[18 November 2019]

The biharmonic equation with Dirichlet and Neumann boundary conditions discretized using the mixed finite element method and piecewise linear functions on triangular elements has been well-studied for domains in $\mathbb{R}^2$. Here we study the analogous problem on polyhedral surfaces. In particular, we provide a convergence proof of discrete solutions to the corresponding smooth solution of the biharmonic equation. We obtain convergence rates that are identical to the ones known for the planar setting. Our proof relies on a novel bound for the $L^\infty$ error of the linear FEM for the Poisson equation on curved surfaces, as well as inverse discrete Laplacians to bound the error between discrete solutions on the surface and the polyhedral mesh approximating it.

Keywords: biharmonic equation; polyhedral surfaces; mixed finite elements; discrete geometry.

1. Introduction

We consider the biharmonic equation on smooth surfaces embedded in three-dimensional Euclidean space: given a function $f$ on a smooth surface, find a function $u$ such that

$$\Delta^2 u = f,$$  \hspace{1cm} (1.1)

†Corresponding author. Email: oded.stein@columbia.edu
where $\Delta$ is the Laplace–Beltrami operator. If boundaries are present, boundary conditions must be taken into account. We consider Dirichlet and Neumann boundary conditions,

$$ u = \frac{\partial u}{\partial n} = 0 \quad \text{at the boundary.} \quad \text{(1.2)} $$

For flat surfaces, this problem is sometimes referred to as the \textit{clamped thin plate problem}. If no boundaries are present, the problem is solved modulo constant functions.

In order to solve the biharmonic problem, we use a \textit{mixed finite element method} with \textit{piecewise linear elements} on polyhedral triangle meshes. Every mesh is required to have \textit{uniformly shape regular triangles}. Moreover, we consider sequences of triangle meshes that converge to a given smooth limit surface such that both \textit{positions} and \textit{normals} converge at a certain rate (to be specified later). We show:

- $L^2$-convergence of order $h$ of discrete solutions $u$;
- $L^2$-convergence of order $h^{3/4}$ of discrete solution gradients $\nabla u$;
- $L^2$-convergence of order $\sqrt{h}$ of the discretization of $\Delta u$;

where $h$ is the maximum edge length of the approximating triangles of the mesh. If no boundaries are present, the problem becomes simpler and better convergence rates can be obtained.

The mixed method consists of solving a linear system of two equations; in $u_1$ (which corresponds to the solution $u$) and in $u_2$ (which corresponds to the Laplacian $\Delta u$ of the solution),

$$ \int_{\Omega} \nabla u_2 \cdot \nabla \xi \, dx = \int_{\Omega} f \xi \, dx \quad \forall \xi \in H^1_0 $$

$$ \int_{\Omega} \nabla u_1 \cdot \nabla \eta \, dx = \int_{\Omega} u_2 \eta \, dx \quad \forall \eta \in H^1. \quad \text{(1.3)} $$

Here we assume that $f \in L^2$, and we seek solutions $u_1 \in H^1_0$ (or a suitable subspace) and $u_2 \in H^1$ (or a suitable subspace). We employ the geometric convention of working with \textit{positive semidefinite} Laplacians.

A convergence result for the mixed finite element approximation to the biharmonic problem (using piecewise linear Lagrange elements) has long been known for the case of \textit{planar domains} (Scholz, 1978). Our convergence rates can be obtained by combining the results of Scholz (1978) with the results of Rannacher & Scott (1982). In a nutshell, the idea is to bound the error between the discrete solution $u_2$ and the Ritz approximation of the exact solution, and then use the fact that the error of the Ritz approximation can be explicitly controlled. Although this approach might seem easily extensible to the case of curved surfaces, the non-flat geometry brings about additional challenges.

There are multiple conceivable approaches for generalizing Scholz’s proof to the curved setting. A first approach might be an attempt to directly bound the error between discrete solutions to (1.3) on polyhedral meshes and the smooth solution on a given limit surface. For this approach, however, a considerable complication arises from the fact that the geometry of the mesh and the geometry of the limit surface are different. A different approach that works for the Poisson problem (Wardetzky, 2006) can also not be used here: It is not possible to first compute a “smooth” solution $u_1 \in H^1_0, u_2 \in H^1$ to

1 Geometrically, polyhedral meshes are Euclidean cone manifolds that are intrinsically flat everywhere, except at isolated \textit{cone points}. Even in the presence of cone points, it is possible to define $L^2$ and $H^1$ spaces (Wardetzky, 2006). It is therefore possible to formulate an analogous “smooth” problem (1.3) on Euclidean cone manifolds. This “smooth” problem, however, does not always have a solution.
(1.3) on the polyhedral mesh and then compare it to the smooth solution on the limit surface, since such smooth solutions on the polyhedral mesh do not necessarily exist. Indeed, even for planar nonconvex Lipschitz domains, problem (1.3) ceases to have a solution (Stylianou, 2010, Section 4.3).

Perhaps surprisingly, discrete solutions to (1.3) using piecewise linear Lagrange elements do indeed exist for meshes. Our approach is to relate these discrete solutions on meshes to certain discrete solutions on the smooth limit surface by leveraging an inverse estimate and (inverse) discrete Laplacians. This allows us to circumvent the above-mentioned problem of nonexistence of a “smooth” solution on polyhedral meshes. Our generalization of Scholz’s proof, which relies on a novel bound for the $L^\infty$ error of the linear FEM for the Poisson equation on curved surfaces, can then be used to bound the error between the discrete solution on the smooth limit surface and the exact solution. Together, these two steps result in an error bound for the mixed finite element approximation of the biharmonic equation.

**MIXED FINITE ELEMENTS FOR THE BIHARMONIC EQUATION IN $\mathbb{R}^2$.** Ciarlet & Raviart (1973) are the first to introduce the mixed finite element method for the biharmonic problem. Their work informs the functional analysis framework that we use here. They solve the same system of equations that we end up solving (in the flat case), but only show convergence for higher-order Lagrangian finite elements. Their approach is later expanded by Monk (1987) to deal with boundary smoothness problems caused by triangulating.

Scholz (1978) proves that the mixed finite element method with linear, first-order Lagrange elements can be used to solve the biharmonic problem, and he gives an error bound of $h \log^2 h$ on the $L^2$ norm of the solution. The result by Scholz is central to understanding the convergence of the linear finite element method for the biharmonic equation, and forms the basis of our proof. The result is remarkable, since it shows convergence of the method, even though the standard convergence conditions for mixed finite elements (the inf-sup conditions (Boffi et al., 2013)) are not fulfilled. Scholz’s error estimate is not optimal, as it relies on an $L^\infty$ estimate of the Ritz approximation error by Nitsche (1978). An application of a later, better bound for the same interpolation error (Rannacher & Scott, 1982) gives convergence of order $h$.

The concept of mixing different function spaces to solve numerical analysis problems is an even older idea. Using hybrid and mixed finite elements to solve the biharmonic equation with Dirichlet and Neumann boundary conditions in $\mathbb{R}^2$ goes back to the works of Herrmann (1967); Brezzi (1975); Miyoshi (1972); and others, who study a saddle point problem formulation based on the Hessian energy
$$J(u) := \frac{1}{2} \int_\Omega u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2 \, dx.$$ Their method is a so-called hybrid method, where, in the derivation of the method, “the variational principle is explicitly dependent upon a given triangulation of the [domain]” (Ciarlet & Raviart, 1973, pp. 125). A good summary of hybrid and mixed finite elements and their history can be found in the work of Boffi et al. (2013).

Oukit & Pierre (1996) provide an analysis of the biharmonic equation with Dirichlet and Neumann boundary conditions that combines the hybrid approach (which they call Hermann-Miyoshi) and the mixed approach (which they call Ciarlet-Raviart). Their analysis holds for first and second order elements. The result by Scholz (1978) is recovered in the limit $p \to \infty$, where $p$ is the degree of the $L^p$ space.

An alternative approach to solving the biharmonic equation using mixed finite elements is the decomposition into four linear equations, such as done by Behrens & Guzmán (2011) (which leads to superconvergence of the solution) and Li & Zhang (2017).
Finites elements on curved surfaces. Dziuk (1988) generalizes the standard result for solving the Poisson equation with linear finite elements from $\mathbb{R}^2$ to smooth surfaces by working with *inscribed* meshes, i.e., requiring that vertices of the approximating mesh be contained in the limit surface. His work has since been used in advanced numerical methods for curved surfaces (Olshanskii et al., 2009; Du et al., 2011; Dziuk & Elliott, 2007). Wardetzky (2006) and Hildebrandt et al. (2006) generalize Dziuk’s result to non-inscribed meshes and provide exact estimates of certain geometric quantities. The work of Wardetzky (2006) provides most of the geometric estimates that we require.

Meanwhile, other methods for solving the biharmonic equation on surfaces exist in the literature; a few examples follow. Larsson & Larson (2017) use the discontinuous Galerkin approach to achieve a method for surfaces without boundary where the $L^2$ error is of order $h$. Unlike this approach, we use a mixed formulation with a conforming approximation, and additionally provide error estimates of the Laplacian, as well as a treatment of surfaces with boundaries. Cockburn & Demlow (2016) use a different kind of discontinuous Galerkin method as well as non-conforming mixed finite elements (Raviart-Thomas, Brezzi-Douglas-Marini, Brezzi-Douglas-Fortin-Marini). In contrast to their method, we use a *conforming* linear element and provide detailed analysis of Dirichlet and Neumann boundary conditions.

Applications of the biharmonic equation on surfaces. Although a convergence proof has been missing so far, discretizations of the biharmonic equation (and its related Helmholtz problem) using a mixed formulation with linear Lagrange elements have been popular in practice (Desbrun et al., 1999; Sorkine et al., 2004; Bergou et al., 2006; Garg et al., 2007; Tosun, 2008; Jacobson et al., 2010, 2011, 2012). We here provide a justification for the use of the linear mixed finite element method for such applications.

2. The Biharmonic Equation on smooth Surfaces

Let $\Omega$ be a compact smooth surface with smooth boundary or no boundary, embedded into $\mathbb{R}^3$. We denote by $L^p$ the usual $L^p$ spaces on surfaces, and we let $W^{k,p}$ denote the Sobolev space with $k$ weak derivatives in $L^p$. We let $H^k := W^{k,2}$, and we denote by $H^1_0$ the space of those functions in $H^1$ with zero trace along the boundary. Whenever the domain is omitted, these spaces are implied to be defined over $\Omega$.

We denote the metric tensor on $\Omega$ by $g(\cdot, \cdot)$, i.e., the restriction of the inner product on $\mathbb{R}^3$ to the tangent spaces of $\Omega$. The metric induces the $L^2$ inner product $\langle \cdot, \cdot \rangle$ and the $H^1_0$ inner product $D(\cdot, \cdot)$,

$$
\langle u, v \rangle = \int_{\Omega} uv \, dx \quad u, v \in L^2
$$

$$
D(u, v) = \int_{\Omega} g(\nabla u, \nabla v) \, dx \quad u, v \in H^1.
$$

The norm on $H^1$ is induced by the inner product $\langle \cdot, \cdot \rangle + D(\cdot, \cdot)$.

**Definition 2.1** For $f \in L^2$, the *biharmonic equation* is defined as follows: find $u \in H^1_0 \cap H^4$, such that

$$
\Delta^2 u = f, \quad (2.1)
$$

where $\Delta$ is the positive semidefinite Laplace–Beltrami operator.

- If $\Omega$ has a boundary, then zero Dirichlet and Neumann boundary conditions apply, $u = \nabla u = 0$;
• if $\Omega$ is closed, $u$ must have zero mean, i.e., $\int_{\Omega} u \, dx = 0$.

The biharmonic equation has a corresponding weak formulation. For $f \in L^2$, find $u \in H^1_0 \cap H^2$ such that

$$
\int_{\Omega} \Delta u \Delta v \, dx = \int_{\Omega} f v \, dx \quad \forall v \in H^1_0 \cap H^2. \tag{2.2}
$$

We assume that there is a unique solution such that $u \in H^4$, $\|u\|_{H^4} \leq C \|f\|_{L^2}$. For closed surfaces this follows from the fact that the biharmonic equation decouples into two Poisson equations. For planar domains, see Gazzola et al. (2010, Section 2.5.2). Additionally, we assume the standard existence and regularity estimates for the Poisson equation: for $g \in L^p$, $1 < p < \infty$ there is a unique $w \in W^{2,p}$ with Dirichlet boundary conditions such that, weakly, $\Delta w = g$ and $\|w\|_{W^{2,p}} \leq C \|g\|_{L^p}$. For planar domains, see, for example, the work of Grisvard (2011, Section 2).

With $u_1 := u$, and using the intermediate variable $u_2 := \Delta u_1$, (2.2) can be rewritten in its mixed form

$$
D(u_2, \xi) = \langle f, \xi \rangle \quad \forall \xi \in H^1_0
$$

$$
D(u_1, \eta) = \langle u_2, \eta \rangle \quad \forall \eta \in H^1. \tag{2.3}
$$

We refer to this system of equations as the smooth mixed formulation of the biharmonic equation with Dirichlet and Neumann boundary conditions. It can be formulated for any $u_1 \in H^1_0$ and $u_2 \in H^1$. By Ciarlet (2002, Theorem 7.1.1), (2.3) has a unique solution such that $u_1 \in H^1_0 \cap H^2$, so by our assumptions it has a unique solution such that $u_1 \in H^1_0 \cap H^4$ and $u_2 \in H^2$.

3. Discretization

3.1 Discretizing the surface

To be able to use a finite element method, we need to discretize our domain. We do so with the help of a triangle mesh—a continuous, piecewise flat, triangular surface. Boundary edges of triangles along the surface boundary are allowed to be curved as long as the curve remains in the plane of the triangle. In the flat case, triangle meshes are only needed to discretize the function space $H^1_0$ in which the solution lives. In the case of a surface $\Omega \subseteq \mathbb{R}^3$, however, the mesh is also used to discretize the geometry itself. Because of that, we require additional conditions of our mesh that are not present in the work of Scholz (1978). These conditions mirror the ones of Wardetzky (2006), whom this section closely follows.

**Definition 3.1** Let $X$ be a topologically closed subset of $\mathbb{R}^3$. The medial axis of $X$ is the set of those points in $\mathbb{R}^3$ that do not have a unique closest neighbor in $X$. The reach of $X$ is the distance of $X$ to its medial axis.

