Abstract

Independence of premise principles play an important role in characterizing the modified realizability and the Dialectica interpretations. In this paper we show that a great many intuitionistic set theories are closed under the corresponding independence of premise rule for finite types over \( \mathbb{N} \). It is also shown that the existence property (or existential definability property) holds for statements of the form \( \neg A \rightarrow \exists x^\sigma F(x^\sigma) \), where the variable \( x^\sigma \) ranges over a finite type \( \sigma \). This applies in particular to Constructive Zermelo-Fraenkel Set Theory (CZF) and Intuitionistic Zermelo-Fraenkel Set Theory (IZF), two systems known not to have the general existence property.

On the technical side, the paper uses the method of realizability with truth from [21] and [8] with the underlying partial combinatory algebra (pca) chosen among the total ones. A particular instance of the latter is provided by the substructure of the graph model formed by the semicomputable subsets of \( \mathbb{N} \), which has the advantage that it forms a set pca even in proof-theoretically weak set theories such as CZF.

Key words: Intuitionistic set theory, Constructive set theory, independence of premise rule, independence of premise schemata

MSC 03B30 03F05 03F15 03F35 03F35

1 Introduction

There are (at least) three types of classically valid principles that figure prominently in constructive mathematics: Choice in Finite Types (AC\(_{FT}\)), Markov’s (MP), and the Independence of Premise (IP) principle. All three are required for a characterization of Gödel’s Dialectica interpretation (see [24 III.5], [23 11.6]) whereas modified realizability for intuitionistic finite-type arithmetic, \( \text{HA}^\omega \), is axiomatized by AC\(_{FT}\) and IP alone (see [24 III.4],
To be more precise, we introduce the following schemata.

\[
\text{IP}_{ef} : (A \rightarrow \exists x^\sigma B(x)) \rightarrow \exists x^\sigma (A \rightarrow B(x))
\]

\[
\text{AC}_{FT} : \forall x^\sigma \exists y^\tau C(x, y) \rightarrow \exists \tau^\sigma \forall x^\sigma C(x, zx)
\]

where \(\sigma\) signifies a finite type, \(x^\sigma\) varies over \(\sigma\), and \(A\) is assumed to be \(\exists\)-free, i.e., \(A\) neither contains existential quantifiers nor disjunctions.\[1\] \(\text{HA}^\omega\) satisfies the following.

**Theorem 1.1.** With \(\vDash_{mr}\) signifying modified realizability, we have:

(i) \(\text{HA}^\omega + \text{AC}_{FT} + \text{IP}_{ef} \vdash A \leftrightarrow \exists x (x \vDash_{mr} A)\).

(ii) \(\text{HA}^\omega + \text{AC}_{FT} + \text{IP}_{ef} \vdash A \leftrightarrow \text{HA}^\omega \vdash t \vDash_{mr} A\) for some term \(t\).

An important application of modified realizability is that \(\text{HA}^\omega\) is closed under the independence of premise rule for \(\exists\)-free formula, \(\text{IPR}_{ef}\), and also satisfies explicit definability, \(\text{ED}^\sigma\).

**Theorem 1.2.**

(i) If \(\text{HA}^\omega \vdash A \rightarrow \exists x^\sigma B(x)\), then \(\text{HA}^\omega \vdash \exists x^\sigma (A \rightarrow B(x))\), when \(A\) is \(\exists\)-free.

(ii) If \(\text{HA}^\omega \vdash \exists x^\sigma C(x)\), then \(\text{HA}^\omega \vdash C(t)\) for a suitable term \(t\).

This paper shows that results similar to Theorem 1.2 hold for a great many set theories \(T\), including Constructive Zermelo-Fraenkel Set Theory (\(\text{CZF}\)) and Intuitionistic Zermelo-Fraenkel Set Theory (\(\text{IZF}\)).

**Theorem 1.3.** Let \(\sigma\) be a finite type on \(\mathbb{N}\). Below \(\sigma\) denotes the corresponding set. We also assume that \(T\) proves the existence of each finite type (as a set).

(i) If \(T \vdash \forall x [\neg A(x) \rightarrow \exists y \in \sigma B(x, y)]\), then

\[T \vdash \exists y \forall x [\neg A(x) \rightarrow y \in \sigma \land B(x, y)].\]

(ii) If \(T \vdash \forall x [\forall u D(u) \rightarrow \exists y \in \sigma B(y)]\) and \(T \vdash \forall u [D(u) \lor \neg D(u)]\), then

\[T \vdash \exists y [\forall u D(u) \rightarrow y \in \sigma \land B(y)].\]

(iii) If \(T \vdash \exists x \in \sigma C(x)\), then

\[T \vdash \exists x \in \sigma [C(x) \land E(x)]\]

for some formula \(E(x)\).

\[1\] Of course, it is also assumed that \(x\) is not a free variable of \(A\).
It is known that $\text{IZF}$ and $\text{CZF}$ have the numerical existence property (see [21]), so Theorem 1.3(iii) extends this property to a larger collection of existential formulas. On the other hand it is known by work of H. Friedman and S. Ščedrov [12] that $\text{IZF}$ does not have the general existence property (EP) while A. Swan [23] proved that EP also fails for $\text{CZF}$.

On the technical side, the paper uses the method of realizability with truth from [21] and [8] with the underlying partial combinatory algebra ($\text{pca}$) chosen among the total ones. A particular instance of the latter is provided by the substructure of the graph model formed by the semicomputable subsets of $\mathbb{N}$, which has the advantage that it forms a set $\text{pca}$ even in proof-theoretically weak set theories such as $\text{CZF}$.

2 The system $\text{CZF}$

2.1 Axioms of constructive set theories

The language of constructive Zermelo-Fraenkel Set Theory $\text{CZF}$ is same first order language as that of classical Zermelo-Fraenkel Set Theory $\text{ZF}$ whose only non-logical symbol is the binary predicate $\in$. We use $u, v, w, x, y$ and $z$, possibly with superscripts, for variables in the language of $\text{CZF}$. The logic of $\text{CZF}$ is intuitionistic first order logic with equality.

The axioms of $\text{CZF}$ are as follows:

**Extensionality:** $\forall x \forall y (\forall z (z \in x \leftrightarrow z \in y) \rightarrow x = y)$.

**Pairing:** $\forall x \forall y \exists z (x \in z \land y \in z)$.

**Union:** $\forall x \exists y \forall z ((\exists w \in x)(z \in w) \rightarrow z \in y)$.

**Infinity:** $\exists x \forall y [y \in x \leftrightarrow \forall z (z \in y \leftrightarrow \bot) \lor (\exists w \in x) \forall v (v \in y \leftrightarrow v \in w \lor v = w)]$.

**Set Induction:** For any formula $\varphi$, $\forall x [\forall y \in x] \varphi(y) \rightarrow \varphi(x) \rightarrow \forall x \varphi(x)$.

**Bounded Separation:** $\exists x \exists y \forall z [z \in y \leftrightarrow z \in x \land \varphi(z)]$, for any bounded formula $\varphi$. A formula is *bounded* or *restricted* if it is constructed from prime formulae using $\rightarrow, \neg, \land, \lor, \forall, \exists x \in y$ and $\exists x \in y$ only.

**Strong Collection:** For any formula $\varphi$,

$$
\forall x [(\forall y \in x) \exists z \varphi(y, z) \rightarrow \exists w [(\forall y \in x) (\exists z \in w) \varphi(y, z) \land (\forall z \in w) (\exists y \in x) \varphi(y, z)]].
$$

**Subset Collection:** For any formula $\varphi$,

$$
\forall x \forall y \exists z \forall u [(\forall v \in x) (\exists w \in y) \varphi(v, w, u) \rightarrow

(\exists y' \in z) [(\forall v \in x) (\exists w \in y') \varphi(v, w, u) \land (\forall w \in y') (\exists v \in x) \varphi(v, w, u)]].
$$
In what follows, we shall assume that the language CZF has constants $\emptyset$ denoting the empty set, $\omega$ denoting the set of von Neumann natural numbers. One can take the axioms $\forall x(x \in \emptyset \leftrightarrow \bot)$ for $\emptyset$ and $\forall u[u \in \omega \leftrightarrow (u = \emptyset \lor (\exists v \in \omega)\forall w(w \in u \leftrightarrow w \in v \land w = v))$ for $\omega$. We write $x + 1$ for $x \cup \{x\}$ and use $l$, $m$, and $n$ for elements of $\omega$.

**Lemma 2.1.** CZF proves the following Full Mathematical Induction Schema for $\omega$:

$$\varphi(\emptyset) \land \forall x \in \omega(\varphi(x) \rightarrow \varphi(x + 1)) \rightarrow \forall x \in \omega\varphi(x).$$

*Proof.* Immediate from Set Induction. \hfill $\square$

**Lemma 2.2.** CZF proves the following Full Iteration Scheme FIS: For any class $A$, any class function $F : A \rightarrow A$ and a set $x \in A$, there uniquely exists a set function $\nu : \omega \rightarrow A$ such that $\nu(\emptyset) = x$ and $\nu(u + 1) = F(\nu(u))$.

*Proof.* Assume that $A$ is a class, $F$ is a class function from $A$ to $A$, and $x \in A$. Define the following $\varphi(y,z)$:

$$\varphi(y,z) \equiv y \in \omega \land z \in \text{func}(y,A) \land (\emptyset \in y \rightarrow (\emptyset,x) \in z) \land$$

$$\forall u \in \omega \forall w((u,w) \in z \land u + 1 \in y \rightarrow (u + 1,F(w)) \in z),$$

where $z \in \text{func}(y,A)$ is

$$\forall u \in y \exists w \in A((u,w) \in z) \land z \subseteq y \times A.$$

By Lemma 2.1 we have that $(\forall y \in \omega)\exists!z\varphi(y,z)$. By Strong Collection, we have the desired function $h$. \hfill $\square$

We consider also several extensions of CZF.

**Full Separation** $\exists x\exists y\forall z[z \in y \leftrightarrow z \in x \land \varphi(z)]$, for any formule $\varphi$.

