To Andrei Alekseevich Slavnov on the occasion of his 80-th birthday,
with respect and gratitude

Abstract. In the present paper we study flag manifold sigma-models that admit a zero-curvature representation. It is shown that these models may be naturally considered as interacting (holomorphic and anti-holomorphic) \( \beta \gamma \)-systems. Besides, using the theory of nilpotent orbits of complex Lie groups, we establish a relation to the principal chiral model.

1. The gauged linear formulation and the \( \beta \gamma \)-systems

In the present paper we will consider sigma-models, whose target spaces are flag manifolds – homogeneous manifolds of the group \( SU(N) \) of the form

\[
\mathcal{F}(n_1, \ldots, n_m) := \frac{SU(N)}{S(U(n_1) \times \ldots \times U(n_m))}, \quad \sum_{i=1}^{m} n_i = N. \tag{1}
\]

Sometimes for brevity we will also denote this quotient as \( \mathcal{G}_F \). This space admits a reductive metric – the so-called normal metric, which will be denoted by \( \mathcal{G} \). It is defined as follows. Let \( g = h \oplus m \) be the standard decomposition of the Lie algebra \( \langle m, h \rangle = 0 \), where \( \langle ., . \rangle \) is the Killing metric. Then the normal metric on \( \mathcal{G}_F \) is induced from the restriction \( \langle ., . \rangle|_m \) of the Killing metric. An interesting fact is that in this metric all geodesics are homogeneous, i.e. they are orbits of one-parametric subgroups of \( G \) [1]. Quite generally, integrability of the geodesic flow on \( \mathcal{G}_F \) is a necessary condition for the integrability of the sigma-model.

In order to define the models we will also require a \( G \)-invariant (homogeneous) complex structure \( \mathcal{J} \) on the target space. On the flag manifold (1) such complex structures are in one-to-one correspondence with the orderings of the set \( (n_1, \ldots, n_m) \).

1
Let us assume that the ordering is given by the index $i$ of $n_i$, otherwise we simply swap the indices. Then the space (1) allows an alternative definition as the quotient

$$\mathcal{F}(n_1, \ldots, n_m) \simeq \frac{GL(N, \mathbb{C})}{\mathcal{P}_{d_1,\ldots,d_m}},$$

where $P_{d_1,\ldots,d_m}$ is a parabolic subgroup of $GL(N, \mathbb{C})$ that stabilizes the flag of linear spaces $0 \subset L_1 \subset \ldots \subset L_m \cong \mathbb{C}^N$, $L_k \cong \mathbb{C}^{d_k}$ and $d_k = \sum_{i=1}^{k} n_i$.

The action schematically has the following form \cite{2} (here $X : \Sigma \to \mathcal{F}$):

$$S[\mathcal{G}, \mathcal{F}] := \int_{\Sigma} d^2 z \|\partial X\|^2_{\mathcal{G}} + \int_{\Sigma} X^* \omega, \quad (3)$$

where $\omega = \mathcal{G} \circ \mathcal{F}$ is the fundamental Hermitian form of the metric $\mathcal{G}$. It is closed if and only if $m = 2$, i.e. when the flag manifold is a Grassmannian \cite{3}. In other cases the second term in the action (3) is not topological.

The $B$-field of the same form as in (3) was considered on other grounds in \cite{4}. Besides, Lax pairs for models of type (3), in the special case of symmetric spaces, were seemingly considered for the first time in \cite{5} (the $\mathbb{C}P^1$-case) and in \cite{6} (mostly in the non-compact case). A detailed study of a similar case of para-compact target spaces may be found in the recent work \cite{7}.

In \cite{3, 8, 9} we constructed the gauged linear sigma-model representation for the models of type (1)–(3). In the case when the target space is a Grassmannian, the metric $\mathcal{G}$ is Kähler, and this representation is equivalent to the Kähler quotient $G(k, N) \simeq \text{Hom}(\mathbb{C}^k, \mathbb{C}^N) / U(k)$. In the general case our construction leads to a quotient w.r.t. a non-reductive group and to the “Killing” metric $\mathcal{G}$, which is not Kähler in general.

