq r_t + 1 \) and \( d(\overline{C}[\overline{R}]) \geq t + 1 \). According to the Singleton bound, we have \( \dim(\overline{C}[\overline{R}]) \leq \# \overline{R} - t \). Since \( C^\perp \overline{R} = C^\perp[\overline{R}] \) (see [15], Proposition 3.1.17), it holds that \( \dim(C^\perp[\overline{R}]) \geq t \). Thus \( d_t(C^\perp) \leq \# \overline{R} \) and the result follows. \( \Box \)

In this paper we are particularly interested in \((r, \delta)\)-locality of LRC codes. The following result is derived from Proposition 1.5

**Corollary 1.6.** The \((r, \delta)\)-locality of a code \( C \) satisfies the following inequality
\[
r + \delta \geq d_{\delta-1}(C^\perp) + 1.
\]

**Proof.** Keep the above notation. From the definition of \((r, \delta)\)-locality it holds \( r_{\delta-1} \leq r + \delta - 2 \). Since \( r_t < r_{t+1} \) for all \( 1 \leq t \leq d - 2 \), we deduce that \( r_{\delta-1} = r + \delta - 2 \). By Proposition 1.5 \( r + \delta - 2 \geq d_{\delta-1}(C^\perp) - 1 \), which concludes the proof. \( \Box \)

2. **J-affine variety codes giving LRC codes**

In this section we are going to show that considering subfield-subcodes of \( J \)-affine variety codes we will get some LRC codes with good recovery properties. The concept of \( J \)-affine variety code was introduced in [7] and used in [4, 5] for constructing quantum and LCD codes with good parameters. Our first subsection recalls its definition and some properties.

2.1. **\( J \)-affine variety codes and their subfield-subcodes.** Let \( q = p^f \) be a power of a prime number \( p \) and set \( \mathcal{R} := \mathbb{F}_q[X_1, X_2, \ldots, X_m] \) the polynomial ring in \( m \geq 1 \) variables over the finite field \( \mathbb{F}_q \). For defining our \( J \)-affine variety codes, we fix positive integers \( N_j > 1, 1 \leq j \leq m \), such that \( N_j - 1 \) divides \( q - 1 \), a subset \( J \) of the indices of the variables \( \{1, 2, \ldots, m\} \) and consider the quotient ring \( \mathcal{R}_J := \mathcal{R}/I_J \), where \( I_J \) is the ideal in \( \mathcal{R} \) generated by the binomials \( X_j^{N_j} - X_j \) when \( j \notin J \) and \( X_j^{N_j - 1} - 1 \) otherwise. Set \( T_j = N_j - 2 \) when \( j \in J \) and \( T_j = N_j - 1 \) otherwise, and
\[
\mathcal{H}_J := \{0,1,\ldots,T_1\} \times \{0,1,\ldots,T_2\} \times \cdots \times \{0,1,\ldots,T_m\}.
\]
The set of zeros of \( I_J \) over \( \mathbb{F}_q \), \( Z_J = \{P_1, P_2, \ldots, P_{n_J}\} \), has cardinality
\[
n_J := \prod_{j \notin J} N_j \prod_{j \in J} (N_j - 1).
\]
and it allows us to provide the map $ev_J : R_J \rightarrow \mathbb{F}_q^n$ defined as

$$ev_J(f) = (f(P_1), f(P_2), \ldots, f(P_n)),$$

where $f$ denotes the polynomial in $R$ and its corresponding equivalence class in $R_J$. Finally, we will often use the monomials in $R$, $X^a = X_1^{a_1}X_2^{a_2} \cdots X_m^{a_m}$ given by the tuples $a = (a_1, a_2, \ldots, a_m) \in H_J$.

With the above notation, next we define the concept of $J$-affine variety code.

**Definition 2.1.** The $J$-affine variety code $E^J_{\Delta}$, given by a non-empty subset $\Delta$ of $H_J$, is the $\mathbb{F}_q$-vector subspace of $\mathbb{F}_q^n$ generated by the vectors $ev_J(X^a)$, $a \in \Delta$.

The linear code $E^J_{\Delta}$ has length $n_J$ and its dimension equals the cardinality of the set $\Delta$. The dual of $E^J_{\Delta}$ will denoted by $E^{J^\perp}_{\Delta}$.

The main goal of this paper is to show the existence of subfield-subcodes of $J$-affine variety codes which are LRC codes with good behaviour. Concepts as cyclotomic sets and polynomials over a field evaluating to some subfield are essential to manage these subcodes. Recall that $q = p^t$ and consider a positive integer $s$ such that $s$ divides $t$; then we will set $q := p^s$.