**Powerset** $\forall x\exists y\forall z(z \subseteq x \rightarrow z \in y)$.

The system CZF + (Full separation) + (Powerset) is called IZF (cf. [18] or [5, VIII.1]).

**MP** (Markov’s principle) $\forall n \in \omega(\varphi(n) \lor \neg\varphi(n)) \land \neg\neg\exists n \in \omega\varphi(n) \rightarrow \exists n \in \omega\varphi(n)$.

**AC$_{\omega}$** (Axiom of Countable Choice)

$$u \in \text{func}(\omega,V) \land \forall n \in \omega \exists x(x \in u(n)) \rightarrow \exists v \in \text{func}(\omega,V) \land \forall n \in \omega(v(n) \in u(n))),$$

where $V$ is the class $\{x : x = x\}$ and $v(n)$ is the unique $y$ such that $\langle n, y \rangle \in v$.

**DC** (Dependent Choices Axiom)

$$v \subseteq u \times u \land (\forall x \in u)(\exists y \in u)((x,y) \in v) \rightarrow$$

$$(\forall x \in u)\exists w(w \in \text{func}(\omega,u) \land w(0) = x \land (\forall n \in \omega)((w(n),w(n + 1)) \in v)).$$

**RDC** (Relativised Dependent Choice Axiom)

$$\forall x(\varphi(x) \rightarrow \exists y(\varphi(y) \land \psi(x,y))) \rightarrow$$

$$\forall x[\varphi(x) \rightarrow \exists v[v \in \text{func}(\omega,\{y : \varphi(y)\}) \land v(0) = x \land (\forall n \in \omega)\psi(v(n),v(n + 1))]].$$
Definition 2.3. A set \( x \) is inhabited if \( \exists y(y \in x) \). An inhabited set \( x \) is regular if \( x \) is transitive, and for every \( y \in x \) and a set \( z \subseteq y \times x \) if \( (\forall u \in y)\exists v(\langle u, v \rangle \in z) \), then there is a set \( w \in x \) such that

\[
\forall u \in y \exists v \in w(\langle u, v \rangle \in z) \land \forall v \in w \forall u \in y(\langle u, v \rangle \in z).
\]

The regular extension axiom \( \text{REA} \) is as follows: Every set is a subset of a regular set.

Definition 2.4. A set \( x \) is projective if for any \( x \)-indexed family \( (y_u)_{u \in x} \) of inhabited sets \( y_u \), there exists a function \( v \) with domain \( x \) such that \( v(u) \in y_u \) for all \( u \in x \). The Presentation Axiom \( \text{PAx} \), is the statement that every set is the surjective image of a projective set.

2.2 Finite types in CZF

The type structure \( T \) is defined inductively, outside of the language of CZF, by the following two clauses:

\[
0 \in T \quad \text{If } \sigma, \tau \in T, \text{ then } \tau^\sigma \in T. \]

We use lower Greek symbols \( \rho, \sigma \) and \( \tau \) for variables varies type structure.

In CZF, we can simulate the type structure by fixing a primitive recursive bijection \( \varphi : \omega \to \{0\} \cup \omega \times \omega \) such that \( \varphi(0) = 0 \) and \( \varphi(n) = \langle m, l \rangle \to \max\{m, l\} < n \). We use \( \varphi(0) = 0 \) as the code for 0 and \( \varphi(n) \) for \( \tau^\sigma \) when \( \varphi(n) = \langle m, l \rangle \) and \( \varphi(m) \) and \( \varphi(l) \) are codes for \( \sigma \) and \( \tau \), respectively. We do not distinguish \( \sigma \) and \( n \) such that \( \varphi(n) \) is a code for \( \sigma \), if it does not cause any confusion.

For sets \( x, y \) and \( z \), let \( x \in \text{Func}(y, z) \) be an abbreviation for “\( x \) is a function from \( y \) to \( z \)”, i.e., \( x \subseteq y \times z \land \forall u \in y \exists v \in z(\langle y, z \rangle \in x) \).

By FIS, we have the set \( FT \) such that

\[
\{\langle 0, \cdot \rangle : x \in \omega \} \subseteq FT, \quad \forall x(x \in FT \to \exists y \exists y(x = \langle \sigma, y \rangle)),
\]

\[
\forall x[\langle \tau^\sigma, x \rangle \in FT \leftrightarrow x \in \{y : \langle \sigma, y \rangle \in FT\}, \{z : \langle \tau, z \rangle \in FT\}]\]

For each finite type \( \rho, \sigma \) and \( \tau \), let \( \rho, \sigma \) and \( \tau \) be sets of the elements with the type, i.e., \( \rho = \{x : \langle \rho, x \rangle \in FT\} \), etc.. Define \( \phi(\sigma, x) \) as follows:

\[
\phi(\sigma, x) \equiv \exists y[y = \text{func}(\sigma + 1, V) \land \langle 0, \omega \rangle \in y \land \forall \tau, \rho(\tau^\rho \leq \sigma \land \langle \tau, u \rangle \in y \land \langle \rho, v \rangle \in y \to \langle \rho^\tau, v^u \rangle \in y) \land \langle \sigma, x \rangle \in y].
\]

Lemma 2.5 (CZF). For each finite type \( \sigma \), we have the following: that

\[
\exists x(\langle x, \sigma \rangle \leftrightarrow \phi(\sigma, x)) \quad \text{and} \quad \forall x \forall y(\phi(\sigma, x) \land \phi(\sigma, y) \to x = y).
\]

Proof. This is proved by induction on finite types. For \( \sigma = 0 \), then it is clear from \( \omega = \{y : \langle \sigma, y \rangle \in FT\} = \sigma \) and \( \forall x \forall y(\psi(\sigma, x) \land \phi(\sigma, y) \to x = y) \). The induction step is easy, since, for any \( x \) and \( y \), the function space \( y^x = \{z : z \in \text{Func}(x, y)\} \) exists uniquely in CZF. \( \Box \)
3 Applicative structure

In order to define a realizability interpretation we must have a notion of realizing functions on hand. A particularly general and elegant approach to realizability builds on structures which have been variably called partial combinatory algebras, applicative structures, or Schönfinkel algebras. These structures are best described as the models of a theory APP. The following presents the main features of APP; for full details cf. [9, 10, 11, 26]. The language of APP is a first-order language with a ternary relation symbol App, a unary relation symbol $N$ (for a copy of the natural numbers) and equality, $=\,$, as primitives. The language has an infinite collection of variables, denoted by $a$, $b$, $c$, $\ldots$, $g$, $h$ and $i$, and nine distinguished constants: $0, s_N, p_N, k, s, d, p_0, p_1$ for, respectively, zero, successor on $N$, predecessor on $N$, the two basic combinators, definition by cases, pairing and the corresponding two projections. There is no arity associated with the various constants. The terms of APP are just the variables and constants, which are denoted by $p$, $q$, $r$, $s$ and $t$ possibly with sub- and superscripts. We write $tt' \simeq s$ for $\text{App}(t,t',s)$.

Formulas are then generated from atomic ones using the propositional connectives and the quantifiers.

In order to facilitate the formulation of the axioms, the language of APP is expanded definitionally with the symbol $\simeq$ and the auxiliary notion of an application term is introduced. We use $p$, $q$, $\ldots$ $t$ also for application terms. The set of application terms is given by two clauses:

1. all terms of APP are application terms; and
2. if $s$ and $t$ are application terms, then $(st)$ is an application term.

For $s$ and $t$ application terms, we have auxiliary, defined formulae of the form:

$$s \simeq t := \forall a (s \simeq a \leftrightarrow t \simeq a),$$

if $t$ is not a variable. Here $s \simeq a$ (for $a$ a free variable) is inductively defined by:

$$s \simeq a \text{ is } \begin{cases} s = a, & \text{if } s \text{ is a term of APP,} \\ \exists x, y[s_1 \simeq x \land s_2 \simeq y \land \text{App}(x, y, a)] & \text{if } s \text{ is of the form } (s_1s_2). \end{cases}$$

Some abbreviations are $t_1t_2\ldots t_n$ for $((\ldots(t_1t_2)\ldots)t_n)$; $t \downarrow$ for $\exists a(t \simeq a)$ and $\phi(t)$ for $\exists a(t \simeq a \land \phi(a))$.

Some further conventions are useful. Systematic notation for $n$-tuples is introduced as follows: $(t)$ is $t$ and $(s, t)$ is $p(st)$, $(t_1, \ldots, t_n)$ is defined by $((t_1, \ldots, t_{n-1}), t_n)$. For projections, we write $(t)_i$ for $p_it$ and $(t)_{ij}$ for $p_j(p_it)$ for $i, j \in \{0, 1\}$. In this paper, the logic of APP is assumed to be that of intuitionistic predicate logic with identity. APP’s non-logical axioms are the following:
Applicative Axioms

1. App(a, b, c_1) \land App(a, b, c_2) \rightarrow c_1 = c_2.

2. (kab) \downarrow \land kab \simeq a.

3. (sab) \downarrow \land sabc \simeq ac(bc).

4. (pa_0 a_1) \downarrow \land (p_0 a) \downarrow \land p_i (pa_0 a_1) \simeq a_i \text{ for } i = 0, 1.

5. N(c_1) \land N(c_2) \land c_1 = c_2 \rightarrow dabc_1 c_2 \downarrow \land dabc_1 c_2 \simeq a.

6. N(c_1) \land N(c_2) \land c_1 \neq c_2 \rightarrow dabc_1 c_2 \downarrow \land dabc_1 c_2 \simeq b.

7. \forall a \left( N(a) \rightarrow [s_N a \downarrow \land s_N a \neq 0 \land N(s_N a)] \right). \tag{7}

8. N(0) \land \forall a \left( N(a) \land x \neq 0 \rightarrow [p_N a \downarrow \land s_N (p_N a) = a] \right). \tag{8}

9. \forall a \left[ N(a) \rightarrow p_N (s_N a) = a \right]. \tag{9}

10. \varphi(0) \land \forall a \left[ N(a) \land \varphi(a) \rightarrow \varphi(s_N a) \right] \rightarrow \forall a \left[ N(a) \rightarrow \varphi(a) \right]. \tag{10}

Let 1 := s_N 0. The applicative axioms entail that 1 is an application term that evaluates to an object falling under N but distinct from 0, i.e., 1 \downarrow, N(1) and 0 \neq 1.