The construction is as follows. We introduce the field $U \in \text{Hom}(\mathbb{C}^M, \mathbb{C}^N)$, where $M = d_{m-1}$, satisfying the orthonormality condition $U^\dagger U = \mathbb{1}_M$, as well as the “gauge” field $\mathcal{A} = \mathcal{A}_z dz + \mathcal{A}_{\bar{z}} d\bar{z}$ of the following special form:

$$\mathcal{A}_z = \begin{pmatrix} \vdots & \vdots & \vdots \\ \mathbf{0} & d_{m-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}, \quad \mathcal{A}_{\bar{z}} = (\mathcal{A}_z)^\dagger. \quad (4)$$

The Lagrangian reads

$$\mathcal{L} = \text{Tr} \left( \|D_z U\|^2 \right), \quad \text{where} \quad D_z U = \partial_z U + i U \mathcal{A}_z. \quad (5)$$

This Lagrangian is equivalent to (3) – it can be proven by eliminating the field $\mathcal{A}$. Due to the orthonormality condition $U^\dagger U = \mathbb{1}_M$ the gauge group of the model is
$U(n_1) \times \cdots \times U(n_m)$. A natural question is whether one can instead use a quotient w.r.t. the complex group of upper/lower-block-triangular matrices. To answer this, we give up the orthonormality condition and assume that $U \in \text{Hom}(C^M, C^N)$ is an arbitrary complex matrix of rank $M$. We then write down the following Lagrangian:

$$\mathcal{L} = \text{Tr} \left( (D\bar{z}U)\dagger D\bar{z}U \frac{1}{U\dagger U} \right).$$  \hspace{1cm} (6)$$

It is easy to see that it is invariant w.r.t. complex gauge transformations $U \rightarrow Ug$, where $g \in P_{d_1,\ldots,d_{m-1}}$. The Gram-Schmidt orthogonalization procedure brings the Lagrangian (6) to the form (5), but for a number of reasons the complex form is preferable. In order to get rid of the denominator in the Lagrangian, we introduce an auxiliary field $V \in \text{Hom}(C^N, C^M)$ and write down a new Lagrangian

$$\mathcal{L} = \text{Tr} (VD\bar{z}U) + \text{Tr} (VD\bar{z}U)\dagger - \text{Tr} (VV\dagger U\dagger U),$$  \hspace{1cm} (7)$$

that turns into the original one upon elimination of the field $V$. Next we perform yet another quadratic transformation, in order to eliminate the quartic interaction. To this end we introduce the complex matrix field $\Phi \in \text{End}(C^N)$ and its Hermitian conjugate:

$$\Phi = (\Phi)^\dagger. \quad (10)$$

The condition (10) is precisely the condition of vanishing of the moment map $\mu_C = 0$ for the action of
the parabolic group $P_{d_1,\ldots,d_{m-1}}$ on the space of matrices $(U,V)$ endowed with the symplectic form $\omega_0 = \text{Tr}(dU \wedge dV)$. As a result,

$$d\theta = \omega_{\text{red}}$$

is the complex symplectic form, arising after the reduction w.r.t. the parabolic group. In order to ensure the condition (10) at the level of the Lagrangian of the model, one needs the gauge field $A_z \in \text{Lie}(P_{d_1,\ldots,d_{m-1}})$. Indeed, differentiating the Lagrangian (8) w.r.t. $A_z$, one arrives at the condition (10).

A large class of integrable sigma-models in the $\beta\gamma$-formulation has been recently proposed in [12] (for background material see also [13, 14]). In the terminology of that work our field $\Phi_z$ should be viewed as the component $A_w$ of the Chern-Simons gauge field along the “topological plane” (i.e. the worldsheet $\Sigma$). The quadratic form in the interaction term $\text{Tr} (\Phi_z \Phi_{\bar{z}})$ in (8) is in this context the inverse propagator of the field $A_w$, which in the present (rational) case is proportional to the identity matrix.