**Definition 2.2.** With the above notation, the subfield-subcode over the field $\mathbb{F}_q := \mathbb{F}_{p^s}$, $E^{J\cdot\sigma}_{\Delta}$, of the code $E^J_{\Delta}$ is the linear code

$$E^{J\cdot\sigma}_{\Delta} := E^J_{\Delta} \cap \mathbb{F}_q^n.$$

The elements in the set $H_J$ can be regarded as tuples of representatives of congruences classes in a particular manner. Indeed, for each $1 \leq j \leq m$, if $j \in J$ we write the congruence ring $\mathbb{Z}/(N_j - 1)\mathbb{Z}$ as $\mathbb{Z}_{T_j}$ and its elements will be represented by $\{0, 1, \ldots, T_j\}$. Otherwise, $j \notin J$, $\{1, 2, \ldots, T_j\}$ represents the elements in $\mathbb{Z}/(N_j - 1)\mathbb{Z}$ and $\mathbb{Z}_{T_j}$ will denote the set $\{0\} \cup \mathbb{Z}/(N_j - 1)\mathbb{Z}$. As a consequence, $H_J$ can be identified with the Cartesian product $\mathbb{Z}_{T_1} \times \mathbb{Z}_{T_2} \times \cdots \times \mathbb{Z}_{T_m}$. Under this identification, a cyclotomic set with respect to $q = p^t$ of $H_J$ is a subset $\mathcal{S}$ such that $q \cdot y \in \mathcal{S}$ for any $y = (y_1, y_2, \ldots, y_m) \in \mathcal{S}$, where $q \cdot y$ is the componentwise product, that is $q \cdot y = (qy_1, qy_2, \ldots, qy_m)$ and the product by 0 is always 0. **Minimal cyclotomic sets** are those whose elements are $q^i \cdot y$, $i \geq 0$, for some fixed element $y$ in $H_J$.

We consider a unique representative $a = (a_1, a_2, \ldots, a_m)$ associated to each minimal cyclotomic set $\mathcal{I}$. The coordinate $a_1$ is the minimum of the coordinates $y_1$ of the representatives of the elements in $\mathcal{I}$, $a_2$ is the minimum of the coordinates $y_2$ of the elements $y \in \mathcal{I}$ having $a_1$ as a first coordinate; the remaining coordinates are defined analogously.

We will denote by $I_a$ the minimal cyclotomic set with representative $a$ and by $\mathcal{A}$ the set of representatives of the minimal cyclotomic sets in $H_J$. The cardinality of each set $\mathcal{I}_a$ is an important datum for us and it is denoted by $\nu_a$.

We are interested in subfield-subcodes of $J$-affine variety codes. Since these last codes are obtained by evaluating polynomials, we are interested in those polynomials whose evaluation supplies values in the field $\mathbb{F}_q$. Our next result extends to any set $J$ as above that proved in [6, Theorem 4] for $J = \{1, 2, \ldots, m\}$ and it can be proved in a similar way. Previously we introduce some notation. For each $a \in \mathcal{A}$, consider the map $T_a : R_J \rightarrow R_J$ defined as follows:

$$T_a(f) = f + f^q + \cdots + f^{q^{\nu_a-1}},$$

and denote by $\xi_a$ a primitive element of the field $\mathbb{F}_{q^{\nu_a}}$. 
Lemma 2.4. Our codes which we will introduce shortly in (4) behaves well.

Proof. Theorem 2.3.

2.2. LRC $J$-affine variety codes. The goal of this section is to present subfield-subcodes of $J$-affine variety codes for which we are able to provide recovery sets. Afterwards, we will consider specific families of the above codes which will be LRC codes whose $(r, \delta)$-locality behaves well.

Considering different sets $J$, $J$-affine variety codes admit different lengths. When $J = \emptyset$, one can evaluate at the point 0, however, this will not be suitable for our purposes. So we will also assume $J \neq \emptyset$. Let $L = \{i_1 < i_2 < \cdots < i_t\}$ be a subset of $J$ and from now on, we assume that $q - 1 = p^s - 1$ divides $N_j - 1$ for all index $j \in L$. We denote by $\alpha$ (respectively, $\eta$) a primitive element of $\mathbb{F}_q$ (respectively, $\mathbb{F}_q$). Also consider the elements $\gamma_j := \alpha^{N_j - 1} \in \mathbb{F}_q$, $1 \leq j \leq m$. We are interested in specific positions within each word of our codes which we will introduce shortly in [3].

Lemma 2.4. With the above notations, for each $j \in L$, the following equality holds

$$\left( \gamma_j \eta^n \right)^{N_j - 1} = 1 \in \mathbb{F}_q,$$

where $l$ and $n$ are nonnegative integers.