Let $\Omega_h$ be a triangle mesh. Then we can define the following map:

**Definition 3.2** Let $\Omega_h$ lie within the reach of $\Omega$. The shortest distance map is the map $\Phi : \Omega \to \Omega_h$ that takes every point $p \in \Omega$ to the closest intersection of the line through $p$ parallel to the normal of $\Omega$ at $p$, and $\Omega_h$, see Figure 1.

Throughout, we require the following conditions of our mesh:\(^2\)

\(^2\)We adopt the convention that, wherever a constant $C$ occurs, the words “there is a constant $C > 0$, dependent only on the surface $\Omega$ and mesh regularity parameters” are implied.
(C1) The triangles of \( \Omega_h \) are uniformly shape regular, i.e., there exist constants \( k, K > 0 \) such that every triangle contains a circle of radius \( kh \) and is contained in a circle of radius \( Kh \).

(C2) The polyhedral surface \( \Omega_h \) is a normal graph over the smooth surface \( \Omega \), i.e., \( \Omega_h \) lies within the reach of \( \Omega \) and the shortest distance map is a bijective function. In particular, the boundary of \( \Omega \) is bijectively mapped to the boundary of \( \Omega_h \).

(C3) The distance of every point under the shortest distance map is bounded by \( Ch^\gamma \) for some \( \gamma \geq \frac{3}{2} \).

(C4) The normals of \( \Omega_h \) converge to the normals of \( \Omega \) such that at almost every point \( p \in \Omega \) the angle between the surface normal and the normal of \( \Omega_h \) at \( \Phi(p) \) is bounded by \( Ch^\epsilon \) for some \( \epsilon \geq 1 \).

(C5) \( \sigma := \min(\gamma, 2\epsilon) \geq \frac{3}{2} \).

Condition (C2) might seem difficult to satisfy for meshes that have nonempty boundary, since we require that the boundary of \( \Omega \) maps exactly to the boundary of \( \Omega_h \) under \( \Phi \). However, this condition is not hard to satisfy. Consider a mesh \( \Omega_h \) within the reach of \( \Omega \), where boundary vertices are inscribed into the smooth boundary such that every triangle has at most two vertices on the boundary of the mesh, and these vertices must be connected by a boundary edge of the mesh. Now, every boundary triangle lies in a unique plane. The image of the map \( \Phi \) onto the triangle’s plane is a collection of flat triangles with at most one curved edge. Thus the boundary triangles of \( \Omega_h \) can be extended such that (C2) is satisfied. This makes condition (C2) very similar to the condition of Scholz (1978) in the flat case, which requires triangles with curved edges that exactly match the boundary of the smooth domain.

Remark 3.1 Condition (C2) is not present in the work of Wardetzky (2006). Because of that, Wardetzky’s result on the convergence of the finite element method for the Poisson equation, Theorem 3.3.3, only holds for solutions that are supported sufficiently far away from the boundary. With Condition (C2), and with the finite element spaces that will be defined in Definition 3.5, the results of Wardetzky (2006) hold for general solutions \( u \in H_0^1 \cap H^2 \).
REMARK 3.2 It might be possible to relax condition (C2) to only require triangles with straight edges and vertices that are inscribed into the boundary. However, such a relaxation could lead to lower convergence rates.

REMARK 3.3 A triangle mesh that is inscribed into the smooth surface \( \Omega \) and that satisfies (C1) and (C2), automatically fulfills (C3), (C4), and (C5).

Using Conditions (C1-C5), we can relate the metric and the function spaces of the mesh \( \Omega_h \) to the metric and the function spaces of \( \Omega \).

DEFINITION 3.3 Let \( g \) denote the metric tensor on the smooth surface \( \Omega \). Consider \( \Omega_h \) as a Euclidean cone manifold, which is flat almost everywhere except at cone points. Let \( g_{\Omega_h} \) be the corresponding metric tensor (defined almost everywhere) on \( \Omega_h \), and let \( g_{\mathbb{R}^3} \) denote the inner product of Euclidean space. Then we can define the distorted metric \( g_A \) on \( \Omega_h \),

\[
g_A(X, Y) := g_{\Omega_h}(d\Phi(X), d\Phi(Y)) = g_{\mathbb{R}^3}(d\Phi(X), d\Phi(Y)) .
\]

We define the unique matrix field \( A \) that relates \( g_A \) to \( g \) almost everywhere,

\[
g_A(X, Y) = g(A X, Y). \quad (3.1)
\]

We define the distorted inner products that relate the inner products on the mesh to the inner products on the surface,

\[
\langle u, v \rangle_A := \int_{\Omega} u v |\det A|^{\frac{1}{2}} \, dx \quad \text{for } u, v \in L^2(\Omega)
\]

\[
D(u, v)_A := \int_{\Omega} g(A^{-1} \nabla u, \nabla v) |\det A|^{\frac{1}{2}} \, dx \quad \text{for } u, v \in H^1(\Omega) . \quad (3.2)
\]

We adopt the convention that for every norm, the same norm subscripted with \( A \) implies that the norm is taken with respect to the distorted metric. For example, \( L^2_A \) is the \( L^2 \) norm in the distorted metric.

We can get explicit bounds on the entries of \( A \). From now on, the statement “for small enough \( h \)” is implied everywhere.

LEMMA 3.1 It holds that

\[
\| A - \Id \|_{L^\infty} \leq C h^\sigma
\]

\[
\left\| |\det A|^{\frac{1}{2}} - 1 \right\|_{L^\infty} \leq C h^\sigma
\]

\[
\left\| |\det A|^{\frac{1}{2}} A^{-1} - \Id \right\|_{L^\infty} \leq C h^\sigma .
\]

where the \( L^\infty \) norm is the essential supremum over the operator norms of the respective matrix fields. The scalar \( \sigma > 0 \) depends on the convergence of the mesh and is defined in (C5).

Proof. By Wardetzky (2006, Theorem 3.2.1) we know that for any point and orthonormal tangent frame there exists a matrix decomposition \( A = P Q P \) such that \( P, Q \) can be diagonalized (possibly in different bases) as

\[
P = \begin{pmatrix} 1 - \phi \kappa_1 & 0 \\ 0 & 1 - \phi \kappa_2 \end{pmatrix}
\]

\[
Q = \begin{pmatrix} \frac{1}{(N \kappa_1)^{\frac{1}{2}}} & 0 \\ 0 & 1 \end{pmatrix} ,
\]
where $\phi$ is the pointwise distance between $\Omega$ and $\Omega_h$ under the map $\Phi$, $N$ and $N_h$ are the surface normals of $\Omega$ and $\Omega_h$ respectively, and $\kappa_1, \kappa_2$ are the principal curvatures of the surface.

Let $\angle (N, N_h)$ be the unsigned angle between the two vectors $N, N_h$ in $\mathbb{R}^3$. Using Taylor expansion we obtain, up to higher order terms,

$$|\det A|^2 \approx 1 \approx -\phi \kappa_1 - \phi \kappa_2 - \frac{1}{2} \angle (N, N_h)^2,$$

which proves the lemma for $\|A - \text{Id}\|_{L_\infty}$, given that $|\phi| \leq Ch^\gamma$ (C3), $|\angle (N, N_h)| \leq Ch^\varepsilon$ (C4), and $\sigma = \min(\gamma, 2\varepsilon)$ (C5). A similar argument works for the other two expressions.

**Lemma 3.2** The following equalities hold as equalities of sets:

$$L^2(\Omega) = L^2_h(\Omega) = L^2(\Omega_h),$$
$$H^1(\Omega) = H^1_h(\Omega) = H^1(\Omega_h),$$
$$H^1_0(\Omega) = H^1_{0,h}(\Omega) = H^1_0(\Omega_h),$$
$$W^{1,\infty}(\Omega) = W^{1,\infty}_h(\Omega) = W^{1,\infty}(\Omega_h),$$

where the bijection $\Phi$ is applied where needed in order to map between $\Omega$ and $\Omega_h$. The norms of the respective spaces are all equivalent independently of the choice of $h$ (for $h$ small enough).

**Proof.** Because of the bijectivity of $\Phi$, every function on $\Omega$ is also well-defined on $\Omega_h$ (and vice-versa).

Under the map $\Phi$, the inner products $\langle \cdot, \cdot \rangle_A$ and $D\langle \cdot, \cdot \rangle_A$ of the spaces $L^2_A(\Omega), H^1_A(\Omega), H^1_{0,A}(\Omega)$, and $W^{1,\infty}_A(\Omega)$ are exactly the inner products of the spaces $L^2(\Omega_h), H^1(\Omega_h), H^1_0(\Omega_h)$, and $W^{1,\infty}(\Omega_h)$, respectively. Lemma 3.1 implies that the respective disturbed inner products induce norms that are bounded if and only if the respective undisturbed norms are bounded. Disturbed and undisturbed norms bound each other independently of $h$, as long as $h$ is small enough. This proves the claim.

**Remark 3.4** The equivalence of norms independently of $h$ also implies a disturbed Poincaré inequality where the constant is independent of $h$,

$$\|u\|_{L^2_\Omega} \leq C\|u\|_{H^1_{0,A}} \quad \forall u \in H^1_0$$
$$\|u - u_{\Omega,A}\|_{L^2_\Omega} \leq C\|u\|_{H^1_{0,A}} \quad \forall u \in H^1,$$

where $u_{\Omega,A}$ is the average of $u$ with respect to integration in the disturbed metric.

**Remark 3.5** Lemma 3.1 and Lemma 3.2 allow for formulating our discrete method entirely on $\Omega$, even though the actual implementation might compute its operators and results on $\Omega_h$.

In order to quantify the differences between the disturbed and undisturbed inner products, we introduce the following bilinear forms:

**Definition 3.4** The difference bilinear forms are defined as follows,

$$c(u,v) := \langle u, v \rangle - \langle u, v \rangle_A$$
$$d(u,v) := D\langle u, v \rangle - D\langle u, v \rangle_A.$$  

(3.3)
LEMMA 3.3 The difference bilinear forms fulfill the inequalities
\[ |c(u, v)| \leq C h^\sigma \|u\|_{L^2} \|v\|_{L^2} \quad \forall u, v \in L^2 \]
\[ |d(u, v)| \leq C h^\sigma \|u\|_{H^1} \|v\|_{H^1_0} \quad \forall u, v \in H^1 . \]

Proof. This is a consequence of Lemma 3.1 and the Cauchy-Schwarz inequality. \qed

3.2 Discretizing the function spaces
Having discretized the geometry of $\Omega$, we now turn to the approximation of function spaces.

DEFINITION 3.5 Let $S_{h,A}$ be the space of continuous functions on the mesh $\Omega_h$ that are linear within each triangle. On boundary triangles (which might have a curved edge), an isoparametric modification is applied (Zlámal, 1973; Scott, 1973), which projects a curved edge of a triangle onto a straight edge while keeping the vertices fixed and minimizing distortion.\(^3\) On the resulting triangle, functions are required to be linear.

The discrete space $S_h \subseteq H^1$ is the pullback of $S_{h,A}$ under the shortest distance map $\Phi$. The space $S_h$ has domain $\Omega$ and inherits the natural inner product from $H^1(\Omega)$. When we refer to “piecewise linear functions” on the surface $\Omega$, we refer to the space $S_h$. Analogously, we define the discrete space $S_{h,0} := S_h \cap H^1_0$, which inherits its inner product from $H^1_0(\Omega)$.

REMARK 3.6 The number of degrees of freedom of $S_h$ is the number of mesh vertices. The number of degrees of freedom of $S_{h,0}$ is the number of mesh vertices minus the number of boundary vertices.

The discrete spaces come with various interpolation operators.

DEFINITION 3.6 Let $I_h : H^2 \to S_h$ denote the per-vertex interpolation operator,\(^4\) i.e., $(I_h u)(p) = u(p)$.
Moreover, $R_h, R_h^A : H^1 \to S_h$ and $R_{h,0}, R_{h,0}^A : H^1_0 \to S_{h,0}$ are the Ritz interpolation operators,
\[
D(u - R_h u, \eta) = D(u - R_h^A u, \eta) = 0 \quad \forall \eta \in S_h, u \in H^1
\]
\[
\langle u - R_h u, 1 \rangle = \langle u - R_h^A u, 1 \rangle = 0
\]
\[
D(u - R_{h,0} u, \xi) = D(u - R_{h,0}^A u, \xi) = 0 \quad \forall \xi \in S_{h,0}, u \in H^1_0 .
\]
This is analogous to the flat case of Scholz (1978, p. 86).

The interpolation operators satisfy certain interpolation inequalities.

LEMMA 3.4 The Ritz-interpolation is $H^1$-stable, i.e.,
\[
\|R_h u\|_{H^1}, \|R_h^A u\|_{H^1} \leq C\|u\|_{H^1} \quad \forall u \in H^1
\]
\[
\|R_{h,0} u\|_{H^1_0}, \|R_{h,0}^A u\|_{H^1_0} \leq C\|u\|_{H^1_0} \quad \forall u \in H^1_0 .
\]

\(^3\)This treatment of the boundary, present in the work of Scholz (1978), does not appear in the work of Wardetzky (2006). The main results of Wardetzky, however, remain true if an optimal isoparametric element is chosen (Bernardi, 1989), with minor modifications to the proofs, as long as Conditions (C1-C5) hold, see Remark 3.1.
\(^4\)The Sobolev embedding theorem implies that $H^2(\Omega) \subseteq C^1(\Omega)$, which justifies pointwise interpolation.
For $u \in H^1_0 \cap H^2$ one has

$$
\|u - I_h u\|_{H^1_0} \leq C \|u\|_{H^2}
$$

$$
\|u - R_{h,0} u\|_{H^1_0} \leq C \|u\|_{H^2}
$$

$$
\|u - R_{h,0} u\|_{H^1} \leq C \|u\|_{H^2}.
$$

(3.4)

If, in addition, $u \in W^{2,\infty}$,

$$
\|u - I_h u\|_{W^{1,\infty}} \leq C \|u\|_{W^{2,\infty}}.
$$

(3.5)

If $u$ is continuous and $H^1$ or $W^{1,\infty}$, but only $H^2$ or $W^{2,\infty}$ within each triangle, then

$$
\|u - I_h u\|_{H^1} \leq C \|u\|_{H^2}
$$

$$
\|u - I_h u\|_{W^{1,\infty}} \leq C \|u\|_{W^{2,\infty}}.
$$

(3.6)

where the tilde above the norm indicates a per-triangle norm, concatenated over all triangles $t$ in the triangulation: $\|u\|_{H^1_t(\Omega)} = \sum_t \|u\|_{H^1_t(\Omega)}$, $\|u\|_{W^{2,\infty}(\Omega)} = \max_t \|u\|_{W^{2,\infty}(\Omega)}$.