§ 1.1. Relation to the quiver formulation

Before passing to further topics, let us clarify the relation of the complex symplectic form, constructed using the symplectic quotient w.r.t. a parabolic subgroup, as above, and the symplectic form that arises as a result of a reductive quotient, defined by the so-called quiver. We recall that $T^*F$ is a hyper-Kähler manifold that maybe be constructed by a hyper-Kähler quotient of flat space (though we stress that the real symplectic form – the Kähler form – will not concern us here). This quotient is based on a linear quiver diagram of the following form:

$$L_1 \rightarrow V_1 \rightarrow L_2 \rightarrow \cdots \rightarrow V_{m-1} \rightarrow L_{m-1} \rightarrow C^N$$

In each node there is a vector space $L_k \simeq \mathbb{C}^{d_k}$, and to each arrow from node $i$ to node $j$ corresponds a field, taking values in $\text{Hom}(L_i, L_j)$. The full space of fields is therefore

$$\mathscr{W}_0 := \oplus_{i=1}^{m-1} (\text{Hom}(L_i, L_{i+1}) \oplus \text{Hom}(L_{i+1}, L_i)).$$

In each node there is an action of a gauge group $GL(L_i)$. We then consider the GIT-quotient $\mathscr{W}/\mathscr{G}$ of the stable subset $\mathscr{W} \subset \mathscr{W}_0$ w.r.t. the group $G := \prod_{i=1}^{m-1} GL(L_i)$. In $\mathscr{W}/\mathscr{G}$ we define a submanifold given by the vanishing conditions for the moment maps ($U_0 = 0, V_0 = 0$):

$$\mathcal{F} := \{ \mu_i = U_{i-1}V_{i-1} - V_iU_i = 0, \quad i = 1,\ldots,m-1 \} \subset \mathscr{W}/\mathscr{G}.$$
The (well-known) statement is that the resulting space is the flag manifold (2), which is why we have denoted it by \( \mathcal{F} \). On \( \mathcal{W}_0 \) there is a natural complex symplectic form

\[
\Omega = \sum_{i=1}^{m-1} \text{Tr}(dU_i \wedge dV_i).
\]  

(15)

The construction just described may be interpreted as the symplectic quotient w.r.t. the complex group \( G \), and it endows \( \mathcal{F} \) with a certain symplectic form \( \Omega_{\mathcal{F}} \). We prove the following statement:

**Lemma.** \( \Omega_{\mathcal{F}} = \omega_{\text{red}} \), where \( \omega_{\text{red}} \) is the symplectic form (11) that arises as a result of the reduction w.r.t. a parabolic subgroup of \( GL(M, \mathbb{C}) \).

**Proof.** First of all, consider the fields \( \{U_i\} \). \( U_i \) is a matrix with \( d_i \) columns and \( d_{i+1} \) rows. By the action of \( GL(d_{i+1}, \mathbb{C}) \) one can bring \( U_i \) to the form where the first \( d_{i+1} - d_i \) rows are zero and the last \( d_i \) rows represent a unit matrix. The stabilizer of this canonical form w.r.t. the joint (left-right) action of \( GL(d_{i+1}, \mathbb{C}) \times GL(d_i, \mathbb{C}) \) is the subgroup \( P_{d_i,d_{i+1}} \subset P_{d_i,d_{i+1}} \times GL(d_i, \mathbb{C}) \), embedded according to the rule \( g \to (g, \pi_i(g)) \), where \( \pi_i(g) \) is the projection on the block of size \( d_i \times d_i \). Iterating this procedure, i.e. bringing all matrices \( U_i \) \( (i = 1, \ldots, m - 2) \) to canonical form, we arrive at the situation, when one is left with a single non-trivial matrix \( U_{m-1} := U \), and the resulting symmetry group is precisely \( P_{d_1,\ldots,d_{m-1}} \). We also denote \( V_{m-1} := V \). Now, let \( a \in \mathfrak{k} = \text{Lie}(P_{d_1,\ldots,d_{m-1}}) \). By definition of the stabilizer \( aU_{m-2} = U_{m-2}\pi_{m-2}(a) \), therefore \( \text{Tr}(aU_{m-2}V_{m-2}) = \text{Tr}(\pi_{m-2}(a)V_{m-2}U_{m-2}) = \text{Tr}(\pi_{m-2}(a)U_{m-3}V_{m-3}) \), where in the second equality we have used the equation (14). Since \( \pi_{m-2}(a) \in \text{Stab}(U_{m-3}) \), we can iterate this procedure, and at the end we will obtain \( \text{Tr}(aU_{m-2}V_{m-2}) = 0 \). Due to the equation \( U_{m-2}V_{m-2} - VU = 0 \) we get \( VU|_{\mathfrak{k}} = 0 \), which coincides with (10). Besides, since the matrices \( U_i \) \( (i = 1, \ldots, m - 2) \) are constant, the restriction of the symplectic form \( \Omega \) coincides with \( \text{Tr}(dU_{m-1} \wedge dV_{m-1}) = \text{Tr}(dU \wedge dV) \). .......................................................... \[ \]

