FUNDAMENTAL GROUPOIDS FOR SIMPLICIAL OBJECTS IN MAL’TSEV CATEGORIES

ARNAUD DUVIEUSART

Abstract. We show that the category of internal groupoids in an exact Mal’tsev category is reflective, and in fact a Birkhoff subcategory of the category of simplicial objects. We then characterize the central extensions of the corresponding Galois structure, and show that regular epimorphisms admit a relative monotone-light factorization system in the sense of Chikhladze. We also draw some comparison with Kan complexes. By comparing the reflections of simplicial objects and reflexive graphs into groupoids, we exhibit a connection with weighted commutators (as defined by Gran, Janelidze and Ursini).

Introduction

Categorical Galois theory, as developed by G. Janelidze ([25, 29, 3, 27]), is a general framework that allows the study of central extensions or coverings of the objects of a category. A large collection of examples has been given, ranging from the Galois theory of commutative rings of Magid ([32, 10]) and the theory of coverings of locally connected spaces to the central extensions of groups, Lie algebras, or more generally exact Mal’tsev categories [28].

The main ingredient of this theory is the notion of Galois structure, which is defined as an adjunction, with the right adjoint often taken to be fully faithful, and a class of morphisms in the codomain of the right adjoint, satisfying suitable conditions, in particular admissibility, which amounts to the preservation by the left adjoint of certain pullbacks. For example, the inclusion of any Birkhoff subcategory of an exact Mal’tsev together with the class of regular epimorphisms always forms an admissible Galois structure ([28]).

In [8], Brown and Janelidze used this theory to describe what they called second order coverings for simplicial sets, using the adjunction given by the nerve functor and the fundamental groupoid, and the class of Kan fibrations. In fact, they restricted their analysis to Kan complexes, as this condition implies the admissibility of these objects for the corresponding Galois structure. Later Chikhladze introduced relative factorization systems, and showed that the induced relative factorization system for Kan fibrations is...
locally stable, so that the Galois structures induces a relative monotone-light factorization (15).

On the other hand regular Mal’tsev categories were characterized in [11] as the categories in which the Kan condition holds for every simplicial object, thus extending a theorem of Moore stating that the underlying simplicial set of a simplicial group is always a Kan complex. Moreover, regular epimorphisms in the category of simplicial objects then coincide with Kan fibrations. This suggests that the inclusion of groupoids into simplicial objects in any exact Mal’tsev category might induce an admissible Galois structure.

The main objective of this paper is to show that this is indeed the case, and more precisely that the category of groupoids in an exact Mal’tsev category is always a Birkhoff subcategory of the category of simplicial objects. The paper is organised as follows: we begin with some preliminaries, to fix notations and provide the background notions. We then construct the reflection of the category of simplicial objects into the subcategory of internal groupoids. Next, we give a characterization of the central extensions for the Galois structure. In the next section we compare our construction with the homotopy relations for the simplices in a Kan complex, which are used to define its homotopy groupoid. Then we prove that the Galois structure admits a relative monotone-light factorization system. We end the paper with a discussion of reflexive graphs, seen as truncated reflexive graphs.

1. Preliminaries

1.1. Simplicial objects. Let $\Delta$ denote the category of finite nonzero ordinals, with monotone functions as morphisms. For a given category $C$, the category $\text{Simp}(C)$ of simplicial objects in $C$ is the category of functors $\Delta^{op} \to C$. Equivalently, an object $X$ of $\text{Simp}(C)$ is a collection of objects $(X_n)_{n \in \mathbb{N}}$ together with face maps $d_i : X_n \to X_{n-1}$ for all $n > 0$ and $0 \leq i \leq n$, and degeneracy maps $s_i : X_n \to X_{n+1}$ for $n \geq 0$ and $0 \leq i \leq n$, satisfying the following simplicial identities, whenever they make sense:

$$
\begin{cases}
    d_i d_j = d_{j-1} d_i & 0 \leq i < j \leq n + 1 \\
    s_i s_j = s_{j+1} s_i & 0 \leq i \leq j \leq n \\
    d_i s_j = s_{j-1} d_i & 0 \leq i < j \leq n - 1 \\
    d_i s_j = 1 & i \in \{j, j + 1\} \\
    d_i s_j = s_j d_{i-1} & 0 \leq j < i - 1 \leq n - 1.
\end{cases}
$$

(1)

When necessary, we will write $d^X_i$ or $s^X_i$ to distinguish the face or degeneracy maps of different simplicial objects. A morphism $f : X \to Y$ in $\text{Simp}(C)$ is then a collection of morphisms $f_n : X_n \to Y_n$ that commute with face and degeneracy maps, in the sense that $d^X_i f_{n+1} = f_n d^Y_i$ and $s^X_i f_n = f_{n+1} s^Y_i$ for all $i, n$.

If $X$ is a simplicial object, we will denote $\text{Dec}(X)$ the simplicial object $(X_{n+1})_{n \geq 0}$, whose face and degeneracies are the same as those of $X$, without the last faces $d_{n+1} : X_{n+1} \to X_n$ and last degeneracies $s_n : X_n \to X_{n+1}$ for all $n \geq 1$. The simplicial identities imply that the maps $d_{n+1} : X_{n+1} \to X_n$ form a morphism of simplicial objects $\epsilon_X : \text{Dec}(X) \to X$. Since all these maps are split (and thus regular) epimorphisms, $\epsilon$ is a regular epimorphism...
in $\text{Simp}(\mathcal{C})$, although it need not be a split epimorphism. Notice that $\text{Dec}$ defines an endofunctor of $\text{Simp}(\mathcal{C})$, and $\epsilon$ is a natural transformation from $\text{Dec}$ to the identity endofunctor.

$\Delta$ is a skeleton of, and thus equivalent to, the category of non-empty finite totally ordered sets. In particular, since this category contains the poset $\mathcal{P}_{f,n.e.}(\mathbb{N})$ of non-empty finite subsets of $\mathbb{N}$ (ordered by inclusion) as a subcategory, there is a canonical functor $\Phi : \mathcal{P}_{f,n.e.}(\mathbb{N}) \to \Delta$ that maps any set with $n + 1$ elements to $\{0, \ldots, n\}$ and any inclusion map to an injective morphism in $\Delta$.

For a given simplicial object $X$, and for every $n \geq 2$, one can consider the restriction of $\Phi$ to the poset of proper subsets of $\{0, 1, \ldots, n\}$; taking the opposite functor and composing with $\mathcal{X} : \Delta^{\text{op}} \to \mathcal{C}$ gives a diagram in $\mathcal{C}$. The limit of this diagram is the $n$-th simplicial kernel of $\mathcal{X}$, and denoted $K_n(\mathcal{X})$. In particular, we have maps $\mu_i : K_n(\mathcal{X}) \to X_{n-i}$ for $i = 0, \ldots, n$, satisfying $d_i \mu_j = d_{j-1} \mu_i$ for all $0 \leq i < j \leq n$, and the maps $\mu_i$ are universal with this property. Thus the face maps $d_0, \ldots, d_n : X_n \to X_{n-1}$ induce a canonical map $\kappa_n : X_n \to K_n(\mathcal{X})$. Following [18], we say that $\mathcal{X}$ is exact at $X_{n-1}$ if $\kappa_n$ is a regular epimorphism, and exact if it is exact at $X_n$ for all $n \geq 1$.

Moreover, for every $n \geq 2$ and $0 \leq k \leq n$, we can also restrict $\Phi$ to the poset of proper subsets of $\{0, \ldots, n\}$ that contain $k$, and then compose the opposite functor with $\mathcal{X}$. The limit of this diagram is the set of $(n, k)$-horns $\Lambda^n_k(\mathcal{X})$, and it is equipped with maps $\nu_i : \Lambda^n_k(\mathcal{X}) \to X_{n-1}$ for $0 \leq i \leq n$ and $i \neq k$ that satisfy the identities $d_i \nu_j = d_{j-1} \nu_i$ for all $0 \leq i < j \leq n$ and $i \neq k \neq j$, and are universal with this property. There is then also a canonical arrow $\lambda^n_k : X_n \to \Lambda^n_k(\mathcal{X})$ induced by the face maps $d_i : X_n \to X_{n-1}$ for $i \neq k$, and $\mathcal{X}$ is said to satisfy the Kan property if all these maps are regular epimorphisms. Moreover, a map $f : \mathcal{X} \to \mathcal{Y}$ between simplicial objects is called a Kan fibration if for all $n$ and $k$ the canonical arrow $\theta^n_k$ in the diagram

\[
\begin{array}{ccc}
X_n & \xrightarrow{\theta^n_k} & \Lambda^n_k(\mathcal{X}) \times_{\Lambda^n_k(\mathcal{Y})} Y_n \\
\downarrow & & \downarrow \\
\Lambda^n_k(\mathcal{X}) & \xrightarrow{\lambda^n_k} & \Lambda^n_k(\mathcal{Y})
\end{array}
\]

(where the inner square is a pullback) is a regular epimorphism.

For every $n \geq 1$, we denote $\Delta_n$ the full subcategory of $\Delta$ consisting of the ordinals with $n + 1$ elements or less, and $\text{Simp}_n(\mathcal{C})$ the category of functors $\Delta_n^{\text{op}} \to \mathcal{C}$, whose objects we called $n$-truncated simplicial objects. The inclusion $\Delta_n \hookrightarrow \Delta$ then induces by precomposition the truncation functor $\text{Simp}(\mathcal{C}) \to \text{Simp}_n(\mathcal{C})$.

An internal reflexive graph in $\mathcal{C}$ is simply a 1-truncated simplicial object. A multiplicative graph is then a reflexive graph endowed with a partial multiplication $m : X_1 \times_{X_0} X_1 \to
that is unital and compatible with the domain and codomain maps ([13]), and an internal category is a multiplicative graph whose multiplication is associative. All these conditions can be summarized by saying that an internal multiplicative graph is an object of $\text{Simp}_2(C)$, such that the square

$$
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array}
$$

is a pullback, and an internal category is an object of $\text{Simp}_3(C)$ such that the square above and the square

$$
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array}
$$

are pullbacks. Moreover an internal category is an internal groupoid if and only if any of the squares

$$
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array}
$$

is a pullback. Internal functors are also the same thing as (restricted) simplicial morphisms. Moreover, any internal category can be extended to a simplicial object by simply taking its nerve. From now on we will thus consider $\text{Cat}(C)$ and $\text{Grpd}(C)$ as full subcategories of $\text{Simp}(C)$; more precisely, a simplicial object $X$ is an internal category if and only if the commutative square

$$
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array} \\
\begin{array}{c}
\text{X} \\
\text{d} \\
\text{d} \\
\end{array}
$$

is a pullback for all $n \geq 2$.

1.2. Mal’tsev categories and higher extensions. A finitely complete category $C$ is called a Mal’tsev category if every internal reflexive relation is an equivalence relation ([11, 12, 13, 2]; in a regular category, this condition is equivalent to the fact that the composition $R \circ S$ of two equivalence relations $R, S$ on the same object $X$ is an equivalence relation. When this is the case, $R \circ S$ is in fact the join of $R$ and $S$ in the poset of
equivalence relations of $X$. Accordingly this poset is a lattice. In fact this is a modular lattice ([12]), i.e. we have the identity

$$R \lor (S \land T) = (R \lor S) \land T$$

for all equivalence relations $R, S, T$ on $X$ such that $R \leq T$.

An important property of Mal’tsev categories is that the inclusion of the category $\text{Grpd}(\mathcal{C})$ of internal groupoids into the category $\text{MRG}(\mathcal{C})$ of multiplicative reflexive graphs is an isomorphism, and that the truncation functor $\text{MRG}(\mathcal{C}) \to \text{RG}(\mathcal{C})$ is fully faithful ([13]).

For a variety, this is also equivalent to the existence of a ternary operation $p$ satisfying the equations $p(x, y, y) = x$ and $p(x, x, y) = y$. In particular, the categories of groups, $R$-modules, rings, Lie algebras and $C^*$-algebras are all examples of Mal’tsev categories; other examples include the category of Heyting algebras, the dual of any topos [5] or any additive category.