Proof. The proof follows from the following chain of equalities:

$$\left( \gamma_j \eta^n \right)^{N_j - 1} = \left( \frac{\alpha^{q - 1}}{\gamma_j \eta^n} \right)^{\frac{l(N_j - 1)}{\gamma_j}} = (\alpha^{q - 1})^l (\eta^{q - 1})^n = (\alpha^{q - 1})^l (\eta^{q - 1})^n N_j - 1.$$

Now we are ready to introduce the above mentioned positions. Given an element $0 \neq \lambda \in \mathbb{F}_q$ and a point $P_t$, $1 \leq t \leq n_J$, the product $\lambda \cdot \eta^n \cdot P_{t_0}$ provides a new element in $\mathbb{F}_q^n$ obtained by multiplying by $\lambda$ the coordinates of $P_t$ corresponding to $L$ and leaving invariant the remaining ones. Then, fixed an evaluation point $P_{t_0}$ and a set $L$ as above, we define the following indices set

$$\mathcal{R}_{t_0} := \{ t : 1 \leq t \leq n_J \text{ and } P_t := \eta^n \cdot P_{t_0} \text{ for some } 0 \leq n \leq q - 2 \}.$$

Notice that $\mathcal{R}_{t_0}$ is well-defined by Lemma 2.4. For simplicity sake, the evaluation point $\eta^n \cdot P_{t_0}$ will be denoted $P_{n,t_0}^L$.

The following results will be useful hereinafter.

Lemma 2.5. Keep the notations in Subsection 2.1 and consider a tuple $a$ in $A$ and any index $0 \leq k \leq i_a - 1$. Then

$$\mathcal{T}_a(\xi_a^k X^a) \left( P_{n,t_0}^L \right) = \eta^n \sum_L a \mathcal{T}_a(\xi_a^k X^a) \left( P_{t_0} \right),$$

where $0 \leq n \leq q - 1$ and $\sum_L a := \sum_{j \in L} a_j$.

Proof. Suppose without loss of generality that $P_{t_0} = (\gamma_1, \gamma_2, \ldots, \gamma_m)$, where, as mentioned, $\gamma_j = \alpha^{N_j - 1}$, $\alpha$ being a primitive element of $\mathbb{F}_q$. Notice that $L \subseteq J$ implies that if
some coordinate of $P_0$ would vanish, it did not belong to the set $L$. Then

$$
(6) \quad \mathcal{T}_a(\xi^k X^a)(P_{n,t_0}) = \sum_{i=0}^{n-1} \left( \xi^k \prod_{l \in L} (\eta^p \gamma^q)^{a_l} \prod_{l \in L} (\gamma^q)^{a_l} \right)^{t_q} = \eta^n \sum_{i=0}^{n-1} \left( \xi^k \prod_{l \in L} (\gamma^q)^{a_l} \right)^{t_q} = \eta^n \sum_{i=0}^{n-1} \mathcal{T}_a(\xi^k X^a)(P_{0}).
$$

The sets $\Delta$ we will use in this paper will be union of minimal cyclotomic sets. Afterwards we will consider even more restrictive conditions. So, set $\Delta = \cup_{i=1}^r \mathcal{J}_{a_i}$, where $\{a_i\}_{i=1}^r$ is some subset of $A$.

**Theorem 2.6.** Fix a set $L \subseteq J$ as above and suppose that the set of congruence classes $\{[\sum L a_i]\}_{i=1}^r$ in $\mathbb{Z}/(q-1)\mathbb{Z}$ has cardinality $r$. Assume also that $r \leq q - 2$. Then, $E_{\Delta}^{\sigma}$ is a LRC code with locality $r$.

**Proof.** It suffices to prove that any consecutive subset of cardinality $r$ in $R_0 \setminus \{t_0\}$ is a recovery set for the coordinate $t_0$.

Indeed, let $c = (c_1, c_2, \ldots, c_n)$ be a codeword in $E_{\Delta}^{\sigma}$. Then $c = ev_{J}(h)$, where by Theorem 2.3 $h$ can be written as

$$
h = h_{a_1} + h_{a_2} + \ldots + h_{a_r},
$$

$h_{a_i}$ being a linear combination with coefficients in $F_q$ of polynomials of the form $\mathcal{T}_a(\xi^k X^a)$, $0 \leq k \leq i_{a_i} - 1$.