Analogous results hold for functions that are nonzero at the boundary using the appropriate interpolation operators. All estimates with the interpolation inequality also hold per triangle.

Proof. We only treat the case of $H^1_0$-type interpolations. The case of $H^1$ follows by using the appropriate norms as well as the condition $\langle u - R_{h} u, 1 \rangle = \langle u - R_{h}^A u, 1 \rangle_A = 0$.

It holds that

$$
\|R_{h,0} u\|_{H^1_0}^2 = D\langle u - R_{h,0} u, R_{h,0} u \rangle + D\langle R_{h,0} u, R_{h,0} u \rangle = D\langle u, R_{h,0} u \rangle \leq C \|u\|_{H^1_0} \|R_{h,0} u\|_{H^1_0}
$$

$$
\|R_{h,0} u\|_{H^1_0} \leq C \|u\|_{H^1_0}.
$$

This proves the stability estimates.

Let $T_h$ be a flat triangle of $\Omega_h$. Both the left and right hand sides of the first line of (3.4) hold by restricting to the subset $\Phi^{-1}(T_h) \subseteq \Omega$, see (Wardetzky, 2006, Thereom 3.3.2). Although this result was only established for triangles $T_h$ with straight edges, the extension to triangles in $\Omega_h$ with curved edges along the surface boundary is straightforward. The first line of (3.4) follows by using that $\Phi : \Omega \rightarrow \Omega_h$ is a bijection and by summing over all triangles $T_h$.

The next line of (3.4) follows by

$$
\|I_h u - R_{h,0} u\|_{H^1_0} = \|R_{h,0} (I_h u - u)\|_{H^1_0} \leq C \|I_h u - u\|_{H^1_0}, \text{ and therefore}
$$

$$
\|u - R_{h,0} u\|_{H^1_0} \leq \|u - I_h u\|_{H^1_0} + \|I_h u - R_{h,0} u\|_{H^1_0} \leq C \|I_h u - u\|_{H^1_0} \leq C \|u\|_{H^2}.
$$

An analogous derivation holds for $R_{h,0}^A$ instead of $R_{h,0}$. This proves the inequalities in (3.4).

The inequality (3.5) is known to hold in the flat case (Brenner & Scott, 2008, Theorem 4.4.4). The arguments used by Wardetzky (2006, Thereom 3.3.2) to generalize the flat $L^2$ case to the surface $\Omega$ also apply for $L^\infty$, since only pointwise calculations ever take place in the proof.

The inequalities in (3.6) follow by noticing that all calculations above for the interpolation operator only ever happen within triangles and by summation over triangles.  

4. An $L^\infty$ estimate for the Ritz approximation on curved surfaces

Rannacher & Scott (1982) measure the $W^{1,\infty}$ error of the Ritz approximation on convex subsets of $\mathbb{R}^2$. We generalize their result to smooth surfaces with shape-regular triangulations.

**Lemma 4.1** (Rannacher & Scott (1982)) Let $U$ be a convex, polygonal subset of the plane, triangulated by a shape-regular triangulation. Let $u \in W^{2,\infty}(U) \cap H^1_0(U)$. Then

$$\|u - R_{h,0}u\|_{W^{1,\infty}(U)} \leq C h \|u\|_{W^{2,\infty}(U)}.$$  

We generalize Lemma 4.1 by following the approach of Brenner & Scott (2008, Theorem 8.1.11), but applying it to the setting of the Poisson equation solved with linear finite elements on curved surfaces. The most important difference between the planar setting and curved surfaces is the fact that first and second derivatives work somewhat differently: there is no simple notion of a constant vector field with zero second derivative, instead we resort to divergence-free, locally-defined vector fields. Moreover, our FEM functions no longer have zero second derivative within curved triangles on the surface, as they do with zero derivative, instead we need to apply multiple subtle changes to deal with the definition of various helper functions on curved surfaces.

**Theorem 4.1** Let $u \in W^{2,\infty}(\Omega) \cap H^1_0(\Omega)$, where $\Omega \subseteq \mathbb{R}^3$ is the smooth surface introduced in Section 2. Then it holds that

$$\|R_{h,0}u\|_{W^{1,\infty}} \leq C \|u\|_{W^{2,\infty}}.$$  

**Proof.** We first note that the Ritz approximation is equivalent to solving the Poisson equation with Dirichlet boundary conditions using piecewise linear finite elements. Let $f := \Delta u \in L^\infty$. Then $u_h := R_{h,0}u \in S_{h,0}$ satisfies

$$D(u_h, \xi) = \langle f, \xi \rangle \quad \forall \xi \in S_{h,0}.$$  

This means that the proof boils down to the stability of the linear finite element method for the Poisson equation with Dirichlet boundary conditions.

We will use the method of weighted estimates (Brenner & Scott, 2008, Section 8.2). For any $z \in \Omega$ contained in the interior of a triangle $T \subseteq \Omega$ (so, for almost any point), consider a smooth function $\delta^z$ compactly supported in an open subset of $T \subseteq \Omega$ such that

$$\langle \delta^z, \xi \rangle_A = \xi(z) \quad \forall \xi \in S_{h,0}$$  

$$\|D_k \delta^z\|_{L^\infty} \leq C_k h^{-2-k} \quad \forall k \geq 0,$$  

where the constant $C_k$ depends only on the triangulation, and $D^k$ is the vector of partial derivatives of order $k$.

Let $V_A := A^{-1} \nabla$ be the gradient pushed from the flat mesh $\Omega_h$ to the surface $\Omega$ (Wardetzky, 2006, p. 58), and let $\cdot_A$ denote a short-hand for the dot product in the disturbed metric from Definition 3.3. Let $\bar{v}$ be any tangent vector to $\Omega$ at $z$ of length 1 under the disturbed dot product $\cdot_A$. Our goal is to bound $\langle \bar{v}_A \nabla_A u_h \rangle(z)$, which will provide a bound for $||\nabla_A u_h||_{L^\infty}$ (since $z$ was arbitrary). By Lemma 3.1, $||\nabla_A u_h||_{L^\infty} \leq C ||u_h||_{L^\infty}$. As $u_h$ is Lipschitz continuous, $||u_h||_{L^\infty} \leq C ||\nabla u_h||_{L^\infty}$, so a bound for $\langle \bar{v}_A \nabla_A u_h \rangle(z)$ is a bound for $||u_h||_{W^{1,\infty}}$.

The vector $\bar{v}$ can be extended to a vector field on all of $T \subseteq \Omega$ via simple translation along the flat triangle $\Phi(T \subseteq \Omega)$, resulting in a constant vector field. We have $\text{div}_A \bar{v} = 0$.  

By definition, $\hat{V} \cdot \nabla_A u_h |_{T^c}$ is a constant function. This implies

$$
(\hat{V} \cdot \nabla_A u_h)(z) = \langle \hat{V} \cdot \nabla_A u_h, \delta^c \rangle_A \quad \text{by the definition of } \delta^c
$$

$$
= -\langle u_h, \hat{V} \cdot \nabla_A \delta^c \rangle_A \quad \text{integration by parts}
$$

$$
= -\langle u_h, |\det A|^{\frac{1}{2}} \hat{V} \cdot AA^{-1} \nabla \delta^c \rangle
$$

$$
= -\langle u_h, \nabla \delta^c \rangle , \quad (4.2)
$$

with $\nu := |\det A|^{\frac{1}{2}} \tilde{\nu}$. We note that,

$$
|\nu|^2 = \nu \cdot \nu \leq C \nu \cdot \nu \quad \text{by Lemma 3.1 both norms are equivalent})
$$

$$
\leq C|\det A|\tilde{\nu} \cdot \tilde{\nu} = C|\det A| \quad \text{(by the definition of } \tilde{\nu}),
$$

$$
|\nu| \leq C \left(1 + \|1 - |\det A|^{\frac{1}{2}} \|_{L^\infty} \right) \leq C \quad \text{(by Lemma 3.1, with a different } C). \quad (4.3)
$$

Our definition of $\nu$ makes it divergence-free. This can be seen with the following calculation. Let $\rho \in H^1_0(T^c)$. Denoting by $\text{d}x_A$ the volume element used for integration in the disturbed metric, we obtain

$$
- \int_{T^c} \rho \, \text{div} \nu \, \text{d}x = \int_{T^c} \nabla \rho \cdot \nu \, \text{d}x = \int_{T^c} (A \nabla_A \rho) \cdot \nu \, \text{d}x = \int_{T^c} \nabla_A \rho \cdot \nu \, \text{d}x
$$

$$
= \int_{T^c} |\det A|^{-\frac{1}{2}} \nabla_A \rho \cdot \nu \, \text{d}x_A = \int_{T^c} \nabla_A \rho \cdot \nu \, \text{d}x_A
$$

$$
= - \int_{T^c} \rho \, \text{div} \tilde{\nu} \, \text{d}x_A = 0 ,
$$

and thus

$$
\text{div} \nu = 0 . \quad (4.4)
$$

We define the helper function $g^c \in H^1_0$ as the solution of a different Poisson problem,

$$
D(g^c, \xi) = \langle -\nu \cdot \nabla \delta^c, \xi \rangle \quad \forall \xi \in H^1_0 ,
$$

which is well-defined as $\delta^c$ is zero outside of an open set contained in $T^c$. It has an associated finite element problem with solution $g^c_h \in S_{h,0}$.

$$
D(g^c_h, \xi) = \langle -\nu \cdot \nabla \delta^c, \xi \rangle \quad \forall \xi \in S_{h,0} .
$$

We continue the calculation from (4.2),

$$
\langle u_h, -\nu \cdot \nabla \delta^c \rangle = D\langle u_h, g^c_h \rangle = D\langle u, g^c \rangle = D\langle u, g^c - g^c_h \rangle
$$

$$
= \langle u, -\nu \cdot \nabla \delta^c \rangle - D\langle u, g^c - g^c_h \rangle , \quad (4.6)
$$

$$
= \langle u, -\nu \cdot \nabla \delta^c \rangle \quad \text{by (4.4), therefore}
$$

$$
\langle u_h, -\nu \cdot \nabla \delta^c \rangle = \langle \nu \cdot \nabla u, \delta^c \rangle - D\langle u, g^c - g^c_h \rangle ,
$$

using the definitions of $g^c$, $g^c_h$, and $u_h$ respectively, as well as integration by parts. The last two terms of (4.6) will now be bounded separately.
The first term from (4.6) can be bounded by a direct calculation using the Hölder inequality,
\[
\langle \delta^z, v \cdot \nabla u \rangle \leq \| \delta^z \|_{L^1} \| v \|_{L^\infty} \| u \|_{W^{1,\infty}} \leq C \| u \|_{W^{1,\infty}}.
\]

To bound the second term from (4.6) we introduce the weight function \( \sigma : \Omega \to \mathbb{R} \),
\[
\sigma(z) = \sqrt{d(z)^2 + \kappa^2 h^2}.
\]
where \( d \) is the geodesic distance on \( \Omega \), and \( \kappa > 0 \) a constant. Let \( U := \{ x \in \Omega \mid d(x, z) < \kappa h \}, \ V := \{ x \in \Omega \mid d(x, z) \geq \kappa h \}. \) The area of \( U \) is bounded by \( C(\kappa h)^2 \). We can estimate, for small enough \( \alpha > 0 \),
\[
\int_{\Omega} \sigma^{-\alpha - 2} \, dx = \left( \frac{1}{2} \right)^{\frac{\alpha + 2}{\alpha - 2}} \int_{\Omega} \left( \frac{1}{2} \right)^{\frac{\alpha + 2}{\alpha - 2}} (d(z)^2 + \kappa^2 h^2)^{-\frac{\alpha - 2}{2}} \, dx
\]
\[
\leq 2 \left( \frac{1}{2} \right)^{\frac{\alpha + 2}{\alpha - 2}} \int_{U} (d(z)^2 + \kappa^2 h^2)^{-\frac{\alpha - 2}{2}} \, dx \quad \text{(by convexity)}
\]
\[
\leq C \left( \int_{U} (\kappa h)^{-\alpha - 2} \, dx + \int_{V} (d(z)^2 + \kappa^2 h^2)^{-\frac{\alpha - 2}{2}} \, dx \right) \quad (4.8)
\]
\[
\leq C \left( \int_{0}^{2\pi} (\kappa h)^{-\alpha - 2} r \, dr \right) \quad \text{(switch to polar coordinates with volume form \( \theta \), bounded from above and below, and surface boundary \( M \) for integration bounds)}
\]
\[
\leq C (\kappa^{-\alpha} + (1 - (\kappa^{-\alpha})^{-1})) \leq C \alpha^{-1} (\kappa^{-\alpha} - \alpha).
\]

While this calculation assumes the surface can be parametrized with geodesic polar coordinates around \( z \), a similar argument works if this is not possible by partitioning the surface into parameterizable patches.