In any regular category, a commutative square

$$
\begin{array}{c}
X \\
\downarrow^f \\
Y \\
\downarrow^j \\
\end{array}
\quad
\begin{array}{c}
Z \\
\downarrow^h \\
W
\end{array}
$$

of regular epimorphisms is called a regular pushout or double extension if the canonical map $\langle f, g \rangle : X \to Y \times_W Z$ is a regular epimorphism ([26]). These double extensions are stable under pullback along a commutative square in any regular category.

**Proposition 1 ([6]).** If $\mathcal{C}$ is a regular Mal’tsev category, then

- any square of the form

$$
\begin{array}{c}
X \\
\downarrow^g \\
Y
\end{array}
\quad
\begin{array}{c}
Z \\
\downarrow^h \\
W
\end{array}
$$

where $hf = jg$, $gs = th$, $fs = 1_Y$, $jt = 1_W$ and $g, h$ are regular epimorphisms is a double extension;

- a square of regular epimorphisms

$$
\begin{array}{c}
X \\
\downarrow^f \\
Y
\end{array}
\quad
\begin{array}{c}
Z \\
\downarrow^j \\
W
\end{array}
$$

is a double extension if and only if $f(Eq[g]) = Eq[h]$, i.e. if and only if the map $Eq[g] \to Eq[h]$ (where $Eq[g]$ and $Eq[h]$ denote the kernel pairs of $g$ and $h$ respectively) induced by $f$ and $j$ is a regular epimorphism.
We can also define a *triple extension* as a commutative cube

\[
\begin{array}{ccc}
X & \xrightarrow{g} & Z \\
\downarrow{\alpha} & & \downarrow{\gamma} \\
X' & \xrightarrow{g'} & Z' \\
\downarrow{f'} & & \downarrow{h'} \\
Y & \xrightarrow{\delta} & W \\
\downarrow{\beta} & & \downarrow{h} \\
Y' & \xrightarrow{j'} & W' \\
\end{array}
\]

for which all faces, as well as the induced commutative square

\[
\begin{array}{ccc}
X & \xrightarrow{(f,g)} & Y \times_W Z \\
\downarrow{\alpha} & & \downarrow{\beta \times \delta \gamma} \\
X' & \xrightarrow{(f',g')} & Y' \times_{W'} Z',
\end{array}
\]

are double extensions. Triple extensions satisfy the same properties as in the previous proposition: in particular, a split cube between double extensions is always a triple extension.

### 1.3. Categorical Galois theory and monotone-light factorization systems.

We recall some definitions from [28, 29].

A *Galois structure* \( \Gamma = (\mathcal{C}, \mathcal{X}, I, U, \mathcal{F}) \) consists of a category \( \mathcal{C} \), a full reflective subcategory \( \mathcal{X} \) of \( \mathcal{C} \), with reflector \( I : \mathcal{C} \to \mathcal{X} \) and inclusion \( U : \mathcal{X} \to \mathcal{C} \) and a class \( \mathcal{F} \) of morphisms of \( \mathcal{C} \) containing all isomorphisms, stable under pullbacks and composition, and preserved by \( I \). We will call the morphisms in \( \mathcal{F} \) *extensions*. Let us write, for any object \( B \) of \( \mathcal{C} \) (resp. of \( \mathcal{X} \)), \( \mathcal{C} \downarrow B \) (resp. \( \mathcal{X} \downarrow B \)) for the full subcategory of the slice category \( \mathcal{C}/B \) (resp. \( \mathcal{X}/B \)) consisting of extensions \( f : X \to B \). Then any arrow \( p : E \to B \) induces a functor \( p^* : \mathcal{C} \downarrow B \to \mathcal{C} \downarrow E \) defined by pulling back. If \( p \) is an extension, this functor has a left adjoint \( p_! \) defined by composition with \( p \); the extension \( p \) is said to be of *effective \( \mathcal{F} \)-descent*, or simply a *monadic extension*, if the functor \( p^* \) is monadic.

Moreover, the reflector \( I \) induces for every \( B \) a functor \( I^B : \mathcal{C} \downarrow B \to \mathcal{X} \downarrow I(B) \) which maps \( f : X \to B \) to \( I(f) : I(X) \to I(B) \); and every such functor has a right adjoint \( U^B : \mathcal{X} \downarrow I(B) \), defined for any \( g : Y \to I(B) \) by the pullback

\[
\begin{array}{ccc}
B \times_{I(B)} Y & \longrightarrow & Y \\
\downarrow{U^B(g)} & & \downarrow{g} \\
B & \xrightarrow{\eta_B} & I(B).
\end{array}
\]
The object $B$ is then said to be admissible if $U^B$ is fully faithful, which is equivalent to the reflector $I$ preserving all pullback squares of the form above. A Galois structure $\Gamma$ is said to be admissible if every object is admissible.

Given an admissible Galois structure, an extension $f : X \to B$ in $C \downarrow B$ is said to be

- **trivial** if it lies in the replete image of $U^B$, or equivalently if the square

$$
\begin{array}{ccc}
X & \xrightarrow{\eta_X} & I(X) \\
\downarrow f & & \downarrow I(f) \\
B & \xrightarrow{\eta_B} & I(B)
\end{array}
$$

is a pullback;

- **central**, or alternatively a *covering*, if there exists a monadic extension $p : E \to B$ such that $p^*(f)$ is trivial;

- **normal**, if it is a monadic extension and if $f^*(f)$ is a trivial extension (that is, if the projections of the kernel pair of $f$ are trivial).

**Example 1.** If $C$ is an exact Mal’tsev category and $\mathcal{X}$ is any Birkhoff (i.e. full reflective and closed under quotients and subobjects) subcategory of $C$, and $\mathcal{F}$ is the class of regular epimorphisms, then the Galois structure $\Gamma$ is admissible, and moreover every extension is monadic and every central extension is also normal \([28]\).

When $C$ is the category of groups and $\mathcal{X}$ the subcategory of abelian groups, the central extensions in this sense are exactly the surjective group homomorphisms whose kernel is included in the center of the domain \([28]\). More generally, in any exact Mal’tsev category with coequalizers, the central extensions of the Galois structure defined by the subcategory of abelian objects are the extensions such that the Smith-Pedicchio commutator $[Eq[f], \nabla_X]$ is trivial \([22]\).

If $\Gamma$ is a Galois structure where $\mathcal{F}$ is the class of all morphisms in $C$, admissibility is equivalent to the reflector $I$ being semi-left-exact in the sense of \([14]\). In that case any morphism $f : X \to B$ in $C$ induces a commutative diagram

$$
\begin{array}{ccc}
X & \xrightarrow{f'} & B \times_{I(B)} I(X) \\
\downarrow f & & \downarrow f'' \\
& & I(X) \\
& \eta_B & \downarrow I(f) \\
& & I(B)
\end{array}
$$

Since the reflector $I$ preserves the pullback in this diagram $I(f')$ is an isomorphism, and $f''$ is a trivial extension by definition. Moreover in that case the classes $\mathcal{E}$ of morphisms inverted by $I$ and the class $\mathcal{M}$ of trivial extensions are orthogonal to one another, and thus the two classes form a factorisation system $(\mathcal{E}, \mathcal{M})$ in $C$ \([14]\). The trivial extensions are then stable under pullbacks, but the class $\mathcal{E}$ does not have this property in general.
In order to obtain a stable factorization system, one can localize \( \mathcal{M} \) and stabilize \( \mathcal{E} \), as in \([9]\): this means that we replace \( \mathcal{E} \) by the class \( \mathcal{E}' \) of maps for which every pullback along a monadic extension is in \( \mathcal{E} \), and \( \mathcal{M} \) by the class \( \mathcal{M}^* \) of maps \( f \) that are locally in \( \mathcal{M} \), in the sense that there exists a monadic extension \( p \) such that \( p^*(f) \in \mathcal{M} \). In the context of Galois Theory these are precisely the central extensions. The two classes \( \mathcal{E}' \) and \( \mathcal{M}^* \) are orthogonal, but in general they do not form a factorization system. When this is the case, the resulting factorization system is called the \textit{monotone-light factorization system} \((\mathcal{E}', \mathcal{M}^*)\) associated with \( \Gamma \).

In the case where \( \mathcal{F} \) is no longer the class of all morphisms in \( \mathcal{C} \), it need not be true that every morphism admits a \((\mathcal{E}, \mathcal{M})\)-factorization. Nevertheless, this is still true for extensions; it is then natural to extend the notion of factorization system to the case where only \textit{some} morphisms have a factorization. This was done by Chikhladze in \([15]\):

\begin{definition}
If \( \mathcal{C} \) is a category and \( \mathcal{F} \) a class of morphisms of \( \mathcal{C} \) containing the identities and closed under composition and pullbacks, a \textit{relative factorization system} for \( \mathcal{F} \) consists of two classes \( \mathcal{E} \) and \( \mathcal{M} \) of maps such that

1. \( \mathcal{E} \) and \( \mathcal{M} \) contain identities and are closed under composition with isomorphisms;
2. \( \mathcal{E} \) and \( \mathcal{M} \) are orthogonal to one another;
3. \( \mathcal{M} \subset \mathcal{F} \);
4. every arrow \( f \) in \( \mathcal{F} \) can be written as \( me \) for some \( m \in \mathcal{M} \) and \( e \in \mathcal{E} \).

Then any admissible Galois structure \( \Gamma = (\mathcal{C}, \mathcal{X}, I, \mathcal{F}) \) yields a relative factorization system for \( \mathcal{F} \) with \( \mathcal{E} \) and \( \mathcal{M} \) consisting of the maps inverted by \( I \) and the trivial extensions, respectively. When moreover this factorization system can be stabilized, then the stable factorization system \((\mathcal{E}', \mathcal{M}^*)\) is called a \textit{relative monotone-light factorization system} for \( \mathcal{F} \).

\begin{example}
If \( \mathcal{C} \) is the category of simplicial sets, \( \mathcal{X} \) the category of groupoids, \( I \) the fundamental groupoid functor, and \( \mathcal{F} \) the class of Kan fibrations, then every Kan complex is an admissible object, and the central extensions were called \textit{second order coverings} in \([8]\).

This Galois structure admits a relative monotone-light factorization system, as shown in \([15]\).

\end{example}

\begin{example}
In a finitely complete category, any object \( X \) has a corresponding discrete internal groupoid. This defines a fully faithful functor \( D : \mathcal{C} \to \text{Grpd}(\mathcal{C}) \). If \( \mathcal{C} \) is exact, then this functor admits a semi-left-exact left adjoint \( \pi_0 : \text{Grpd}(\mathcal{C}) \to \mathcal{C} \) \((4)\). When \( \mathcal{C} \) is moreover Mal’tsev, \( \mathcal{C} \) is in fact a Birkhoff subcategory of \( \text{Grpd}(\mathcal{C}) \), and the central extensions of the Galois structure \((\text{Grpd}(\mathcal{C}), \mathcal{C}, \pi_0, \mathcal{F})\) (where \( \mathcal{F} \) is the class of regular epimorphisms) are precisely the regular epimorphic discrete fibrations \((21)\). This Galois structure admits a relative monotone-light factorization system \((16)\).

\end{example}
2. The reflection of simplicial objects into groupoids

**Convention.** From now on, $\mathcal{C}$ will denote a regular Mal’tsev category. For a given simplicial object $(X_n)_{n \geq 0}$ with face maps $d_i : X_n \to X_{n-1}$ for $n \geq 1$ and $0 \leq i \leq n$, we will denote $D_i$ the kernel pair of $d_i$.

Note that $\text{Simp}(\mathcal{C})$, being a functor category, is also regular Mal’tsev.