Employing the axioms for the combinators k and s one can deduce an abstraction lemma yielding \lambda-terms of one argument. This can be generalized using n-tuples and projections.

Lemma 3.1. (cf. [9]) (Abstraction Lemma) For each application term t there is a new application term t^* such that the parameters of t^* are among the parameters of t minus a_1...a_n and such that

\[
\text{APP} \vdash t^* \downarrow \land t^* a_1...a_n \simeq t.
\]

\[\lambda(a_1...a_n).t \text{ is written for } t^*.\]

The most important consequence of the Abstraction Lemma is the Recursion Theorem. It can be derived in the same way as for the \lambda-calculus (cf. [9], [10], [7], VI.2.7). Actually, one can prove a uniform version of the following in APP.

Corollary 3.2. (Recursion Theorem)

\[\forall f \exists g \forall a_1...a_n g(a_1,...,a_n) \simeq f(g, a_1,...,a_n).\]
4 Graph models in constructive set theories

In this section, we present an easiest example of a model of total applicative structure constructed in constructive set theories without the powerset axioms, such as CZF.

Plotkin and Scott independently developed a PCA whose universe is the power set of the integers, \( \mathcal{P}(\mathbb{N}) \). This construction exploits the fact that finite subsets of \( \mathbb{N} \) can be coded as integers; the finite set \( \{k_0, \ldots, k_r\} \) with \( k_0 < \cdots < k_r \) can be coded by

\[
[k_0, \ldots, k_r] := \sum_{i=0}^{r} 2^{k_i}, \quad [\emptyset] := 0
\]  

(1)

\[ e_n := \{k_0, \ldots, k_r\} \text{ iff } n = [k_0, \ldots, k_r]. \]  

(2)

We use \( X, Y, Z \) for arbitrary subsets of \( \mathbb{N} \). Since the coding of finite sets is onto \( \mathbb{N} \), we can use integer variables for finite sets. We shall often neglect the distinction between finite sets and their codes in our notation, and thus write, e.g.,

\[ n \subseteq Y := e_n \subseteq Y, \quad n \in m := n \in e_m; \quad n \subseteq m := e_n \subseteq e_m. \]

We take \( \pi : \mathbb{N} \times \mathbb{N} \to \mathbb{N} \) to be a standard primitive recursive pairing function with projections \( \pi_0 \) and \( \pi_1 \); i.e., \( \pi_i(\pi(n_0, n_1)) = n_i \) for \( i = 0, 1 \); for \( \pi(n, m) \) we also use the abbreviation \((n, m)\).

Then, the application is defined as follows

\[ X \cdot Y \simeq \{n \in \mathbb{N} | \exists k \subseteq Y \ (k, n) \in X\}. \]

The whole construction of graph models can be found in [5, IV.7.5], for example, or can be done as described in Proposition 4.1 below. An important aspect of this model is the application defined \textit{totally}, i.e., for each \( X, Y \subseteq \mathbb{N} \), there is \( Z \) with \( X \cdot Y \simeq Z \). In such a model, we prefer to use \( = \) instead of \( \simeq \).

In CZF, we have no powerset \( \mathcal{P}(\omega) \) and so we cannot simulate the above construction. As it was mentioned in [5, IV.7.5], the set of semicomputable or recursively enumerable subsets of \( \mathbb{N} \) also forms a model of APP, which we can construct in CZF as follows: Using the canonical interpretation of the language of the first order arithmetic \( L_1 \) into the language of set theory \( L_s \), we can regard a formula in \( L_1 \) as a one in \( L_s \). Let \( T \) be the Kleene’s \( T \)-predicate. Then, for each \( n \), Bounded Separation yields the set \( \{x \in \omega : (\exists y \in \omega)Tnxy\} \) and Strong Collection yields the set \( \mathcal{R}\mathcal{E}(\omega) \) of recursively enumerable sets of natural numbers, i.e.,

\[ \mathcal{R}\mathcal{E}(\omega) = \{x \in \omega : (\exists y \in \omega)Tnxy : n \in \omega\}. \]

Furthermore, we have the graph

\[ \{(\langle X, Y \rangle, Z) \mid X, Y, Z \in \mathcal{R}\mathcal{E}(\omega) \land Z = \{x \in \omega \mid \exists y \in \omega (y \subseteq Y(y, x) \in X)\}\} \]

of application defined above is a set again by Bounded Separation. The next proposition ensures that \( \mathcal{R}\mathcal{E}(\omega) \) actually forms a model of APP in CZF.
**Proposition 4.1.** There is an interpretation \((\cdot)\dagger\) from formulae the language \(L_{\text{APP}}\) of \(\text{APP}\) into the ones in \(L_s\) such that \((\bot)\dagger \equiv \bot\) and that \(\text{APP} \vdash \varphi(\vec{x})\) implies \(\text{CZF} \vdash \forall \vec{x} \in \mathcal{RE}(\omega)(\varphi(\vec{x}))\dagger\) for each formula \(\varphi(\vec{x})\) with only displayed free variables.

**Proof.** Fix a bijection \(\dagger\) from the variables in \(L_{\text{APP}}\) into the ones in \(L_s\). We extend \(\dagger\) to an interpretation from the formulae in \(L_{\text{APP}}\) into the ones in \(L_s\). First, we set the interpretation of constants in \(\text{APP}\). Define \(k\dagger, s\dagger, p\dagger, p_0, p_1, d, s_N, p_N\) and \(0\) as follows:

\[
\begin{align*}
k\dagger &= \{(x, (y, z))|z \in x\}; & s\dagger &= \{(x, (y, (z, w)))|\exists a Q(a, x, y, w, z)\}; 
p\dagger &= \{(2^n, (y, 2n))|n \in \omega\} \cup \{(x, (2^m, 2m + 1))|m \in \omega\}; 
p_0\dagger &= \{(2^n, n)|n \in \omega\}; & p_1\dagger &= \{(2^{n+1}, n)|n \in \omega\}; 
d\dagger &= \{(y, (x, (2^m, (2^n, z))))|(m = n \land z \in x) \lor (m \neq n \land z \in y)\}; 
s_N\dagger &= \{(2^n, 2^{n+1})|n \in \omega\}; & p_N\dagger &= \{(2^{n+1}, 2^n)|n \in \omega\}; 
0\dagger &= \{\emptyset\},
\end{align*}
\]

where

\[
Q(a, x, y, w, z) \iff \exists z_1 \subseteq z (z_1, (a, w)) \in x \land \forall c \in a \exists z_2 \subseteq z(z_2, c) \in y. \quad (3)
\]

Then, for an application term \(ts\), define \((ts)\dagger \equiv \{x \in \omega : (\exists y \subseteq s\dagger(y, x) \in t\dagger\}\).

For atomic formulae in \(L_{\text{APP}}\), set \((\bot)\dagger \equiv \bot, (N(x))\dagger \equiv \exists n \in \omega(x\dagger = \{n\})\), \((\text{App}(a, b, c))\dagger \equiv (ab)\dagger = c\dagger\) and \((t = s)\dagger \equiv t\dagger = s\dagger\), respectively. For compound formulae in \(L_{\text{APP}}\), define \(\dagger\) inductively by

\[
(\varphi \circ \psi)\dagger \equiv (\varphi)\dagger \circ (\psi)\dagger \text{ for } o \in \{\land, \lor, \rightarrow\}; \quad (Qx \varphi(x))\dagger \equiv \exists x\dagger \in \mathcal{RE}(\omega)(\varphi(x))\dagger; \text{ for } Q \in \{\exists, \forall\}.
\]

Now it is enough to show that \(\text{CZF} \vdash \varphi\dagger\) for each universal closure \(\varphi\) of the axioms of \(\text{APP}\). Let \(X, Y\) and \(Z\) be subsets of \(\omega\). For \(k\), we have \(k\dagger X = \{(y, z)|z \in X\}\), so \(k\dagger XY = \{z|z \in X\} = X\); thus verifying the axioms for the combinator \(k\). For \(s\), we have

\[
\begin{align*}
s\dagger X &= \{(y, (z, w))|\exists x \subseteq X \exists a Q(a, x, y, w, z)\} 
\end{align*}
\]

\[
\begin{align*}
s\dagger XY &= \{(z, w)|\exists x \subseteq X \exists y \subseteq Y \exists a Q(a, x, y, w, z)\} 
\end{align*}
\]

\[
\begin{align*}
s\dagger XYZ &= \{w|\exists x \subseteq X \exists y \subseteq Y \exists z \subseteq Z \exists a Q(a, x, y, w, z)\} 
\end{align*}
\]

\[
\begin{align*}
XZ(YZ) &= \{w|\exists a \subseteq YZ (a, w) \in XZ\}.
\end{align*}
\]

From the last two set equations one easily computes that \(s\dagger XYZ = XZ(YZ)\), so that \(s\dagger\) satisfies the axiom for \(s\). For other constants, it is easy to show that each of them has the desired properties by noticing that \(2^n\) codes the set \(\{n\}\).

\[\square\]

## 5 The general realizability structure

Realizability semantics are ubiquitous in the study of intuitionistic theories. In the case of set theory, they differ in important aspects from Kleene’s [13] realizability in their treatment of
the quantifiers. Its origin is Kreisel’s and Troelstra’s [14] definition of realizability for second order Heyting arithmetic. The latter was applied to systems of higher order arithmetic and (intensional) set theory by Friedman [11] and Beeson [5]. McCarty [15] and [16] adapted Kreisel-Troelstra realizability directly to the extensional intutionistic set theories such as IZF. This type of realizability can also be formalized in CZF (see [20]) to yield a self-validating semantics for CZF. [21] introduced the general realizability structure with truth over an arbitrary (set) model $A$ of APP.