Assume the existence of an erasure at position $t_0$ and that we know $r$ values $\{h(P_{n,t_0})\}_{i=1}^r$ for consecutive $n_i$‘s among those in $\{h(P_{n,t_0})\}_{i=1}^{r \leq q - 2}$. Then, by linearity

$$
h(P_0) = h_{a_1}(P_0) + h_{a_2}(P_0) + \ldots + h_{a_r}(P_0).
$$

By Lemma 2.3 one gets the following chain of equalities

$$
h(\eta^{n_1} \cdot L P_0) = \eta^{n_1} \sum_{a_1} h_{a_1}(P_0) + \eta^{n_1} \sum_{a_2} h_{a_2}(P_0) + \ldots + \eta^{n_1} \sum_{a_r} h_{a_r}(P_0),
$$

$$
h(\eta^{n_2} \cdot L P_0) = \eta^{n_2} \sum_{a_1} h_{a_1}(P_0) + \eta^{n_2} \sum_{a_2} h_{a_2}(P_0) + \ldots + \eta^{n_2} \sum_{a_r} h_{a_r}(P_0),
$$

$$
\vdots
$$

$$
h(\eta^{n_r} \cdot L P_0) = \eta^{n_r} \sum_{a_1} h_{a_1}(P_0) + \eta^{n_r} \sum_{a_2} h_{a_2}(P_0) + \ldots + \eta^{n_r} \sum_{a_r} h_{a_r}(P_0).
$$

As a consequence, setting $\eta_i := \eta^{n_i} \cdot a_i$, $1 \leq i \leq r$, one obtains a system of linear equations

$$
\begin{pmatrix}
\eta^{n_1}_1 & \cdots & \eta^{n_1}_r \\
\eta^{n_2}_1 & \cdots & \eta^{n_2}_r \\
\vdots & \vdots & \vdots \\
\eta^{n_r}_1 & \cdots & \eta^{n_r}_r
\end{pmatrix}
\begin{pmatrix}
h_{a_1}(P_0) \\
h_{a_2}(P_0) \\
\vdots \\
h_{a_r}(P_0)
\end{pmatrix}
= 
\begin{pmatrix}
h(\eta^{n_1} \cdot L P_0) \\
h(\eta^{n_2} \cdot L P_0) \\
\vdots \\
h(\eta^{n_r} \cdot L P_0)
\end{pmatrix}.
$$

This is a square system. The determinant of its matrix of coefficients is a product of a Vandermonde determinant and a power of $\eta$. As a consequence, it has a unique solution which gives the values $h_{a_i}(P_0)$, $1 \leq i \leq r$, in (7) and therefore the required erasure $h(P_0)$. This concludes the proof. \[ \square \]
Our next result gives conditions for enlarging the locality of the codes $E_{\Delta}^{\ell,\sigma}$. For simplicity’s sake and up to the end of this section, the set $L$ involved in products $\cdot_L$ will be $L = \{1\} \subset J$. We will write $a_l$ the first coordinate of $a_l$.

**Theorem 2.7.** With the above notations, consider tuples in $A$, denoted $\{a_i\}_{i=1}^{q-1}$, such that the congruence classes of their first coordinates $\{a_i\}_{i=1}^{q-1}$ are different modulo $q - 1$. Assume the existence of some index $1 \leq v \leq q - 1$ such that

1. $a_v$ divides $N_1 - 1$,
2. $\gcd(a_v, a_l) = 1$ for $l \neq v$, $1 \leq l \leq q - 1$, and
3. $\gcd(a_v, q - 1) = 1$.

Set $\Delta = \bigcup_{l=1}^{q-1} \mathcal{T}_{a_l}$. Then $E_{\Delta}^{\ell,\sigma}$ is a LRC code of locality $q - 1 + (a_v - 1)$.

**Proof.** Fix an evaluation point $P_{t_0}$ where the erasure appears and consider the sets of indices

$$R_{t_0}^1 := \{t : 1 \leq t \leq n_J \text{ and } P_t := \eta^{n_l} \cdot_L P_{t_0} \text{ for some } 0 \leq n \leq q - 1\}$$

and

$$R_{t_0}^2 := \{t : 1 \leq t \leq n_J \text{ and } P_t := \omega^k \eta^{n_l} \cdot_L P_{t_0} \text{ for some } 1 \leq k \leq a_v - 1\},$$

where $\omega$ is a primitive $a_v$-root of unity.

We are going to show that the set $(R_{t_0}^1 \cup R_{t_0}^2) \setminus \{t_0\}$ is a recovery set for the coordinate $t_0$.