**Lemma 1.** If $X$ is a simplicial object in $\mathcal{C}$, all the commutative squares given by $d_i d_j = d_{j-1} d_i$ for $i < j$ are double extensions. Moreover if $f : X \to Y$ is a regular epimorphism of simplicial objects, then the corresponding commutative cubes are triple extensions.

**Proof.** If $i < j - 1$, the two squares in the diagram
\[
\begin{array}{ccc}
X_{n+2} & \xrightarrow{d_i} & X_{n+1} \\
\downarrow d_i & & \downarrow d_i \\
X_{n+1} & \xleftarrow{d_{j-1}} & X_n
\end{array}
\]
commute. On the other hand, if $j = i+1$, then at least one of the inequalities $1 \leq j \leq n+2$ is strict, hence at least one of the squares
\[
\begin{array}{ccc}
X_{n+2} & \xrightarrow{d_i} & X_{n+1} \\
\downarrow d_i & & \downarrow d_i \\
X_{n+1} & \xleftarrow{d_{j-1}} & X_n
\end{array}
\]
will commute; in any case, the commutative square is a double extension.

Moreover, any morphism $f : X \to Y$ of simplicial objects has to commute with the face and degeneracies; hence, when $f$ is a regular epimorphism, every square
\[
\begin{array}{ccc}
X_{n+1} & \xrightarrow{f_{n+1}} & Y_{n+1} \\
\downarrow d_i & & \downarrow d_i \\
X_n & \xrightarrow{f_n} & Y_n
\end{array}
\]
is a double extension. The resulting cube will then always be a split epimorphism between double extensions, hence a triple extension. □

**Remark.** The pullback $X_1 \times_{X_0} X_1$ of $d_0$ along $d_1$ coincides with the object of $(2, 1)$-horns $\Lambda_1^2(X)$, and similarly the other two pullbacks $X_1 \times_{X_0} X_1$, which define the kernel pairs of $d_0$ and $d_1$, coincide with the objects of $(2, 2)$ and $(2, 0)$-horns, respectively. In particular, the previous lemma shows that every simplicial object satisfies the Kan property and that every regular epimorphism is a Kan fibration for 2-horns. The proof for the higher order horns can be done in the same way, using $n$-fold extensions for $n \geq 3$, as in [18].

As a consequence we have
Corollary 1. If \( f : X \to Y \) is a regular epimorphism in \( \text{Simp}(C) \), then \( f(D^X_i \wedge D^Y_j) = D^Y_i \wedge D^Y_j \). Moreover, for any \( i < j < k \), we have
\[
\begin{align*}
d_k(D_i \wedge D_j) &= D_i \wedge D_j \\
d_j(D_i \wedge D_k) &= D_i \wedge D_{k-1} \\
d_i(D_j \wedge D_k) &= D_{j-1} \wedge D_{k-1}.
\end{align*}
\]

Proof. By the previous lemma \( f : X \to Y \) induces a triple extension. In particular the square
\[
\begin{array}{c}
X_n \xrightarrow{(d^X_i, d^X_j)} X_{n-1} \times X_{n-2} X_{n-1} \\
\downarrow f_n \\
Y_n \xrightarrow{(d^Y_i, d^Y_j)} Y_{n-1} \times Y_{n-2} Y_{n-1}
\end{array}
\]
is a double extension, so that
\[
\begin{align*}
f(D^X_i \wedge D^X_j) &= f(Eq([d^X_i, d^X_j])) = \langle d^Y_i, d^Y_j \rangle = D^Y_i \wedge D^Y_j.
\end{align*}
\]
Moreover, \( d_k \) can be identified with a component of the regular epimorphism \( \epsilon_X : \text{Dec}(X) \to X \), and thus the cube
\[
\begin{array}{c}
X_{n+3} \xrightarrow{d_j} X_{n+2} \xrightarrow{d_{k-1}} X_n \\
\downarrow d_i \\
X_{n+2} \xrightarrow{d_{j-1}} X_{n+1} \xrightarrow{d_i} X_n \\
\downarrow d_i \\
X_{n+1} \xrightarrow{d_{j-2} d_{j-1}} X_{n} \\
\end{array}
\]
is a triple extension; in particular the squares
\[
\begin{align*}
X_{n+3} \xrightarrow{(d_i, d_j)} X_{n+2} \times X_{n+1} X_{n+2} \\
\downarrow d_k \\
X_{n+2} \xrightarrow{(d_i, d_j)} X_{n+1} \times X_{n} X_{n+1}
\end{align*}
\]
and
\[
\begin{align*}
X_{n+3} \xrightarrow{(d_j, d_k)} X_{n+2} \times X_{n+1} X_{n+2} \\
\downarrow d_i \\
X_{n+2} \xrightarrow{(d_j-1, d_{k-1})} X_{n+1} \times X_{n} X_{n+1}
\end{align*}
\]
are all double extensions, which implies the desired equalities. \qed

**Lemma 2.** For any simplicial object \( X \), the following equivalence relations in \( X_1 \) are all equal:

\[
d_0(D_1 \wedge D_2) = d_1(D_0 \wedge D_2) = d_2(D_0 \wedge D_1).
\]

*Proof.* We prove the first identity; the other one is obtained in a similar way. Since \( D_1 \wedge D_2 = d_2(D_1 \wedge D_3) \), we have

\[
d_0(D_1 \wedge D_2) = d_0(d_2(D_1 \wedge D_3)) = d_1(d_0(D_1 \wedge D_3)) = d_1(D_0 \wedge D_2).
\] \qed

**Definition 2.** We will call \( H_1(X) \) this equivalence relation.

**Proposition 2.** Let \( X \) be a simplicial object in \( C \). Then for all \( n \geq 2 \) the following conditions are equivalent:

1. \( D_i \wedge D_j = \Delta_{X_n} \) for all \( 0 \leq i < j \leq n \);
2. \( D_0 \wedge D_n = \Delta_{X_n} \);
3. there exist \( 0 \leq i < j \leq n \) such that \( D_i \wedge D_j = \Delta_{X_n} \).

Moreover, \( X \) is an internal groupoid if and only if it satisfies these conditions for all \( n \geq 2 \).

*Proof.* The implications (1) \( \Rightarrow \) (2) \( \Rightarrow \) (3) are trivial; we prove (3) \( \Rightarrow \) (1) by induction. We first consider the case where \( n = 2 \); for this case it is enough to prove that \( D_i \wedge D_k = \Delta_{X_2} \) for all \( k \not\in \{i,j\} \). We have \( d_i(D_i \wedge D_k) = \Delta_{X_1} \) and

\[
d_j(D_i \wedge D_k) = d_k(D_i \wedge D_j) = \Delta_{X_1}
\]
by Lemma 2 and thus \( D_i \wedge D_k \leq D_i \wedge D_j = \Delta_{X_2} \).

Assuming now that the condition holds for \( n \), we prove that it holds for \( n + 1 \). Assume that \( D_i \wedge D_j = \Delta_{X_{n+1}} \); then taking images by \( d_k \) (for \( k \not\in \{i,j\} \)) on both sides shows that \( D_i \wedge D_k = \Delta_{X_n} \) for some \( i', j' \), and thus, by the induction hypothesis, for all \( i', j' \). In particular, for any \( 0 \leq r < s \leq n + 1 \), we have for some \( r', s' \)

\[
d_i(D_r \wedge D_s) \leq D_{r'} \wedge D_{s'} = \Delta_{X_n},
\]
so that \( D_r \wedge D_s \leq D_i \); and similarly \( D_r \wedge D_s \leq D_j \), so that \( D_r \wedge D_s = \Delta_{X_{n+1}} \).

Now \( X \) is an internal groupoid if and only if the squares

\[
\begin{array}{ccc}
X_n & \xrightarrow{d_0} & X_{n-1} \\
d_n \downarrow & & \downarrow d_{n-1} \\
X_{n-1} & \xrightarrow{d_0} & X_{n-2}
\end{array}
\]

are all pullbacks. Since we know already that they are all double extensions, this is equivalent to the fact that the pair \( d_0, d_n \) is jointly monic, and this is equivalent to (2).
Thus any internal category always satisfies the second condition, and conversely any simplicial object satisfying the first one is an internal category where the square

$$
\begin{array}{ccc}
X_2 & \xrightarrow{d_0} & X_1 \\
\downarrow{d_1} & & \downarrow{d_0} \\
X_1 & \xrightarrow{d_0} & X_0
\end{array}
$$

is a pullback. This condition is equivalent to the internal category being a groupoid. □

Note that in the above proof we only needed to know that \( X \) was an internal category to prove that it satisfied the conditions; so this gives us a new proof of the fact that any internal category in a regular Mal’tsev category is an internal groupoid.

**Corollary 2.** The subcategory \( \text{Grpd}(C) \) of \( \text{Simp}(C) \) is closed under quotients and subobjects.

**Proof.** All the intersections that characterize internal groupoids in the previous proposition are preserved by regular epimorphisms of simplicial objects, which shows that groupoids are closed under quotients. Moreover they are also closed under subobjects; indeed, if \( m : X \to Y \) is a monomorphism in \( \text{Simp}(C) \) with \( Y \) a groupoid, then for any \( 0 \leq i < j \leq n \), the cube induced by the identity \( d_id_j = d_{j-1}d_i \) and \( m \) yields a commutative square

$$
\begin{array}{ccc}
X_n & \xrightarrow{m_n} & Y_n \\
\downarrow{\langle d_i,d_j \rangle} & & \downarrow{\langle d_i,d_j \rangle} \\
X_{n-1} \times X_{n-2} & \xrightarrow{m} & Y_{n-1} \times Y_{n-2}
\end{array}
$$

where the horizontal sides are monomorphisms and the right-hand vertical side is an isomorphism, and thus the left-hand vertical side is a monomorphism. Since it is also a regular epimorphism (by Lemma 1), this means \( \langle d_i,d_j \rangle \) is an isomorphism, hence \( X \) is an internal groupoid. □

**Remark.** In fact the previous corollary also characterizes Mal’tsev categories among the regular (or even finitely complete) ones: indeed a reflexive relation \( R \hookrightarrow X \times X \) is just a subobject of the reflexive graph \( (X \times X, X, \pi_1, \pi_2, \delta_X) \), and by taking iterated simplicial kernels, one can extend this to a monomorphism in \( \text{Simp}(C) \), whose codomain is just the nerve of the indiscrete equivalence relation/groupoid on \( X \). Thus every reflexive relation is a subobject of a groupoid, and a relation is a groupoid if and only if it is an equivalence relation. Accordingly:

**Corollary 3.** A regular category \( C \) is a Mal’tsev category if and only if \( \text{Grpd}(C) \) is closed under subobjects in \( \text{Simp}(C) \).

**Convention.** We now assume that the category \( C \) is also exact.

In this setting, we have
Theorem 1. The inclusion $\text{Grpd}(\mathcal{C}) \to \text{Simp}(\mathcal{C})$ admits a left adjoint $I : \text{Simp}(\mathcal{C}) \to \text{Grpd}(\mathcal{C})$, which makes $\text{Grpd}(\mathcal{C})$ a Birkhoff subcategory of $\text{Simp}(\mathcal{C})$.

