We theoretically explore optical bistability for possible signature of all optical switching and their performance in a hybrid quantum optomechanical system comprising of two semiconductor microcavity coupled optically. One of the cavity is driven by an external optical pump laser while the second cavity which contains a quantum dot is indirectly driven by light transmitted from the first cavity. The generated bistable behavior due to optomechanical nonlinearity shows a typical optical switching behavior and it can be controlled by changing the laser power, QD cavity coupling, rocking parameter, and the optomechanical coupling. A clear signature of energy exchange between mechanical optical modes is visible from the mechanical displacement spectrum. These results suggest that the present system can be used for an application in sensitive optical switch and optical sensors.

I. INTRODUCTION

With the aim to construct all optical logic gates by overcoming the obstacles of Moore's law, optical physicists are trying to regulate the transmission of another optical signal using light [1, 2]. One method to achieve this is optical bistability, in which for a given input power two different output power can be obtained [3]. Thus, the output power is controlled with a shift in the input signal by transition between two stable states. To transfer data over short distances, there is increasing trend of building optical interconnects. In addition these Optical systems could be a fresh computing method [4, 5] for which bistable optical devices are key component. Optical carrier injection [6], thermo-optic effects [7], a combination of both [8], or optoelectronic feedback [9] etc. are some methods to achieve bistability. Usually these methods depend on carrier generation which makes it rather slow to use. Second method to get optical bistability is via nonlinear optical effects [10]. The nonlinear optical effects in bulk materials are very weak so, a large amount of power is required. This limits the practicality of the device. By enhancing the strength of nonlinear light matter interaction, one can decrease the operating optical power. Taking high quality factor(Q) cavities and small mode volume we can increase the interaction strength.

There has been a major attempt over the previous decade to build solid state optical devices at micro-scale. The primary drive behind this study is the development of chip-to-chip [11–13] optical device and the processing [14–17] of quantum information. Modulators play a key role in transmission and routing of data on these networks. In order to minimize operating strength optical components are miniaturized down to scales as such active element is represented by a single quantum emitter. One of the primary obstacles in the development of high-speed electronic devices is currently the big loss in high-frequency metal interconnection. Developing light switches, working at a rate of just a few quanta of energy can be a solution.

Another significant manifestation of strongly coupled system is Normal mode splitting (NMS). It occurs when the energy exchange between two subsystem is faster than it's dissipation to the atmosphere [18]. The necessity of this regime is to observe coherent quantum dynamics of the interacting system and to manipulate as well as controlling the quantum system is one of its aim [19, 20]. Since the system has inherent Kerr nonlinearity and in addition parametric driving field is introduced, it leads to an interesting concept known as Rocking which essentially transforms a phase invariant self-oscillatory system into the bistable phase[21, 22]. Where as Kerr nonlinearity weakens NMS, the rocking parameter has been studied to see its effect on controlling it[23].

In this paper we particularly, study the optical bistability for analysing the possible signature of all optical switches and their performance via switch Ratio, Gain and Band width. Specifically, by modeling the dynamics of the bistable switch, we evaluate how the necessary optical power scales with cavity parameters and examine switching speeds. Also, we study about the movable distributed Bragg reflector's (DBR) displacement spectrum which leads to NMS.

II. THEORY AND MODEL

The model considered in this article is shown in Fig.1. In the present model, we consider a system comprising of two semiconductor microcavity A and B coupled optically showing two field modes. Cavity A is coupled with movable mirror which is guided using a laser field having frequency ω_p . Two level quantum dot is contained in cavity B that is directly driven by the pump field along y-axis with a frequency of ω_L and provide coupling strength λ . The fabrication of micro-cavities done by a set of distributed Bragg reflectors (DBR). There are some known techniques by which the confinement of light along the longitudinal and transverse direction in the DBR can be achieved [24]. DBR mirror comprises of layers of low and high refractive index of quarter-wavelength having AlGaAs as the first and last layer. The refractive index of AlGaAs is greater than that of air and

lower than that of GaAs[25]. Hence, this structure results into an enhancement of the coupling of light.