For simplicity reasons and without loss of generality we set $v = 1$. As in Theorem 2.6 $c = ev_J(h) \in E_{\Delta}^{\ell,\sigma}$ and $h$ can be written as

$$h = h_{a_1} + h_{a_2} + \ldots + h_{a_{q-1}},$$

$h_{a_l}$ being a linear combination with coefficients in $\mathbb{F}_q$ of polynomials of the form $\mathcal{T}_{a_l}(\xi^k, X^{a_l})$, $0 \leq k \leq i_{a_l} - 1$. So,

$$h(\eta^{n_l} \cdot_L P_{t_0}) = \eta^{a_1} h_{a_1} (P_{t_0}) + \eta^{a_2} h_{a_2} (P_{t_0}) + \ldots + \eta^{a_{q-1}} h_{a_{q-1}} (P_{t_0}),$$

$$h(\omega^{k} \eta^{n_l} \cdot_L P_{t_0}) = \eta^{a_1} h_{a_1} (P_{t_0}) + \eta^{a_2} h_{a_2} (\omega \cdot_L P_{t_0}) + \ldots + \eta^{a_{q-1}} h_{a_{q-1}} (\omega^{a_{q-1}} \cdot_L P_{t_0}),$$

$$\vdots$$

$$h(\omega^{a_1 - 1} \eta^{n_l} \cdot_L P_{t_0}) = \eta^{a_1} h_{a_1} (P_{t_0}) + \eta^{a_2} h_{a_2} (\omega^{a_1 - 1} \cdot_L P_{t_0}) + \ldots + \eta^{a_{q-1}} h_{a_{q-1}} (\omega^{a_{q-1}} \cdot_L P_{t_0}).$$

Notice that the facts that $a_1$ divides $N_1 - 1$ and $\gcd(a_1, q - 1) = 1$ imply that none of the points $\omega^{k} \eta^{n_l} \cdot_L P_{t_0}$, $0 \leq k \leq a_1 - 1$, coincide neither with $P_{t_0}$ nor among them. Now, summing up the equalities in (8) one gets on the left hand a known value from our recovery set. On the right hand, the obtained value has the form

$$(a_1 - 1) (\eta^{a_1} h_{a_1} (P_{t_0}))$$

$$+ \eta^{a_2} n_2 \left(1 + \omega^{a_2} + (\omega^{a_2})^2 + \ldots + (\omega^{a_2})^{a_1 - 1}\right) + \ldots + \eta^{a_{q-1}} n_{q-1} \left(1 + \omega^{a_{q-1}} + (\omega^{a_{q-1}})^2 + \ldots + (\omega^{a_{q-1}})^{a_1 - 1}\right),$$

where $n_l$, $2 \leq l \leq q - 1$, are values obtained when evaluating the polynomials $h_{a_l}$. Now, taking into account that $\gcd(a_1, a_l) = 1$, $2 \leq l \leq q - 1$, each sum

$$1 + \omega^{a_2} + (\omega^{a_2})^2 + \ldots + (\omega^{a_2})^{a_1 - 1}$$

is the sum of all $a_1$ roots of unity and, therefore equals zero. Then the expression in (9) equals

$$(a_1 - 1) (\eta^{a_1} h_{a_1} (P_{t_0})).$$
Therefore, we are able to obtain \( h_{a_1} (P_0) \).

Finally, applying to the polynomial \( h - h_{a_1} \), the procedure given in the proof of Theorem 2.6 we are able compute \((h - h_{a_1})(P_0)\) since \(h - h_{a_1}\) is a sum of polynomials attached to \(q - 2\) minimal cyclotomic sets. This concludes the proof because \((h - h_{a_1})(P_0) + h_{a_1} (P_0)\) determines the erasure.

\[ \square \]

2.3. The \((r, \delta)\)-locality of \(\{1, 2, \ldots, m\}\)-affine variety codes. In this subsection we consider products \(J_L\) as in Subsection 2.2 and subfield-subcodes \(E := E^j_{\Delta} \sigma\) where \(J = \{1, 2, \ldots, m\}\) and \(\Delta \subseteq \bigcup_{i=1}^z J_{a_i}\) is a union of minimal cyclotomic sets such that the set
\[
\left\{ \sum_{L} a_i : 1 \leq i \leq z \right\}
\]
has exactly \(r \leq q - 2\) consecutive positive integers. Abusing of notation, set \(\Delta' = \{a_i\}_{i=1}^r\) the representatives of cyclotomic sets such that the set \(\{\sum_{L} a_i : 1 \leq l \leq r\}\) has cardinality \(r\).

Our first result concerns only the case when \(m = 1\). So we are considering \(r \leq q - 2\) consecutive elements \(a_1 < a_2 < \cdots < a_r\) in \(\mathcal{A}\) and \(\Delta = \bigcup_{i=1}^r J_{a_i}\). Reasoning as in the proof of [8, Proposition 11] it holds that
\[
(E^j_{\Delta})^\perp = \left((E^j_{\Delta})^\perp\right)^\sigma.
\]

The proof of the above result follows from Delsarte theorem [2] and the fact that \(\Delta\) is a union of minimal cyclotomic sets. A consequence of the above result is that the minimum distance of the code \((E^j_{\Delta})^\perp\) is larger than or equal to \(a_r + 1\). Finally, the facts that \(r \leq q - 2\) and the cyclotomic sets are with respect to \(q\) show that one can consider a set \(\Delta\) with \(r\) consecutive natural numbers and
\[
d \left((E^j_{\Delta})^\perp\right) \geq r + 1. \tag{10}
\]

The following result follows from Proposition 1.1 and Inequality (10).