Proof. Note first that since by definition $H_1(\mathbb{X}) \leq D_0 \land D_1$, $d_0$ and $d_1 : X_1 \to X_0$ both factor through the coequalizer $\eta_1$ of $H_1(\mathbb{X})$, and their factorizations have a common section $\eta_1 s_0$, which we will also denote $s_0$, so that we get a morphism of reflexive graphs

$$
\begin{array}{ccc}
X_1 & \xrightarrow{\eta_1} & X_{H_1(\mathbb{X})} \\
\downarrow d_1 & \Downarrow d_0 & \Downarrow d_1 \\
X_0 & &
\end{array}
$$

Let us then form the pullback

$$
\begin{array}{ccc}
\frac{X_1}{H_1(\mathbb{X})} \times X_0 & \xrightarrow{X_1}{\times} & X_1 \\
\downarrow \bar{d}_0 & & \downarrow \bar{d}_0 \\
\frac{X_1}{H_1(\mathbb{X})} \times X_0 & \xrightarrow{\bar{d}_2} & X_0
\end{array}
$$

By Proposition 4.1 in [6], $\eta_1 \times \eta_1 : X_1 \times X_0 \to \frac{X_1}{H_1(\mathbb{X})} \times X_0 \frac{X_1}{H_1(\mathbb{X})}$ is a regular epimorphism, and as a consequence so is

$$\langle \eta_1 d_0, \eta_1 d_2 \rangle = (\eta_1 \times \eta_1) \circ (d_0, d_2) : X_2 \to \frac{X_1}{H_1(\mathbb{X})} \times X_0 \frac{X_1}{H_1(\mathbb{X})},$$

which we will denote $\eta_2$. We also define $H_2(\mathbb{X}) = Eq[\eta_2]$. Now we need to show that $\eta_1 d_1 : X_2 \to \frac{X_1}{H_1(\mathbb{X})}$ factorizes through $\eta_2$; for this it is enough to show that $\eta_1 d_1(H_2(\mathbb{X})) = \Delta X_2$, which is equivalent to $d_1(H_2(\mathbb{X})) \leq H_1(\mathbb{X})$. Since $\bar{d}_0$ and $\bar{d}_2$ are jointly monic by construction, we find that

$$H_2(\mathbb{X}) = d_0^{-1}(H_1(\mathbb{X})) \land d_2^{-1}(H_1(\mathbb{X}))$$

$$= d_0^{-1}(d_0(D_1 \land D_2)) \land d_2^{-1}(d_2(D_0 \land D_1))$$

$$= (D_0 \lor (D_1 \land D_2)) \land (D_2 \lor (D_0 \land D_1)).$$

Using the modularity of the lattice of equivalence relations on $X_2$, one sees that this is equal to

$$((D_0 \lor (D_1 \land D_2)) \land D_2) \lor (D_0 \land D_1) = (D_0 \land D_2) \lor (D_1 \land D_2) \lor (D_0 \land D_1).$$

From this last expression, we get that $d_1(H_2(\mathbb{X})) = d_1(D_0 \land D_2) = H_1(\mathbb{X})$. This proves the existence of $\bar{d}_1$ such that $\bar{d}_1 \eta_2 = \eta_1 d_1$. Let us also denote $\bar{s}_0$ the unique map $\frac{X_1}{H_1(\mathbb{X})} \to \frac{X_1}{H_1(\mathbb{X})} \times X_0 \frac{X_1}{H_1(\mathbb{X})}$ such that $\bar{d}_0 \bar{s}_0 = 1_{\frac{X_1}{H_1(\mathbb{X})}}$ and $\bar{d}_2 \bar{s}_0 = \bar{s}_0 \bar{d}_1$, and $\bar{s}_1$ the unique map $\frac{X_1}{H_1(\mathbb{X})} \to \frac{X_1}{H_1(\mathbb{X})} \times X_0 \frac{X_1}{H_1(\mathbb{X})}$ such that $\bar{d}_2 \bar{s}_1 = 1_{\frac{X_1}{H_1(\mathbb{X})}}$ and $\bar{d}_0 \bar{s}_1 = \bar{s}_0 \bar{d}_1$. Using the fact that $\eta_1$ and $\eta_2$ are regular epimorphisms, one can now easily prove that all the simplicial identities are satisfied. This endows the quotient graph with the structure of a multiplicative
graph, which is then automatically a groupoid, which we denote $I(\mathbb{X})$. We also denote $\eta_\mathbb{X} : \mathbb{X} \to I(\mathbb{X})$ the morphism of simplicial objects induced by $1_{\mathbb{X}_0}$, $\eta_1$ and $\eta_2$. We can show that $\eta_n$ is is a regular epimorphism for all $n$, by iterating the argument showing that $\eta_2$ is a regular epimorphism.

The only thing that remains to be checked is that this construction is universal. For this we must prove that for every morphism $f : \mathbb{X} \to \mathbb{Y}$ to a groupoid $\mathbb{Y}$, there exists a factorization of $f_n$ through $\eta_n : X_n \to I(\mathbb{X})_n$ for all $n$ (note that such a factorization is unique, as every $\eta_n$ is a regular epimorphism). The case $n = 0$ is trivial as $\eta_0$ is the identity. For $n = 1$, it is enough to prove that $Eq[f_1] \geq H_1(\mathbb{X})$, or equivalently $f_1(H_1(\mathbb{X})) = \Delta_{Y_1}$.

Now $f_1(H_1(\mathbb{X})) = f_1d_1^\mathbb{X}(D_0^\mathbb{X} \land D_2^\mathbb{X}) = d_1^\mathbb{X}f_2(D_0^\mathbb{X} \land D_2^\mathbb{X}) \leq d_1^\mathbb{X}(D_0^\mathbb{Y} \land D_2^\mathbb{Y}) = \Delta_{Y_1}$.

This shows that the truncation of $f$ to a morphism $(f_1, f_0)$ of reflexive graph factors through the groupoid $X_1/H_1(\mathbb{X})$, with a factorization $(g_1, g_0 = f_0)$; applying the nerve functor allows us to extend this factorization to higher levels, resulting in morphisms $g_n : I(\mathbb{X})_n \to Y_n$. Then the factorizations $f_n = g_n\eta_n$ for $n \geq 2$ can be obtained from the universal property of the pullbacks defining each $\mathbb{X}_n$ and $Y_n$. Then since each $\eta_n$ is a regular epimorphism, the morphisms $g_n$ define a morphism of simplicial objects.

Let us denote $H_n(\mathbb{X})$ the kernel pair of $\eta_n$. We have proved already that $H_2(\mathbb{X}) = (D_0 \land D_1) \lor (D_0 \land D_2) \lor (D_1 \land D_2)$. For the next section, it will be useful to prove a similar formula for $H_n(\mathbb{X})$ for $n \geq 3$:

**Proposition 3.** For all $n \geq 2$, we have

$$H_n(\mathbb{X}) = \bigvee_{0 \leq i < j \leq n} (D_i \land D_j).$$

**Proof.** We prove the result by induction on $n$. The case $n = 2$ was done in the proof of Theorem 1. Now let us assume that it holds for $n$; since by construction the square

$$
\begin{array}{ccc}
I(\mathbb{X})_{n+1} & \xrightarrow{d_0} & I(\mathbb{X})_n \\
\downarrow{d_{n+1}} & & \downarrow{d_n} \\
I(\mathbb{X})_n & \xrightarrow{d_0} & I(\mathbb{X})_{n-1}
\end{array}
$$

is a pullback, so that the two maps $d_0, d_{n+1}$ are jointly monic, we have for $n + 1$

$$H_{n+1}(\mathbb{X}) = Eq[\eta_{n+1}] = Eq[d_0\eta_{n+1}] \land Eq[d_{n+1}\eta_{n+1}]
= Eq[\eta_n] \land Eq[\eta_n, d_{n+1}] = d_0^{-1}(H_n(\mathbb{X})) \land d_{n+1}^{-1}(H_n(\mathbb{X}))$$

Moreover, by the induction hypothesis we have the identities

$$H_n(\mathbb{X}) = \bigvee_{0 \leq i < j \leq n} (D_i \land D_j) = d_0\left(\bigvee_{0 < i < j \leq n+1} (D_i \land D_j)\right)$$
and
\[ H_n(X) = \bigvee_{0 \leq i \leq j \leq n} (D_i \wedge D_j) = d_{n+1} \left( \bigvee_{0 \leq i < j < n+1} (D_i \wedge D_j) \right). \]
Combining all these, we get the identity
\[ H_{n+1}(X) = \left( D_0 \lor \bigvee_{0 < i < j \leq n+1} (D_i \wedge D_j) \right) \land \left( D_{n+1} \lor \bigvee_{0 \leq j < n+1} (D_i \wedge D_j) \right). \]
From there we already see that
\[ H_{n+1}(X) \geq \bigvee_{0 \leq i < j \leq n+1} (D_i \wedge D_j). \]
For the converse inequality, first note that
\[ \bigvee_{0 < i < j \leq n+1} (D_i \wedge D_j) \leq \left( D_{n+1} \lor \left( \bigvee_{0 \leq j < n+1} (D_i \wedge D_j) \right) \right), \]
and thus, since the lattice of equivalence relations of \( X_{n+1} \) is modular, we have
\[ H_{n+1}(X) = \bigvee_{0 < i < j \leq n+1} (D_i \wedge D_j) \lor \left( D_0 \land \left( D_{n+1} \lor \bigvee_{0 \leq j < n+1} (D_i \wedge D_j) \right) \right). \]
Now to conclude the proof it is enough to prove that
\[ D_0 \land \left( D_m \lor \bigvee_{0 \leq i < j < m+1} (D_i \wedge D_j) \right) = \bigvee_{0 < j \leq m} (D_0 \wedge D_j) \quad (3) \]
for all \( m \geq 1 \), which we will do by induction. The case where \( m = 1 \) is trivial, so let us now assume that (3) holds for some \( m \). Then we have
\[
\begin{align*}
d_m \left( D_0 \land \left( D_{m+1} \lor \bigvee_{0 \leq i < j < m+1} (D_i \wedge D_j) \right) \right) \\
\leq d_m(D_0) \land \left( d_m(D_{m+1}) \lor \bigvee_{0 \leq i < j < m+1} d_m(D_i \wedge D_j) \right) \\
= D_0 \land \left( D_m \lor \bigvee_{0 \leq i < j < m+1} (D_i \wedge D_j) \right) \\
= \bigvee_{0 < j \leq m} (D_0 \wedge D_j) \\
= d_m \left( \bigvee_{0 < j \leq m+1} (D_0 \wedge D_j) \right),
\end{align*}
\]
and as a consequence we have

\[ D_0 \land \left( D_{m+1} \lor \bigvee_{0 \leq i < j < m+1} (D_i \land D_j) \right) \leq D_m \lor \bigvee_{0 < j \leq m+1} (D_0 \land D_j). \]

It follows that the left-hand side must be equal to

\[ D_0 \land \left( D_{m+1} \lor \bigvee_{0 \leq i < j < m+1} (D_i \land D_j) \right) \land \left( D_m \lor \bigvee_{0 < j \leq m+1} (D_0 \land D_j) \right). \]

Now since \( \bigvee_{0 < j \leq m+1} (D_0 \land D_j) \leq D_0 \), using again the modularity law, we find that

\[ D_0 \land \left( D_{m+1} \lor \bigvee_{0 < j \leq m+1} (D_0 \land D_j) \right) = \bigvee_{0 < j \leq m+1} (D_0 \land D_j), \]

and this is smaller than \( \left( D_{m+1} \lor \bigvee_{0 \leq i < j < m+1} (D_i \land D_j) \right) \), which concludes the proof. \( \square \)

**Remark.** If the category \( \mathcal{C} \) is not only exact Mal’tsev but also arithmetical (\([36]\)), then the category \( \text{Grpd}(\mathcal{C}) \) coincides with the category of equivalence relations, which is thus a Birkhoff subcategory of \( \text{Simp}(\mathcal{C}) \). Note that in that case, \( H_1(X) = d_0(D_1 \land D_2) = D_0 \land D_1 \), since direct images preserve intersections of equivalence relations (by Theorem 5.2 of \([7]\)). Accordingly our reflection becomes a reflection of \( \text{Simp}(\mathcal{C}) \) into \( \text{Eq}(\mathcal{C}) \).

Since every groupoid is a quotient of an equivalence relation, \( \text{Eq}(\mathcal{C}) \) is closed under quotients in \( \text{Simp}(\mathcal{C}) \) if and only if \( \text{Eq}(\mathcal{C}) = \text{Grpd}(\mathcal{C}) \).

**Corollary 4.** An exact Mal’tsev category is arithmetical if and only if \( \text{Eq}(\mathcal{C}) \) is a Birkhoff subcategory of \( \text{Simp}(\mathcal{C}) \).