In [21], the general realizability structure over $\omega$ as a model of APP is defined. In this paper, we define it over arbitrary models $A$ of APP such that both $|A|$ and the graph $\{ (x, y, z) \in |A|^3 : \text{App}(x, y, z) \}$ are sets, such as $\text{RE}(\omega)$ defined in the previous section. If $z$ is an ordered pair, i.e., $z = (x, y)$ for some sets $x, y$, then we use $1^{st}(z)$ and $2^{nd}(z)$ to denote the first and second projection of $z$, respectively; that is, $1^{st}(z) = x$ and $2^{nd}(z) = y$.

**Definition 5.1.** Ordinals are transitive sets whose elements are transitive also. As per usual, we use lower case Greek letters $\alpha$ and $\beta$ to range over ordinals. Let $A$ be a model of APP such that $|A|$ is a set. Besides $V_\alpha$ and $V$, we define $V_{A,\alpha}$ and $V^*_A$ as follows:

$$V_{A,\alpha} = \bigcup_{\beta \in \alpha} \{ (x, y) : x \in V_\beta; y \subseteq |A| \times V^*_{A,\beta}; (\forall z \in y) 1^{st}(2^{nd}(z)) \in x \} \quad (4)$$

$$V_\alpha = \bigcup_{\beta \in \alpha} \mathcal{P}(V_\beta)$$

$$V^*_A = \bigcup_{\alpha} V^*_{A,\alpha}$$

$$V = \bigcup_{\alpha} V_\alpha.$$

As the power set operation is not available in CZF it is not clear whether the classes $V$ and $V^*_A$ can be formalized in CZF. However, employing the fact that CZF accommodates inductively defined classes this can be demonstrated in the same vein as in [20], Lemma 3.4.

The definition of $V^*_{A,\alpha}$ in [14] is perhaps a bit involved. Note first that all the elements of $V^*_{A,\alpha}$ are ordered pairs $(x, y)$ such that $y \subseteq |A| \times V^*_A$. For an ordered pair $(x, y)$ to enter $V^*_{A,\alpha}$ the first conditions to be met are that $x \in V_\beta$ and $y \subseteq |A| \times V^*_{A,\beta}$ for some $\beta \in \alpha$. Furthermore, it is required that $x$ contains enough elements from the transitive closure of $x$ in that whenever $(u, v) \in y$ then $1^{st}(u) \in x$.

**Lemma 5.2.** (CZF).

(i) $V$ and $V^*_A$ are cumulative: for $\beta \in \alpha$, $V_\beta \subseteq V_\alpha$ and $V^*_{A,\beta} \subseteq V^*_{A,\alpha}$.

(ii) For all sets $x$, $x \in V$.

(iii) If $x, y$ are sets, $y \subseteq |A| \times V^*_A$ and $(\forall z \in y) 1^{st}(2^{nd}(z)) \in x$, then $(x, y) \in V^*_A$.

**Proof.** This is proved in the same way as [21, Lemma 4.2].
6 Defining realizability

We now proceed to define a notion of realizability over \( V^*_A \). We use lower case gothic letters \( a, b, \ldots, t \), possibly with superscripts as variables to range over elements of \( V^*_A \) while variables \( a, b, \ldots, j \) will be reserved for elements of \( |A| \). Each element \( a \) of \( V^*_A \) is an ordered pair \( \langle x, y \rangle \), where \( x \in V \) and \( y \subseteq A \times V^*_A \); and we define the components of \( a \) by

\[
a^o := 1^{st}(a) = x \\
a^* := 2^{nd}(a) = y.
\]

**Lemma 6.1.** For every \( a \in V^*_A \), if \( (e, c) \in a^* \) then \( c^o \in a^o \).

**Proof.** This is immediate by the definition of \( V^*_A \).

If \( \varphi \) is a sentence with parameters in \( V^*_A \), then \( \varphi^o \) denotes the formula obtained from \( \varphi \) by replacing each parameter \( a \) in \( \varphi \) with \( a^o \).

**Definition 6.2.** We define \( e \models_{rt} \phi \) for elements \( e \in |A| \) and sentences \( \phi \) with parameters in \( V^*_A \). Bounded quantifiers will be treated as quantifiers in their own right, i.e., bounded and unbounded quantifiers are treated as syntactically different kinds of quantifiers. (The subscript \( rt \) is supposed to serve as a reminder of “realizability with truth”.)

\[
e \models_{rt} a \in b \quad \text{iff} \quad a^o \in b^o \land \exists c \left[ ((e)_0, c) \in b^* \land (e)_1 \models_{rt} a = c \right]
\]

\[
e \models_{rt} a = b \quad \text{iff} \quad a^o = b^o \land \forall f \forall c \left[ (f, c) \in a^* \rightarrow (e)_0 f \models_{rt} c \in b \right] \\
\quad \land \forall f \forall c \left[ (f, c) \in b^* \rightarrow (e)_1 f \models_{rt} c \in a \right]
\]

\[
e \models_{rt} \phi \land \psi \quad \text{iff} \quad (e)_0 \models_{rt} \phi \land (e)_1 \models_{rt} \psi
\]

\[
e \models_{rt} \phi \lor \psi \quad \text{iff} \quad \left[ (e)_0 = 0 \land (e)_1 \models_{rt} \phi \right] \lor \left[ (e)_0 = 1 \land (e)_1 \models_{rt} \psi \right]
\]

\[
e \models_{rt} \neg \phi \quad \text{iff} \quad \neg \phi^o \land \forall f \forall \neg f \models_{rt} \phi
\]

\[
e \models_{rt} \phi \rightarrow \psi \quad \text{iff} \quad \phi^o \rightarrow \psi^o \land \forall f \left[ f \models_{rt} \phi \rightarrow e f \models_{rt} \psi \right]
\]

\[
e \models_{rt} (\forall x \in a) \phi \quad \text{iff} \quad (\forall x \in a^o) \phi^o \land \forall f \forall b \left( (f, b) \in a^* \rightarrow e f \models_{rt} \phi[x/b] \right)
\]

\[
e \models_{rt} (\exists x \in a) \phi \quad \text{iff} \quad \exists b \left( ((e)_0, b) \in a^* \land (e)_1 \models_{rt} \phi[x/b] \right)
\]

\[
e \models_{rt} \forall x \phi \quad \text{iff} \quad \forall a e \models_{rt} \phi[x/a]
\]

\[
e \models_{rt} \exists x \phi \quad \text{iff} \quad \exists a e \models_{rt} \phi[x/a]
\]

**Lemma 6.3.** If \( e \models_{rt} \phi \) then \( \phi^o \).

**Proof.** See Lemma 5.7 in [21].

**Lemma 6.4.** Negated formulas are self-realizing, that is to say, if \( \psi \) is a statement with parameters in \( V^*_A \), then

\[
\neg \psi^o \rightarrow 0 \models_{rt} \neg \psi.
\]
Proof. Assume \( \neg \psi \). From \( f \vdash_{rt} \psi \) we would get \( \psi \) by Lemma 6.3. But this is absurd. Hence \( \forall f \neg f \vdash_{rt} \psi \), and therefore \( 0 \vdash_{rt} \neg \psi \).

**Lemma 6.5.** There are closed application terms \( i_r, i_s, i_t, i_0, i_1 \) such that for all \( a, b, c \in V^* \),

1. \( i_r \vdash_{rt} a = a \).
2. \( i_s \vdash_{rt} a = b \rightarrow b = a \).
3. \( i_t \vdash_{rt} (a = b \land b = c) \rightarrow a = c \).
4. \( i_0 \vdash_{rt} (a = b \land b \in c) \rightarrow a \in c \).
5. \( i_1 \vdash_{rt} (a = b \land c \in a) \rightarrow c \in b \).
6. Moreover, for each formula \( \varphi(v, u_1, \ldots, u_k) \) of CZF all of whose free variables are among \( v, u_1, \ldots, u_k \) there exists a closed application term \( i_\varphi \) such that for all \( a, b, c_1, \ldots, c_k \in V^*_A \),

\[
i_\varphi \vdash_{rt} \varphi(a, \bar{c}) \land a = b \rightarrow \varphi(b, \bar{c}),
\]

where \( \bar{c} = c_1, \ldots, c_k \).

Proof. See [21, Lemma 5.12]. □

**Definition 6.6.** The extended bounded formulas are the smallest class of formulas containing the formulas of the form \( x \in y, x = y, e \vdash_{rt} x \in y, e \vdash_{rt} x = y \) (where \( x, y \) are variables or elements of \( V^*_A \)) which is closed under \( \land, \lor, \neg, \rightarrow \) and bounded quantification.

**Lemma 6.7.** (CZF) Separation holds for extended bounded formulas, i.e., for every extended bounded formula \( \varphi(v) \) and set \( x, \{ v \in x : \varphi(v) \} \) is a set.

Proof. See [21, Lemma 5.15]. □

**Proposition 6.8** (Soundness theorem). Let \( S \) any combination of the axioms and schemes Full Separation, Powerset, REA, MP, AC_\omega, DC, RDC, and PAx. Then, for every theorem \( \theta \) of CZF + \( S \), there exists an application term \( t \) such that \( \text{CZF} + S, t \vdash_{rt} \theta \).

In particular, CZF, CZF + REA, IZF, IZF + REA satisfy this property. Moreover, the proof of this soundness theorem is effective in that the application term \( t \) can be constructed from the CZF + \( S \) proof of \( \theta \).

Proof. This is proved in the same way as [21, Theorem 6.1, Theorem 7.2 and Theorem 9.1] and [22, Theorem 7.4]. □
7 Realizing IPR for finite types

In this section, we prove CZF and several constructive set theories are closed under IPR for finite types. We fix an applicative structure $\mathcal{A}$ such that $|\mathcal{A}|$ and its graph $\{(a, b, c) \in |\mathcal{A}|^3 : ab = c\}$ of its application are sets, as $\mathcal{R}(\omega)$ in Section 4. In what follows, we use $a, b, \ldots, i$ for elements of $\mathcal{A}$. By SIA, $N = \{x \in |\mathcal{A}| : N(x)\}$ is a set.