The optomechanical nonlinearity is introduced into the system through the coupling of the microcavity A to the micro-mechanical resonator. The quantum dot (QD) is considered as two-level system with ground state denoted by $|g\rangle$ and excited state by $|e\rangle$.

Figure 1: Schematic depiction of the system. DBR mirrors formed two cavity modes coupled with each other. The QD is kept in mode b which interacts with external pump field of frequency ω_L . Green strip correspond to AlGaAs and white strip represents GaAs layer.

Applying the rotating-wave approximation on the total Hamiltonian for this hybrid optomechanical system along with the dipole approximation, it can be stated as-

$$\begin{aligned}
 H = & \hbar\Delta_a a^\dagger a + \hbar\Delta_b b^\dagger b + \hbar\Delta_d \sigma_z + \frac{p^2}{2m} + \frac{1}{2}m\omega_m^2 q^2 + \hbar g(b^\dagger \sigma_{ge} + b \sigma_{eg}) - \hbar G a^\dagger a q \\
 & + \hbar J (a^\dagger b + b^\dagger a) + i\eta(t) (a + a^\dagger) + \lambda (e^{i\delta t + i\theta} \sigma_{ge} + e^{-i\delta t - i\theta} \sigma_{eg}). \quad (1)
 \end{aligned}$$

The free energies of cavity A and B optical modes are described by the first and second terms respectively. a^\dagger is the creation operator and a is the annihilation operator for cavity A. Similarly b^\dagger is the creation operator and b is the annihilation operator for mode B. $\Delta_a = \omega_a - \omega_p$ is detuning for cavity A and $\Delta_b = \omega_b - \omega_p$ is detuning for cavity B with respect to pump laser. Resonance frequencies of both cavity are denoted by ω_a and ω_b . The third term shows the energy for the two-level QD. The transition frequency ω_d between two levels of the QD results in its detuning $\Delta_d = \omega_d - \omega_L$. We have taken $\sigma_{ee} - \sigma_{gg}$ as σ_z , where σ_{ee} and σ_{gg} are the atomic populations in the excited and ground levels respectively. Fourth and fifth terms give the mechanical oscillator energy having q and p are position and momentum operator respectively and satisfy $[q, p] = i\hbar$. The interaction in cavity B of the single QD with the optical field is denoted by the sixth term,

where g is the coupling strength between QD and photon. The seventh term gives optomechanical interaction, where constant G represents the optomechanical coupling of the mechanical oscillator with field in cavity A. The coupling of two cavities is accounted by the eighth term having coupling strength J between the two cavities [26–30]. Ninth term denotes the driving term with temporally modulated field $\eta(t) = \eta_0 + P_{amp} \cos(\Omega t)$, where η_0 is constant driving amplitude that takes real value, P_{amp} is the amplitude of the modulation and Ω is the frequency of modulation. The last term shows the interaction between QD and transverse pump along y -axis, where λ is the interaction constant and θ shows the relative phase between two laser fields.

The system dynamics can be described by the following quantum Langevin equations after using the Hamiltonian resulting from Equation (1):

$$\dot{a}(t) = -i\Delta_a a - iJb(t) + \eta(t) + iGa(t)q(t) - \kappa_a a(t) + \sqrt{\kappa_a} a_{in}(t), \quad (2)$$

$$\dot{b}(t) = -i\Delta_b b - ig\sigma_{ge} - iJa - \kappa_b b + \sqrt{2\kappa_b} b_{in}(t), \quad (3)$$

$$\dot{\sigma}_{ge}(t) = (-i\Delta_d - \kappa_d)\sigma_{ge} + igb(t)\sigma_z(t) - i\lambda e^{-i\delta t - i\theta} \sigma_z \quad (4)$$

$$\dot{q}(t) = \omega_m p(t), \quad (5)$$

$$\dot{p}(t) = -\omega_m q(t) + Ga^\dagger a - \gamma_m p(t) + \zeta(t), \quad (6)$$

We have assumed $a_{in}(t)$ and $b_{in}(t)$ having zero mean as input vacuum noise operator for cavity A and B respectively. Now behavior of the nonlinear cavity can be analyzed by re-writing the operators in terms of mean classical values.