**Remark.** Note that, by contrast with the Smith-Pedicchio commutator, whose quotient gives a left adjoint of the forgetful/inclusion functor \( \text{Grpd}(\mathcal{C}) \rightarrow \text{RG}(\mathcal{C}) \), we don’t need to assume the existence of any colimits to define \( H_1(X) \).

### 3. Characterization of central extensions

Being a Birkhoff subcategory of the exact Mal’tsev category \( \text{Simp}(\mathcal{C}) \), \( \text{Grpd}(\mathcal{C}) \) is admissible in the sense of categorical Galois theory, when \( \mathcal{F} \) is the class of all regular epimorphisms. In this section we will characterize the central extensions with respect to this reflection.

**Convention.** If \( f : X \rightarrow Y \) is a map in \( \text{Simp}(\mathcal{C}) \), we will denote \( F_n \) the kernel pair of the corresponding map \( f_n : X_n \rightarrow Y_n \), for all \( n \geq 0 \). Similarly, for maps \( g : Z \rightarrow W \) and \( f' : X' \rightarrow Y' \) in \( \text{Simp}(\mathcal{C}) \), we will denote the corresponding kernel pairs \( G_n \) and \( F'_n \) (for \( n \geq 0 \)), respectively.

First, we note that Proposition 4.2 of \([28]\) implies, in our case, that trivial extensions \( f : X \rightarrow Y \) are characterized by the property that \( F_n \land H_n(X) = \Delta_{X_n} \) for all \( n \geq 0 \), that is:

...
\[ F_n \land \left( \bigvee_{0 \leq i < j \leq n} D_i \land D_j \right) = \Delta_{X_n} \]

for \( n \geq 2 \) and

\[ F_1 \land d_0(D_1 \land D_2) = \Delta_{X_1}. \]

Our characterization of central extensions is then obtained simply by "distributing" the intersection with \( F_n \) appearing in these equations with the join or image. In other words we have

**Theorem 2.** A regular epimorphism \( f : X \to Y \) is a central extension with respect to the Galois structure induced by the reflection of \( \text{Simp}(\mathcal{C}) \) into \( \text{Grpd}(\mathcal{C}) \) if and only if

\[ d_1(F_1 \land D_0 \land D_2) = \Delta_{X_1} \quad (4) \]

and

\[ F_n \land D_i \land D_j = \Delta_{X_n} \quad \forall 0 \leq i < j \leq n \quad (5) \]

for all \( n \geq 2 \).

To prove this we will need a couple of lemmas.

**Lemma 3.** Let

\[
\begin{array}{ccc}
P & \xrightarrow{g'} & X \\
\downarrow{f'} & & \downarrow{f} \\
Z & \xrightarrow{g} & Y
\end{array}
\]

be a pullback square of regular epimorphisms in \( \text{Simp}(\mathcal{C}) \), and let \( n \geq 2 \) and \( 0 \leq i < j \leq n \). Let us denote \( d'_i \) the face maps of the simplicial object \( P \), and \( D'_i \) their kernel pairs. Then

\[ F_n \land D_i \land D_j = \Delta_{X_n} \leftrightarrow F'_n \land D'_i \land D'_j = \Delta_{P_n}. \]

**Proof.** Since pullbacks in \( \text{Simp}(\mathcal{C}) \) are computed "levelwise" in \( \mathcal{C} \), for all \( n \) the square

\[
\begin{array}{ccc}
P_n & \xrightarrow{g'_n} & X_n \\
\downarrow{f'_n} & & \downarrow{f_n} \\
Z_n & \xrightarrow{g} & Y_n
\end{array}
\]
is a pullback. Since moreover limits commute with limits, in the cube

\[
\begin{aligned}
P_n & \xrightarrow{g'_n} X_n & \xrightarrow{f_n} Y_n \\
\downarrow & & \downarrow \\
P_{n-1} \times P_{n-2} P_{n-1} & \xrightarrow{X_{n-1} \times X_{n-2} X_{n-1}} & \xrightarrow{Y_{n-1} \times Y_{n-2} Y_{n-1}} \\
\downarrow & & \downarrow \\
Z_{n-1} \times Z_{n-2} Z_{n-1} & \xrightarrow{g_n} & \xrightarrow{(d_i,d_j)} \xrightarrow{(d',d')_n} \xrightarrow{(d,d)_n} \xrightarrow{(d_i,d_j)} \xrightarrow{(d',d')_n} \\
\end{aligned}
\]

the top and bottom faces are pullbacks; one can then show that the square

\[
\begin{aligned}
P_n & \xrightarrow{g'_n} X_n \\
\downarrow & & \downarrow \\
(P_{n-1} \times P_{n-2} P_{n-1}) \times Z_{n-1} \times Z_{n-2} Z_{n-1} Z_n & \xrightarrow{(X_{n-1} \times X_{n-2} X_{n-1}) \times Y_{n-1} \times Y_{n-2} Y_{n-1}} Y_n \\
\end{aligned}
\]

is a pullback, which implies that

\[
g'_n(F'_n \wedge D'_i \wedge D'_j) = F_n \wedge D_i \wedge D_j. \tag{6}
\]

In particular, \(F'_n \wedge D'_i \wedge D'_j = \Delta_{P_n}\) implies that \(F_n \wedge D_i \wedge D_j = \Delta_{X_n}\).

For the converse, the equation (6) shows already that if \(g'_n(F'_n \wedge D'_i \wedge D'_j) \leq G'_n\), then \(F'_n \wedge D'_i \wedge D'_j \leq G'_n\). Since it is also smaller than \(F'_n\), and since \(f'_n\) and \(g'_n\) are jointly monic by construction, we have \(F'_n \wedge D'_i \wedge D'_j = \Delta_{P_n}\). \(\square\)

**Lemma 4.** Let \(f : X \to Y\) be a split epimorphism, with section \(s : Y \to X\), and let \(A, B\) be two equivalence relations on \(X\), with respective coequalizers \(q_A, q_B\). Assume that we have a diagram

\[
\begin{aligned}
X/A & \xleftarrow{q_A} X & \xrightarrow{q_B} X/B \\
\downarrow & s \downarrow f & \downarrow \\
Y/A' & \xleftarrow{q_{A'}} Y & \xrightarrow{q_{B'}} Y/B'
\end{aligned}
\]

where the vertical downward arrows are split epimorphisms, and the upward and downward squares commute. Then the following conditions are equivalent:

1. \(Eq[f] \wedge (A \cup B) = \Delta_X\)
2. \(Eq[f] \wedge A = \Delta_X = Eq[f] \wedge B.\)

**Proof.** First of all, we have the inequality

\[(Eq[f] \wedge A) \cup (Eq[f] \wedge B) \leq Eq[f] \wedge (A \cup B),\]

which immediately proves that the first condition implies the second.
For the converse, we can complete the diagram (7) by taking the pushouts of the top and bottom spans. This yields a cube

\[
\begin{array}{cccccc}
X & \xrightarrow{q_B} & X/B & \xleftarrow{\langle q_A, f \rangle} & X/A \\
Y & \xrightarrow{q_{B'}} & Y/B' & \xleftarrow{\gamma} & Y/A'
\end{array}
\]

which is a split epimorphism between double extensions, hence a triple extension. In particular, the square

\[
\begin{array}{ccc}
X & \xrightarrow{q_B} & X/B \\
X/A \times_{Y/A'} Y & \xrightarrow{\gamma} & X/(A \lor B) \times_{Y/(A' \lor B')} Y/B'
\end{array}
\]

is a double extension. Assume now that \( Eq[f] \land A = \Delta_X = Eq[f] \land B. \) The first equality implies that \( \langle q_A, f \rangle \) is a mono, hence an iso; then so is \( \gamma \) in the diagram above, and thus the left and right faces of the cube are pullbacks. Similarly, the second equality \( B \land Eq[f] \) implies that the top face is a pullback as well, and then so is the square

\[
\begin{array}{ccc}
X & \xrightarrow{q_{A \lor B}} & X/(A \lor B) \\
Y & \xrightarrow{f} & Y/(A' \lor B'),
\end{array}
\]

since it is the composite of the top and right faces. This implies that \( Eq[f] \land (A \lor B) = \Delta_X. \)

Proof of Theorem 2. Let us consider the diagram

\[
\begin{array}{cccc}
I(X \times_Y X) & \xrightarrow{\pi_X \times_Y X} & X \times_Y X & \xrightarrow{\pi_2} & X \\
I(\pi_1) & \xleftarrow{\eta_X} & X & \xrightarrow{f} & Y.
\end{array}
\]

Now assume first that \( f \) is a central extension, so that the left-hand square is a pullback. Since by construction \( I(X \times_Y X) \) is an internal groupoid, \( \Box \) holds for \( I(\pi_1) \), and then by Lemma \( \Box \) it also holds for \( \pi_1 \) and thus for \( f \).
Assuming now that (5) holds, then again by Lemma 3 it also holds with $\pi_1 : X \times_Y X \to X$, so that
\[ Eq((\pi_1)_n] \land D'_i \land D'_j = \Delta_{X \times_Y X_n} \land 0 \leq i < j \leq n. \]
But $\pi_1$ is a split epimorphism in the category of simplicial objects of $C$. Thus in particular, for all $0 \leq i < j \leq n$, $(\pi_1)_n$ and $D'_i \land D'_j$ satisfy the assumptions of Lemma 4 and thus we have
\[ Eq((\pi_1)_n] \land H_n(X \times_Y X) = Eq((\pi_1)_n] \land \left( \bigvee_{0 \leq i < j \leq n} D'_i \land D'_j \right) = \Delta_{X \times_Y X_n}. \]
This implies that the left-hand square is a pullback; thus $\pi_1$ is a trivial extension, and $f$ is a central extension.

The equivalence relation $F_2 \land D_0 \land D_1$ is the kernel pair of the arrow $\theta_2^2 : \Lambda^2(X_2) \times \Lambda^2(Y_2)$ defined as in (2). Since $\theta_2^2$ is a regular epimorphism in $C$ whenever $f$ is in $F$, $F_2 \land D_0 \land D_1$ is trivial if and only if the square
\[
\begin{array}{ccc}
X_2 & \xrightarrow{f_2} & Y_2 \\
\downarrow \lambda_2^2 & & \downarrow \lambda_2^2 \\
\Lambda^2(X_2) & \xrightarrow{\Lambda^2(f)} & \Lambda^2(Y_2)
\end{array}
\]
is a pullback. The triviality of $F_2 \land D_0 \land D_2$ and $F_2 \land D_1 \land D_2$ can be interpreted in the same way with the horn objects $\Lambda^2_0$ and $\Lambda^2_1$.

Moreover, the higher order conditions $F_n \land D_i \land D_j = \Delta_{X_n}$ imply that all the morphisms $\theta^n_k$ for $n \geq 2$ are isomorphisms, and thus that all squares
\[
\begin{array}{ccc}
X_n & \xrightarrow{f_n} & Y_n \\
\downarrow \lambda^n_k & & \downarrow \lambda^n_k \\
\Lambda^n_k(X) & \xrightarrow{\Lambda^n_k(f)} & \Lambda^n_k(Y)
\end{array}
\]
are isomorphisms. One can prove that the converse is true as well.

**Corollary 5.** An extension $f : X \to Y$ in $\text{Simp}(C)$ is central with respect to the reflection of $\text{Simp}(C)$ into $\text{Grpd}(C)$ if and only if $f$ is an exact fibration at all dimensions $n \geq 2$ in the sense of Glenn ([20]).