We need several properties of ordered pairs in $V^*_\mathcal{A}$. For any $a$ and $b$, define $\{a, b\}$ by

$$\{a^0, b^0\}, \{p0g, a\} : g \models_{rt} a = a \cup \{p1g, b\} : g \models_{rt} b = b\}.$$ 

By Lemma 6.7, we can prove that $2^{nd}(\{a, b\})$ is a set such that for each $x \in 2^{nd}(\{a, b\}$, $1^{st}(2^{nd}(x)) \in \{a^0, b^0\}$. By Lemma 6.2 (iii), we have $\{a, b\} \in V^*_\mathcal{A}$. The following lemma shows that $\{a, b\}$ acts as the pair of $a$ and $b$ in $V^*_\mathcal{A}$.

**Lemma 7.1 (CZF).** There is a closed term $t$ such that $t \models_{rt} \forall x(x \in \{a, b\} \leftrightarrow x = a \lor x = b)$.

**Proof.** See (Pair) and (Bounded Separation) in the proof of [21, Theorem 6.1].

We often write $\{a\}$ for $\{a, a\}$. For ordered pair, we write $\langle a, b\rangle$ for $\{\{a\}, \{a, b\}\}$.

**Lemma 7.2 (CZF).** There are closed terms $t_{op}$ and $t_{op'}$ such that

$$\forall \theta, \theta', c, c'(t_{op} \models_{rt} \theta = \theta' \land c = c' \rightarrow \langle \theta, c\rangle = \langle \theta', c'\rangle),$$

$$\forall \theta, \theta', c, c'(t_{op'} \models_{rt} \langle \theta, c\rangle = \langle \theta', c'\rangle \rightarrow \theta = \theta' \land c = c').$$

**Proof.** This is implied by Proposition 6.8.

Let $\Psi(a)$ be as follows:

$$\forall a \forall c \forall \theta(\langle a, \theta\rangle \in a^* \land \langle a, c\rangle \in a^* \rightarrow \theta = c) \land$$

$$\exists b \forall \langle h, h\rangle, \langle h', h'\rangle \in a^*(\exists c(c \models_{rt} h = h') \rightarrow bh \models_{rt} h = h').$$

An intuitive idea for $\Psi(a)$ is that each element of $a^*$ is injectively indexed by some element of $|\mathcal{A}|$ and $a$ has a canonical realizer for the equality between its elements.

**Lemma 7.3 (CZF).** For each $a$ and $b$, there is $c$ such that

$$\forall a \forall b(\Psi(a) \land \Psi(b) \rightarrow \exists c(\Psi(c) \land \exists a(a \models_{rt} \forall x(x \in c \leftrightarrow x \in \text{Func}(a, b)))).$$

**Proof.** Assume $\Psi(a) \land \Psi(b)$. Take $i_a$ and $i_b$ such that

$$\forall \langle h, h\rangle, \langle h', h'\rangle \in a^*(\exists a(a \models_{rt} h = h') \rightarrow i_a h \models_{rt} h = h'),$$

$$\forall \langle h, h\rangle, \langle h', h'\rangle \in b^*(\exists a(a \models_{rt} h = h') \rightarrow i_b h \models_{rt} h = h').$$

13
For each \( f \in |A| \), define \( \hat{f} \) and \( f \in (a \Rightarrow b) \) as follows:

\[
\hat{f} = \{ \langle d, (\bar{d}, c) \rangle : (d, \bar{d}) \in a^* \land \exists e(f \bar{d} = e \land \langle e, c \rangle \in b^*) \},
\]

\[
f \in (a \Rightarrow b) \equiv \forall \bar{d}, d' \forall \bar{d}' \langle \langle d, \bar{d} \rangle \in a^* \land \langle d', \bar{d}' \rangle \in a^* \land i_d d' \parallel_{rt} \bar{d} = \bar{d}' \rightarrow \\
\exists e, e' \exists \bar{e}, \langle f \bar{d} = e \land f d' = e' \land \langle e, c \rangle \in b^* \land \langle e', c' \rangle \in b^* \land i_{d'} e' \parallel_{rt} c = c' \},
\]

\[
f^{\text{real}} = \{ \langle \bar{d}, c \rangle : \exists d(\langle d, (\bar{d}, c) \rangle \in \hat{f}) \}.
\]

Then \( \hat{f} \) is a set by Bounded Separation and \( f \in (a \Rightarrow b) \) is equivalent to an extended bounded formula. Define \( c \) by

\[
c = \langle (b^o)^a, \{ \langle f, (f^{\text{real}}, \hat{f}) \rangle : f \in (a \Rightarrow b) \} \rangle.
\]

Then 2\(^{nd}\)(c) is a set by Strong Collection. For each \( x \in 2^{nd}(c) \), it has the form 1\(^{st}\)(2\(^{nd}\)(x)) = \( f^{\text{real}} \) for some \( f \) such that \( f \in (a \Rightarrow b) \). Since \( b \) satisfies \( \forall a \forall \bar{c} \forall e' \langle \langle a, c \rangle \in b^* \land \langle a, c' \rangle \in b^* \rightarrow c = c' \rangle \), we have 1\(^{st}\)(2\(^{nd}\)(x)) in \( (b^o)^a \). Hence \( c \in V_x \). Then, it is easy to see that

\[
\forall x(\langle c, x \rangle \in \text{c} \leftrightarrow x \in \text{Func}(a^o, b^o)) \quad \text{and} \quad \forall a \forall \bar{d} \forall \bar{d}' \langle \langle a, \bar{d} \rangle \in c^* \land \langle a, \bar{d}' \rangle \in c^* \rightarrow \bar{d} = \bar{d}' \rangle.
\]

Define \( i_c \) as follows:

\[
i_c = \lambda f.g.p(\lambda h. ph(t_{op}(p(i_{a^o}hh)(i_b(fh)(gh))))))(\lambda h. ph(t_{op}(p(i_{a^o}hh)(i_b(gh)(fh))))).
\]

We show that \( \forall f, g \forall f, g(\langle f, f \rangle \in c^* \land (g, g) \in c^* \land \exists b(b \parallel_{rt} f = g) \rightarrow i_c fg \parallel_{rt} f = g \). Assume \( \langle f, f \rangle \in c^* \land \langle g, g \rangle \in c^* \) and \( b \parallel_{rt} f = g \). Then

\[
f^o = g^o \land \forall \langle h, (\bar{h}, i) \rangle \in f^* \exists \langle b', i' \rangle \langle \langle (b)_{0}h \rangle_0, \langle b', i' \rangle \rangle \in g^* \land \langle (b)_{0}h \rangle_1 \parallel_{rt} \langle h, i \rangle = \langle b', i' \rangle.
\]

Fix \( \langle h, (\bar{h}, i) \rangle \in f^* \) and take \( \langle b', i' \rangle \in g^* \) such that \( \langle \langle (b)_{0}h \rangle_0, \langle b', i' \rangle \rangle \in g^* \land \langle (b)_{0}h \rangle_1 \parallel_{rt} \langle h, i \rangle = \langle b', i' \rangle \). Then there are application terms \( p \) and \( q \) such that \( p \parallel_{rt} h = b' \) and \( q \parallel_{rt} i = i' \). Since \( h, (\bar{h}, i) \rangle \in f^* \) implies \( (b, \bar{b}) \in a^* \) and \( \langle f, h, i \rangle \in b^* \) and since \( \langle \langle (b)_{0}h \rangle_0, \langle b', i' \rangle \rangle \in g^* \) implies \( \langle \langle (b)_{0}h \rangle_0, \langle b', i' \rangle \rangle \in b^* \) and \( \langle g, (b)_{0}h \rangle_0, \langle i' \rangle \rangle \in b^* \), we have \( i_{a}h((b)_{0}h)_{0} \parallel_{rt} b = b' \) and \( i_{b}(fh)(gh((b)_{0}h)_{0}) \parallel_{rt} i = i' \). By \( g \in (a \Rightarrow b) \) and \( \langle h, b \rangle \in a^* \), there is \( i'' \) such that \( \langle gh, i'' \rangle \in b^* \) and \( i_{b}(fh)(gh((b)_{0}h)_{0}) \parallel_{rt} i'' = i' \). Then we can construct \( r \) such that \( r \parallel_{rt} i = i'' \) by using \( i_3 \) and \( i_4 \) and so \( \langle \hat{f}, gh \rangle \parallel_{rt} i = i'' \). Then we have

\[
\exists i'' \langle \langle h, (\bar{h}, i'' \rangle \rangle \in g^* \land t_{op}(p(i_{a^o}hh)(i_b(fh)(gh)))) \parallel_{rt} \langle h, i \rangle = \langle b, i'' \rangle.
\]

In a similar way, we can show that, for each \( \langle h, (\bar{h}, i) \rangle \in g^* \),

\[
\exists i'' \langle \langle h, (\bar{h}, i'' \rangle \rangle \in f^* \land t_{op}(p(i_{a^o}hh)(i_b(fh)(gh)))) \parallel_{rt} \langle h, i \rangle = \langle b, i'' \rangle.
\]

Therefore, \( i_c \) defined as above gives \( i_c fg \parallel_{rt} f = g \).