$$\langle \dot{a}(t) \rangle = -i\Delta_a \langle a \rangle - iJ \langle b(t) \rangle + \eta(t) + iG \langle a(t) \rangle \langle q(t) \rangle - \kappa_a \langle a(t) \rangle + \sqrt{\kappa_a} \langle a_{in}(t) \rangle, \quad (7)$$

$$\langle \dot{b}(t) \rangle = -i\Delta_b \langle b \rangle - ig \langle \sigma_{ge} \rangle - iJ \langle a \rangle - \kappa_b \langle b \rangle + \sqrt{2\kappa_b} \langle b_{in}(t) \rangle, \quad (8)$$

$$\langle \dot{\sigma}_{ge}(t) \rangle = (-i\Delta_d - \kappa_d) \langle \sigma_{ge} \rangle + ig \langle b(t) \rangle \langle \sigma_z(t) \rangle - i\lambda e^{-i\delta t - i\theta} \langle \sigma_z \rangle, \quad (9)$$

$$\langle \dot{q}(t) \rangle = \omega_m \langle p(t) \rangle, \quad (10)$$

$$\langle \dot{p}(t) \rangle = -\omega_m \langle q(t) \rangle + G \langle a^\dagger \rangle \langle a \rangle - \gamma_m \langle p(t) \rangle + \zeta(t), \quad (11)$$

The interaction between system and external degrees of freedom leads to dissipation. where the decay constants are characterized by κ_a and κ_b for the cavity fields A and B respectively and spontaneous emission decay rate of QD is given by κ_d . The γ_m is the decay constant for mechanical DBR coupled with cavity A.

To analyze further, we consider large and fast modulating input signal, i.e., $P_{amp} \gg \eta_0$ and $\Omega \gg \omega_q, \Delta_a, \Delta_b, \kappa_a, \kappa_b, G, \gamma_m, J$. Further a and b are slowly varying amplitudes and by using few mode expansion[22], can be written as $a \rightarrow a_s + a_\pm e^{\pm i\Omega t}$ and $b \rightarrow b_s + b_\pm e^{\pm i\Omega t}$ respectively. Now putting these expression into equation (7)-(11) and neglecting the higher harmonics and also equating the time derivatives to zero, this gives,

$$b_s = \frac{-\left(iJa + \frac{g\lambda e^{-i\delta t - i\theta} N}{i\Delta_d + \kappa_d}\right)}{\left(\kappa_b + i\Delta_b - \frac{g^2 N}{i\Delta_d + \kappa_d}\right)}, \quad (12)$$

$$\sigma_{eg,s} = -i \frac{(gb_s - \lambda e^{-i\delta t - i\theta}) N}{(i\Delta_d + \kappa_d)}, \quad (13)$$

$$p_s = 0, \quad (14)$$

$$q_s = \chi(|a_s|^2 + C), \quad (15)$$

$$a_s = \frac{\eta_0 (A_1 + iA_2) + iJg\lambda e^{-i\delta t - i\theta} N}{(i\Delta + \kappa_a)(A_1 + iA_2) + J^2(i\Delta_d + \kappa_d)}, \quad (16)$$

Hence by eliminating the mode b in the steady state, we get-

$$\begin{aligned}
& (A_1^2 + A_2^2)\omega_m^2\chi^4 P_{trans}^3 - (2(A_1^2 + A_2^2)(\Delta_a - \omega_m\chi^2 C)\omega_m\chi^2 - 2J^2\omega_m\chi^2(\kappa_a A_2 - \Delta_d A_1))P_{trans}^2 \\
& + ((\kappa_a A_1 + J^2\kappa_d)^2 + (\kappa_a A_1 + J^2\Delta_d)^2 + (\Delta_a - \omega_m\chi^2 C)^2(A_1^2 + A_2^2)) \\
& + 2J^2(\Delta_a - \omega_m\chi^2 C)(\Delta_d A_1 - \kappa_a A_2)P_{trans} \\
& = |\eta_0|^2(A_1^2 + A_2^2) + 2\eta_0 A_2 g J \lambda \cos \theta N + J^2 g^2 \lambda^2 N^2
\end{aligned} \tag{17}$$