4. Comparison with simplicial sets

As noted before, the left adjoint to the nerve functor between groupoids and simplicial sets is the fundamental groupoid functor [19]. For a simplicial set $X$ which satisfies the Kan condition, also called a quasigroupoid, this left adjoint can alternatively be described as the homotopy groupoid (see [1 31]). One defines the homotopy relation on $X_1$ by saying that two elements (or 1-simplices) $f, g \in X_1$ are homotopic if and only if there
exists $\alpha \in X_2$ such that $d_0(\alpha) = f$, $d_1(\alpha) = g$ and $d_2(\alpha) = s_0d_1f = s_0d_1g$. This is always a reflexive relation (since for a given $f$ one can take $\alpha = s_0f$), and using the Kan condition one can then prove that this is actually an equivalence relation. The homotopy groupoid is then the groupoid whose objects are just the elements of $X_0$, arrows are homotopy classes of 1-simplices, identities defined by the classes of degenerate 1-simplices, and composition defined by the existence of fillers for (2,1)-horns (with two sided inverses defined by the existence of fillers for the outer horns).

This relation can be interpreted in any regular category as follows: first take the pullback

$$
\begin{array}{ccc}
X_2 \times_{X_1} X_0 & \overset{\pi_2}{\longrightarrow} & X_0 \\
\downarrow_{\pi_1} & & \downarrow_{s_0} \\
X_2 & \underset{d_2}{\longrightarrow} & X_1,
\end{array}
$$

and then factorize the map $(d_0, d_1)\pi_1 : X_0 \times_{X_1} X_2 \rightarrow X_1 \times X_1$ as a regular epimorphism $q : P \rightarrow R$ followed by a monomorphism $r = (\rho_1, \rho_2) : R \rightarrow X_1 \times X_1$, so that $R$ is a relation on $X_1$. As in the case of sets, this is a reflexive relation; indeed, the simplicial identities imply that

$$(\rho_1, \rho_2)(q(d_1, s_0)) = (d_0, d_1)\pi_2(d_1, s_0) = (d_0, d_1)s_0 = (1_{X_1}, 1_{X_1}).$$

This relation is in fact equal to $d_0(D_1 \land F_1)$ whenever $\mathbb{X}$ satisfies the Kan condition, as we shall now see. In fact it will be helpful to prove a slightly more general result:

**Lemma 5.** Given any regular epimorphism $f : \mathbb{X} \rightarrow \mathbb{Y}$ between two simplicial objects, if we take the pullback

$$
\begin{array}{ccc}
X_1 \times_{Y_1} Y_0 & \overset{\pi_2}{\longrightarrow} & Y_0 \\
\downarrow_{\pi_1} & & \downarrow_{s_0^Y} \\
X_1 & \underset{f_1}{\rightarrow} & Y_1,
\end{array}
$$

then $d_0(D_1 \land F_1)$ is equal to the regular image of $(d_0, d_1)\pi_1 : X_1 \times_{Y_1} Y_0 \rightarrow X_0 \times X_0$.

The case where $f$ is the morphism $\epsilon_\mathbb{X} : Dec(\mathbb{X}) \rightarrow \mathbb{X}$ gives the desired identity.
Proof. Consider the diagram

\[
\begin{array}{ccccccccccc}
Y_1 \times_{Y_2} X_2 & \xrightarrow{\pi'_1} & X_2 & \xrightarrow{\pi_1} & X_1 \\
\downarrow d_0 \times d_0 & & \downarrow d_0 & & \downarrow \pi'_2 & & \downarrow d_0 & & \downarrow \pi_2 \\
Y_0 \times_{Y_1} X_1 & \xrightarrow{\pi'_2} & Y_1 & \xrightarrow{s_1'} & Y_2 & \xrightarrow{s_0'} & Y_0 \\
\end{array}
\]

where the top and bottom faces of the cube are pullbacks. Since all the vertical arrows are split by a degeneracy map \(s_0\), and the horizontal maps commute with these sections, the dotted arrow is a split epimorphism as well. In particular, the image factorization of \((d_0^X, d_1^X)\pi_1\) is the same as that of \((d_0^X, d_0^X)\pi_1(d_0 \times d_0) = (d_0^X \times d_0^X)(d_1^X, d_2^X)\pi'_1\). If we prove that the image of \((d_0^X, d_0^X)(d_1^X, d_2^X)\pi'_1\) in \(X_1 \times X_1\) is the equivalence relation \(D_1 \wedge F_1\), then it would follow that the image of \((d_0^X \times d_0^X)(d_1^X, d_2^X)\pi_1\) is \(d_0(D_1 \wedge F_1)\), which would conclude the proof.

Since we have a decomposition of \(f_2\) given by the diagram

\[X_2 \xrightarrow{\phi_2} Y_2 \xrightarrow{\varphi_2} Y_2\]

we can rewrite the top pullback in (9) as the upper rectangle in the following diagram:

\[
\begin{array}{ccccccccccc}
X_2 \times_{Y_2} Y_1 & \xrightarrow{q} & P & \xrightarrow{m} & Y_1 \\
\downarrow \pi'_1 & & \downarrow m & & \downarrow s_1' \\
X_2 & \xrightarrow{\theta_0^2} & \Lambda_0^2(\mathcal{X}) \times_{\Lambda_0^2(\mathcal{Y})} Y_2 & \xrightarrow{\varphi_2} & Y_2 \\
\downarrow \lambda_0 & & \downarrow \lambda_0 & & \downarrow \lambda_0 \\
\Lambda_0^2(\mathcal{X}) & \xrightarrow{\varphi_1} & \Lambda_0^2(\mathcal{X}) \times_{\Lambda_0^2(\mathcal{Y})} Y_2 & \xrightarrow{\varphi_2} & Y_2 \\
\end{array}
\]

Now since \(\Delta_{Y_1} = (d_1^Y, d_2^Y)s_1' : Y_1 \rightarrow Y_1 \times Y_1\), the composition \(\lambda_0^2s_1\) is a monomorphism, and thus so is \(\varphi_1m\). Since \(\lambda_0^2\) is the regular epimorphism in the factorization of \((d_1^X, d_2^X)\):
$X_2 \to X_1 \times X_1$, $P$ is the image of the map $(d_1^X, d_2^X)\pi'_1$. On the other hand, the right-hand rectangle above coincides with the left-hand square in the rectangle

$$
\begin{array}{ccc}
P & \longrightarrow & Y_1 \\
\varphi_{1m} \downarrow & & \downarrow \Delta \\
\Lambda_0^2(X) \longrightarrow \Lambda_0^2(Y) & \longrightarrow & Y_1 \times Y_1.
\end{array}
$$

Since the two squares are pullbacks, the whole rectangle is one as well. But this is the same as the outer rectangle in

$$
\begin{array}{ccc}
P & \longrightarrow & F_1 \\
\varphi_{1m} \downarrow & & \downarrow \Delta \\
\Lambda_0^2(X) & \longrightarrow & X_1 \times X_1 \\
& \longrightarrow & Y_1 \times Y_1,
\end{array}
$$

where the two squares are again pullbacks. Thus $P$ coincides with the intersection $D_1 \land F_1$, which concludes the proof. □

**Remark.** If one sees a Kan complex as a quasigroupoid or $\infty$-groupoid, then the left adjoint to the nerve or inclusion functor $\text{Grpd} \to \text{Kan}$ is in a sense a "strictification", which turns quasigroupoids into actual groupoids.

The equivalence relation $d_0(D_1 \land D_2 \land F_2)$ which appears in our characterization of central extensions admits an alternative construction, similar to that of $H_1(X)$. More precisely, if we take now $L$ to be the limit of the lower part of the diagram

$$
\begin{array}{ccc}
X_0 & \stackrel{k}{\longrightarrow} & L \\
\downarrow_{s_0} & & \downarrow_{p_1} \\
X_2 & \longrightarrow & Y_1 \\
\end{array}
$$

(with the dotted arrows forming the limit cone) then $d_0(D_1 \land D_2 \land F_2)$ is equal to the image of the map $(d_0, d_1)\rho_2 : L \to X_1 \times X_1$.

Indeed, the limit in diagram (10) can also be obtained as the pullback

$$
\begin{array}{ccc}
L & \longrightarrow & X_0 \times Y_1 \\
\rho_2 \downarrow & & \downarrow_{s_0 \times s_0} \\
X_2 & \stackrel{(d_2, f_2)}{\longrightarrow} & X_1 \times Y_2.
\end{array}
$$
Now the image of the map \((d_2, f_2)\) is the pullback \(X_1 \times_{Y_1} Y_2\) of \(f_1\) along \(d_2\). Moreover, we have

\[
f_0 \rho_1 = d_0 s_0 f_0 \rho_1 = d_0 f_1 s_0 \rho_1 = d_0 f_1 d_2 \rho_2 = d_0 d_2 f_2 \rho_2 = d_0 d_2 s_0 \rho_3 = d_1 d_0 s_0 \rho_3 = d_1 \rho_3,
\]

so that \((\rho_1, \rho_3)\) factors through \(X_0 \times_{Y_0} X_1\). Thus the pullback square above factorises as a rectangle

\[
\begin{array}{ccc}
L & \xrightarrow{(\rho_1, \rho_3)} & X_0 \times_{Y_0} X_1 \\
\downarrow & & \downarrow \text{seg}\times \text{seg} \\
X_2 & \xrightarrow{(d_2, f_2)} & X_1 \times_{Y_1} Y_2
\end{array}
\]

and one can easily show that the right-hand square is a pullback, and as a consequence so is the left-hand side square. But this square is exactly the pullback that appears if we apply Lemma 5 to the induced map \(\langle \epsilon_X, \text{Dec}(f) \rangle : \text{Dec}(X) \to X \times_X \text{Dec}(Y)\), which is a regular epimorphism between simplicial objects because the square

\[
\begin{array}{ccc}
\text{Dec}(X) & \xrightarrow{\text{Dec}(f)} & \text{Dec}(Y) \\
\downarrow \epsilon_X & & \downarrow \epsilon_Y \\
X & \xrightarrow{f} & Y
\end{array}
\]

is a double extension in \(C\) for all \(n\). Thus Lemma 5 implies that the two constructions are equal.

5. The Relative Monotone-Light Factorization System

In order to prove that our Galois structure admits a relative monotone-light factorization system, we use the following criterion, due to Carboni, Janelidze, Kelly and Paré in the absolute case and to Chikhladze in the relative case:

**Proposition 4** ([9, 15]). Let \((C, \mathcal{X}, I, \mathcal{F})\) be an admissible Galois structure. The class \(\mathcal{F}\) admits monotone-light factorization if for each object \(B\) of \(C\) there is an effective \(\mathcal{F}\)-descent morphism \(p : C \to B\) where \(C\) is a stabilizing object, i.e. an object such that if \(h = \text{me}\) is the \((\mathcal{E}, \mathcal{M})\)-factorization of any morphism \(h : X \to C\), then any pullback of \(e\) along a map in \(\mathcal{F}\) is still in \(\mathcal{E}\).

We will prove that, in our case, the shifting \(\text{Dec}(X)\) of a simplicial object \(X\) is always stabilizing. For this it suffices to prove that exact objects are stabilizing since we have:

**Proposition 5** ([18], Proposition 3.9). Any simplicial object that is contractible and also satisfies the Kan condition is exact.

As a consequence, if \(X\) satisfies the Kan condition, then its shifting \(\text{Dec}(X)\) is exact. We will need the following characterization of images in regular categories:
Lemma 6. If \( Y \) is exact at \( Y_2 \), and \( f : X \to Y \) is a regular epimorphism in \( \text{Simp}(C) \), then
\[
d_0(D_1 \wedge D_2) \wedge F_1 = d_0(D_1 \wedge D_2 \wedge F_2).
\]

Note that this equality means that an extension whose codomain is exact is trivial if and only if it is central.

Proof. The inequality
\[
d_0(D_1 \wedge D_2 \wedge F_2) \leq d_0(D_1 \wedge D_2) \wedge F_1
\]
always hold. To prove the converse, we consider the inclusion \( \varphi = (\varphi_1, \varphi_2) \) of the equivalence relation \( d_0(D_1 \wedge D_2) \wedge F_1 \) into \( X_1 \times X_1 \). Since this relation is smaller than \( d_0(D_1 \wedge D_2) \), by the characterization given in Proposition 6 and the alternative construction of \( d_0(D_1 \wedge D_2) \) given in Section 6, there must exist a regular epimorphism \( p : Z \to d_0(D_1 \wedge D_2) \wedge F_1 \) and a morphism \( \alpha = (\alpha_1, \alpha_2) : Z \to X_2 \times_{X_i} X_0 \) such that \( d_0\alpha_1 = \varphi_1 p \) and \( d_1\alpha_1 = \varphi_2 p \); and since moreover it is smaller than \( F_1 \) we have \( f_1 d_0\alpha_1 = f_1 d_1\alpha_1 \), which can be rewritten \( d_0 f_2 \alpha_1 = d_1 f_2 \alpha_1 \).