Application of Hölder’s inequality and (4.8) to the second remaining part of (4.2) gives, for appropriate \( \lambda \),
\[
|D(u, g^z - g_h^z)| \leq \|u\|_{W^{1,\infty}} \int_{\Omega} \left| \nabla (g^z - g_h^z) \right| \, dx
\]
\[
\leq \|u\|_{W^{1,\infty}} \left( \int_{\Omega} \left| \nabla (g^z - g_h^z) \right|^2 \sigma^2 \, dx \right)^{1/2} \left( \int_{\Omega} \sigma^{-2-\lambda} \, dx \right)^{1/2}
\]
\[
\leq C\lambda^{-1} (\kappa h)^{-\frac{1}{2}} \|u\|_{W^{1,\infty}} \left( \int_{\Omega} \left| \nabla (g^z - g_h^z) \right|^2 \sigma^2 \, dx \right)^{1/2}. \quad (4.9)
\]

By Lemma A.7, for appropriate \( \kappa, \lambda > 0 \), we have \( \int_{\Omega} \left| \nabla (g^z - g_h^z) \right|^2 \sigma^2 \, dx \leq C_{\kappa, \lambda} h^\lambda \). Plugging this into (4.9) gives
\[
|D(u, g^z - g_h^z)| \leq C_{\kappa, \lambda} \lambda^{-1} \kappa^{-\frac{1}{2}} \|u\|_{W^{1,\infty}},
\]
Having bounded the two terms from (4.6), we now have
\[ \| \nabla u_h \|_{L^\infty} \leq C \| u \|_{W^{1,\infty}}, \]
where finally the constant \( C \) depends on \( \kappa \) and \( \lambda \). This proves the theorem. \( \square \)

**Corollary 4.1** Let \( u \in W^{2,m}(\Omega) \). Then we have
\[ \| u - R_{h,0} u \|_{W^{1,\infty}} \leq Ch \| u \|_{W^{2,\infty}} \]

**Proof.** Using the vertexwise interpolation \( I_h \) from Wardetzky (2006, Section 3.3.2), as well as estimates for the flat case (Braess, 2007) (which transfer seamlessly (Wardetzky, 2006, Lemma 3.3.1)), we know that
\[ \| u - R_{h,0} u \|_{W^{1,\infty}} \leq \| u - I_h u \|_{W^{1,\infty}} + \| I_h u - R_{h,0} u \|_{W^{1,\infty}} \leq \| u - I_h u \|_{W^{1,\infty}} + \| R_{h,0} (I_h u - u) \|_{W^{1,\infty}} \]
\[ \leq \| u - I_h u \|_{W^{1,\infty}} + \| I_h u - u \|_{W^{1,\infty}} \leq C h \| u \|_{W^{2,\infty}}. \]

\( \square \)

5. Mixed Finite Elements

With the discrete geometry and discrete function spaces in place, we can now turn towards discretizing the problem (2.2) in its mixed form (2.3).

Using the disturbed and undisturbed inner products on \( \Omega \) leads to two discrete mixed problems. The discrete problem with respect to the undisturbed metric takes the form
\[
\begin{align*}
D \left( \tilde{u}_h^1, \xi \right) & = \langle f, \xi \rangle \quad \forall \xi \in S_{h,0} \\
D \left( \tilde{u}_h^2, \eta \right) & = \langle \tilde{u}_h^2, \eta \rangle \quad \forall \eta \in S_h,
\end{align*}
\]
(5.1)

where \( \tilde{u}_h^1 \in S_{h,0} \), \( \tilde{u}_h^2 \in S_h \), and \( f \in L^2 \). This problem is only an auxiliary problem for our proof. Its operators are never computed in practice. In practice, one only solves the discrete problem with respect to the disturbed metric,
\[
\begin{align*}
D \left( u_h^1, \xi \right)_A & = \langle f, \xi \rangle_A \quad \forall \xi \in S_{h,0} \\
D \left( u_h^2, \eta \right)_A & = \langle u_h^2, \eta \rangle_A \quad \forall \eta \in S_h,
\end{align*}
\]
(5.2)

where \( u_h^1 \in S_{h,0} \), \( u_h^2 \in S_h \), and \( f \in L^2 \). If the surface has no boundary, the solutions of (5.1) and (5.2) additionally have to fulfill the zero mean property from Definition 2.1.

Notice that, although the latter problem is formulated in terms of the distorted inner products on \( \Omega \), it is actually the discrete mixed problem with operators computed on the mesh \( \Omega_h \). The distorted \( L^2 \) inner product corresponds to the mass matrix, and the distorted \( H^1_0 \) inner product corresponds to the Lagrangian piecewise linear FEM stiffness matrix. In the planar case of Scholz (1978) the two discrete problems coincide.

Existence and uniqueness for (5.1) and (5.2) follow from an argument by Ciarlet (2002, Section 7), which we repeat here for convenience.
**Definition 5.1** We define the following three linear spaces:

\[ V := \{ (v_1, v_2) \in H_0^1 \times L^2 \mid D(v_1, \mu) = \langle v_2, \mu \rangle \forall \mu \in H^1 \} \]

\[ V^h := \{ (v_1, v_2) \in S_{h,0} \times S_{hL^2} \mid D(v_1, \mu) = \langle v_2, \mu \rangle \forall \mu \in S_h \} \quad (5.3) \]

\[ V^h_A := \{ (v_1, v_2) \in S_{h,0} \times S_{hL^2} \mid D(v_1, \mu)_A = \langle v_2, \mu \rangle_\Lambda \forall \mu \in S_h \} , \]

where the space \( S_{hL^2} \) is the space \( S_h \), but with the \( L^2 \) norm instead of its usual \( H^1 \) norm.

These spaces are Hilbert spaces, as they are closed linear subspaces of a Hilbert space. As an immediate consequence of Poincaré’s inequality we obtain that the resulting product norms on these spaces are equivalent to (simpler) norms that we heavily rely on going forward:

**Lemma 5.1** The product norms on \( V, V^h, V^h_A \) are equivalent to the norms induced by the inner products

\[ (v_1, v_2), (w_1, w_2) \mapsto \langle v_2, w_2 \rangle \text{ on } V, V^h \]

\[ (v_1, v_2), (w_1, w_2) \mapsto \langle v_2, w_2 \rangle_A \text{ on } V^h_A \] (5.4)

**Proof.** The symmetric bilinear mappings defined by (5.4) are indeed positive definite since \( v_2 = 0 \) implies \( v_1 = 0 \) for all elements \((v_1, v_2)\) in \( V, V^h, V^h_A \). Poincaré’s inequality implies that

\[ \| v_1 \|^2_{H^1_0} = D(v_1, v_1) = \langle v_2, v_1 \rangle = \| v_2 \|_{L^2} \| v_1 \|_{L^2} \leq C\| v_2 \|_{L^2} \| v_1 \|_{H^1_0} . \]

Therefore, \( \| v_1 \|^2_{H^1_0} \leq C\| v_2 \|_{L^2} \), which proves the lemma for \( V \). By Lemma 3.2, an identical derivation holds for \( V^h, V^h_A \). \( \square \)

On these linear spaces we can define the functionals

\[ J((v_1, v_2)) := \frac{1}{2} \langle v_2, v_2 \rangle - F((v_1, v_2)) \]

\[ J_A((v_1, v_2)) := \frac{1}{2} \langle v_2, v_2 \rangle_A - F((v_1, v_2)) \]

for some dual function \( F \in V', (V^h)' \), \((V^h_A)'\).

The functionals from (5.5) have unique minimizers:

**Lemma 5.2** (Existence and uniqueness for the mixed biharmonic problem) Minimizing \( J \) over \( V, V^h \) and minimizing \( J_A \) over \( V^h_A \) has a unique solution.

**Proof.** A simple consequence of Lemma 5.1 together with the Riesz representation theorem. \( \square \)

We write

\[
(u_1, u_2) = \arg\min_{(v_1, v_2) \in V} J((v_1, v_2))
\]

\[
(\hat{u}_1^h, \hat{u}_2^h) = \arg\min_{(v_1, v_2) \in V^h} J((v_1, v_2))
\]

\[
(\tilde{u}_1^h, \tilde{u}_2^h) = \arg\min_{(v_1, v_2) \in V^h_A} J_A((v_1, v_2)) .
\]

(5.6)
The Euler–Lagrange equations corresponding to these minimization problems take the form
\[
\langle u_2, v_2 \rangle = F((v_1, v_2)) \quad \forall (v_1, v_2) \in V
\]
\[
\langle \tilde{u}_2^h, v_2 \rangle = F((v_1, v_2)) \quad \forall (v_1, v_2) \in V^h
\]
\[
\langle u_2^h, v_2 \rangle_A = F((v_1, v_2)) \quad \forall (v_1, v_2) \in V_A^h.
\]  
(5.7)

Combined with the linear constraints from the definition of the spaces \( V, V^h, V_A^h \) in (5.3), these are the mixed problems from (2.3), (5.1), and (5.2), respectively, by defining \( F(v_1, v_2) := \langle v_1, f \rangle \) on \( V, V^h \) and \( F(v_1, v_2) := \langle v_1, f \rangle_A \) on \( V_A^h \).

Lemma 5.2 ensures existence and uniqueness of the mixed formulation of the biharmonic equation. Notice, however, that Lemma 5.2 does not show that \( u_1 \in H^4 \). Indeed, one requires an additional argument to show that \( u_1 \in H^2 \) (Ciarlet, 2002, Theorem 7.1.1), and then standard regularity estimates (Gazzola et al., 2010, Section 2.5.2) to show \( u_1 \in H^4 \). If these regularity estimates do not hold—for example because the surface or its boundary are not smooth enough—the minimization problem on \( V \) still has a unique minimizer, but this minimizer does not solve the weak biharmonic equation (2.2), see Stylianou (2010, Section 4.3). This in itself does not lead to problems in our setting, since we assume regularity of \( u_1 \). For the same reason, however, Lemma 5.2 only shows that the \( H^4_0 \) norms of \( \tilde{u}_1^h, u_1^h \) are bounded independently of \( h \) and likewise, that the \( L^2 \) norms of \( \tilde{u}_2^h, u_2^h \) are bounded independently of \( h \). We cannot infer boundedness of the \( H^4 \) norms of \( \tilde{u}_2^h, u_2^h \) independently of \( h \)—these norms could blow up as \( h \) decreases.

6. Convergence of the Numerical Method

It is somewhat surprising that the derivatives of \( \tilde{u}_2^h, u_2^h \) appear in the linear systems that we are solving, but the \( L^2 \)-norms of these derivatives cannot be bounded independently of \( h \). This indeed complicates the task of bounding errors between solutions of (2.3), (5.1), and (5.2). Scholz (1978) elegantly solves this issue by utilizing the Ritz interpolation in order to cancel contributions of derivatives of \( \tilde{u}_2^h \). However, this approach ceases to work for the case of curved geometries that are approximated by piecewise flat geometries. This is precisely why the curved case is more intricate than the flat one.

In the planar case, we have that \( u_1^h = \tilde{u}_1^h \) and \( u_2^h = \tilde{u}_2^h \) by construction. Scholz (1978) splits up the proof for the planar case into showing that \( u_2^h \) converges to \( u_2 \) and that \( u_1^h \) converges to \( u_1 \). In the curved case, a similar argument only works to show that \( \tilde{u}_2^h \) converges to \( u_2 \), and \( \tilde{u}_1^h \) converges to \( u_1 \), using the generalized \( L^\infty \) estimate of Section 4. Therefore, we require an additional step in order to show that \( u_2^h \) converges to \( \tilde{u}_2^h \).

6.1 Convergence of the discrete problem on the mesh to the discrete problem on the surface

In this section and Section 6.2 we treat the case of surfaces with nonempty boundary; the case of empty boundaries (treated later) is significantly simpler.

We rewrite the linear problem from (5.7) using linear operators.

**Lemma 6.1** Let \( L : V \rightarrow V' \), \( L^h : V^h \rightarrow (V^h)' \), and \( L_A^h : V_A^h \rightarrow (V_A^h)' \) denote the respective Riesz maps using the inner products defined in Lemma 5.1. The mixed biharmonic equation can be written as
\[
Lu = F, \quad L^h u^h = F^h, \quad L_A^h u_A^h = F_A^h,
\]  
(6.1)
for $F(v_1, v_2) := \langle v_1, f \rangle$ on $V$, $F^h(v_1, v_2) := \langle v_1, f \rangle$ on $V_h$, and $F^h_A(v_1, v_2) := \langle v_1, f \rangle_A$ on $V^h_A$.

So far, our treatment for the mixed biharmonic problem has considered the smooth setting alongside the two discrete settings. The next step, however, only works in the two discrete settings. We define a discrete Laplace operator $T$ that maps into the $L^2$-like space $S_{hL^2}$ from $S_{h,0}$. Such a construction is of course not possible in the smooth setting. In the discrete setting, however, we can identify the dual space of $S_{h,0}$ with a subspace of $S_{hL^2}$.

**Lemma 6.2 (Discrete Laplacians)** There exist bounded linear and injective operators $T^h, T^h_A : S_{h,0} \rightarrow S_{hL^2}$ such that

$$
\begin{align*}
\langle v_1, T^h v_1 \rangle &\in V^h & \forall v_1 \in S_{h,0} \\
\langle v_1, T^h_A v_1 \rangle &\in V^h_A & \forall v_1 \in S_{h,0}.
\end{align*}
$$

(6.2)

Moreover, every element in $V^h$ can be written as the pair $(v_1, T^h v_1)$, and every element in $V^h_A$ can be written as the tuple $(v_1, T^h_A v_1)$.

**Proof.** We prove the lemma for $T^h$, the proof for $T^h_A$ is similar. For all $(v_1, v_2) \in V^h$ we have that

$$D(v_1, \mu) = \langle v_2, \mu \rangle \quad \forall \mu \in S_h.$$ 

Written as a discrete linear equation, the right-hand side involves the mass matrix $M$ for piecewise linear Lagrange finite elements. This matrix is invertible. We can thus define $T^h v_1 := v_2 = M^{-1} S v_1$, where $S$ denotes the discrete Laplacian stiffness matrix with columns in $S_{h,0}$ and rows in $S_h$. The resulting operator is well-defined and linear.

Injectivity follows from the solvability of the Poisson equation. Indeed, $D(v_1, \eta) = 0 \forall \eta \in S_{h,0}$ has a unique solution $v_1 = 0 \in S_{h,0}$. This implies that the discrete Laplacian stiffness matrix has full column rank (it is not invertible, since we test with all $\mu \in S_h$). Since the mass matrix is invertible, $T^h$ has full column rank and is thus injective.

It remains to show that every element in $V^h$ can be written as a pair $(v_1, T^h v_1)$. In order to see that, let $(v_1, v_2) \in V^h$. Then, the definition of $V^h$ implies that

$$0 = D(0, \mu) = \langle v_2 - T^h v_1, \mu \rangle \quad \forall \mu \in S_h.$$ 

Therefore, $T^h v_1 = v_2$. \qed

**Remark 6.1** The linear operators $T^h, T^h_A$ are bounded, as they are discrete operators. This bound, however, is not independent of $h$.

The next result is central for relating solutions from the two discrete spaces.