Where $P_{trans} = \langle a_s^\dagger a_s \rangle$ is the power transmitted from fundamental cavity mode A,

Where, $A_1 = -g^2 \langle N \rangle + \kappa_b \kappa_d - \Delta_b \Delta_d$,

$A_2 = \Delta_b \kappa_d + \kappa_b \Delta_d$,

$\Delta = \Delta_a - \omega_m \chi^2 P_{trans} - \omega_m \chi^2 C$ is the effective detuning in the optomechanical cavity

$C = \frac{P_{amp}^2}{2\Omega^2}$ is rocking parameter.

$\chi = G/\omega_m$ is the rescaled optomechanical coupling constant.

P_{amp} is the amplitude of the modulating wave and Ω is the modulating frequency.

Now the dynamics of quantum fluctuations in the system around its stable state will be analyzed.

For this, the value of quantum Langevin equations are written as $p(t) \rightarrow p_s + p(t)$, $q(t) \rightarrow q_s + q(t)$, $b(t) \rightarrow b_s + b(t)$ and $a(t) \rightarrow a_s + a(t)$. Here we assume zero fluctuation for operator of QD.

Introducing the quadrature of phase and amplitude for the field, $v_1 = i(b^\dagger - b)/\sqrt{2}$, $u_1 = (b + b^\dagger)/\sqrt{2}$, $v_2 = i(a^\dagger - a)/\sqrt{2}$, $u_2 = (a + a^\dagger)/\sqrt{2}$, $v_{1in} = i(b_{in}^\dagger - b_{in})/\sqrt{2}$, $u_{1in} = (b_{in} + b_{in}^\dagger)/\sqrt{2}$, $v_{2in} = i(a_{in}^\dagger - a_{in})/\sqrt{2}$, $u_{2in} = (a_{in} + a_{in}^\dagger)/\sqrt{2}$. Hence the quantum Langevin equations for the quadrature becomes:

$$\dot{u}_1(t) = \Delta_b v_1(t) + J v_2(t) - \kappa_b u_1(t) + \sqrt{\kappa_b} u_{1in}(t), \tag{18}$$

$$\dot{v}_1(t) = -\Delta_b u_1(t) - J u_2(t) - \kappa_b v_1(t) + \sqrt{\kappa_b} v_{1in}(t), \tag{19}$$

$$\dot{u}_2(t) = \Delta_a v_2(t) + J v_1(t) + i a_- q(t) - \kappa_a u_2(t) + \sqrt{\kappa_a} u_{2in}(t), \tag{20}$$

$$\dot{v}_2(t) = -\Delta_a u_2(t) - J u_1(t) + a_+ q(t) - \kappa_a v_2(t) + \sqrt{\kappa_a} v_{2in}(t), \tag{21}$$

$$\dot{q}(t) = \omega_m p(t), \quad (22)$$

$$\dot{p}(t) = -\omega_m q(t) + a_+ u_2(t) - i a_- v_2(t) - \gamma_m p(t) + \zeta(t), \quad (23)$$

Where,

$$a_{\pm} = \frac{\omega_m \chi (a_s \pm a_s^*)}{\sqrt{2}} \quad (24)$$

III. OPTICAL SWITCH AND IT'S PERFORMANCE

The vast development of worldwide data and huge demands of communication networks with larger capacity of data transmission and processing information with fast rates requires large bandwidth and low consumption of power[31, 32] and for this Optical interconnects is more preferable than electronic interconnects. The foundation of all-optical switching rests on nonlinear Kerr effect which arises due to refractive index variation of nonlinear material induced by a control light[33]. The primary interest of optical switching is that it allows the optical data signals to be routed without the need for conversion to electrical signals hence it is not dependent on data protocol or rate[34]. Therefore all optical switching can taken as a key element, playing a critical and important role in construction on-chip ultrafast all-optical switch networks.