Now consider the maps
\[
y_0 = y_1 = s_1 d_0 f_2 \alpha_1 = s_1 d_1 f_2 \alpha_1
\]
\[
y_2 = s_0 d_1 f_2 \alpha_1
\]
\[
y_3 = f_2 \alpha_1.
\]

One can check that the identity \( d_i y_j = d_{j-1} y_i \) holds for all \( 0 \leq i < j \leq 3 \), so that these maps determine a map \( y \) from \( Z \) to the third simplicial kernel \( K_3(Y) \), and we can consider the pullback

\[
Z' \xrightarrow{p'} Z
\]
\[
\alpha' \downarrow \quad y \downarrow
\]
\[
Y_3 \xrightarrow{\kappa_3} K_3(Y).
\]

\( Y \) being exact at \( Y_2 \) means that \( \kappa_3 \) is a regular epimorphism, and as a consequence so is \( p' \). Consider now the maps
\[
x_0 = s_1 d_0 \alpha_1 p'
\]
\[
x_1 = s_1 d_1 \alpha_1 p'
\]
\[
x_3 = \alpha_1 p',
\]
from \( Z' \) to \( X_2 \). One can check that the identity \( d_i x_j = d_{j-1} x_i \) holds for all \( i < j \) and \( i \neq 2 \neq j \), thus they determine a map \( x : Z' \to \Lambda^3_2(X) \); and moreover we have
\[
d_i \alpha' = \mu_i \kappa_3 \alpha' = \mu_i y p' = y_i p' = f_2 x_i
\]
for \( i = 0, 1, 3 \), which implies that \( \lambda^3_2 \alpha' = \Lambda^3_2(f)x \). Thus \( x \) and \( \alpha' \) induce a map \( Z' \to \Lambda^3_2(X) \times_{\Lambda^3_2(Y)} Y_3 \). Consider then the pullback

\[
\begin{array}{ccc}
Z'' & \xrightarrow{p''} & Z' \\
\downarrow{\alpha''} & & \downarrow{(x, \alpha')} \\
X_3 & \xrightarrow{\theta^3_2} & \Lambda^3_2(X) \times_{\Lambda^3_2(Y)} Y_3.
\end{array}
\]

Since \( \theta^3_2 \) is a regular epimorphism, so is \( p'' \), and by construction we have \( d_i \alpha'' = x_i p'' \) for \( i = 0, 1, 3 \) and \( f_3 \alpha'' = \alpha' p'' \). Now the map \( d_2 \alpha'' : Z'' \to X_2 \) is such that

\[
f_2 d_2 \alpha'' = d_2 f_3 \alpha'' = d_2 \alpha' p'' = y_2 p' p'' = s_0 d_1 f_2 \alpha_1 p' p''
\]

and

\[
d_2 d_2 \alpha'' = d_2 d_3 \alpha'' = d_2 x_3 p'' = d_2 \alpha_1 p' p'' = s_0 \alpha_2 p' p''.
\]

hence there exists a unique map \( \beta : Z'' \to L \) (where \( L \) is defined by (10)) such that

\[
\rho_1 \beta = \alpha_2 p' p'', \quad \rho_2 \beta = d_2 \alpha'' \quad \text{and} \quad \rho_3 \beta = f_1 d_1 \alpha_1 p' p''.
\]

Now we can check that

\[
(d_0, d_1) \rho_2 \beta = (d_0, d_1) d_2 \alpha'' = (d_1 d_0, d_1 d_1) \alpha'' = (d_1 x_0, d_1 x_1) p''
\]

\[
= (d_1 s_1 d_0, d_1 s_1 d_1) \alpha_1 p' p'' = (d_0, d_1) \alpha_1 p' p''
\]

\[
= (\varphi_1, \varphi_2) p p' p''.
\]

This proves that \( d_0(D_1 \land D_2) \land F_1 \leq d_0(D_1 \land D_2 \land F_2) \). \qed

**Lemma 7.** If \( \mathcal{Y} \) is exact, then \( \mathcal{Y} \) is stabilizing : given any morphism \( f : X \to \mathcal{Y} \), the induced map \( \langle f, \eta_X \rangle : X \to \mathcal{Y} \times_{I(\mathcal{Y})} I(X) \) is stably in \( \mathcal{E} \).

**Proof.** To simplify the diagrams, we denote \( \mathbb{P} = \mathcal{Y} \times_{I(\mathcal{Y})} I(X) \). Let us consider a pullback square

\[
\begin{array}{ccc}
\mathbb{Q} & \xrightarrow{g'} & X \\
\downarrow{h} & & \downarrow{(f, \eta_X)} \\
\mathcal{Z} & \xrightarrow{g} & \mathbb{P}
\end{array}
\]

with \( g \) a regular epimorphism in \( \text{Simp}(\mathcal{C}) \).

We need to prove that \( I(h) : I(\mathbb{Q}) \to I(\mathbb{Z}) \) is invertible. Since it is a map between internal groupoids, it is enough to prove that \( I(h)_0 \) and \( I(h)_1 \) are invertible. Note that the functor \( I \) leaves the objects \( X_0 \) unchanged, and thus \( \langle f_0, \eta_0 \rangle \) is an isomorphism, and thus so are \( h_0 \) and \( I(h)_0 \). So we only need to prove is that \( I(h)_1 \) is an isomorphism.

Since \( \text{Grpd}(\mathcal{C}) \) is a Birkhoff subcategory of \( \text{Simp}(\mathcal{C}) \) and \( h \) is a regular epimorphism, the square

\[
\begin{array}{ccc}
\mathbb{Q} & \xrightarrow{\eta_2} & I(\mathbb{Q}) \\
\downarrow{h} & & \downarrow{I(h)} \\
\mathcal{Z} & \xrightarrow{\eta_2} & I(\mathbb{Z})
\end{array}
\]
is a double extension in $\text{Simp}(C)$, and thus the square

$$
\begin{array}{ccc}
Q_1 & \xrightarrow{(\eta_2)_1} & Q_1/H_1(Q) \\
\downarrow h_1 & & \downarrow h_1 \\
Z_1 & \xrightarrow{(\eta_2)_1} & Z_1/H_1(Z)
\end{array}
$$

(12)

is a (regular) pushout in $C$. This already proves that $\overline{h_1} = I(h_1)$ is a regular epi. Now if there exists a map $t : Z_1 \rightarrow Q_1/H_1(Q)$ such that $th_1 = (\eta_Q)_1$, then using the universal property of the pushout (12) we can construct a retraction for $\overline{h_1}$, which proves that it is an isomorphism. So we are left to prove that such a map $t$ exists; since $h_1$ is a regular epimorphism, it is enough to prove that $Eq[h_1] \leq H_1(Q)$.

To prove this, we denote $\psi_1, \psi_2 : Eq[h_1] \rightarrow Q_1$ the two projections of the kernel pair. Then the commutativity of (11) (or rather, the corresponding commutative square involving $h_1$ in $C$) implies that

$$g_1'(Eq[h_1]) \leq Eq[(f_1, (\eta_X)_1] = F_1 \wedge H_1(X) = d_0(D_1 \wedge D_2 \wedge F_2)$$

where the last equality is the preceding lemma. As a consequence, we know that there must exist an arrow $\alpha : A \rightarrow L$ and a regular epimorphism $p : A \rightarrow Eq[h_1]$ such that $(d_0, d_1, \rho_2)\alpha = (g_1' \times g_1')(\psi_1, \psi_2)p$.

We now prove that $\langle f_2, \eta_2 \rangle \rho_2 \alpha$ factors through a degeneracy of $P$. More precisely, we prove that

$$\langle f_2, \eta_2 \rangle \rho_2 \alpha = s_0^P d_0^P \langle f_2, \eta_2 \rangle \rho_2 \alpha.$$  

(13)

Since the degeneracy map $s_0^P$ is induced by those of $I(X)$ and $Y$, it is enough to prove that $f_2 \rho_2 \alpha$ and $\eta_2 \rho_2 \alpha$ factorize in the same manner through $s_0^Y$ and $s_0^I(X)$ respectively.

By construction we must have

$$s_0^Y d_0^Y f_2 \rho_2 \alpha = s_0^Y d_0^Y s_0^Y s_0^Y \rho_3 \alpha = s_0^Y \rho_3 \alpha = f_2 \rho_2 \alpha.$$  

On the other hand we have

$$d_0^I(X) \eta_2 \rho_2 \alpha = d_0^I(X) s_0^I(X) d_0^I(X) \eta_2 \rho_2 \alpha$$

by the simplicial identities, and

$$d_1^I(x) \eta_2 \rho_2 \alpha = \eta_1 d_1^I \rho_2 \alpha = \eta_1 g_1' \psi_2 p = g_1 h_1 \psi_2 p = g_1 h_1 \psi_1 p$$

$$= \eta_1 g_1' \psi_1 p = \eta_1 d_0^I \rho_2 \alpha = d_0^I(X) \eta_2 \rho_2 \alpha$$

$$= d_1^I(x) s_0^I(X) d_0^I(X) \eta_2 \rho_2 \alpha.$$  

By construction the two maps $d_0^I(X), d_1^I(X) : \frac{X_2}{H_2(X)} \rightarrow \frac{X_1}{H_1(X)}$ are jointly monic, and thus these equalities implies that

$$\eta_2 \rho_2 \alpha = s_0^I(X) d_0^I(X) \eta_1 \rho_2 \alpha,$$
and this in turn implies that (13) hold. From this we find that
\[
\langle f_2, \eta_2 \rangle \rho_2 \alpha = s_0^F d_0^F (f_2, \eta_2) \rho_2 \alpha \\
= s_0^F (f_1, \eta_1) d_0^F \rho_2 \alpha \\
= s_0^F (f_1, \eta_1) g'_1 \psi_1 p \\
= s_0^F g_1 h_1 \psi_1 p \\
= g_2 s_0^F h_1 \psi_1 p.
\]

Since \(Q_2\) is the pullback of \(g_2\) along \(\langle f_2, \eta_2 \rangle\), there exists a unique map \(\alpha' : A \to Q_2\) such that \(h_2 \alpha' = s_0^F h_1 \psi_1 p\) and \(g_2' \alpha' = \rho_2 \alpha\). From this, we find that
\[
g'_1 d_0^Q \alpha' = d_0^Q g'_1 \alpha' = d_0^Q \rho_2 \alpha = g'_1 \psi_1 p
\]
and
\[
h_1 d_0^Q \alpha' = d_0^Q h_2 \alpha' = d_0^Q s_0^Q h_1 \psi_1 p = h_1 \psi_1 p,
\]
and since \(g'_1\) and \(h_1\) are jointly monic, we have \(d_0^Q \alpha' = \psi_1 p\), and similarly \(d_1^Q \alpha' = \psi_2 p\).