Let us clarify the role of the field \( \Phi_z \). Differentiating the Lagrangian (8) w.r.t. \( \Phi_z \), we obtain

\[
\Phi_z = -iUV.
\]  

(16)

This coincides with the expression for the \( z \)-component of the Noether current for the action of the group \( GL(N, \mathbb{C}) \) on the space of matrices \( (U, V) \). For the \( \beta\gamma \)-system written above \( \Phi_z \) is nothing but the moment map for the action of this group.

2. **Relation to the principal chiral model**

Recall that the equations of motion of the principal chiral model may be written as follows:

\[
j = -g^{-1}dg, \quad d * j = 0.
\]  

(17)
Analogously one can write down the equations of motion for a sigma-model with a symmetric target space. Let $\sigma : G \rightarrow G$ be the Cartan homomorphism, $\sigma^2 = 1$. Then the equations of motion have the form:

\begin{align}
  j_s &= -\tilde{g}^{-1}d\tilde{g}, & d * j_s &= 0, \quad (18) \\
  \text{where} & \quad \tilde{g} = \sigma(g)g^{-1}. \quad (19)
\end{align}

Note that the map $g \rightarrow \tilde{g}$, written in the second line, is nothing but the Cartan embedding $\hat{\sigma} : G_H \hookrightarrow G$. In both cases $j, j_s$ are the Noether currents of the sigma-model, calculated using the standard action $S = \int d^2z \sqrt{\partial X}^2$.

In other words, suppose $X : \Sigma \rightarrow G$ is a harmonic map. If its image lies in the symmetric space $G_H$, i.e. $X(\Sigma) \subset G_H \subset \hat{\sigma}G$, the map $X : \Sigma \rightarrow G_H$ is harmonic. The converse is also true: if $X : \Sigma \rightarrow G_H$ is a harmonic map, $\hat{\sigma} \circ X : \Sigma \rightarrow G$ is also harmonic. This can be alternatively understood by recalling that $\hat{\sigma}$ is a totally geodesic embedding. By definition, this means that the second fundamental form of $\hat{\sigma}(G_H) \subset G$ vanishes: $(\nabla_X Y)_{\perp} = 0$ for any two vectors $X, Y \in T(\hat{\sigma}(G_H))$. It is easy to check that if $\hat{\sigma} : M \subset N$ is a totally geodesic submanifold, and $X : \Sigma \rightarrow M$ is a harmonic map, then $\hat{\sigma} \circ X : \Sigma \rightarrow N$ is also harmonic.

§ 2.1. Nilpotent orbits

After this intermezzo let us return to the formulas (10)-(16):

$$
\Phi_2 z = -i UV, \quad \mu_C = \sqrt{\partial X}^2 \big|_{t_*} = 0, \quad (20)
$$

where $\mathfrak{k} = \text{Lie}(P_{d_1, \ldots, d_{m-1}})$.

§§ 2.1.1. Grassmannian

To start with, we consider the case of a Grassmannian, i.e. $m = 2$. Then the vanishing of the moment map is simply $V U = 0$. Therefore $\Phi_2^2 = 0$. From the expression for $\Phi_2$ it also follows that $\text{Im}(\Phi_2) \subset \text{Im}(U) \subset \text{Ker}(\Phi_2)$. As is well-known,

$$
\{(U, \Phi_2) : \text{rk}(U) = M, \Phi_2^2 = 0, \text{Im}(\Phi_2) \subset \text{Im}(U) \subset \text{Ker}(\Phi_2)\} \simeq T^*G(M, N) \quad (21)
$$

is the cotangent bundle to a Grassmannian, and the forgetful map

$$
T^*G(M, N) \rightarrow \{\Phi_2 : \Phi_2^2 = 0\} \quad (22)
$$

provides a resolution of singularities of the nilpotent orbit in the r.h.s. (the Springer resolution). The conditions in the l.h.s. of (21) imply the factorization (20) for $\Phi_2$, and the non-uniqueness in this factorization corresponds exactly to the gauge symmetry $U \rightarrow Ug, V \rightarrow g^{-1}V$, where $g \in GL(M, \mathbb{C})$.