In our model, a bistable device is used as the base to analyze the performance of an optical switch. The input signal consists of a modulated optical signal and a fixed bias power P_{bias} .

Using equation(17) we plot the bistability graph between output power and input power (Fig.2). Here we define P_{trans} as output power and η^2 as input power. For $N=0$ (i.e, equal population in the ground state and excited state) we plot bistability graphics for different values of Rocking parameter (C).

As we increase the value of C the maximum output shift towards lower value of input power. This indicates that the rocking parameter influence the output behavior in a significant manner. Using this, we further illustrate the switch ratio(S.R) and gain of the switch.

During the driving curve of bistability, the switching ratio is defined as the proportion of the maximum to minimum cavity output. Fig.3(a) shows the graph of switching ratio versus input amplitude P_{amp} . We find that the switch behaves like a low pass filter. The ratio decreases as

Figure 2: The bistability plot in steady state for different values of C to identify the bias-points, around which the input power can be modulated to observe the output power change; Parameters used for graph are- $J=0.5$, $\chi = 0.3$, $\kappa_d = 1.8\omega_m$, $N=0$, $g=1\omega_m$, $\theta = 0.238$, $\lambda=0.02$, $\kappa_a = 0.1\omega_m$, $\kappa_b = 0.1\omega_m$, $\Delta_a = \omega_m$, $\Delta_b = \omega_m$, $\Delta_d=0$.

the value of P_{amp} increases. Fig.3(b), shows the graph of switching ratio versus output signal as a function of frequency of modulating signal. We observe switching ratio increases with modulation frequency. The larger ratio indicates that switch is controlling the propagating light signal more precisely. This suggests that the input amplitude and modulation frequency influence the switch performance significantly.

Figure 3: The graph of (a)-Switching ratio v/s P_{amp} for fix $\Omega=1$; (b)- Switching ratio v/s Modulation frequency(Ω) for fix $P_{amp} = 0.5$. Parameters are used for graph are; $J=\omega_m$, $\chi = 0.3\omega_m$, $\gamma_m=1.8\omega_m$, $N=0$, $g=0.5\omega_m$, $\theta = 0.238$, $\lambda=0.02$, $\kappa_a = 0.1\omega_m$, $\kappa_b = 0.1\omega_m$, $\Delta_a=\omega_m$, $\Delta_b = 1\omega_m$, $\Delta_d=0$.

The Gain of the switch is defined as the ratio of output and input power amplitude. By analyzing gain as a function of P_{amp} we find that initially the gain value is higher for lower P_{amp} and subsequently the value of gain smoothly decreases as the value of P_{amp} increases (see(Fig. 4(a)). We also notice that from Fig.(4(b)) the gain increases as the value of Ω increases and then

become constant. It may be noted that for a good optical switch a large gain is required.

Figure 4: The graph of (a)-Switching ratio v/s P_{amp} for fix $\Omega=1$; (b)- Switching ratio v/s Modulation frequency for fix $P_{amp} = 0.5$. Parameters are used for graph are; $J=0.5\omega_m$, $\chi = 0.3\omega_m$, $\kappa_d = 1.8\omega_m$, $N=0$, $g=\omega_m$, $\theta = 0.238\omega_m$, $\lambda=0.02\omega_m$, $\kappa_a = 0.1\omega_m$, $\omega_m = 1$, $\kappa_b = 0.1\omega_m$, $\Delta_a=1\omega_m$, $\Delta_b=1\omega_m$, $\Delta_d=0$.

We find that by increasing P_{amp} , the gain decreases while the bandwidth increases in Sinusoidal way for equal population in ground and excited state of quantum dot (i.e., $N=0$). Initially the band width is lower for P_{amp} as we increase its value the band width increases up to value $2.0\omega_m$ and after that further increment of P_{amp} band width slow down. This indicates that less transmission of output will occur for lower input signal i.e., "OFF" state for optical switch and as we increase the input signal the bandwidth is increasing, it leads to higher transmission of signal light i.e., "ON" state. Therefore, all-optical switching behavior is obtained.