To show \( \exists a(a \parallel_{rt} \forall x(\langle c, x \rangle \in \text{c} \leftrightarrow x \in \text{Func}(a^o, b^o))) \), we have to construct \( s \) and \( t \) such that, for any \( f \)

\[
s \parallel_{rt} f \in c \rightarrow \forall y \in a \exists z \in b(\langle y, z \rangle \in f \land \forall w \in f \exists y \in a \exists z \in b(\langle y, z \rangle \rangle) \), and
\]

\[
t \parallel_{rt} \forall y \in a \exists z \in b(\langle y, z \rangle \in f \land \forall w \in f \exists y \in a \exists z \in b(\langle y, z \rangle \rangle) \rightarrow f \in c.
\]
First we construct $s$ with the above property. Assume that $a \models_{rt} f \in c$. Then,

$$a \models_{rt} f \in c$$

$$\leftrightarrow \exists \mathbf{f}^* \in \text{Func}(a, b) \land \exists \mathbf{g}((\langle a \rangle_0, \mathbf{g}) \in \mathbf{c}^* \land (a)_1 \models_{rt} f = \mathbf{g})$$

$$\leftrightarrow \exists \mathbf{f}^* \in \text{Func}(a, b) \land \exists \mathbf{g}((\langle a \rangle_0, \mathbf{g}) \in \mathbf{c}^* \land \mathbf{f}^* = \mathbf{g}^*$$

$$\land \forall h \forall \mathbf{h}(\langle h, \mathbf{h} \rangle \in \mathbf{f}^* \rightarrow (a)_1 \models_{rt} h \in \mathbf{f})$$

$$\land \forall h \forall \mathbf{h}(\langle h, \mathbf{h} \rangle \in \mathbf{g}^* \rightarrow (a)_1 \models_{rt} h \in \mathbf{g}))$$

$$\leftrightarrow \exists \mathbf{f}^* \in \text{Func}(a, b) \land \exists \mathbf{g}((\langle a \rangle_0, \mathbf{g}) \in \mathbf{c}^* \land \mathbf{f}^* = \mathbf{g}^*$$

$$\land \forall h \forall \mathbf{h}(\langle h, \mathbf{h} \rangle \in \mathbf{f}^* \rightarrow h \in \mathbf{g}^* \land \exists \mathbf{i}(\langle \langle \langle \langle \langle a \rangle_11 \rangle_0 \rangle_0 \rangle_1 \rangle_0, \mathbf{i}) \in \mathbf{f}^* \land (\langle \langle \langle \langle a \rangle_11 \rangle_0 \rangle_0 \rangle_1 \rangle_0 \models_{rt} h = \mathbf{i}))$$

(5)

$$\land \forall h \forall \mathbf{h}(\langle h, \mathbf{h} \rangle \in \mathbf{f}^* \rightarrow h \in \mathbf{f}^* \land \exists \mathbf{i}(\langle \langle \langle \langle a \rangle_11 \rangle_0 \rangle_0 \rangle_1 \rangle_0, \mathbf{i}) \in \mathbf{f}^* \land (\langle \langle \langle \langle a \rangle_11 \rangle_0 \rangle_0 \rangle_1 \rangle_0 \models_{rt} h = \mathbf{i}))$$

(6)

and so take $\mathbf{g}$ such that

$$\langle \langle a \rangle_0, \mathbf{g} \rangle \in \mathbf{c}^* \land (a)_1 \models_{rt} f = \mathbf{g}. \quad (7)$$

Since $\forall a \forall \mathbf{d}((\langle d \rangle, \mathbf{d}) \in \mathbf{a}^* \rightarrow \exists \mathbf{e}(\mathbf{ad} = e \land \langle e, \mathbf{e} \rangle \in \mathbf{b}^* \land (\langle d, \langle \mathbf{d}, \mathbf{c} \rangle \rangle \in \mathbf{g}^*))$, we have, by (3),

$$\forall a \forall \mathbf{d}((\langle d \rangle, \mathbf{d}) \in \mathbf{a}^* \rightarrow \exists \mathbf{e}(\mathbf{ad} = e \land \langle e, \mathbf{e} \rangle \in \mathbf{b}^* \land \exists \mathbf{i}(\langle \langle \langle \langle a \rangle_11 \rangle_0 \rangle_0 \rangle_1 \rangle_0, \mathbf{i}) \in \mathbf{f}^* \land (\langle \langle \langle \langle a \rangle_11 \rangle_0 \rangle_0 \rangle_1 \rangle_0 \models_{rt} \langle \langle \langle \langle a \rangle_11 \rangle_0 \rangle_0 \rangle_1 \rangle_0 = \mathbf{i})))$$

Therefore $s' \equiv \lambda d.(a)_1 d$ satisfies, for a such that $a \models_{rt} f \in c$,

$$s'a \models_{rt} \forall y \in \mathbf{a} \exists z \in \mathbf{b}(\langle y, z \rangle \in \mathbf{f}).$$

Assume that $\langle d \rangle, \mathbf{d} \rangle \in \mathbf{a}^*$, $\langle e, \mathbf{e} \rangle, \langle e', \mathbf{e}' \rangle \in \mathbf{b}^*$ and $b \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 \rangle_0 \in \mathbf{f} \land \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 \rangle_0 \in \mathbf{f}$ and take $h$ and $i$ such that

$$\langle \langle (b)_00, h \rangle \in \mathbf{f}^* \land (b)_00 \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 \rangle_0 = h, \quad \langle \langle (b)_10, i \rangle \in \mathbf{f}^* \land (b)_10 \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 \rangle_0 = i.$$

Then, by (5) and (7), we have $j$, $j'$, $\mathbf{f}$ and $\mathbf{f}'$ such that

$$\mathbf{h}^* \in \mathbf{g}^* \land \langle \langle (a)_10 (b)_00 \rangle_0, \langle j, \mathbf{f} \rangle \rangle \in \mathbf{g}^* \land (\langle (a)_10 (b)_00 \rangle_1 \models_{rt} h = \langle j, \mathbf{f} \rangle),$$

$$\mathbf{i}^* \in \mathbf{g}^* \land \langle \langle (a)_10 (b)_10 \rangle_0, \langle j', \mathbf{f}' \rangle \rangle \in \mathbf{g}^* \land (\langle (a)_10 (b)_10 \rangle_1 \models_{rt} i = \langle j', \mathbf{f}' \rangle).$$

Define $p_0, p_1, p_2, p_3, p_4, p_5, p_6, p_7$ and $p_8$ be as follows:

$$p_0 \equiv \lambda ab.(a)_10 \langle b \rangle_000,$$

$$p_1 \equiv \lambda ab.(a)_10 \langle b \rangle_00,$$

$$p_2 \equiv \lambda ab.i_\mathbf{t}(p(b)_01 (p_0ab)_1),$$

$$p_3 \equiv \lambda ab.i_\mathbf{t}(p(b)_11 (p_1ab)_1),$$

$$p_4 \equiv \lambda ab.i_\mathbf{t}(p(i_\mathbf{s}(p_0 \langle \mathbf{t}_{op'}(p_2ab) \rangle))(p_0 \langle \mathbf{t}_{op'}(p_3ab) \rangle)))$$

$$p_5 \equiv \lambda ab.i_\mathbf{t}(g(p_0ab)_0 \langle g(p_1ab)_0 \rangle)$$

$$p_6 \equiv \lambda ab.p_1 \langle \mathbf{t}_{op'}(p_2ab) \rangle$$

$$p_7 \equiv \lambda ab.p_1 \langle \mathbf{t}_{op'}(p_3ab) \rangle$$

$$p_8 \equiv \lambda ab.i_\mathbf{t}(p_7ab \langle i_\mathbf{s}(p_6ab)_0(p_5ab) \rangle).$$

Then we have

$$p_2ab \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j, \mathbf{f} \rangle, \quad \langle \langle (b)_00 \rangle_0 \rangle_0 \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j', \mathbf{f}' \rangle,$$

$$\mathbf{p}_0 \langle \mathbf{t}_{op'}(p_2ab) \rangle \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j, \mathbf{f} \rangle, \quad \mathbf{p}_0 \langle \mathbf{t}_{op'}(p_2ab) \rangle \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j', \mathbf{f}' \rangle.$$

$$p_4ab \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j, \mathbf{f} \rangle, \quad i_\mathbf{s}(p_0 \langle \mathbf{t}_{op'}(p_2ab) \rangle) \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j', \mathbf{f}' \rangle,$$

$$p_6ab \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j, \mathbf{f} \rangle, \quad p_7ab \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j', \mathbf{f}' \rangle.$$

$$p_8ab \models_{rt} \langle \langle \langle \langle a \rangle_1 \rangle_0 \rangle_0 \rangle_1 = \langle j, \mathbf{f} \rangle.$$
Therefore \(s'' \equiv \lambda a.b.i_a.(p patriab))(ia(p\tau ab))\) satisfies \(s'' ab \models_{rt} c = c'\), when \(a \models_{rt} f \in c\) and \(b \models_{rt} \langle \dot{d}, c \rangle \in f \land \langle \dot{d}, c' \rangle \in f\).

Again by (\(\S\)), we have

\[
\forall h \forall h' \langle h, h' \rangle \in f \rightarrow b^* \in g^* \land \exists i \langle ((a)_{10}h)_{0}, i \rangle \in g^* \land ((a)_{10}h)_{1} \models_{rt} h = i),
\]

which implies

\[
\forall h \forall h' \langle h, h' \rangle \in f \rightarrow b^* \in g^* \land \exists d \exists e \langle ((a)_{10}h)_{0}, e \rangle \in a^* \land \langle g((a)_{10}h)_{0}, e \rangle \in b^* \land\]

\[
\langle ((a)_{10}h)_{0}, \langle \dot{d}, e \rangle \rangle \in g^* \land ((a)_{10}h)_{11} \models_{rt} h = \langle \dot{d}, e \rangle).
\]

Hence \(s'''' \equiv \lambda a.b.p(((a)_{10}h)_{0})(p(g((a)_{10}h)_{0})(a)_{10}h)_{11})\) satisfies \(s'''' a \models_{rt} \forall w \in f \exists y \in a \exists z \in b(w = \langle y, z \rangle)\), when \(a \models_{rt} f \in c\).