**Proposition 2.8.** Assume that \(m = 1\), \(J = \{1\}\) and consider the code \(E^j_{\Delta} \sigma\) where \(\Delta\) is given by \(r \leq q - 2\) consecutive natural numbers. Then \(E^j_{\Delta} \sigma\) is sharp, that is \(d \left((E^j_{\Delta})^\perp\right) = r + 1\).

Finally, we are going to prove that in the general case, \(m \geq 1\), the codes \(E^j_{\Delta} \sigma\) introduced at the beginning of this subsection have locality \((r, q - r)\) and Conditions (a) and (b) in the definition of \((r, \delta)\)-locality are satisfied with equality.

**Theorem 2.9.** Let \(E := E^j_{\Delta} \sigma\) a code as above. Let \(t_0\) be the index corresponding to an evaluation point \(P_{t_0}\) and consider the set \(\mathcal{R}_{t_0}\) of indices defined in (4). Then, the punctured code \(E[R_{t_0}]\) is linear with parameters \([q - 1, r, q - r]_q\).

**Proof.** The code \(E[R_{t_0}]\) consists in evaluating classes of polynomials in \(\mathcal{R}_L\) at the ordered set of points \(P := (P_{t_0}, \eta \cdot L P_{t_0}, \ldots, \eta^{k-2} \cdot L P_{t_0})\). So, the length of the code is clear because \(L \subseteq J\). With respect to the dimension, we start by observing that, by Theorem 2.3, the following vectors generate \(E[R_{t_0}]\):
\[
T_a \left(\xi_a X^a\right) (P), \tag{11}
\]
where \( a \) runs over the representatives of the cyclotomic classes that form \( \Delta \) and, for each \( a, 0 \leq k \leq i_a - 1 \).

By Lemma 2.3 [11] any two vectors as in \( \mathbf{T} \) corresponding to the same representative \( a \) (with different values \( k \)) are proportional because both are a multiple (with factor \( \mathbf{T}_a \left( \xi^k a^x \right)(P_{l_0}) \)) of the vector \((1, \eta \sum L a_1, \ldots, \eta \sum L a^{(q-2)})\). The same argument proves that vectors corresponding to representatives \( a \in \Delta' \), i.e., representatives \( a \) with different values \( \sum L a \), are linearly independent. Now we are going to prove that, for each \( a \), there exists some value \( k \) such that \( \mathbf{T}_a \left( \xi^k a^x \right)(P_{l_0}) \neq 0 \) and, as a consequence, the dimension of our code coincides with the number \( r \) of cyclotomic sets with different values \( \sum L a \) that constitute \( \Delta \).

For the above mentioned proof, we reason by contradiction and assume that

\[
\mathbf{T}_a \left( \xi^k a^x \right)(P_{l_0}) = 0
\]

for every value \( 0 \leq k \leq i_a \). For simplicity’s sake, set in this contradiction argument, \( t := q \), \( \xi a = \xi i := i_a \) and \( P_{l_0} \) the evaluation of the monomial \( X^a \) at the point \( P_{l_0} \). Notice that \( P_{l_0} \neq 0 \) since \( J = \{1, 2, \ldots, m\} \). It is straightforward to see that, for suitable elements in the field \( \mathbb{F}_q \) denoted by \( P_{l_0}^k, 1 \leq l \leq i - 1 \), it holds that

\[
\mathbf{T}_a(X^a)(P_{l_0}) = P_{l_0}^a(1 + P_{l_0}^{b_1} + \cdots + P_{l_0}^{b_{i-1}}),
\]

\[
\mathbf{T}_a(\xi X^a)(P_{l_0}) = P_{l_0}^a(\xi + \xi^t P_{l_0}^{b_1} + \cdots + \xi^{(i-1)t} P_{l_0}^{b_{i-1}}),
\]

\[
\mathbf{T}_a(\xi^{i-1} X^a)(P_{l_0}) = P_{l_0}^a(\xi^{i-1} + (\xi^{i-1})^t P_{l_0}^{b_1} + \cdots + (\xi^{i-1})^{(i-1)t} P_{l_0}^{b_{i-1}}).
\]

This means that the vector \( v = (1, P_{l_0}^{b_1}, \ldots, P_{l_0}^{b_{i-1}}) \) is a solution of a homogeneous square linear system of size \( i \) whose matrix is of Vandermonde type. This gives the desired contradiction since \( v \neq 0 \).