**Lemma 6.3 (Inverse estimate)** We have that

$$
\left\| T^h v_1 - T^h_A v_1 \right\|_{L^2} \leq C h^{\sigma-1} \left\| v_1 \right\|_{H^1_0} \quad \forall v_1 \in S_{h,0},
$$

where the constant $C$ is independent of $h$. 

Proof. For \( \mu \in S_{hL^2} \) it holds that

\[
\langle T^h v_1 - T_A^h v_1, \mu \rangle = \langle T^h v_1, \mu \rangle - \langle T_A^h v_1, \mu \rangle - c(T_A^h v_1, \mu) = D(v_1, \mu) - D(v_1, \mu)_A - c(T_A^h v_1, \mu)
\]

\[
= d(v_1, \mu) - c(T_A^h v_1, \mu) \leq Ch^\sigma \|v_1\|_{H^0} \|\mu\|_{H^0} + Ch^\sigma \|T_A^h v_1\|_{L^2} \|\mu\|_{L^2}.
\]

Using the standard inverse estimate, we have that

\[
\|T_A^h v_1\|_{H^0} \leq Ch^{-1} \|T_A^h v_1\|_{L^2}.
\]

Therefore,

\[
\left\|T_A^h v_1\right\|_{L^2} \leq C \left\|T_A^h v_1\right\|_{L^2}^2 = CD \left\langle v_1, T_A^h v_1 \right\rangle_A \leq Ch^{-1} \|v_1\|_{H^0} \|T_A^h v_1\|_{L^2}
\]

\[
\|T_A^h v_1\|_{L^2} \leq C \|v_1\|_{H^0},
\]

which proves the lemma. \( \square \)

Using the maps \( T^h, T_A^h \) allows for constructing a map that relates the two spaces \( V^h \) and \( V_A^h \).

**Lemma 6.4** Let \( W : V^h \rightarrow V_A^h \) be the linear map such that

\[
W \left( \left( v_1, T^h v_1 \right) \right) = \left( v_1, T_A^h v_1 \right). \tag{6.3}
\]

\( W \) is well-defined, bounded independently of \( h \), invertible, and the inverse is also bounded independently of \( h \).

**Proof.** Well-definedness is clear by Lemma 6.2. \( W \) is invertible, as the inverse mapping is given by \( (v_1, T_A^h v_1) \mapsto (v_1, T^h v_1) \).

We now show the bound for \( W \); a similar argument works to show boundedness of the inverse. Let \( v_1 \in S_{h0} \). Then we obtain

\[
\|W \left( \left( v_1, T^h v_1 \right) \right) \|_{L^2} \leq C \|T_A^h v_1\|_{L^2} \leq C \|T^h v_1\|_{L^2} + C \|T_A^h v_1 - T^h v_1\|_{L^2}
\]

\[
\leq C \|T^h v_1\|_{L^2} + Ch^{\sigma - 1} \|v_1\|_{H^0},
\]

where the last inequality follows from Lemma 6.3. Using that \( \sigma > 1 \) and the equivalence of norms from Lemma 5.1, the claim follows. Thus, \( W \) is bounded independently of \( h \). \( \square \)

We denote by \( W' : (V^h)' \rightarrow (V_A^h)' \) the dual operator to \( W \). This operator is bounded independently of \( h \), it is invertible, and its inverse is bounded independently of \( h \). The operators \( W, W' \) provide the tool for relating the two discrete problems.

**Lemma 6.5** We have

\[
\left\|T^h W^{-1} - W' L^h A\right\| \leq Ch^{\sigma - 1}.
\]
Proof. Let \((v_1, T^h_{A} v_1) \in V^h, (w_1, T^h_{A} w_1) \in V^h\). Then
\[
(L^hW^{-1} - W'^{h}L^h_{A}) \left( (v_1, T^h_{A} v_1) \right) \left( (w_1, T^h_{A} w_1) \right) = \left\langle T^h_{A} v_1, T^h_{A} w_1 \right\rangle - \left\langle T^h_{A} v_1, T^h_{A} w_1 \right\rangle_A
\]
\[
= c(T^h_{A} v_1, T^h_{A} w_1) + \left\langle T^h_{A} v_1 - T^h_{A} v_1, T^h_{A} w_1 \right\rangle
\]
\[
+ \left\langle T^h_{A} v_1, T^h_{A} w_1 - T^h_{A} w_1 \right\rangle
\]
\[
\leq Ch^{-1}\left\| T^h_{A} v_1 \right\|_{L^2} \left\| T^h_{A} w_1 \right\|_{L^2},
\]
where we used Lemma 5.1 and Lemma 6.3.

We can now estimate the error for the solutions of the two discrete linear systems in Lemma 6.1.

**Lemma 6.6** Consider the following two linear problems for \(F^h \in (V^h)'\), \(F^h_{A} \in (V^h_A)'\),
\[
L^h u^h = F^h \quad \text{and} \quad L^h u^h_{A} = F^h_{A}.
\]
Then we have that
\[
\left\| W u^h - u^h_{A} \right\| \leq Ch^{-1}\left\| F^h_{A} \right\| + C \left\| F^h - W'F^h_{A} \right\|.
\]

Proof. By assumption we have that
\[
W'L^h_{A} u^h_{A} = W'F^h_{A} \quad \Rightarrow \quad u^h_{A} = \left( W'L^h_{A} \right)^{-1} W'F^h_{A}
\]
\[
u^h = \left( L^h \right)^{-1} F^h \quad \Rightarrow \quad W u^h = \left( L^hW^{-1} \right)^{-1} F^h.
\]
Combining these gives
\[
W u^h - u^h_{A} = \left( \left( L^hW^{-1} \right)^{-1} - \left( W'L^h_{A} \right)^{-1} \right) (W'F^h_{A}) + \left( L^hW^{-1} \right)^{-1} (F^h - W'F^h_{A}).
\]
Using Lemma 6.5 and the fact that all relevant operators are invertible and bounded independently of \(h\) gives
\[
\left\| \left( L^hW^{-1} \right)^{-1} - \left( W'L^h_{A} \right)^{-1} \right\| \leq \left\| \left( L^hW^{-1} \right)^{-1} \right\| \left\| L^hW^{-1} - W'L^h_{A} \right\| \left\| \left( W'L^h_{A} \right)^{-1} \right\| \leq Ch^{-1},
\]
and thus
\[
\left\| W u^h - u^h_{A} \right\| \leq Ch^{-1}\left\| F^h_{A} \right\| + C \left\| F^h - W'F^h_{A} \right\|.
\]

The main result of this section relates the two discrete problems (5.1) and (5.2) that we use in our mixed finite element method.

**Theorem 6.1** Let \(\tilde{u}^h_1, \tilde{u}^h_2\) solve problem (5.1), and let \(u^h_1, u^h_2\) solve problem (5.2). Then
\[
\left\| u^h_2 - \tilde{u}^h_2 \right\|_{L^2} \leq Ch^{-1}\|f\|_{L^2}.
\]
Proof. Let $\mathbf{u}^h = (\tilde{u}_1^h, \tilde{u}_2^h)$, $\mathbf{u}^*_h = (u_1^h, u_2^h)$, $F^h((v_1, v_2)) = \langle f, v_1 \rangle$, $F^h_A((v_1, v_2)) = \langle f, v_1 \rangle_A$. Then

$$
\left\| \mathbf{u}^h_2 - \mathbf{u}^*_h \right\|_{L^2} = \left\| T^h_A \mathbf{u}_1^h - T^h_A \mathbf{u}_1^*_h \right\|_{L^2} \\
\leq \left\| T^h_A \mathbf{u}_1^h - T^h_A \mathbf{u}_1^*_h \right\|_{L^2} + \left\| T^h_A \mathbf{u}_1^*_h - T^h \mathbf{u}_1^h \right\|_{L^2} \\
\leq C \left\| \mathbf{u}^h_A - W \mathbf{u}^h \right\| + \left\| T^h A \mathbf{u}_1^h - T^h \mathbf{u}_1^h \right\|_{L^2} \quad \text{(by Lemma 6.4)} \\
\leq C \left\| \mathbf{u}^h_A - W \mathbf{u}^h \right\| + C\sigma^{-1} \left\| \mathbf{u}^h_A \right\|_{H^0} \quad \text{(by Lemma 6.3)} \\
\leq C\sigma^{-1} \left( \left\| F^h \right\| + \left\| F^h_A \right\| \right) + C \left\| F^h - W^T F^h_A \right\| \quad \text{(by Lemma 6.6)} .
$$

It remains to deal with the right-hand sides. By the equivalence of norms, $\left\| F^h \right\|, \left\| F^h_A \right\| \leq C \left\| f \right\|_{L^2}$.

For $(v_1, T^h v_1) \in V^h$ we have that

$$
\left( F^h - W^T F^h_A \right) \left( (v_1, T^h v_1) \right) = \langle f, v_1 \rangle - \langle f, v_1 \rangle_A = \mathcal{E}(f, v_1) \quad \text{and hence}
$$

$$
\left\| F^h - W^T F^h_A \right\| \leq C\sigma \left\| f \right\|_{L^2} \left\| T^h v_1 \right\|_{L^2} \quad \text{(by Lemma 5.1)} ,
$$

$$
\left\| F^h - W^T F^h_A \right\| \leq C\sigma \left\| f \right\|_{L^2} .
$$

This proves the result. \[\square\]

6.2 Convergence of the discrete problem on the surface to the exact solution

Having successfully bounded the error between the discrete problem on the mesh (with solution $(u_1^h, u_2^h)$) and the discrete problem on the surface (with solution $(\tilde{u}_1^h, \tilde{u}_2^h)$), we move on to bounding the error between $(\tilde{u}_1^h, \tilde{u}_2^h)$ and the exact solution, $(u_1, u_2)$. Our proof follows the roadmap laid out by Scholz (1978). However, we require considerable adjustments to extend this approach to curved surfaces.

We start with an extension of Scholz’s Lemma to curved surfaces, using the generalization of the theorem of Rannacher & Scott (1982) from Section 4.

**Lemma 6.7 (Scholz’s Lemma)** Let $u \in H^1_0 \cap W^{2,\infty}$. Let $\eta \in S_h$. Then

$$
\left| D \langle u - R_{h,0} u, \eta \rangle \right| \leq C\sqrt{h} \left\| u \right\|_{W^{2,-}} \left\| \eta \right\|_{L^2} .
$$

**Proof.** The proof is virtually identical to the proof of Scholz (1978). Let $\xi \in S_{h,0}$ interpolate $\eta$ on all interior vertices of the mesh. Let $\varphi := \eta - \xi$.

By the definition of Ritz interpolation, we have that

$$
D \langle u - R_{h,0} u, \eta \rangle = D \langle u - R_{h,0} u, \varphi \rangle .
$$

As $\varphi$ is only supported on the boundary triangles $T$, the last equation can be simplified to

$$
\left| D \langle u - R_{h,0} u, \eta \rangle \right| = \left| \sum_{t \in T} \int_T \nabla (u - R_{h,0} u) \cdot \nabla \varphi \, dx \right| \leq C h^2 \left\| u - R_{h,0} u \right\|_{W^{1,-}(t)} \sum_{t \in T} \left\| \varphi \right\|_{W^{1,-}(t)} .
$$
where we used the fact that the area of a triangle is bounded by \( Ch^2 \), where the \( C \) depends on the triangle regularity constants.

By the standard inverse estimate we can conclude that \( \| \varphi \|_{W^{1,\infty}(T)} \leq C h^{-1} \| \varphi \|_{L^2(T)} \). By definition, \( \| \varphi \|_{L^2(T)} \leq C \| \eta \|_{L^2(T)} \). Moreover, using a per-triangle calculation, we can obtain that \( \| \eta \|_{L^2(T)} \leq C h^{-1} \| \eta \|_{L^2(T)} \). Thus we conclude

\[
| D(u - R_{h,0}u, \eta) | \leq C \| u - R_{h,0}u \|_{W^{1,\infty}} \sum_{i \in T} \| \eta \|_{L^2(i)} \leq Ch^{-1} \| u - R_{h,0}u \|_{W^{1,\infty}} \| \eta \|_{L^2},
\]

where we used the fact that the number of triangles in \( T \) is \( \sim h^{-1} \).

The estimate by Rannacher & Scott (1982), which is generalized to curved surfaces in Corollary 4.1, states that

\[
\| u - R_{h,0}u \|_{W^{1,\infty}} \leq Ch \| u \|_{W^{2,\infty}},
\]

which proves the lemma.

Using this lemma we can now estimate the error in \( u_2 \). This mirrors the first part of Theorem 1 by Scholz (1978), but we achieve a bound of order \( \sqrt{h} \) instead of Scholz’s \( \log h \) due to the improved Lemma 6.7.

**Theorem 6.2** Let \( u_{1,2} \) solve the smooth mixed biharmonic problem (2.3), and let \( u_{1,2}^h \) solve the discrete mixed biharmonic problem (5.2) on the mesh. Then one has

\[
\| u_2 - u_{\bar{h}}^2 \|_{L^2} \leq C \sqrt{h} \| f \|_{L^2}.
\]

**Proof.** Using Theorem 6.1 (together with the fact that \( \sigma \geq \frac{3}{2} \)), it suffices to prove the estimate with \( \bar{u}_2^h \) instead of \( u_2 \). Using Lemma 3.4, it is enough to prove the estimate with \( R_{h,2} \) instead of \( u_2 \).

We note that

\[
D\left( \bar{u}_2^h - R_{h,0}u_1, \bar{u}_2^h - R_{h,0}u_2 \right) = D\left( \bar{u}_1^h - R_{h,0}u_1, \bar{u}_2^h - R_{h,0}u_2 \right) = 0,
\]

using the definition of Ritz interpolation for the first equality and using the smooth and discrete formulations of the mixed biharmonic problems for the second equality.