Let us now derive the equations of motion for the field $\Phi_2$. First of all, the Lagrangian (8) implies the following equations of motion for the fields $U$ and $V$:

$$
\mathcal{D}_z U = 0, \quad \mathcal{D}_z V = 0. \quad (23)
$$
Therefore $\mathcal{D}_z \Phi_z = 0$, i.e.

$$\partial_z \Phi_z + i [\Phi_z, \Phi_z] = 0 . \tag{24}$$

This equation is nothing but the equation of motion of the principal chiral field. Indeed, introduce a 1-form $j = i(\Phi_z dz + \Phi_z d\bar{z})$ with values in the Lie algebra $\mathfrak{u}_N$. In this case (24) together with the Hermitian conjugate equation may be written in the form of two conditions

$$d \ast j = 0, \quad dj - j \wedge j = 0, \tag{25}$$

which are the e.o.m. of the principal chiral field. This is consistent with the fact, proven in [2], that the Noether current of the model (3) is flat.

In other words, in the case of a Grassmann sigma-model the field $\Phi_z$ satisfies the equations

$$\partial_z \Phi_z + i [\Phi_z, \Phi_z] = 0, \quad \Phi_z^2 = 0 . \tag{26}$$

It is rather clear, though, that these equations do not completely characterize the Grassmannian sigma-model. Indeed, for example the solution $\Phi_z = 0$ of the equations (26) corresponds in fact to a whole large class of sigma-model solutions: $D_z U = 0$, $D_z V = 0$, $UV = 0$. Since, according to the assumption, $U^\dagger U$ is a non-degenerate matrix, it follows from the latter condition that $V = 0$, and as a result one is left with the equation $D_z U = 0$, i.e. a holomorphic map $U$ to $G(M, N)$. The converse is also true: if $D_z U = 0$, then $\Phi_z U = 0$, and it follows from $\Phi_z = UV$ that $\Phi_z^2 = \Phi_z^1 \Phi_z = 0$, i.e. $\Phi_z = 0$. As a result, one has the correspondence

$$\Phi_z = 0 \quad \leftrightarrow \quad \text{holomorphic curves in } G(M, N) . \tag{27}$$

Therefore the equation for $U$ is essential in general. As for the field $V$, it can be completely excluded and replaced by the field $\Phi_z$. Indeed, from the conditions in the l.h.s. of (21) one obtains the factorization $\Phi_z = UV$, and the equations $\mathcal{D}_z U = 0$, $\mathcal{D}_z \Phi_z = 0$ imply $U \mathcal{D}_z V = 0$. The condition that $U$ is a matrix of rank $M$ leads to $\mathcal{D}_z V = 0$. In other words, an alternative formulation of the model is as follows: we consider the fields $(U, \Phi_z)$, satisfying

$$(U, \Phi_z) : \text{rk}(U) = M, \quad \Phi_z^2 = 0, \quad \text{Im}(\Phi_z) \subset \text{Im}(U) \subset \text{Ker}(\Phi_z) . \tag{28}$$

In this case the equations of motion take the form

$$\mathcal{D}_z U = 0, \quad \mathcal{D}_z \Phi_z = 0 . \tag{29}$$

Next we describe the situation when the equation for $U$ is indeed redundant:

**Lemma.** The equation $\mathcal{D}_z U = 0$ follows from $\mathcal{D}_z \Phi_z = 0$ and from the conditions (28) if and only if $\text{Ker}(\Phi_z) \simeq \text{Im}(U)$.