Therefore \(s \equiv \lambda a.b.p(s'a)(\lambda b.s'' ab)(s'''' a)\) satisfies

\[
s \models_{rt} f \in c \rightarrow \forall y \in a \exists z \in b(\langle y, z \rangle \in f) \land \forall w \in f \exists y \in a \exists z \in b(w = \langle y, z \rangle).
\]

To construct \(t\) such that

\[
t \models_{rt} \forall y \in a \exists z \in b(\langle y, z \rangle \in f) \land \forall w \in f \exists y \in a \exists z \in b(w = \langle y, z \rangle) \rightarrow f \in c,
\]

assume that \(a \models_{rt} \forall y \in a \exists z \in b(\langle y, z \rangle \in f) \land \forall w \in f \exists y \in a \exists z \in b(w = \langle y, z \rangle)\). Then, we have

\[
(a)_{00} \models_{rt} \forall y \in a \exists z \in b(\langle y, z \rangle \in f), \tag{8}
\]

\[
(a)_{01} \models_{rt} \forall y \in a, \forall z, w \in b(\langle y, z \rangle \in f) \land \langle y, w \rangle \in f \rightarrow y = w, \tag{9}
\]

\[
(a)_{1} \models_{rt} \forall w \in f \exists y \in a \exists z \in b(w = \langle y, z \rangle). \tag{10}
\]

(\(\S\)) implies

\[
\forall d \forall \dot{d}'(\langle d, \dot{d}' \rangle \in a^* \rightarrow \exists e \langle ((a)_{00}d)_{0}, e \rangle \in b^* \land ((a)_{00}d)_{1} \models_{rt} \langle \dot{d}', e \rangle \in f). \tag{\(\S\)}
\]

Set \(g \equiv \lambda d.((a)_{00}d)_{0}\). If \(\langle d, \dot{d} \rangle \in a^*, \langle d', a^* \rangle \in a^*\) and \(a \models_{rt} \langle d, \dot{d} \rangle \equiv \dot{d}'\), then there are \(c\) and \(c'\) such that

\[
\langle gd, c \rangle \in b^* \land ((a)_{00}d)_{1} \models_{rt} \langle \dot{d}, c \rangle \in f\quad \text{and} \quad \langle gd', c' \rangle \in b^* \land ((a)_{00}d)_{1} \models_{rt} \langle \dot{d}', c' \rangle \in f.
\]

By (\(\S\)) and \(\models_{rt} \langle d, \dot{d} \rangle = \dot{d}'\), we have \(b\) such that \(b \models_{rt} c = c'\) and so \(i_b(gd)(gd') \models_{rt} c = c'\).

Hence \(g \in (a \models \dot{b})\).

First we show \(\langle g, \langle \dot{p}, \dot{g} \rangle \rangle \in c^*\). It is enough to show \(g^* = \{\langle \dot{d}, e \rangle : \exists d \langle \langle d, \dot{d}, e \rangle \in \dot{g} \} = f^*\). Take any \(x \in \dot{g}\). Then \(x = \langle d, \langle \dot{d}, e \rangle \rangle\) for some \(\langle d, \dot{d} \rangle \in a^*\) and \(\langle e, c \rangle \in b^*\) such that \(e = gd = ((a)_{00}d)_{0}\). By (\(\S\)), we have \(c'\) such that \(\langle e, c' \rangle \in b^* \land ((a)_{00}d)_{1} \models_{rt} \langle \dot{d}', c' \rangle \in f\). Since \(\psi(b)\) yields \(\langle e, c \rangle \in b^* \land \langle e, c' \rangle \in b^* \rightarrow c = c'\), we have \(c = c'\) and so \(1^{st}(2^{nd}(x)) = \langle \dot{d}, e \rangle\),
which is in \( f^* \). Conversely, for each \( w \in f^* \), there are \( d, \bar{d} \) and \( c \) such that \( \langle d, \bar{d} \rangle \in a^* \), 
\( \langle gd, c \rangle \in b^* \) and \( w = \langle \bar{d}, c' \rangle \) by \((\mathcal{S})\) and \((\mathcal{I})\) and so \( \langle d, \bar{d}, c \rangle \in \hat{g} \).

Set \( g = \langle f^*, \hat{g} \rangle \). We show that there is an application term \( t' \) such that \( t' \vdash_{rt} f = g \).
Assume \( \langle h, h \rangle \in f^* \). By \((\mathcal{I})\), there are \( d \) and \( c \) such that \( \langle ((a)_1 h)_0, \bar{d} \rangle \in a^* \), \( \langle ((a)_1 h)_{10}, c \rangle \in b^* \)
and \( \langle (a)_1 h_{11} \rangle \vdash_{rt} h = \langle \bar{d}, c \rangle \), which implies \( ph(i_s((a)_1 h)_{11}) \vdash_{rt} \langle \bar{d}, c \rangle \in f \). By \((\mathcal{O})\), there is \( e' \) such that \( \langle g((a)_1 h)_0, c' \rangle \in b^* \) and \( \langle (a)_{00}((a)_1 h)_0 \rangle \vdash_{rt} \langle \bar{d}, c' \rangle \in f \). Therefore we have \( q_0 \equiv \lambda a g h. (((a)_1 h)_0((a)_1 h)_{10}((g((a)_1 h)_0))(p(ph(i_s((a)_1 h)_{11}))))((a)_{00}((a)_1 h)_0)_1) \),
which implies
\[
q_1 \equiv \lambda a g h. t_{op}(p_i r(q_0 \equiv \lambda a g h. (((a)_1 h)_0((a)_1 h)_{10}((g((a)_1 h)_0))(p(ph(i_s((a)_1 h)_{11}))))((a)_{00}((a)_1 h)_0)_1), \quad q_2 \equiv \lambda a g h. t_{op}(p((a)_1 h)_{11}(t_{op}(p_i r(q_0 a g h))))).
\]
By the construction of \( \hat{g} \), \( \langle ((a)_1 h)_0, \langle \bar{d}, c \rangle \rangle \in g^* \), and so we have
\[
\forall h \forall h'(\langle h, h \rangle \in f^* \rightarrow p((a)_1 h)_0(q_2 a g h) \vdash_{rt} h \in g).
\]
Hence we have \( \forall h \forall h'(\langle h, h \rangle \in f^* \rightarrow \exists i((((a)_1 h)_0, i) \in g \land ((a)_1 h_1 \vdash_{rt} h = i)) \). Next, assume that \( \langle h, h \rangle \in g^* \). Since \( g^* = \{ \langle d, \bar{d}, c \rangle : \langle d, \bar{d} \rangle \in a^* \land \exists e(gd = e \land \langle e, c \rangle \in b^* \} \), we have \( h = \langle \bar{d}, c \rangle \) for some \( \langle h, d \rangle \in a^* \) and \( \langle e, c \rangle \in b^* \) such that \( gh = e \). Recall that \( g = \lambda d.((a)_{00}d)_0 \) and \((\mathcal{O})\). Take \( e' \) such that \( \langle ((a)_{00}h)_0, c' \rangle \in b^* \land ((a)_{00}h)_1 \vdash_{rt} \langle d, c' \rangle \in f \). Again by \( \Psi(b) \), we have \( c = c' \). Then \( \exists i((((a)_{00}h)_0, i) \in f^* \land ((a)_{00}h)_{11} \vdash_{rt} \langle \bar{d}, c \rangle = i) \). Hence \( \forall h \forall h'(\langle h, h \rangle \in g^* \rightarrow \exists i((((a)_{00}h)_{10}, i) \in f^* \land ((a)_{00}h)_{11} \vdash_{rt} h = i) \)). Therefore \( p(\lambda d.((a)_{00}d)_0)(\lambda d.((a)_{00}d)_1) \vdash_{rt} f \equiv g \).

Set \( t \equiv \lambda a. p(\lambda d.((a)_{00}d)_0)(\lambda d.((a)_{00}d)_1) \).
Then
\[
t \vdash_{rt} \forall y \in a \exists z \in b(\langle y, z \rangle) \in f \land \forall w \in f \exists y \in a \exists z \in b(\langle w, (y, z) \rangle) \rightarrow f \in c.
\]
\[
\square
\]

**Lemma 7.4.** For any \( a, b \) in \( \mathbb{V}_A \) and \( a \in A \), \( \langle a, a \rangle \in b^* \) implies \( \mathcal{P}_A \vdash_{rt} a \in b \).

**Proof.** It follows from the definition of \( e \vdash_{rt} a \in b \).
\[
\square
\]

For each \( n \in \omega \), define \( n_A \) by
\[
0_A \equiv 0 \quad (n + 1)_A \equiv s_n n_A,
\]
and let
\[
\underline{n} = \langle n, \{ m_A, m \} : m < n \rangle \quad \omega = \langle \omega, \{ n_A, \underline{n} : n \in \omega \} \rangle.
\]

**Lemma 7.5 (CZF).** There is a such that
\[
a \vdash_{rt} \forall y[y \in \omega \leftrightarrow \forall z(z \in y \leftrightarrow \perp) \land (\exists w \in \omega) \forall v(v \in y \leftrightarrow v \in w \lor v = w)] \land \forall w \in \omega \forall v(v \in y \leftrightarrow v \in w \lor v = w).
\]
\[
17
\]
Proof. See [21] Theorem 6.1 (Infinity)].

Recall that each finite type is coded by a natural number and we do not distinguish a type \( \sigma \) and its code. By \( \sigma \), we mean \( n \) for the code \( n \) of a type \( \sigma \).

Lemma 7.6 (CZF). For each finite type \( \sigma \), there is \( \sigma \) such that \( \Psi(\sigma) \) and \( \exists a(a \vdash rt \phi(\sigma, \sigma)) \).

Proof. This is proved by induction on the type structure. For \( \sigma = 0 \), we can prove \( \Psi(\omega) \) as follows. It is clear that \( \omega^0 = \omega \). For each \( a, c \) and \( d \), if \( (a, c) \in (\omega)^* \land (a, d) \in (\omega)^* \), then there is \( n \in \omega \) such that \( a = n_A \) and so \( c = d = n \) by the construction of \( \omega \), which implies \( c = d \). Assume that \( b \vdash rt \mu = m \) for some \( n, m \in \omega \) and \( b \in |A| \). Then \( (n)^o = (m)^o \) and so \( \mu = m \). Therefore \( c = p(\lambda x. x)(\lambda x. x) \) satisfies \( c \vdash rt \mu = m \). By Lemma 2.5 and Lemma 7.5 we have \( a \) such that \( a \vdash rt \phi(0, \omega) \).