Thus we can compute

\[
\| \bar{u}_2^h - R_{h,0}u_2 \|_{L^2}^2 = \left( \bar{u}_2^h - R_{h,0}u_2, \bar{u}_2^h - R_{h,0}u_2 \right) - D\left( \bar{u}_1^h - R_{h,0}u_1, \bar{u}_2^h - R_{h,0}u_2 \right) = \left( u_2 - R_{h,0}u_2, \bar{u}_2^h - R_{h,0}u_2 \right) + D\left( R_{h,0}u_1 - u_1, \bar{u}_2^h - R_{h,0}u_2 \right),
\]

where we again used the (smooth and discrete) formulations of the mixed biharmonic problems. The first of the two remaining terms can be estimated using (3.4). The second remaining term is covered by Lemma 6.7 and the fact that \( \| u_1 \|_{W^{2,\infty}} \leq C \| u_1 \|_{H^4} \leq C \| f \|_{L^2} \). Division by \( \| \bar{u}_2^h - R_{h,0}u_2 \|_{L^2} \) then proves the theorem.
It remains to compute the error in $u_1$. The next theorem follows the second part of Theorem 1 by Scholz (1978), but requires additional work due to the curved geometries. Because of Lemma 6.7, we achieve convergence of order $h$ here.

**Theorem 6.3** We have that 

$$ \left\| u_1 - u_1^h \right\|_{L^2} \leq Ch\|f\|_{L^2}.$$  

**Proof.** Since $u_1 - u_1^h \in H_0^1$, by assumption the biharmonic equation $\Delta^2 w = u_1 - u_1^h$ with zero Dirichlet and Neumann boundary conditions has a unique solution $w \in H_0^1 \cap H^4$. As before, we use the geometers’ convention that the Laplacian be positive semidefinite.

We use the mixed biharmonic PDEs, Ritz interpolation, and integration by parts repeatedly to obtain

$$ \left\| u_1 - u_1^h \right\|_{L^2}^2 = \left\langle u_1 - u_1^h, \Delta^2 w \right\rangle = D\left\langle u_1 - u_1^h, \Delta w \right\rangle - d(u_1^h, R_h \Delta w) - d(u_1^h, R_h \Delta w) - d(u_1^h, R_h \Delta w) - d(u_1^h, R_h \Delta w) .$$

Using (3.4), the first term of the last expression can be bounded by

$$ D\left\langle u_1 - u_1^h, \Delta w - R_h \Delta w \right\rangle \leq C h^2 \|f\|_{L^2} \|w\|_{H^4} .$$

We can bound the second term as follows,

$$ \left| D\left\langle u_2 - u_1^h, \Delta w - R_h \Delta w \right\rangle \right| \leq \left| D\left\langle u_2 - R_h u_2, w - R_h w \right\rangle \right| + \left| D\left\langle u_2 - R_h u_2, w - R_h w \right\rangle \right| \leq C h^2 \|u_2^h\|_{H^2} \|w\|_{H^2} + C h \|f\|_{L^2} \|w\|_{L^2} .$$

Using (3.4) and Theorem 6.2, the bound for the third term is

$$ \left| \left\langle u_2 - u_1^h, \Delta w - R_h \Delta w \right\rangle \right| \leq C h^2 \|f\|_{L^2} \|w\|_{H^4} .$$

Finally, three of the remaining terms can be bounded as

$$ \left| d(u_1^h, R_h \Delta w) \right| + \left| c(u_2^h, R_h \Delta w) \right| + \left| c(f, R_h w) \right| \leq C h^2 \|f\|_{L^2} \|w\|_{H^4} ,$$

where we used Lemma 3.3 and (3.4).

In order to bound the last remaining term, observe that

$$ \left| d(u_2^h, R_h w) \right| \leq C h^2 \|u_2^h\|_{H^1} \|R_h w\|_{H^1} \leq C h^2 \|u_2^h\|_{H^1} \|w\|_{H^1} ,$$

$$ \|u_2^h\|_{H^1} \leq \|R_h u_2\|_{H^1} + \|u_2^h - R_h u_2\|_{H^1} \leq C \|u_2\|_{H^1} + C h^2 \|u_2^h - R_h u_2\|_{L^2} \leq C \|f\|_{L^2} + C h^{-\frac{1}{2}} \|f\|_{L^2} \leq C h^{-\frac{1}{2}} \|f\|_{L^2} ,$$

$$ \left| d(u_2^h, R_h w) \right| \leq C h^{-\frac{1}{2}} \|f\|_{L^2} \|w\|_{H^1} .$$
where we used Lemma 3.3, Lemma 3.4, and Theorem 6.2.

Using that $\Delta^2 w = u_1 - u_h^1$, we obtain $\|w\|_{H^4} \leq C \|u_1 - u_h^1\|_{L^2}$. Together with the assumption that $\sigma \geq \frac{3}{2}$, these estimates show that

$$\|u_1 - u_h^1\|_{H^1} \leq Ch \|f\|_{L^2}$$

which proves the theorem. $\square$

A simple corollary provides a convergence rate of $h^{3/4}$ for the gradient of $u_1$.

**Corollary 6.1** We have that $\|u_1 - u_h^1\|_{H^1} \leq Ch^{3/4} \|f\|_{L^2}$

**Proof.** Using the mixed biharmonic problem, it follows that

$$D\left(u_h^1 - u_1, u_h^1 - u_1\right) = \left<u_h^1 - u_2, u_h^1 - u_1\right> + d(u_h^1, u_h^1 - u_1) - c(u_h^1, u_h^1 - u_1)$$

$$\|u_1 - u_h^1\|_{H^1}^2 \leq Ch^{2}\|f\|_{L^2} + Ch^{\sigma} \|f\|_{L^2}^2 + Ch^{\sigma+1} \|f\|_{L^2}^2$$

where we applied the estimates from Lemma 3.3, the fact that the solution of the discrete problem is bounded, and going through the Ritz approximation as an intermediate. Since we assumed that $\sigma \geq \frac{3}{2}$, this proves the corollary. $\square$

### 6.3 The no-boundary case

Here we provide the proof for the case of empty boundary, which is much simpler than the case of a nonempty boundary. If there is no boundary, the mixed formulation decouples, as $H^1_0 = H^1$ and $S_{h,0} = S_h$. In this case, we obtain the better convergence rate:

**Theorem 6.4** It holds that

$$\|u_1 - u_h^1\|_{L^2} + h \|u_1 - u_h^1\|_{H^1} \leq Ch^2 \|f\|_{L^2}$$

**Proof.** Since $H^1_0 = H^1$ and $S_{h,0} = S_h$, equations (2.3) and (5.2) decouple into two Poisson equations. By Wardetzky (2006, Theorem 3.3.3) it holds that

$$\|u_1 - u_h^1\|_{L^2} + h \|u_1 - u_h^1\|_{H^1} \leq Ch^2 \|f\|_{L^2} .$$

We ensured that our solutions are modulo harmonic functions in Definition 2.1.

To bound the error in $u_h^1$ we turn to the solution $v_1 \in S_{h,0}$ of the discrete Poisson problem

$$D\left(v_h^1, \eta\right)_A = \left<u_2, \eta\right>_A \quad \forall \eta \in S_{h,0} .$$

(6.5)
As $v_1^h$ is the solution to a discrete Poisson problem, we obtain

$$\left\| v_1^h - u_1 \right\|_{L^2}^2 + h \left\| v_1^h - u_1 \right\|_{H^1}^2 \leq Ch^2 \left\| u_2 \right\|_{L^2} \leq Ch^2 \left\| f \right\|_{L^2} . \quad (6.6)$$

As for the error between $u_1^h$ and $v_1^h$, we know that

$$\left\| u_1^h - v_1^h \right\|_{H^1_0}^2 \leq C \left\| (u_2^h - u_2, u_1^h - v_1^h) \right\|_{A} \leq C \left\| u_2^h - u_2 \right\|_{L^2} \left\| u_1^h - v_1^h \right\|_{H^1_0} , \quad (6.7)$$

Combining (6.6) and (6.7), and using the classical Aubin-Nitsche trick for the Poisson problem we obtain that

$$\left\| u_1^h - u_1 \right\|_{L^2} + h \left\| u_1^h - u_1 \right\|_{H^1} \leq Ch^2 \left\| f \right\|_{L^2} ,$$

which proves the theorem.

7. Experiments

We performed a variety of experiments using the mixed finite element method to solve the biharmonic equation on a curved surface approximated by a triangle mesh.

Figure 2 shows a boundary value problem solved on a spherical cap using the mixed finite element method. The observed convergence rates obey the theoretical convergence rates of Section 6: convergence of order $h$ in the solution, convergence of order $h^3_1$ in the derivative of the solution, and convergence of order $h^5_1$ in the Laplacian of the solution.

In Figure 3 the importance of the triangle regularity condition can be seen. The standard Schwarz lantern fulfills conditions (C1-C5) if it fulfills the triangle regularity condition. This is only the case if
Convergence depends on the proportion of the number of vertices along the equator $m$ and the number of vertices along the axis of rotational symmetry $n$. While we observe convergence for $m \sim n$, we no longer observe it for $m \sim n^2$.

the ratio between the number of vertices along its equator $m$ is proportional to the number of vertices along its axis of rotational symmetry $n$. If, on refinement, $m$ increases much more quickly than $n$, such as when $m \sim n^2$, the mixed finite element method does not converge anymore, even though the discrete surface converges to the smooth surface pointwise.

Acknowledgments

We thank Prof. Qiang Du for insightful discussion on the topic of finite elements for curved surfaces. We thank Henrique Maia and Anne Fleming for proofreading.

REFERENCES

Appendix A: An $L^\infty$ estimate for the flat Poisson equation with a discontinuous differential operator

In this section we prove an important lemma that is used in the proof of Theorem 4.1. It corresponds to Lemma 8.2.6 by Brenner & Scott (2008), but the proof follows the simpler approach by Rannacher & Scott (1982), since we only deal with basic piecewise linear finite elements. The proof is very similar with small adjustments to account for the fact that the calculation happens on curved surfaces. We use the terminology and definitions of Section 4 in this appendix.

We start by stating a few basic facts about our weight function.

**Lemma A.1** For the weight function $\sigma_z(x) = \sqrt{d(x, z)^2 + \kappa^2 h^2}$ from (4.7), we have

$$
\left| D^k \sigma^j_z \right| \leq C \sigma^j_z - \kappa^j h^{j-k} ,
$$

where $D^k$ is the vector of all partial derivatives of order $k$. The constant $C$ smoothly depends on $j$ and $k$. For fixed $\kappa$ and $j - k < 0$, the bound is just $C(\kappa h)^{j-k}$, since there is always a $h$ small enough, and “for small enough $h$” is implied everywhere.

Additionally, let $v$ be a continuous function in $H^1$, and let it be $H^2$ within triangles, i.e., the summed per-triangle $H^2$ norm is bounded. Let $\alpha \in \mathbb{R}$. We have

$$
\int_\Omega \sigma^2_z \left| \nabla (v - I_h v) \right|^2 \, dx \leq Ch^2 \int_\Omega \sigma^2_z \left| D^2 v \right|^2 \, dx ,
$$

where $\int$ denotes integration over the interior of each triangle, summed up. The constant $C$ smoothly depends on $\alpha$ (for large enough $\kappa > 0$). If $\alpha$ is uniformly bounded, so is $C$.

**Proof.** (A.1) is clear from the definition of $\sigma_z$.

For (A.2), we first notice that for every triangle $T$ in our triangulation, since the surface is compact, and $\kappa, h > 0$,

$$
\sup_{x \in T} \sigma^2_z(x) / \inf_{x \in T} \sigma^2_z(x) \leq C ,
$$

with $C$ independent of the triangle or the triangulation (Brenner & Scott, 2008, (8.1.4)). Using (3.6) from Lemma 3.4 per triangle, this proves the lemma. $\square$

A helpful tool that will be used is Young’s inequality for products (Brenner & Scott, 2008, (0.9.5)). For any $a, b \in \mathbb{R}$, $\delta > 0$

$$
ab \leq \frac{\delta}{2} a^2 + \frac{1}{2\delta} b^2 .
$$

We will use it with $\delta = 2C$ to get $C a b \leq C^2 a^2 + \frac{1}{4}\delta b^2$. This trick allows us to separate a product into a sum, while making one summand so small that it can later be moved to the left side of an inequality.

The main goal of this appendix is bounding $\int_\Omega \left| \nabla (g - g_h) \right|^2 \sigma^{2+\lambda} \, dx$. This will be done in a sequence of consecutive lemmas.

**Lemma A.2** For sufficiently large $\kappa > 0$,

$$
\int_\Omega \left| \nabla (g - g_h) \right|^2 \sigma^{2+\lambda} \, dx \leq C \int_\Omega h^2 \sigma^{2+\lambda} \left| D^2 (g - g_h) \right|^2 + \sigma^\lambda \left( g - g_h \right)^2 \, dx .
$$
LINEAR MIXED FEM FOR THE BIHARMONIC EQUATION ON SURFACES

This is very similar to a result by Rannacher & Scott (1982), but in their version there is no $D^2 g^h$ on the right-hand side of the inequality, since in the flat case that term is zero.