Figure 5: The graph of (a)-Switching ratio v/s P_{amp} for fix $\Omega=1$; (b)- Switching ratio v/s Modulation frequency for fix $P_{amp} = 0.5$. Parameters are used for graph are; $J=0.5$, $\chi = 0.3\omega_m$, $\kappa_d = 1.8\omega_m$, $N=0$, $g=\omega_m$, $\theta = 0.238\omega_m$, $\lambda = 0.02\omega_m$, $\omega_m = 1$, $\kappa_a = 0.1\omega_m$, $\kappa_b = 0.1\omega_m$, $\Delta_a = 1\omega_m$, $\Delta_b = 1\omega_m$, $\Delta_d = 0\omega_m$, $\eta=0.1$, $C=0.36$

IV. NORMAL MODE SPLITTING

An interesting phenomenon occurs in the movable cavity mirror displacement spectrum known as NMS owing to the mixing of the system's various modes [35–39]. These spectrum characteristics of the probe field may prove further beneficial for achieving the optical switch in experiments and possible applications for coherent control of the light pulses[20].

The NMS, is studied in this section to deduce the spectrum in presence of QD for small fluctuations in the movable DBR's position quadrature. Fourier transformation is used to convert the equation of motion(18-23) from the time domain to frequency domain for calculating the NMS. It is also possible to express these equations in condensed form $\dot{O}(t)=MO(t) + f(t)$, where M being a 6×6 time-independent matrix.

$$M = \begin{bmatrix} 0 & \omega_m & 0 & 0 & 0 & 0 \\ -\omega_m & -\gamma_m & 0 & 0 & a_+ & -ia_- \\ 0 & 0 & -\kappa_b & \Delta_b & 0 & J \\ 0 & 0 & -\Delta_b & -\kappa_b & -J & 0 \\ ia_- & 0 & 0 & J & -\kappa_a & \Delta \\ a_+ & 0 & -J & 0 & -\Delta & -\kappa_a \end{bmatrix},$$

$f(t)=[0, \zeta(t), \sqrt{\kappa_b}u_{1in}(t), \sqrt{\kappa_b}v_{1in}(t), \sqrt{\kappa_a}u_{2in}(t), \sqrt{\kappa_a}v_{2in}(t)]^T$ and

$O(t) = [q(t), p(t), u_1(t), v_1(t), u_2(t), v_2(t)]^T$ are column vectors for noise sources and fluctuations respectively. Consequently displacement spectrum in Fourier space is given by,

$$S_q(\omega) = \frac{1}{4\pi} \int \left(\langle \delta q(\omega) \delta q(\omega') \rangle + \langle \delta q(\omega') \delta q(\omega) \rangle \right) e^{-i(\omega+\omega')t} d\omega' \quad (25)$$

Now the system for Oscillating DBR displacement is obtained by applying correlation function(appendix A) in the Fourier space[40–48] as,

$$S_q(\omega) = \frac{1}{|Dd(\omega)|^2} \left(|K_1(\omega)|^2 + |K_2(\omega)|^2 + |K_3(\omega)|^2 + |K_4(\omega)|^2 + |K_5(\omega)|^2 \right) \quad (26)$$

Figure 6(a) illustrates movable DBR displacement spectrum ($S_q(\omega)$) versus frequency (ω/ω_m) (dimensionless). Three different values of coupling strength between two cavity modes produces displacement spectrum for $J=0$ (red solid line), $J=1$ (green dashed line) and $J=1.5$ (blue dash-dot line). Fig.6-(b) shows the mechanical DBR's displacement spectrum ($S_q(\omega)$) against frequency

(ω/ω_m) (dimensionless) for $\chi= 0.2$ (red solid line), $\chi= 0.1$ (green dashed line) as different optomechanical coupling values. We can see three peaks are arising in the NMS which are due to fluctuation of the two optical modes and coupling between the fluctuation of movable DBR's mechanical mode.