**Proof.** Multiplying $D_z U$ by $\Phi_z$ and using the equation $D_z \Phi_z = 0$ and the condition $\Phi_z U = 0$, we obtain $\Phi_z D_z U = D_z (\Phi_z U) = 0$. Therefore the equation $\Phi_z D_z U = 0$ holds identically. It is equivalent to $\mathcal{D}_z U = 0$ if and only if $\text{Ker}(\Phi_z) \simeq \text{Im}(U)$.

The condition $\Phi_z^2 = 0$ means that the Jordan structure of $\Phi_z$ consists of $m$ cells of sizes $2 \times 2$ and $n$ cells of sizes $1 \times 1$. In this case $N = 2m + n$ and $\dim \text{Ker}(\Phi_z) = m + n$. 

7
Since $\text{Im}(U) \subset \ker(\Phi_z)$ and $\text{rk}(U) = M$, we get the condition $M \leq m + n$. This easily leads to $m \leq N - M$, $n \geq 2M - N$, and the inequalities are saturated precisely in the case $\ker(\Phi_z) \simeq \text{Im}(U)$ considered earlier. In this case the number of $2 \times 2$ cells is maximal and equal to $N - M$, and the number of cells of size $1 \times 1$ is $2M - N$. Note that this is only possible in the case $M \geq \frac{N}{2}$. Reduction of the number of cells of type $2 \times 2$ corresponds to the degeneration of the matrix $\Phi_z$.

The dynamical equation (26) imposes severe constraints on the way, in which the Jordan structure of the matrix $\Phi_z$ can change as one varies the point $z, \bar{z}$ on the worldsheet. Indeed, it implies that $\Phi_z = kQ(z)k^{-1}$, where $Q(z)$ is a matrix that depends holomorphically on $z$. The Jordan structure of the matrix $Q(z)$ is the same as that of $\Phi_z$, and the vanishing of the Jordan blocks occurs holomorphically in $z$. In particular, the Jordan structure changes only at "special points" - isolated points on the worldsheet. As a result, "almost everywhere" the dimension of the kernel $\dim \ker(\Phi_z) := \bar{M}$ is the same, and the map $\lambda : (z, \bar{z}) \to \ker(\Phi_z)$ is a map to the Grassmannian $G(M, N)$. A more careful analysis of the behavior of $\Phi_z$ at a special point would show that $\lambda$ may be extended to these points. We have come to the following conclusion: let $g(z, \bar{z})$ be a solution of the principal chiral model, i.e. a harmonic map to the group $G$, satisfying the condition $\Phi_z^2 = 0$, where $\Phi_z := g^{-1}\partial_z g$ is a component of the Noether current, and let the dimension of the kernel of $\Phi_z$ at a typical point of the worldsheet be $\bar{M}$. Then one can construct a harmonic map to the Grassmannian $G(M, N)$ by the rule $(z, \bar{z}) \to \ker(\Phi_z)$.

§ 2.1.2. The $SU(2)$-case.

We consider the special case $N = 2$, i.e. when $G = SU(2)$. In this case $\text{Tr}(\Phi_z) = 0$, and the condition $\Phi_z^2 = 0$ is equivalent to $\text{Tr}(\Phi_z^2) = 0$. The latter condition is, in turn, the Virasoro constraint, i.e. the condition that the harmonic map is minimal. As a result, to a minimal surface in $G = SU(2)$, satisfying $\Phi_z \neq 0$, we can prescribe a harmonic map into $\mathbb{C}P^1$. Let us construct it explicitly. The Cartan embedding $\mathbb{C}P^1 \hookrightarrow SU(2)$ has the form $g = 1_2 - 2w \otimes \bar{w}$, where $w \in \mathbb{C}P^1$ ($\|w\| = 1$). The Noether current is $\Phi_z = 2(\bar{w} \otimes D_z w - D_z \bar{w} \otimes w)$, where $D_z w = \partial_z w - (\bar{w} \otimes \partial_z w)w$, and its square is $\Phi_z^2 = -4(D_z \bar{w} \otimes D_z \bar{w} + (D_z \bar{w} \otimes D_z w)w \otimes \bar{w})$. Multiplying the condition $\Phi_z^2 = 0$ by $w$ from the right and, taking into account that $D_z \bar{w} \circ w = 0$, we get $D_z \bar{w} \circ D_z w = 0$, therefore $D_z w \otimes D_z \bar{w} = 0$. We see that the map $w(z, \bar{z})$ is either holomorphic or anti-holomorphic. If $D_z \bar{w} = 0$, the null-vector $\chi$ of the matrix $\Phi_z$ ($\Phi_z \chi = 0$) satisfies the constraint $\bar{w} \circ \chi = 0$, i.e. $\chi$ is the antipodal point to $w$ on $\mathbb{C}P^1$. If $D_z w = 0$, then, as is easy to verify, $D_z w$ is a holomorphic map, and the null-vector $\chi$ satisfies the condition $D_z \bar{w} \circ \chi = 0$. Therefore in both cases we are led to the conclusion that $\chi$ is an anti-holomorphic map, related to a holomorphic map $(w \circ D_z w)$ by the antipodal involution.