Next we prove the induction step. Assume that \( \sigma \equiv \rho^\tau \). By the induction hypothesis, we have \( \tau, \rho, \tau, p \), and \( q \) such that

\[
\begin{align*}
\Psi(\tau, \tau) & \quad p \vdash rt \phi(\tau, \tau); \\
\Psi(\rho, \rho) & \quad q \vdash rt \phi(\rho, \rho).
\end{align*}
\]

By Lemma 7.3 we can take \( \rho^\tau \) satisfying \( \Psi(\tau, \tau) \). Set \( \sigma = \rho^\tau \). Then there is \( r \) such that

\[
\begin{align*}
\tau \vdash rt \forall w (w \in \sigma & \leftrightarrow w \in Func(\tau, \sigma)); \\
& \text{Since CZF proves that } \forall x \forall y (\phi(\tau, x) \land \phi(\tau, y) \rightarrow x = y) \land \forall x \forall y (\phi(\sigma, x) \land \phi(\sigma, y) \rightarrow x = y) \text{ by Lemma 2.5 and that } \forall x \forall y (\forall x' \forall y' (x = x' \land y = y' \rightarrow \forall w (w \in Func(x, y) \leftrightarrow w \in Func(x', y')))), \end{align*}
\]

we can construct a realizer for \( \phi(\sigma, \sigma) \).

Lemma 7.7. Let \( \phi(x) \) be a formula whose unique free variable is \( x \). Then, for any finite type \( \sigma \), \( \text{CZF} \vdash \phi(\sigma) \) implies \( \text{CZF} \vdash \exists a (a \vdash rt \phi(\sigma)) \).

Proof. Assume \( \phi(x) \) is a formula whose unique free variable is \( x \). If \( \text{CZF} \vdash \phi(\sigma) \), then we have \( \text{CZF} \vdash \forall x(\phi(\sigma, x) \rightarrow \phi(x)) \). By Proposition 6.8 and Lemma 7.6 we have \( t \) and \( s \) such that \( t \vdash rt \forall x (\phi(\sigma, x) \rightarrow \phi(x)) \) and \( s \vdash rt \phi(\sigma, \sigma) \). Hence we have \( ts \vdash rt \phi(\sigma) \).

Lemma 7.8. For any finite type \( \sigma \), \( \text{CZF} \vdash \exists x (x \in \sigma) \).

Proof. This is proved by induction on types. For \( \sigma = 0 \), \( 0 \in \omega = \sigma \). Assume that \( 0_r \in \tau \). Then \( \lambda x. x \cdot 0_r \in \sigma \rightarrow \tau \).

In the proof of 1 of the following theorem, the totality of the applicative structure is crucial.

Theorem 7.9. Let \( T \) be a set theory such that Proposition 6.8 holds and let \( \phi(y), \psi(x, y) \) and \( \theta(y) \) be formulae whose free variables are all displayed.

1. If \( T \vdash \forall y (\neg \phi(y) \rightarrow (\exists x \in \sigma) \psi(x, y)) \), then \( T \vdash \exists x \forall y (\neg \phi(y) \rightarrow x \in \sigma \land \psi(x, y)) \).

2. If \( T \vdash \forall y (\forall z \theta(y, z) \rightarrow (\exists x \in \sigma) \psi(x, y)) \) and \( T \vdash \forall y (\forall z \theta(y, z) \land \neg \theta(y, z)) \), then \( T \vdash \exists x \in \sigma \forall y (\forall z \theta(y, z) \rightarrow \psi(x, y)) \).
3. If $T \vdash \forall y(\neg \varphi(y) \rightarrow \exists x \in \sigma \psi(x, y))$ and $T \vdash \exists y \neg \varphi(y)$, then $T \vdash \exists x \in \sigma \forall y(\neg \varphi(y) \rightarrow \psi(x, y))$.

**Proof.** Assume that $T$ is a set theory and $\varphi(y)$, $\psi(x, y)$ and $\theta(y)$ are formulas as they are stated. Fix a total applicative structure $A$ such that both $A$ and the graph $\{\{a, b\}, c\} \in A^3 : App(a, b, c)$ are sets in $T$, such as $\mathcal{RE}(\omega)$.

1. Assume $T \vdash \forall y(\neg \varphi(y) \rightarrow (\exists x \in \sigma)\psi(x, y))$.

    We reason in $T$. By Lemma 7.3, we have an application term $t$ such that $t 
\vdash_{rt} \forall a(\neg \varphi[y/a] \rightarrow (\exists x \in \sigma \psi[x, y/a]))$). Note that $(t)_0 \downarrow$ and $(t)_1 \downarrow$ because of the totality of $A$. Take the following $c$.

    \[
    c = (\bigcup\{b^o \colon \langle(t)_0, b\rangle \in (\sigma)^*\}, \bigcup\{b^* \colon \langle(t)_0, b\rangle \in (\sigma)^*\}).
    \]

    Then, for each $x \in 2^{nd}(c)$, there is $b$ such that $x \in b^o$ and $\langle(t)_0, b\rangle \in (\sigma)^*$, which implies $1^st(2^{nd}(x)) \in 1^{st}(c)$. Hence $c \in \mathcal{V}_A$. Let $c = c$. By Lemma 6.4, if $a \vdash_{rt} \neg \varphi[y/a]$, then $\varnothing \vdash_{rt} \forall x \in \sigma \psi[x, y/a]$, which implies $\exists b(\langle(t)_0, b\rangle \in (\sigma)^* \land (t)_1 \vdash_{rt} \psi(x, b, y/a))$. By the definition of $\sigma$, such that $\langle(t)_0, b\rangle \in (\sigma)^*$ is unique. Hence $c = (\bigcup\{b^o\}, \bigcup\{b^*\})$ for such $b$. Therefore $p(t)_0 \vdash c \in \sigma$ by Lemma 7.3 and $(t)_1 \vdash_{rt} \psi(x, c, y/a)$. Let $s = \lambda a.p(p(t)_0i_1)(t)_1$, where $a$ is a fresh variable. Then $\forall a(s \vdash_{rt} \neg \varphi[y/a] \rightarrow c \in \sigma \land \psi(x, c, y/a))$ and so we have $s \vdash_{rt} \exists x \forall y(\neg \varphi(y) \rightarrow \psi(c, y))$. By Lemma 6.3 we have $\exists x \forall y(\neg \varphi(y) \rightarrow \psi(c, y))$.

2. Assume that $T \vdash \forall y(\forall z \theta(y, z) \rightarrow \exists x \in \sigma \psi(x, y))$ and $T \vdash \forall y(\forall z (\theta(y, z) \land \neg \theta(y, z)))$. We reason in $T$. By Proposition 6.8 there are application terms $t$ and $s$ such that $t \vdash_{rt} \forall y(x \varphi(y, z) \rightarrow \exists x \in \sigma \psi(x, y))$ and $s \vdash_{rt} \forall y(x \varphi(y, z) \rightarrow \psi(c, y))$. Then $(s)_0 = 0$ or $(s)_1 = 1$.

    If $(s)_0 = 0$, then we have $(s)_1 \vdash_{rt} \forall z \theta(y, z)$ and so there is $c$ such that $\langle(t(s)_1), c\rangle \in (\sigma)^* \land (t(s)_1) \vdash_{rt} \psi(c, a)$ for any $a$. Therefore $\lambda a.(t(s)_1) \vdash_{rt} \forall y(\forall z \varphi(y, z) \rightarrow \psi(c, y))$ and so

    \[
    p(t(s)_1)0 \vdash_{rt} \exists x \in \sigma \forall z \varphi(y, z) \rightarrow \psi(c, y))
    \]

    which implies $\exists x \in \sigma \forall z \varphi(y, z) \rightarrow \psi(c, y))$.

    If $(s)_0 = 1$, then we have $(s)_1 \vdash_{rt} \neg \theta(y/a, z/d)$ for any $a$ and $d$. Hence, for any $a$, there is no $a$ such that $a \vdash_{rt} \forall z \theta(y, z/a)$. By Lemma 7.8 there is $\langle b, b\rangle \in \sigma$. Then we have $\lambda a.0 \vdash_{rt} \forall y(\forall z \varphi(y, z) \rightarrow \psi(b, y))$ and so

    \[
    pb(\lambda a.0) \vdash_{rt} \exists x \in \sigma \forall y(\forall z \varphi(y, z) \rightarrow \psi(b, y))
    \]

    which implies $\exists x \in \sigma \forall y(\forall z \varphi(y, z) \rightarrow \lambda \psi(c, y))$.

3. Assume that $T \vdash \forall y(\neg \varphi(y) \rightarrow \exists x \in \sigma \psi(x, y))$ and $T \vdash \exists y \neg \varphi(y)$.

    We reason in $T$. By Proposition 6.8 there are application terms $t$ and $s$ such that $t \vdash_{rt} \neg \varphi[y/a] \rightarrow \exists x \in \sigma \psi(x, y/a)$ and so $\exists x(\langle(t)_0, c\rangle \in (\sigma)^* \land (t)_1 \vdash_{rt} \forall y(\neg \varphi[y/a] \rightarrow \psi(x/c, y/a))$. The last implies $T \vdash \exists x \forall y(\neg \varphi(y) \rightarrow \psi(x, y))$. □
8 Open problems

We conclude the paper with some open problems.

Problem 8.1 (Independence of Premise Rule in general). Is the following independence of premise rule an admissible rule of CZF or any other familiar constructive/intuitionistic set theory T?

If $T \vdash \neg \varphi \to \exists x \psi(x)$, then $T \vdash \exists x (\neg \varphi \to \psi(x))$, where $\varphi$ and $\psi$ have no free variables other than displayed, and where $x$ is not free in $\varphi$.

In Theorem [7.9.1] we proved it in the case in which $\exists x$ is bounded by some finite type. We do not know yet whether this generalizes to other bounded for $\exists x$ or whether we can even remove it. The key to generalize this bound seems to be to construct a (total) PCA which injectively represents each element of the bound, like in Lemma [7.3]

Problem 8.2 (Choice Rule, AC$_{FT}$-rule). In [24 3.7.5], it was shown that HA$^\omega$ is closed under the choice rule for finite type (dubbed ACR there), i.e.,

If $HA^\omega \vdash \forall x^\sigma \exists y^\tau \varphi(x, y)$, then $HA^\omega \vdash \exists z^\tau \forall x^\sigma \varphi(x, z)$

We expect that the set theories we treat in this paper are also closed under AC$_{FT}$-rule, but we do not know yet if we can prove it with the model of PCA in this paper but problems with extensionality one faces seem to render it highly unlikely.