Figure 6: The graph of Displacement Spectrum versus dimensionless frequency. In above figure, plot (a) displays the spectrum for varying coupling strength values between two cavity modes (J) for $\chi = 0.2$ and plot (b) displays the spectrum for various optomechanical coupling constant values (χ) for $J=0.5$. Here, $\left(\frac{\hbar\omega_m}{\kappa_b T}\right) = 10^{-6}$, $\kappa_d = 1.8\omega_m$, $N=0$, $g=1\omega_m$, $\theta = 0.238$, $\lambda = 0.02\omega_m$, $\kappa_a = 0.1\omega_m$, $\kappa_b = 0.1\omega_m$, $\Delta_a=1$, $\Delta_b = 1\omega_m$, $\Delta_d = -1\omega_m$, $\eta = 0.1\omega_m$, $C=0.10$

The coherent energy exchange between the three modes can be observed. For NMS, each mode's coherence must be lower than energy exchange timescale between the three modes. Fig. 6-(b), shows that when $\chi = 0.2$, then peaks have very high amplitude rather than for the value of $\chi=0.1$. This observation is because of the fact that there would be lesser energy swap between the optical and mechanical mode of cavity A if the optomechanical coupling is less. Thus the high amplitude peak shows the dominant behavior of energy swapping between the two optical modes.

V. CONCLUSION

In this paper we have analyzed the bistable behavior of the optical switch and its performance. A hybrid optomechanical system is studied for its mechanical displacement spectrum, where it consists of two semiconductor microcavities coupled optically and containing a QD. The generated bistable behavior due to optomechanical nonlinearity shows an optical switching behavior and it can be regulated by altering the laser power, rocking parameter, optomechanical coupling and QD cavity coupling. A three peak NMS is seen due to the movable DBR displacement spectrum.

The spectrum consisting of three peaks is a consequence from the exchange of energy among two optical and a mechanical mode. As revealed by the results, this system has the capacity to employed in sensitive optical switch and optical sensors. Two optically coupled cavity modes in which mechanical and optical modes are present show tunable entanglement by coherent exchange of energy. It shows that this type of hybrid optomechanical system in future can be used for transfer and storage of data signals and becomes a part of large quantum information processing unit.

VII. APPENDIX A

The operators of input noise fulfill the following set of correlation functions [49–52]

$$\langle a_{in}^\dagger(t)a_{in}(t') \rangle = \langle a_{in}(t)a_{in}(t') \rangle = 0, \quad (\text{A1})$$

$$\langle b_{in}^\dagger(t)b_{in}(t') \rangle = \langle b_{in}(t)b_{in}(t') \rangle = 0, \quad (\text{A2})$$

$$\langle a_{in}(t)a_{in}^\dagger(t') \rangle = \delta(t - t'), \quad (\text{A3})$$

$$\langle b_{in}(t)b_{in}^\dagger(t') \rangle = \delta(t - t'). \quad (\text{A4})$$

The following correlation function is satisfies by the mechanical mirror's Brownian force noise operator [51],

$$\langle \zeta(t)\zeta(t') \rangle = \frac{\gamma_m}{2\pi\omega_m} \int \left[1 + \coth\left(\frac{\hbar\omega}{2\kappa_b T}\right) \right] \omega e^{-i\omega(t-t')} d\omega. \quad (\text{A5})$$

where temperature of mechanical mirror-connected thermal bath is represented by T and κ_b is Boltzmann Constant. Due to the connection between movable mirror and thermal bath, the mirror generates the Brownian noise due to random motion. In essence this sort of noise is Non-Markovian [47, 50].

The correlation function in Fourier space for various amplitude and phase noise quadrature along with the Brownian noise operator for displacement spectrum can be described as follows[52]:

$$\langle u_{2in}(\omega)u_{2in}(\Omega') \rangle = 2\pi\delta(\omega + \Omega') \quad (\text{A6})$$

$$\langle v_{2in}(\omega)u_{2in}(\Omega') \rangle = -2i\pi\delta(\omega + \Omega') \quad (\text{A7})$$

$$\langle u_{2in}(\omega)v_{2in}(\Omega') \rangle = 2i\pi\delta(\omega + \Omega') \quad (\text{A8})$$

$$\langle v_{2in}(\omega)v_{2in}(\Omega') \rangle = 2\pi\delta(\omega + \Omega') \quad (\text{A9})$$