\footnote{Note that the condition $\Phi_z = 0$ implies $g(z, \bar{z}) = g_0$, i.e. in this case the map is trivial.}
§§ 2.1.3. The partial flag manifold

Let us extend the results of the previous section to more general flag manifolds. We return first to the equation for $\Phi_z$:

$$\partial_z \Phi_z + i [\Phi_z, \Phi_z] = 0,$$

but this time we assume that the matrix $\Phi_z$ satisfies, in a typical point $(z, \bar{z}) \in \Sigma$, the condition

$$\Phi_z^m = 0 \quad \text{and} \quad \Phi_z^{m-1} \neq 0. \quad (31)$$

The matrix $\Phi_z$ naturally defines a flag

$$f := \{0 \subset \text{Ker}(\Phi_z) \subset \text{Ker}(\Phi_z^2) \subset \cdots \subset \text{Ker}(\Phi_z^m) \sim \mathbb{C}^N\} \quad (32)$$

**Proposition.** Given a matrix $\Phi_z$ satisfying (30)-(31), the map $(z, \bar{z}) \rightarrow f$ is a solution to the e.o.m. of the flag manifold sigma-model (8).

**Proof.** Consider a matrix $U$ of the form $U = (U_{m-1} \cdots | U_1)$, where $U_i$ is a matrix, whose columns are the linearly independent vectors from $\text{Ker}(\Phi_z^i)/\text{Ker}(\Phi_z^{i-1})$. Let us relate the dimensions of these spaces to the dimensions of the Jordan cells of the matrix $\Phi_z$. To this end we bring $\Phi_z$ to the Jordan form

$$\Phi_z(0) = \text{Diag}\{J_{s_1}, \ldots, J_{s_\ell}\}, \quad \sum_{j=1}^\ell \ s_j = N, \quad (33)$$

where $J_s$ is a Jordan cell of size $s \times s$. We have chosen the ordering $s_1 \geq \cdots \geq s_\ell$, where, according to the supposition (31), $s_1 = m$. We denote by $\kappa_i$ the number of Jordan cells of size at least $i$ ($\kappa_1 = \ell$). The following two properties are obvious:

- $\kappa_{i+1} \leq \kappa_i$, i.e. $\kappa_1, \ldots, \kappa_m$ is a non-increasing sequence.
- $\dim \text{Ker}(\Phi_z) = \kappa_1, \dim \text{Ker}(\Phi_z^2) = \kappa_1 + \kappa_2$ etc.,
- therefore $\dim \text{Ker}(\Phi_z^i)/\text{Ker}(\Phi_z^{i-1}) = \kappa_i$.

Therefore $U_i \in \text{Hom}(\mathbb{C}^{s_i}, \mathbb{C}^N)$ and $U \in \text{Hom}(\mathbb{C}^M, \mathbb{C}^N)$, where $M = \sum_{i=1}^{m-1} \kappa_i$.