Now we prove that \(d_2^Q \alpha' = s_0^Q d_0^Q d_2^Q \alpha'\); from the definition of \(Q_1\) it suffices to check that the identity holds after composition with \(h_1\) and \(g'_1\). We have
\[
h_1 s_0^Q d_0^Q d_2^Q \alpha' = d_2^Q h_2 s_0^Q d_0^Q \alpha' = d_2^Q s_0^Q h_2 \alpha' = s_0^Q d_1^Q s_0^Q h_1 \psi_1 p
\]
\[
= s_0^Q d_1^Q h_1 \psi_1 p = d_2^Q s_0^Q h_1 \psi_1 p = d_2^Q h_2 \alpha' = h_1 \alpha'
\]
and
\[
g'_1 s_0^Q d_0^Q d_2^Q \alpha' = s_0^Q d_0^Q d_2^Q g'_1 \alpha' = s_0^Q d_0^Q d_2^Q \rho_2 \alpha = s_0^Q d_0^Q s_0^Q \rho_1 \alpha
\]
\[
= s_0^Q \rho_1 \alpha = d_2^Q \rho_2 \alpha = d_2^Q g'_1 \alpha' = g'_1 d_2^Q \alpha'.
\]

Thus \(\alpha'\) factorizes through the pullback of \(s_0^Q\) along \(d_2^Q\), and thus \((\psi_1, \psi_2) p = (d_0^Q, d_1^Q) \alpha'\) factorizes through the inclusion of \(H_1(Q)\) in \(Q_1 \times Q_1\), which concludes the proof. \(\square\)

As a consequence, we then have

**Theorem 3.** The Galois structure \((\text{Simp}(C), \text{Grpd}(C), I, U, F)\) admits a relative monotone-light factorization system \((\mathcal{E}', \mathcal{M}^*)\), where \(\mathcal{E}'\) is the class of maps stably inverted by \(I\) and \(\mathcal{M}^*\) is the class of central extensions of this Galois structure.

### 6. Truncated simplicial objects and weighted commutators

For all \(n \geq 2\), the inclusion \(\text{Grpd}(C) \hookrightarrow \text{Simp}_n(C)\) factorizes through \(\text{Simp}(C)\), and the characterization of groupoids in truncated simplicial objects is identical. Moreover the construction of the equivalence relations \(H_n(X)\) does not depend on the objects \(X_m\) for \(m > n\). Thus \(\text{Grpd}(C)\) can also be seen as a Birkhoff subcategory of \(\text{Simp}_n(C)\), with the reflection defined in the same way, in the sense that the reflectors commute with the truncation functor. The characterization of central extensions also extends in the same way.
The inclusion $\text{Grpd}(\mathcal{C}) \hookrightarrow \text{Simp}_1(\mathcal{C}) = \text{RG}(\mathcal{C})$ also factors through $\text{Simp}(\mathcal{C})$, as every reflexive graphs admits at most one groupoid structure ([13]). On the other hand, this time the reflection does not commute with the truncation, as the construction of $H_1(\mathcal{X})$ is dependent on $X_2$ and the face maps $X_2 \to X_1$. In fact, the reflection $\text{RG}(\mathcal{C}) \to \text{Grpd}(\mathcal{C})$ is obtained by taking the quotient of $X_1$ by the Smith-Pedicchio commutator $[D_0, D_1]_{SP}$ ([35]). The central extensions of reflexive graphs in exact Mal’tsev categories (with coequalizers) with respect to this adjunction have been characterized in [17]. Note that this commutator is preserved by regular images, and is always smaller than the intersection; as a consequence, we always have the inequalities

$$[D_0, D_1]_{SP} \leq H_1(\mathcal{X}) = d_2(D_0 \wedge D_1) \leq D_0 \wedge D_1.$$  \hspace{1cm} (14)

It turns out that this reflection can also be obtained by applying our results, at least when the category $\mathcal{C}$ is finitely cocomplete.

Indeed, in that case the truncation functor $\text{Simp}(\mathcal{C}) \to \text{RG}(\mathcal{C})$ has a left adjoint $G$, defined by taking left Kan extensions along the inclusion $\Delta_2^p \to \Delta^p$. Now since the inclusion $\text{Grpd}(\mathcal{C}) \to \text{RG}(\mathcal{C})$ is the composition of the nerve functor and the truncation $T$, the functor $IG$ must be a left adjoint to this inclusion. Thus our work can be used to give an alternative description of the Smith-Pedicchio commutator as the equivalence relation $H_1(G(X_1, X_0, d_0, d_1, s_0))$.

Let us make this construction explicit. The object $X_2 = (G(X_1, X_0, d_0, d_1, s_0))_2$ is the pushout $X_1 +_{X_0} X_1$ of $s_0 : X_0 \to X_1$ along itself, with $s_0$ and $s_1$ the two canonical maps $X_1 \to X_1 +_{X_0} X_1$. In order to satisfy the simplicial identities we must then define $d_0$ to be the unique map for which $d_0s_0 = 1$ and $d_0s_1 = s_0d_0$, which we denote $[1, s_0d_0] : X_1 +_{X_0} X_1 \to X_1$; similarly, we must have $d_1 = [1, 1]$ and $d_2 = [s_0d_1, 1]$.

In the case where $\mathcal{C}$ is not only exact Mal’tsev but also semi-abelian ([30, 2]), there is for every object an order-preserving bijection between equivalence relations and normal subobjects, which is also compatible with regular images. Accordingly, our results can be easily translated in terms of normal subobjects, by replacing every kernel pair by the kernel of the corresponding morphism.

In the case where $X_0 = 0$ is the zero object in $\mathcal{C}$, $X_2$ is simply the coproduct $X_1 + X_1$, and the face maps are just the maps $[1, 0], [1, 1], [0, 1]$. Then our construction of $d_1(D_0 \wedge D_2)$ is nothing but the Higgins commutator $[X_1, X_1]_H$ (which coincides with the Smith-Pedicchio commutator $[\nabla_{X_1}, \nabla_{X_1}]_{SP}$), as defined in [24, 34]. In general, $d_1(D_0 \wedge D_2)$ coincides with a weighted commutator ([23]):

**Theorem 4.** When $\mathcal{C}$ is a semi-abelian category, the subobject $d_1(Ker(d_0) \wedge Ker(d_2))$ coincides with the weighted commutator $[Ker(d_0), Ker(d_1)]_{X_0}$, where $X_0$ is the subobject $s_0 : X_0 \to X_1$.

**Proof.** Let us denote $K_1 \leq X_1$ the kernel of $d_i : X_1 \to X_0$ (for $i = 0, 1$). We recall from [23] the construction of the weighted commutator $[K_0, K_1]_{X_0} :$ we first define $\psi$ as the
map making the diagram

\[
\begin{array}{c}
X_0 + K_0 + K_1 \\
\downarrow \psi \\
(X_0 + K_0) \times_{X_0} (X_0 + K_1) \\
\downarrow \\
X_0 + K_0 \\
\end{array}
\]

commute. Then \([K_0, K_1]_{X_0}\) is the image of the kernel of \(\psi\) through the map \([s_0, k_0, k_1] : X_0 + K_0 + K_1 \to X_1\).

To prove the equivalence, consider the following commutative diagram:

\[
\begin{array}{c}
X_0 + K_0 \xleftarrow{[s_0, k_0]} X_0 \xrightarrow{[1, 0]} X_0 + K_1 \\
\downarrow d_0 \downarrow \downarrow d_0 = [1, s_0 d_0] \downarrow d_1 \\
X_1 \xleftarrow{s_0} X_0 \xrightarrow{s_0} X_1 \\
\end{array}
\]

Since all the vertical maps are regular epimorphisms, the induced map between the pushouts of the upper and lower spans (i.e. the cokernel pairs of \(\iota_1\) and \(s_0\)) is also a regular epimorphism. This gives a commutative cube

\[
\begin{array}{c}
X_0 + K_0 + K_1 \xleftarrow{[1, 0]} X_0 + K_0 \xrightarrow{[1, 0]} X_0 + K_1 \\
\downarrow \gamma \downarrow \downarrow \downarrow \downarrow d_0 = [1, s_0 d_0] \downarrow d_1 \\
X_0 + K_0 \xrightarrow{[s_0, k_0]} X_0 + K_0 \xrightarrow{d_0 = [1, s_0 d_0]} X_1 \\
\downarrow \downarrow \downarrow \downarrow \downarrow d_0 \\
X_1 + X_0 \xleftarrow{d_2 = [s_0 d_1, 1]} X_1 \xrightarrow{d_1} X_1 \\
\end{array}
\]

where every edge is a regular epimorphism. In fact this cube is a triple extension, as it can be seen as a split morphism between (vertical) double extensions. As a consequence the induced square

\[
\begin{array}{c}
X_0 + K_0 + K_1 \xrightarrow{\psi} (X_0 + K_0) \times_{X_0} (X_0 + K_1) \\
\downarrow \gamma \\
X_1 + X_0 \xrightarrow{[\langle d_0, d_2 \rangle]} X_1 \times_{X_0} X_1 \\
\end{array}
\]
is a double extension; in particular, we have $\gamma(Ker(\psi)) = Ker(\langle d_0, d_2 \rangle) = Ker(d_0) \wedge Ker(d_2)$. Now we also have
\[ d_1 \gamma = [1, 1] \circ ([s_0, k_0] + [s_0, k_1]) = [s_0, k_0, k_1], \]
and thus the image of $Ker(\psi)$ under $[s_0, k_0, k_1]$ is $d_1(Ker(d_0) \wedge Ker(d_2))$, which completes the proof.

\[ \square \]

**Corollary 6.** For any reflexive graph in a semi-abelian category $\mathcal{C}$, the weighted commutator $[Ker(d_0), Ker(d_1)]_{s_0: X_0 \to X_1}$ coincides with the Ursini commutator $[Ker(d_0), Ker(d_1)]_{Urs}$ as defined by Mantovani in [33].

**Proof.** This just follows from the fact that the Ursini commutator is the normalization of the Smith-Pedicchio commutator of the corresponding equivalence relations.

\[ \square \]

We have shown that using the left adjoint of the truncation functor produced a simplicial object for which the first inequality of (14) is an equality, so that $H_1(X)$ is as small as possible. We can also define a right adjoint $R$ to the truncation functor $T$, using right Kan extensions along the inclusion $\Delta_1^{op} \to \Delta^{op}$. Such a right extension amounts to iteratively define $X_n$ as the simplicial kernel of the truncated simplicial object $X_{n-1} \xrightarrow{d_0} X_{n-2} \ldots$, and the face maps $d_i : X_n \to X_{n-1}$ as the canonical projections.

If we apply this construction, then the induced equivalence relation $H_1(X)$ turns out to be equal to $D_0 \wedge D_1$, so that this time $H_1(X)$ is as big as possible. In fact we can prove something a bit more general:

**Proposition 7.** If $X$ is a simplicial object exact at $X_1$, i.e. if $\kappa_2 : X_2 \to K_2(X)$ is a regular epimorphism, then $d_0(D_1 \wedge D_2) = D_0 \wedge D_1$.

**Proof.** Consider the following diagram, where all the squares are pullbacks:
\[
\begin{array}{ccc}
X_2 \times X_1 & X_0 \xrightarrow{q} & K_2(X) \times X_1 & X_0 \\
\pi_1 \downarrow & & \downarrow & \downarrow s_0 \\
X_2 & \xrightarrow{\kappa_2} & K_2(X) & \xrightarrow{\nu_2} X_1 \\
& \xrightarrow{\langle d_0, d_1 \rangle} & & \xrightarrow{(d_0, d_1)} D_0 \\
& \xrightarrow{\nu_0, \nu_1} D_0 \times X_0 & & \xrightarrow{d_0 \times d_1} X_0 \times X_0.
\end{array}
\]

By definition $\nu_2 \kappa_2 = d_2$, and thus the upper rectangle is the pullback of $d_2$ along $s_0$, i.e. it is the same pullback as in (3), and thus $d_0(D_1 \wedge D_2)$ is the image of the composition $\langle d_0, d_1 \rangle \pi_1$. Since the upper left square is a pullback and $\kappa_2$ is a regular epimorphism by hypothesis, $q$ is a regular epimorphism, and thus the image of this map $\langle d_0, d_1 \rangle \pi_1$ is the image of the middle vertical map. Moreover the right-hand rectangle is the pullback of $d_1 \times d_1$ along $\Delta_{X_0}$, and thus this middle vertical map is a monomorphism, and the corresponding subobject of $D_0$ coincides with $D_0 \wedge D_1$, which concludes the proof.

\[ \square \]