$$\langle u_{2in}(\omega)u_{1in}(\Omega') \rangle = 2\pi\delta(\omega + \Omega') \quad (\text{A10})$$

$$\langle v_{1in}(\omega)u_{1in}(\Omega') \rangle = -2i\pi\delta(\omega + \Omega') \quad (\text{A11})$$

$$\langle u_{1in}(\omega)v_{1in}(\Omega') \rangle = 2i\pi\delta(\omega + \Omega') \quad (\text{A12})$$

$$\langle v_{1in}(\omega)v_{1in}(\Omega') \rangle = 2\pi\delta(\omega + \Omega') \quad (\text{A13})$$

$$\langle u_{1in}(\omega)u_{1in}(\Omega') \rangle = 2\pi\delta(\omega + \Omega') \quad (\text{A14})$$

$$\langle \zeta(\omega)\zeta(\Omega') \rangle = 2\pi\frac{\gamma_m}{\omega_m}\omega \left[1 + \coth\left(\frac{\hbar\omega}{2\kappa_b T}\right) \right] \delta(\omega + \Omega'). \quad (\text{A15})$$

VIII. APPENDIX B

The following are the unknown coefficients used in equation (26):

$$\begin{aligned} Dd(\omega) = & (-i\omega - \gamma_m) (-iJ^4\omega + 2iJ^2\omega^3 - i\omega^5 + 2J^2\omega^2\kappa_a - 2\omega^4\kappa_a + i\omega^3\kappa_a^2 + 2J^2\omega^2\kappa_b - 2\omega^4\kappa_b \\ & - 2iJ^2\omega\kappa_a\kappa_b + 4i\omega^3\kappa_a\kappa_b + 2\omega^2\kappa_a^2\kappa_b + i\omega^3\kappa_b^2 + 2\omega^2\kappa_a\kappa_b^2 - i\omega\kappa_a^2\kappa_b^2 + i\omega^3\Delta^2 + 2\omega^2\kappa_b\Delta^2 \\ & - i\omega\kappa_b^2\Delta^2 + 2iJ^2\omega\Delta\Delta_b + i\omega^3\Delta_b^2 + 2\omega^2\kappa_a\Delta_b^2 - i\omega\kappa_a^2\Delta_b^2 - i\omega\Delta^2\Delta_b^2) - \omega_m (-J^4\omega_m + 2J^2\omega^2\omega_m \\ & - \omega^4\omega_m - 2iJ^2\omega\kappa_a\omega_m + 2i\omega^3\kappa_a\omega_m + \omega^2\kappa_a^2\omega_m - 2iJ^2\omega\kappa_b\omega_m + 2i\omega^3\kappa_b\omega_m - 2J^2\kappa_a\kappa_b\omega_m \\ & + 4\omega^2\kappa_a\kappa_b\omega_m - 2i\omega\kappa_a^2\kappa_b\omega_m + \omega^2\kappa_b^2\omega_m - 2i\omega\kappa_a\kappa_b^2\omega_m - \kappa_a^2\kappa_b^2\omega_m + \omega^2a_-^2\Delta - \omega^2a_+^2\Delta - 2i\omega a_-^2\kappa_b\Delta \\ & + 2i\omega a_+^2\kappa_b\Delta - a_-^2\kappa_b^2\Delta + a_+\kappa_b^2\Delta + \omega^2\omega_m\Delta^2 - 2i\omega\kappa_b\omega_m\Delta^2 - \kappa_b^2\omega_m\Delta^2 + J^2a_-^2\Delta_b^2 - J^2a_+^2\Delta_b \\ & + 2J^2\omega_m\Delta\Delta_b + \omega^2\omega_m\Delta_b^2 - 2i\omega\kappa_a\omega_m\Delta_b^2 - \kappa_a^2\omega_m\Delta_b^2 - a_-^2\Delta\Delta_b^2 + a_+^2\Delta\Delta_b^2 - \omega_m\Delta^2\Delta_b^2), \end{aligned} \quad (2)$$