It only remains to determine the minimum distance of \( E[R_{l_0}] \). Assume without loss of generality that \( \mathbf{T}_a(X^a)(P_{l_0}) \neq 0 \) for all \( a \in \Delta' \). The generator matrix of this code is the following one

\[
\begin{pmatrix}
\mathbf{T}_{a_1}(X^{a_1})(P_{l_0}) & \eta \sum L a_1 \mathbf{T}_{a_1}(X^{a_1})(P_{l_0}) & \cdots & \eta \sum L a_1^{(q-2)} \mathbf{T}_{a_1}(X^{a_1})(P_{l_0}) \\
\mathbf{T}_{a_2}(X^{a_2})(P_{l_0}) & \eta \sum L a_2 \mathbf{T}_{a_2}(X^{a_2})(P_{l_0}) & \cdots & \eta \sum L a_2^{(q-2)} \mathbf{T}_{a_2}(X^{a_2})(P_{l_0}) \\
\vdots & \vdots & \ddots & \vdots \\
\mathbf{T}_{a_r}(X^{a_r})(P_{l_0}) & \eta \sum L a_r \mathbf{T}_{a_r}(X^{a_r})(P_{l_0}) & \cdots & \eta \sum L a_r^{(q-2)} \mathbf{T}_{a_r}(X^{a_r})(P_{l_0})
\end{pmatrix}.
\]

For deciding about independence of columns, it suffices to consider the matrix

\[
A = \begin{pmatrix}
1 & \eta \sum L a_1 & \cdots & \eta \sum L a_1^{(q-2)} \\
1 & \eta \sum L a_2 & \cdots & \eta \sum L a_2^{(q-2)} \\
\vdots & \vdots & \ddots & \vdots \\
1 & \eta \sum L a_r & \cdots & \eta \sum L a_r^{(q-2)}
\end{pmatrix}.
\]

According [18] Definition 6.6.4 the set \( \{\eta \sum L a_1, \eta \sum L a_2, \ldots, \eta \sum L a_r\} \) is a consecutive set. By [18] Lemma 6.6.5 any submatrix of \( A \) obtained by taking any \( r \) columns has rank \( r \). Then, the minimum distance of the dual code, \( E[R_{l_0}]^\perp \) of \( E[R_{l_0}] \) is \( r + 1 \). So, the parameters of \( E[R_{l_0}]^\perp \) are \([q, q - 1 - r, r + 1]_q\) and then it is an MDS code. Thus \( E[R_{l_0}] \) is also MDS with parameters as in the statement. \( \square \)
As an immediate consequence of the above result we have the following.

**Proposition 2.10.** Let $J$ and $\Delta$ as the beginning of this section. Then the code $E^{J,\sigma}_\Delta$ corrects up to $q - 1 - r$ erasures and $\left\lfloor \frac{q-1-r}{2} \right\rfloor$ errors.

### 3. Examples

In this section we give some examples of LRC codes derived from $J$-affine variety codes whose $(r, \delta)$-locality behaves well. In fact many of our codes are optimal or near to be optimal with respect to the bound (2). Our supporting result is Theorem 2.9. We structure this section in two subsections: The first one provides examples with $m = 1$ and $J = \{1\}$; in the second one we show bivariate codes ($m = 2$) improving some results obtained in the univariate case. We also show that this improvement does not always happen (see Subsection 3.2, Example 6).

#### 3.1. LRC codes coming from the univariate case.

Our first example shows codes obtained from Theorem 2.9 when $p = 2$, $n = N_1 - 1 = 21$, $\ell = 6$ and $s = 3$. For the remaining cases in this subsection, Tables 2, 3, 4 and 5 contain parameters of codes over the fields $\mathbb{F}_9$, $\mathbb{F}_{11}$, $\mathbb{F}_{25}$ and $\mathbb{F}_{27}$ having small defect. As usual, in all tables $n, k, d$ are the standard parameters of the code and $d^\perp$ the minimum distance of the dual code. We also provide the $(r, \delta)$-locality of each code and compute its $(\delta - 1)$-th Singleton defect. Notice that $D_{\delta-1}$ is the defect with respect to the bound (2), i.e.,

$$D_{\delta-1} := n + 1 - \left( d + k + \left\lfloor \frac{k}{r} \right\rfloor - 1 \right) (\delta - 1)$$

and that our examples provide several $(\delta - 1)$-optimal LRC codes.