Since, by construction, $\text{Im}(U) \simeq \text{Ker}(\Phi_z^{m-1})$ and $\text{Im}(\Phi_z) \subset \text{Ker}(\Phi_z^{m-1})$, we have $\text{Im}(\Phi_z) \subset \text{Im}(U)$, i.e. there exists a matrix $V \in \text{Hom}(\mathbb{C}^N, \mathbb{C}^M)$, such that $\Phi_z = -i U V$. Let us now derive the equations of motion for the matrices $U$ and $V$. Since $\Phi_z^k U_k = 0$ and $D_z \Phi_z = 0$, one has $\Phi_z^k D_z U_k = 0$. The columns of the matrix $(U_k | \cdots | U_1)$ span the kernel of $\Phi_z^k$, hence $D_z U_k = -i \sum_{j \leq k} U_j A_{jk}$, where $A_{jk}$ are matrices of relevant sizes. Out of the matrices $A_{jk}$ ($1 \leq j \leq k \leq m - 1$) we form a single matrix $A_z$, which schematically looks as in (4). Then, clearly, the following equation is satisfied:

$$\mathcal{L}_z U = \partial_z U + i U A_z + i \Phi_z U = 0. \quad (34)$$
As $\Phi_z = -iUV$, from the non-degeneracy of $U$ it follows that $\mathcal{D}_z V = 0$. Because $U_1, \ldots, U_k \subset \text{Ker}(\Phi^k_z)$, in the matrix $\Phi^k_z U \sim U(VU)^k$ the last $\sum_{i=1}^k \kappa_i$ columns vanish, therefore the matrix $(VU)^k$ is strictly-lower-triangular and has zeros on the first $k$ block diagonals (the main diagonal is counted as the first one). We denote by $\mathfrak{f}$ the parabolic subalgebra of $\mathfrak{gl}_M$ that stabilizes the subflag of $(32)$ with the last element omitted. We have proven that $VU|_{\mathfrak{f}^*} = 0$. Therefore a solution $\Phi_z(z, \bar{z})$ of the system (30)-(31) produces a solution $(U, V)$ to the equations of motion of the sigma-model with target space the flag manifold

$$\frac{U(N)}{U(\kappa_1) \times \cdots \times U(\kappa_m)}, \quad \text{where} \quad \kappa_j = \text{dim Ker}(\Phi^j_z)/\text{Ker}(\Phi^{j-1}_z)$$

is a non-increasing sequence.

The complex structure on the flag is uniquely determined by the structure of the complex flag (32).

3. Discussion

In the present paper we described two principal results. First of all, we showed that the flag manifold introduced earlier by the author allow an alternative formulation as two coupled $\beta\gamma$-systems, interacting via an auxiliary field $\Phi_z$. This proves the equivalence of these models to the flag manifold models described in [12] (in the terminology of that paper the field $\Phi_z$ should be interpreted as the holomorphic component of the gauge field $A_w$ along the “topological plane” that coincides with the worldsheet $\Sigma$ of the sigma-model. We believe that the gauged linear formulation of the $\beta\gamma$-system for flag manifold models introduced in the present paper will also prove useful for the investigation of their trigonometric ($\eta$) deformations (there is a vast literature on the subject: see, for example, [15, 16, 17, 18, 19, 20, 21]).

Besides, we investigated the relation between the flag manifold sigma-models and the principal chiral model. It was shown that the solutions of the principal chiral model, which define a map into the nilpotent orbit of the corresponding complexified group, correspond to solutions of the flag manifold sigma-models (see [22] for a nice review of the theory of nilpotent orbits). It seems likely that the full analysis of this correspondence will require the theory of the Springer resolution (see, for example, [23]) and will be a subject of further investigation.

Acknowledgments.

I would like to express my sincere gratitude to A. A. Slavnov for his yearslong support and warm attitude. I wish Andrey Alekseevich health, cheerfulness and the pleasure of creative work.

I would like to thank A. Bourget, R. Donagi, S. Frolov, A. Hanany, C. Klimčík, T. McLoughlin, V. Pestun, E. Sharpe, S. Shatashvili, S. Theisen, A. Tseytlin and
P. Zinn-Justin for useful discussions, as well as D. Lüst for support. I am grateful to the Institut des Hautes Études Scientifiques (Bures-sur-Yvette, France), where part of this work was done, and in particular to V. Pestun, for hospitality. My work is partially supported by the ERC grant in the framework of the European Union “Horizon 2020” program (QUASIFT, grant № 677368).