Proof. Let $\psi = \sigma^{2+\lambda} (g^z - g^h)$. Then we have

$$\int_\Omega |\nabla (g^z - g^h)|^2 \sigma_z^{2+\lambda} \, dx = D\langle g^z - g^h, \psi \rangle = \int_\Omega (g^z - g^h) \nabla (g^z - g^h) \cdot \nabla \big( \sigma_z^{2+\lambda} \big) \, dx = D\langle g^z - g^h, \psi \rangle = \frac{1}{2} \int_\Omega \nabla ((g^z - g^h)^2) \cdot \nabla \big( \sigma_z^{2+\lambda} \big) \, dx.$$  (A.4)

Using the fact that $g^z$ and $g^h$ solve the Poisson equation and the discrete Poisson equation, respectively, we have $D\langle g^z - g^h, I_h \psi \rangle = 0$. Using Young’s and Hölder’s inequalities, this gives

$$|D\langle g^z - g^h, \psi \rangle| \leq C \int_\Omega |\nabla (g^z - g^h)||\nabla (\psi - I_h \psi)| \, dx \leq C \int_\Omega \sigma_z^{2+\lambda} |\nabla (g^z - g^h)|^2 \, dx \leq C \int_\Omega \sigma_z^{2+\lambda} |\nabla (\psi - I_h \psi)|^2 \, dx \leq \frac{1}{4} \int_\Omega \sigma_z^{2+\lambda} |\nabla (g^z - g^h)|^2 \, dx + C^2 \int_\Omega \sigma_z^{2-\lambda} |\nabla (\psi - I_h \psi)|^2 \, dx.$$

We continue, using (A.2) (and a new constant $C$),

$$|D\langle g^z - g^h, \psi \rangle| \leq \frac{1}{4} \int_\Omega \sigma_z^{2+\lambda} |\nabla (g^z - g^h)|^2 \, dx + C \int_\Omega \sigma_z^{2-\lambda} |\nabla (\psi - I_h \psi)|^2 \, dx \leq \frac{1}{4} \int_\Omega \sigma_z^{2+\lambda} |\nabla (g^z - g^h)|^2 \, dx + C \int_\Omega \sigma_z^{2-\lambda} |D^2 \psi|^2 \, dx,$$

$$\int_\Omega \sigma_z^{2-\lambda} |D^2 \psi|^2 \, dx \leq \int_\Omega \sigma_z^{2-\lambda} \big( \sigma_z^{2+\lambda} |D^2 (g^z - g^h)|^2 + 2 |\nabla \sigma_z^{2+\lambda}||\nabla (g^z - g^h)| + |D^2 \sigma_z^{2+\lambda}||g^z - g^h|^2 \big) \, dx \leq C \int_\Omega \sigma_z^{2+\lambda} |D^2 (g^z - g^h)|^2 + \sigma_z^{2-\lambda} |\nabla (g^z - g^h)|^2 + \sigma_z^{2-2} (g^z - g^h)^2 \, dx.$$

We now use (A.1) to bound $\sigma_z$ and its derivatives,

$$\int_\Omega \sigma_z^{2-\lambda} |D^2 \psi|^2 \, dx \leq C \int_\Omega \sigma_z^{2+\lambda} |D^2 (g^z - g^h)|^2 + (\kappa h)^{-2} \sigma_z^{2+\lambda} |\nabla (g^z - g^h)|^2 + (\kappa h)^{-2} \sigma_z^{2+\lambda} (g^z - g^h)^2 \, dx,$$

$$|D\langle g^z - g^h, \psi \rangle| \leq C h \int_\Omega \sigma_z^{2+\lambda} |D^2 (g^z - g^h)|^2 \, dx + \left( C \kappa^{-2} + \frac{1}{4} \right) \int_\Omega \sigma_z^{2+\lambda} |\nabla (g^z - g^h)|^2 \, dx + C \kappa^{-2} \int_\Omega \sigma_z^{2+\lambda} (g^z - g^h)^2 \, dx.$$  

This bounds the first term on the right side of the last line of (A.4), provided that $\kappa$ is large enough.

By (A.1),

$$\int_\Omega (g^z - g^h)^2 \Delta \big( \sigma_z^{2+\lambda} \big) \, dx \leq C \int_\Omega (g^z - g^h)^2 \sigma_z^{2+\lambda} \, dx.$$
This bounds the second term on the right side of the last line of (A.4), and proves the lemma.

The first term on the right side of Lemma A.2 contains the second derivatives of a function, weighted by powers of the function \( \sigma_z \). The following two lemmas provide a bound for this quantity.

**Lemma A.3** There is \( \lambda > 0 \) small enough such that,

\[
\int_{\Omega} \sigma_z^{2+\lambda} |D^2 g^\gamma|^2 \, dx \leq C \int_{\Omega} \sigma_z^{2+\lambda} |\nabla \delta^\gamma|^2 + \lambda^{-1} (\kappa h)^{-2} \sigma_z^{2+\lambda} |\delta^\gamma|^2 \, dx,
\]

where \( \delta^\gamma \) was defined in (4.1).

**Proof.** Using the product rule and (A.1) we have

\[
\int_{\Omega} \sigma_z^{2+\lambda} |D^2 g^\gamma|^2 \, dx \leq C \int_{\Omega} |D^2 \left( \sigma_z^{2+\lambda} g^\gamma \right)|^2 \, dx + C \int_{\Omega} \sigma_z^{1/2} |\nabla g^\gamma|^2 + \sigma_z^{\lambda-2} (g^\gamma)^2 \, dx
\]

\[
\leq C \int_{\Omega} \Delta \left( \sigma_z^{2+\lambda} g^\gamma \right) \, dx + C \int_{\Omega} \sigma_z^{1/2} |\nabla g^\gamma|^2 + \sigma_z^{\lambda-2} (g^\gamma)^2 \, dx.
\]

In the last step, we applied the regularity estimate \( \|v\|_{H^2} \leq C \|\Delta v\|_{L^2} \) to \( \sigma_z^{2+\lambda} g^\gamma \). Let \( \xi \in H_0^1 \). We now use the definition of \( g^\gamma \) from (4.5), integration by parts, (4.3), and (A.1) to obtain

\[
\left\langle \xi, \Delta \left( \sigma_z^{2+\lambda} g^\gamma \right) \right\rangle = D \left\langle \xi, \sigma_z^{2+\lambda} g^\gamma \right\rangle = \int_{\Omega} \nabla \xi \cdot \nabla \sigma_z^{1/2} \nabla g^\gamma + \nabla \xi \cdot \nabla \left( \sigma_z^{2+\lambda} g^\gamma \right) \, dx
\]

\[
= \int_{\Omega} \nabla \xi \cdot \nabla \left( \sigma_z^{2+\lambda} g^\gamma \right) \, dx - \xi \nabla \left( \sigma_z^{2+\lambda} g^\gamma \right) \cdot \nabla g^\gamma \, dx
\]

\[
= \left\langle \xi, \sigma_z^{2+\lambda} \nabla g^\gamma \right\rangle + \int_{\Omega} \nabla \xi \cdot \nabla \left( \sigma_z^{2+\lambda} g^\gamma \right) \, dx.
\]

Since \( H_0^1 \) is \( L^2 \)-dense in \( L^2 \), this gives us a bound for the \( L^2 \) norm of \( \Delta \left( \sigma_z^{2+\lambda} g^\gamma \right) \).

Plugging this into (A.5) gives

\[
\int_{\Omega} \Delta \left( \sigma_z^{2+\lambda} g^\gamma \right) \, dx \leq C \int_{\Omega} \sigma_z^{2+\lambda} |\nabla \delta^\gamma|^2 + \sigma_z^{1/2} |\nabla g^\gamma|^2 + \sigma_z^{\lambda-2} (g^\gamma)^2 \, dx,
\]

\[
\int_{\Omega} \sigma_z^{2+\lambda} |D^2 g^\gamma|^2 \, dx \leq C \int_{\Omega} \sigma_z^{2+\lambda} |\nabla \delta^\gamma|^2 \, dx + C \int_{\Omega} \sigma_z^{1/2} |\nabla g^\gamma|^2 + \sigma_z^{\lambda-2} (g^\gamma)^2 \, dx.
\]
Continuing the calculation, we obtain
\[
\int_{\Omega} \sigma_z^2 |\nabla g|^2 \, dx = \int_{\Omega} \nabla g \cdot \nabla \left( \sigma_z^2 g \right) - \nabla g \cdot \left( \nabla \sigma_z^2 \right) \, dx \quad \text{(product rule),}
\]
\[
\int_{\Omega} \nabla g \cdot \left( \nabla \sigma_z^2 \right) \, dx = \int_{\Omega} (g^z)^2 \left( \Delta \sigma_z^2 \right) - g^z \nabla g \cdot \left( \nabla \sigma_z^2 \right) \, dx \quad \text{(integration by parts),}
\]
\[
\int_{\Omega} \sigma_z^2 |\nabla g|^2 \, dx = \int_{\Omega} \nabla g \cdot \nabla \left( \sigma_z^2 g \right) - \frac{1}{2} (g^z)^2 \left( \Delta \sigma_z^2 \right) \, dx \quad \text{(A.7)}
\]
\[
\leq C \int_{\Omega} \nabla g \cdot \left( \sigma_z^2 g \right) + (g^z)^2 \sigma_z^{\lambda-2} \quad \text{(A.1)}
\]
\[
\leq C \int_{\Omega} -v \cdot \nabla \sigma_z^2 g + (g^z)^2 \sigma_z^{\lambda-2} \, dx \quad \text{(4.5).}
\]

After using (4.3), we can further bound \( \int_{\Omega} v \cdot \nabla \sigma_z^2 g \) using Young’s and Hölder’s inequalities,
\[
\int_{\Omega} v \cdot \nabla \sigma_z^2 g \, dx \leq C \int_{\Omega} |\nabla \sigma_z^2|^2 dx \leq C \left( \int_{\Omega} |\nabla \sigma_z^2|^2 + (g^z)^2 \alpha \right) \left( \int_{\Omega} (g^z)^2 \sigma_z^{\lambda-2} \, dx \right)^{\frac{1}{2}}.
\]

which, plugged back into (A.7) and then (A.6), gives
\[
\int_{\Omega} \sigma_z^{\lambda+2} |D^2 g|^2 \, dx \leq C \int_{\Omega} |\nabla \sigma_z^2|^2 \sigma_z^{\lambda+2} + (g^z)^2 \sigma_z^{\lambda-2} \, dx. \quad \text{(A.8)}
\]

We now use Hölder’s inequality as well as (4.8) to obtain
\[
\int_{\Omega} (g^z)^2 \sigma_z^{\lambda-2} \, dx \leq \left( \int_{\Omega} \sigma_z^{\lambda-2} \, dx \right) \left( \int_{\Omega} g^z \alpha \, dx \right)^{\frac{1}{2}} \left( \int_{\Omega} g^z \alpha \, dx \right)^{\frac{1}{2}} \leq C \left( \alpha^{-1} (\kappa h)^{-\lambda} \right) \left( \int_{\Omega} g^z \alpha \, dx \right)^{\frac{1}{2}} \left( \int_{\Omega} g^z \alpha \, dx \right)^{\frac{1}{2}}. \quad \text{(A.9)}
\]

This application of Hölder’s inequality is allowed for appropriate choices of \( \lambda > 0 \).

Let now \( w \in H_0^1 \cap H^2 \) such that \( Aw = \text{sign}(g^z) g^z \). We use the PDEs for \( g^z \) (found in (4.5)) and \( w \), integration by parts, as well as (4.4) to get
\[
\int_{\Omega} |g^z|^2 \alpha \, dx = \langle \text{sign}(g^z) g^z, \alpha \rangle = D(w, g^z) = \langle w, -v \cdot \nabla g^z \rangle = \langle v \cdot \nabla w, g^z \rangle.
\]

The last equality follows because \( v \) was defined carefully to be divergence-free.

To simplify notation, let \( \|w\|_{L^p} \) be the \( W^{k,p} \) norm, and \( \|w\|_p \) the \( L^p \) norm. Using the Hölder and Sobolev (Gilbarg & Trudinger, 2001, Theorem 7.10) inequalities, (4.3), (4.8), as well as the standard regularity estimate for the Poisson equation, we have
\[
\int_{\Omega} |g^z|^2 \alpha \, dx \leq C \|w\|_{L^p} \|\delta^2\|_{L^p} \leq C \|w\|_{L^p} \|\delta^2\|_{L^p},
\]
\[
\int_{\Omega} |\nabla g^z|^2 \alpha \, dx \leq C \left( \int_{\Omega} \sigma_z^{\lambda+2} |\delta^2|^2 \, dx \right)^{\frac{1}{2}} \left( \int_{\Omega} \sigma_z^{\lambda+2} \, dx \right)^{\frac{1}{2}},
\]
\[
\leq C \left( \lambda^{-1} (\kappa h)^{-\lambda} \right) \left( \int_{\Omega} \sigma_z^{\lambda+2} \, dx \right)^{\frac{1}{2}}.
\]
Plugged into (A.9) this gives
\[ \int_{\Omega} (g^2) \sigma_z^{2-\lambda} \, dx \leq C \left( \frac{1}{\lambda} (kh)^{-\lambda} \right)^{\lambda + \lambda} \left( \frac{h}{\lambda} (kh)^{-\lambda + \lambda} \right)^{\frac{\lambda}{2}} \int_{\Omega} \sigma_z^{\lambda+2} |\delta|^2 \, dx \]
\[ \leq C \lambda^{-1} (kh)^{-2} \int_{\Omega} \sigma_z^{\lambda+2} |\delta|^2 \, dx . \]

Now, plugging this into (A.8) gives
\[ \int_{\Omega} \sigma_z^{\lambda+2} |D^2 g|^2 \, dx \leq C \int_{\Omega} |\nabla \delta|^2 \sigma_z^{\lambda+2} + \lambda^{-1} (kh)^{-2} \sigma_z^{\lambda+2} |\delta|^2 \, dx . \]

**Lemma A.4** There is \( \lambda > 0 \) small enough such that,
\[ \int_{\Omega} \sigma_z^{2+\lambda} |\nabla g|^2 \, dx \leq C \int_{\Omega} \sigma_z^{2+\lambda} |\nabla \delta|^2 + \lambda^{-1} (kh)^{-2} \sigma_z^{2+\lambda} |\delta|^2 \, dx . \]

**Proof.** Using the product rule, (A.1), and the standard regularity estimate,
\[ \int_{\Omega} \sigma_z^{2+\lambda} |\nabla g|^2 \, dx \leq C \int_{\Omega} |\nabla \left( \sigma_z^{2+\lambda} g^2 \right)|^2 + \sigma_z^{2+\lambda} |g|^2 \, dx \leq C \int_{\Omega} |\Delta \left( \sigma_z^{2+\lambda} g^2 \right)|^2 + \sigma_z^{2+\lambda} |g|^2 \, dx \]
Because the surface \( \Omega \) is compact, for \( \lambda \) small enough we have \( \sigma_z^{2+\lambda} (x) \leq C \sigma(x)^{2+\lambda} \) pointwise. Thus \( \int_{\Omega} \sigma_z^{2+\lambda} |\nabla g|^2 \, dx \) is bounded by the same expression as the right-hand side of (A.5), and Lemma A.3 implies the result of this lemma.