**Table 1.** Univariate LRC codes over $\mathbb{F}_8$

Look, for example, at the $[21, 6, 12]_8$ code of the third row of Table 1. It has $(r, \delta)$-locality $(4, 4)$, so $r_3 \leq 6$ and thus $r_2 \leq 5, r_1 \leq 4$. Since $d^\perp = 5$, from Proposition 1.5 we get equality in all cases. A computation gives $D_1 = 3, D_2 = 2$ and $D_3 = 1$. Note furthermore that the best known $[21, 6]$ code over $\mathbb{F}_8$ has minimum distance $d = 13$, [13], so first defect $D_1 \geq 2$.

#### 3.2. LRC codes coming from the bivariate case.

Next we show some examples of LRC codes of the type $E^{J,\sigma}_\Delta$, where $m = 2$, $J = \{1, 2\}$ and $L = \{1\}$. The first two examples show that, in some cases, bivariate codes improve univariate ones.

**Example 1.** With our previous notation set $p = 3$, $\ell = s = 3$, $N_1 = 27$ and $N_2 = 3$. The obtained codes have length $n = 52$. Table 6 contains the parameters of our codes (including, apart from the standard ones, the $(r, \delta)$-locality and the $(\delta - 1)$-defect, $D_{\delta-1}$). The defining set of the first one is

$$\Delta = \mathcal{J}_{(0,0)} \cup \mathcal{J}_{(0,1)} \cup \mathcal{J}_{(1,0)} \cup \mathcal{J}_{(1,1)} \cup \mathcal{J}_{(2,0)} \cup \mathcal{J}_{(3,0)}.$$
The defining sets of the remaining ones are obtained by successively adding to $\Delta$ the following cyclotomic sets: $\mathcal{I}(4,0)$, $\mathcal{I}(5,0)$, $\mathcal{I}(6,0)$, $\mathcal{I}(7,0)$, $\mathcal{I}(8,0)$, $\mathcal{I}(9,0)$, $\mathcal{I}(10,0)$ and $\mathcal{I}(11,0)$. Note that we get codes with better defect $D_{\delta-1}$ than in Table 5.

**Example 2.** As in Example 1 set now $p = 5$, $\ell = s = 2$, $N_1 = 25$ and $N_2 = 3$. The obtained codes have length $n = 48$ and Table 7 shows the parameters of our codes. For
the first code, the defining set is
\[ \Delta = \mathcal{I}(0,0) \cup \mathcal{I}(0,1) \cup \mathcal{I}(1,0) \cup \mathcal{I}(1,1) \cup \mathcal{I}(2,0). \]

The defining sets of the remaining ones are obtained by successively adding to \( \Delta \) the following cyclotomic sets: \( \mathcal{I}(3,0), \mathcal{I}(4,0), \mathcal{I}(5,0), \mathcal{I}(6,0), \mathcal{I}(7,0), \mathcal{I}(8,0) \) and both \( \mathcal{I}(9,0) \cup \mathcal{I}(10,0) \). Note that again we get codes with better defect \( D_{\delta-1} \) than in Table 4.

**Example 3.** In this example \( p = 2, \ell = s = 4, N_1 = 16, N_2 = 4 \). Parameters are showed in Table 8. The defining set of our first code is

\[ \Delta = \mathcal{I}(0,0) \cup \mathcal{I}(0,1) \cup \mathcal{I}(1,1) \cup \mathcal{I}(2,0) \cup \mathcal{I}(3,0), \]

and the remaining ones are obtained by successively adding to \( \Delta \) the following cyclotomic sets: \( \mathcal{I}(4,0), \mathcal{I}(5,0), \) and both \( \mathcal{I}(6,1) \) and \( \mathcal{I}(6,1) \).

Univariate codes are bad in this case.

**Example 4.** Now \( p = 11, \ell = s = 1, N_1 = 11, N_2 = 3 \). We display the parameters in Table 9. The defining set of our first code is \( \Delta = \mathcal{I}(0,0) \cup \mathcal{I}(0,1) \cup \mathcal{I}(1,0) \cup \mathcal{I}(2,0) \). We get the remaining ones by successively adding to \( \Delta \) the following cyclotomic sets: \( \mathcal{I}(3,0), \mathcal{I}(4,0), \mathcal{I}(5,0), \) both \( \mathcal{I}(1,1) \) and \( \mathcal{I}(6,0) \), and \( \mathcal{I}(7,1) \).

Example 6. To conclude this subsection we show the parameters of some univariate LRC codes of length 93 over $F_{32}$ which cannot be improved in the bivariate case. The reason for this impossibility is that in the bivariate case we would have to consider $p = 2$, $\ell = 10$, $s = 5$, $N_1 = 32$ and $N_2 = 4$, using the same field extension than in the univariate case. We show the parameters in Table 11.