**Lemma A.5** Let \( v, w \in H^1_0 \) such that
\[ \Delta v = w . \]
Then, for \( \lambda > 0 \) small enough,
\[ \int_{\Omega} \sigma_z^{2-\lambda} |D^2 v|^2 \, dx \leq C \lambda^{-1} (kh)^{-2} \int_{\Omega} \sigma_z^{2-\lambda} |\nabla w|^2 \, dx \]

**Proof.** Using Hölder’s inequality and (4.8), we have, for small enough \( \lambda > 0 \)
\[ \int_{\Omega} \sigma_z^{2-\lambda} |D^2 v|^2 \, dx \leq \left( \int_{\Omega} \sigma_z^{\lambda-\lambda} \, dx \right)^{\lambda} \|v\|_{\frac{2}{1-\lambda}}^2 \leq C \lambda^{-\lambda} (kh)^{-2-\lambda+2\lambda \|v\|_{\frac{2}{1-\lambda}}^2 , \]
where again, to simplify notation, \( \|v\|_{k,p} \) is the \( W^{k,p} \) norm. Using the standard regularity estimate for the Poisson equation, as well as Sobolev’s and Hölders inequality,
\[ \int_{\Omega} \sigma_z^{2-\lambda} |D^2 v|^2 \, dx \leq C \lambda^{-\lambda} (kh)^{-2} \|w\|_{\frac{2}{1-\lambda}}^2 \leq C \lambda^{-\lambda} (kh)^{-2} \|\nabla w\|_{\frac{2}{1-\lambda}}^2 \]
\[ \leq C \lambda^{-\lambda} (kh)^{-2} \left( \int_{\Omega} \sigma_z^{\lambda-\lambda} \, dx \right)^{1-\lambda} \int_{\Omega} \sigma_z^{2-\lambda} |\nabla w|^2 \, dx \]
\[ \leq C \lambda^{-1} (kh)^{-2} \int_{\Omega} \sigma_z^{2-\lambda} |\nabla w|^2 \, dx , \]
where we used (4.8) in the last step. This proves the lemma.

In their version of Lemma A.5, Rannacher & Scott (1982) use the fact that $\lambda > 0$ can be chosen to be arbitrarily small in order to use a regularity estimate of the form

$$\|u\|_{2,2+\mu} \leq C\|\Delta u\|_{2+\mu}.$$  

For polygonal boundaries, this only holds for small enough $\mu > 0$, depending on the polygon angles. In this work, we work with smooth boundaries, where this technique is not needed to apply the regularity estimate.

**Lemma A.6** For sufficiently large $\kappa > 0$, dependent on a sufficiently small $\lambda > 0$,

$$\int_{\Omega} \sigma_\kappa^2 (g^\kappa - g_h^\kappa)^2 \, dx \leq C\lambda^{-1} \kappa^{-1} \int_{\Omega} \sigma_\kappa^{2+\lambda} |\nabla (g^\kappa - g_h^\kappa)|^2 \, dx$$

**Proof.** We define another auxiliary Poisson problem. Let $v \in H^1_0 \cap H^2$ solve

$$\Delta v = \sigma_\kappa^2 (g^\kappa - g_h^\kappa).$$

By Lemma A.5 and (A.1) we have

$$\int_{\Omega} \sigma_\kappa^{-2-\lambda} |D^2 v|^2 \, dx \leq C\lambda^{-1} (\kappa h)^{-2} \int_{\Omega} \sigma_\kappa^{2-\lambda} |\nabla (\sigma_\kappa (g^\kappa - g_h^\kappa))|^2 \, dx$$

$$\leq C\lambda^{-1} (\kappa h)^{-2} \int_{\Omega} \sigma_\kappa^{2+\lambda} |\nabla (g^\kappa - g_h^\kappa)|^2 + \sigma_\kappa^{3} (g^\kappa - g_h^\kappa)^2 \, dx$$

Using the Poisson equation, the definition of $g_h$, and the Hölder inequality,

$$\int_{\Omega} \sigma_\kappa^{3} (g^\kappa - g_h^\kappa)^2 \, dx = D\langle g^\kappa - g_h^\kappa, v \rangle = D\langle g^\kappa - g_h^\kappa, v - I_h v \rangle$$

$$\leq \left( \int_{\Omega} \sigma_\kappa^{2+\lambda} |\nabla (g^\kappa - g_h^\kappa)|^2 \, dx \right)^{1/2} \left( \int_{\Omega} \sigma_\kappa^{2-\lambda} |\nabla (v - I_h v)|^2 \, dx \right)^{1/2}.$$

Using Lemma 3.4 and then (A.10) gives

$$\left( \int_{\Omega} \sigma_\kappa^{3} (g^\kappa - g_h^\kappa)^2 \, dx \right)^2 \leq C h^2 \left( \int_{\Omega} \sigma_\kappa^{2+\lambda} |\nabla (g^\kappa - g_h^\kappa)|^2 \, dx \right) \left( \int_{\Omega} \sigma_\kappa^{2-\lambda} |D^2 v|^2 \, dx \right)$$

$$\leq C\lambda^{-1} \kappa^{-2} \left( \int_{\Omega} \sigma_\kappa^{2+\lambda} |\nabla (g^\kappa - g_h^\kappa)|^2 \, dx \right)^2$$

$$+ \left( \int_{\Omega} \sigma_\kappa^{2+\lambda} |\nabla (g^\kappa - g_h^\kappa)|^2 \, dx \right) \left( \int_{\Omega} \sigma_\kappa^{3} (g^\kappa - g_h^\kappa)^2 \, dx \right).$$

Now, using Young’s inequality on the last line of (A.11) and choosing $\kappa$ large enough (possibly dependent on $\lambda$) gives

$$\int_{\Omega} \sigma_\kappa^{3} (g^\kappa - g_h^\kappa)^2 \, dx \leq C\lambda^{-1} \kappa^{-1} \int_{\Omega} \sigma_\kappa^{2+\lambda} |\nabla (g^\kappa - g_h^\kappa)|^2 \, dx.$$

Putting all of these bounds together, we come to the final result of this appendix.
Proof. Combining Lemma A.2 with Lemma A.6 gives

\[ \int_\Omega |\nabla (g^\circ - g^\circ_h)|^2 \sigma_z^{2+\lambda} \, dx \leq C_{\lambda,\kappa} h^2. \]

The constant \( C_{\lambda,\kappa} \) here now depends on \( \lambda, \kappa \).

LEMMA A.7 There is a \( \lambda > 0 \) such that for sufficiently large \( \kappa > 0 \)

\[ \int_\Omega |\nabla (g^\circ - g^\circ_h)|^2 \sigma_z^{2+\lambda} \, dx \leq C_{\lambda,\kappa} h^2. \]

for a large enough \( \kappa \), dependent on \( \lambda \).

We now deal with \( g^\circ_h \) by doing a pointwise estimate. Let \( x \) be a point not on any triangle edge. By Wardetzky (2006, Lemma 3.3.1),\(^5\) after exchanging curved and flat triangles and doing all computations pointwise, we obtain for a function \( v \) which is \( C^2 \) within triangles,

\[ |D^2 v(x)| \leq C |D^2 v(x)| + C h |\nabla v(x)|, \]

where \( D^2 \) is the vector of all second partial derivatives on the flat triangle in the mesh \( \Omega_h \). We can use this same relation with \( D \) and \( D_A \) exchanged. For \( g^\circ - g^\circ_h \) (which are both \( C^2 \) within triangles, as \( g^\circ \) solves a Poisson equation with smooth right-hand side, and \( g^\circ_h \) is a finite element function) this means

\[ |D^2 (g^\circ(x) - g^\circ_h(x))|^2 \leq C |D^2 (g^\circ(x) - g^\circ_h(x))|^2 + C h^2 |\nabla (g^\circ(x) - g^\circ_h(x))|^2. \]

We now use that \( g^\circ_h \) is linear within mesh triangles in the interior, so its second derivatives on these triangles is zero. On boundary triangles, Lemma A.8 applies, and an additional term involving the gradient \( \nabla g^\circ_h \) has to be added. Using this, as well as Lemma 3.1, we have

\[ |D^2 (g^\circ(x) - g^\circ_h(x))|^2 \leq C |D^2 (g^\circ(x) - g^\circ_h(x))|^2 + C h^2 |\nabla (g^\circ(x) - g^\circ_h(x))|^2. \]

Plugging this back into (A.12), gives, for small enough \( h \),

\[ \int_\Omega |\nabla (g^\circ - g^\circ_h)|^2 \sigma_z^{2+\lambda} \, dx \leq C h^2 \int_\Omega \sigma_z^{2+\lambda} (|D^2 g^\circ|^2 + h^2 |\nabla g^\circ|^2) \, dx. \]

Applying Lemma A.3 and Lemma A.4 gives

\[ \int_\Omega |\nabla (g^\circ - g^\circ_h)|^2 \sigma_z^{2+\lambda} \, dx \leq C h^2 \int_\Omega \sigma_z^{2+\lambda} |\nabla \delta|^2 + \lambda^{-1} (kh)^{-2} \sigma_z^{2+\lambda} |\delta|^2 \, dx. \]

\(^5\)The scenario mentioned in Wardetzky’s Footnote 5 does not apply in our setting, as in our setting the interpolation operator maps into functions which vanish at the boundary (see Remark 3.1). Because of that, Lemma 3.3.1 holds at boundary triangles as well.
The definition of $\delta^c$ gives

$$\int_\Omega \left| \nabla \left( g^c - g^c_h \right) \right|^2 \sigma^c_{2+\lambda} \, dx \leq C h^2 \int_{T^c} \sigma^c_{2+\lambda} |\nabla \delta^c|^2 + \lambda^{-1} (kh)^{-2} \sigma^c_{2+\lambda} |\delta^c|^2 \, dx .$$

By definition, the value of $d(x,z)$ within $T^c$ is bounded by the edge length $Ch$. This means that, within $T^c$,

$$\sigma_0(x) \leq \sqrt{C^2 h^2 + \kappa^2 h^2} \leq \sqrt{C^2 + \kappa^2 h} .$$

With a different $C$, and for large enough $\kappa$,

$$\sigma_0(x) \leq C \sqrt{1 + \kappa^2 h} \leq C h .$$

Together with the bounds for $\delta^c$ from (4.1) and using the fact that the area of $T^c$ is bounded by $Ch^2$, this gives

$$\int_\Omega \left| \nabla \left( g^c - g^c_h \right) \right|^2 \sigma^c_{2+\lambda} \, dx \leq C h^2 \kappa^3 \int_{T^c} h^2 + h^{-6} + \lambda^{-1} (kh)^{-2} h^{-2} h^2 + h^{-4} \, dx \leq C \kappa^3 h^2 , \quad \text{(A.13)}$$

provided $\kappa$ is large enough (dependent on $\lambda$). This proves the lemma. \qed

**Appendix B: A treatment of curved boundary triangles**

In Definition 3.5, we use an isoparametric modification of boundary triangles to achieve a finite element on a discrete surface whose boundary exactly corresponds to the boundary of the continuous surface $\Omega$. This approximation, however, can affect the derivatives of the formerly linear FEM functions on these boundary triangles. In this appendix we summarize a result about this effect.

**Lemma A.8** Let $\Psi_T : \hat{T} \to T$ be the isoparametric map of Scott (1973) that maps a straight-edged triangle $\hat{T}$ onto the triangle $T$ which has one curved edge. Let $f \in C^2(T)$, $\hat{f} = f \circ \Psi_T$. Then we have $\forall x \in T, x = \Psi_T(y)$

$$|\nabla \hat{f}(y)| \leq C |\nabla f(x)|,$$

$$|D^2 \hat{f}(y)| \leq C \left( |D^2 f(x)| + h |\nabla f(x)| \right) ,$$

where $D^2$ is the vector of all second derivatives. The constant $C$ is independent of the triangle $T$, $f$ or $h$.

The same estimates also hold in reverse, when $\hat{f}(y)$ is exchanged with $f(x)$.

**Proof.** Let $\hat{F}_T : \hat{T} \to \hat{T}$ be the affine map that maps the standard reference triangle to the flat triangle $\hat{T}$. Then, by Bernardi (1989, Theorem 6.1), there is a map $\Phi_T : \hat{T} \to \mathbb{R}^2$ such that

$$\Psi_T = \text{Id} + \Phi_T \circ \hat{F}_T^{-1} ,$$

$$|D^m \Phi_T(z)| \leq Ch^{m+1} \quad \forall z \in \hat{T} , \, m = 1,2 .$$

where $D^m$ is the vector of all derivatives of order $m$.

By definition, $|D \left( \hat{F}_T^{-1} \right)| \leq Ch^{-1}$, and $D^2 \left( \hat{F}_T^{-1} \right) = 0$. By the chain rule,

$$|D \Psi_T(y)| \leq 2 + |D \Phi_T||D (\hat{F}_T^{-1})| \leq 2 + Ch \leq C \quad \forall y \in \hat{T} ,$$

$$|D^2 \Psi_T(y)| \geq 1 \quad \forall y \in \hat{T} , \quad \text{(A.14)}$$

$$|D^2 \Psi_T(y)| \leq |D^2 \Phi_T||D (\hat{F}_T^{-1})|^2 + (2 + |D \Phi_T|)|D^2 (\hat{F}_T^{-1})| \leq Ch \quad \forall y \in \hat{T} .$$
We now calculate the derivatives of \( \tilde{f} \). Let \( x = \Psi_T(y) \). Using (A.14), we have,

\[
\begin{align*}
|\nabla \tilde{f}(y)| &= |\nabla (f \circ \Psi_T)(y)| \leq |\nabla f(x)||\nabla \Psi_T(y)| \leq C|\nabla f(x)| \\
|D^2 \tilde{f}(y)| &= |D^2 (f \circ \Psi_T)(y)| \leq |D^2 f(x)||\nabla \Psi_T(y)|^2 + |\nabla f(x)||D^2 \Psi_T(y)| \\
&\leq C \left(|D^2 f(x)| + h|\nabla f(x)|\right),
\end{align*}
\]

which proves one direction of the lemma.

We now prove the lemma in the other direction, with \( \tilde{f}(y) \) exchanged with \( f(x) \). Note that, by the inverse function theorem, (A.14) implies for \( x = \Psi_T(y) \) that

\[
\begin{align*}
|D\Psi_T^{-1}(x)| &\leq C|D\Psi_T(y)|^{-1} \leq 3 \leq C \quad \forall x \in T, \\
|D^2 \Psi_T^{-1}(x)| &\leq C|D^2 \Psi_T(y)||D\Psi_T(y)|^{-3} \leq Ch \quad \forall x \in T.
\end{align*}
\]

The bounds for \( \Psi_T^{-1} \) are the same ones as the bounds for \( \Psi_T \) in (A.14), and thus the calculations from (A.15) still hold with \( \tilde{f}(y) \) and \( f(x) \) exchanged. \( \square \)
