Abstract

We investigate the quantum numbers of the pentaquark states P_c^+ , which are composed of four (three flavors) quarks and an antiquark, by analyzing their inherent nodal structure in this paper. Assuming that the four quarks form a tetrahedron or a square, and the antiquark locates at the center of the four quark cluster, we determine the nodeless structure of the states with orbital angular momentum $L \leq 3$, and in turn, the accessible low-lying states. Since the inherent nodal structure depends only on the inherent geometric symmetry, we propose the quantum numbers J^P of the low-lying pentaquark states P_c^+ may be $\frac{3}{2}^-$, $\frac{5}{2}^-$, $\frac{3}{2}^+$, $\frac{5}{2}^+$, independent of dynamical models.

I. INTRODUCTION

Searching for the multiquark states has been attracted great attentions for more than four decades [1–7]. Analyzing the J/ψ p resonances in experiment at LHCb indicates that there exist pentaquark states including heavy quarks (c and \bar{c}) [8]. One of the two resonances has a mass of $4380 \pm 8 \pm 29$ MeV and a width of $205 \pm 18 \pm 86$ MeV, and another has a mass of $4449.8 \pm 1.7 \pm 2.5$ MeV and a width of $39 \pm 5 \pm 19$ MeV. They are proposed to hold opposite parity, with one state having spin $3/2$ and the other $5/2$. Even though quite a lot of theoretical investigations have been accomplished consequently (see for example, Refs. [9–29], for reviews, see Refs. [3, 4]), the concrete spin and parity have not yet been well assigned to the two states. Recently the pentaquark states are updated as 4312 MeV with a width about 9.8 MeV, 4440 MeV with a width about 20.6 MeV and 4457 MeV with a width about 6.4 MeV [30], and the quantum numbers of the states have not yet been determined [31] either although many theoretical works have tried to shed light on that (for instance, by considering the states with molecular structure, the quantum numbers are proposed as $J^P = \frac{1}{2}^-, \frac{1}{2}^-, \frac{3}{2}^-$ (or $\frac{5}{2}^-$) (see, e.g., Refs. [32–39]), or $\frac{1}{2}^-$ (or $\frac{3}{2}^-$) and excited states with $J^P = \frac{1}{2}^-$ [40], which are not consistent with those proposed in Ref. [41]). Furthermore, stringently speaking, pentaquark states refer to the color singlets composed of four quarks and one antiquark. In such a compact pentaquark scenario, their quantum numbers are proposed as $J^P = \frac{3}{2}^-, \frac{1}{2}^-, \frac{3}{2}^-$ via considering the uncertainty and the rearrangement decay properties (see, e.g., Refs. [42]). Since fundamental calculation for the pentaquark states via QCD is not available at the present stage, we investigate the quantum numbers by analyzing the symmetry, more explicitly the intrinsic nodal structure, of the color singlets including four three flavor quarks and one antiquark in this paper.

The remainders of this paper are organized as follows. In section II, we give a classification of the wave functions of the pentaquark states according to the symmetries of the quarks. Then in section III we assume that the four quarks form a tetrahedron or a square and analyze the nodeless structure of the states with orbital angular momentum $L \leq 3$, in turn, propose the quantum numbers of the pentaquark states. Finally, we give our conclusion and some remarks in the last section.

II. STRUCTURE OF THE WAVE-FUNCTIONS

It has been known that the wave functions of few-body systems can usually be written as a coupling of the orbital part and an internal part, and the inherent nodal surface (INS) analysis approach is quite powerful to assign the quantum numbers to a system (see, e.g., Refs. [43–46]). One can definitely take the INS analysis approach to investigate the pentaquark states ($q^4\bar{q}$ systems) at quark model level since they are typically few-body systems. Since quark and antiquark can never identified with each other, there does not exist anti-symmetric restriction on the wave function when interchanging a quark with the antiquark. However, if we consider only the four quarks, it should be antisymmetric, i.e., it has the symmetry $[1^4]$, if we ignore the current quark mass difference. Considering the system that the four quarks involve three flavors (e.g., $uudc$, $uuds$, $uudb$, and so on), one knows well that the system possesses the internal symmetry $SU_{CFS}(18) \supset SU_C(3) \otimes SU_F(3) \otimes SU_S(2)$. Meanwhile the orbital part holds the symmetry of the permutation group S_4 . Let $[f]_O$, $[f]_C$ and $[f]_{FS}$ be the irreducible representation (IRREP) of the groups associated with the orbital, the color and the flavor-spin space, respectively, we should have

$$[1^4] \in [f]_O \otimes [f]_C \otimes [f]_{FS}. \quad (1)$$

The lack of experimental observation of free “color charge” indicates that all the hadronic states should be $SU(3)$ color-singlets. For the $qqqq\bar{q}$ system, the IRREP of the $SU(3)$ color space should be $[222]$. Consequently, we have the IRREP of the color part of the four quark system as $[f]_C = [211]$. Then the $[f]_O \otimes [f]_{FS}$ should be $[3\ 1]$, which is the conjugate of $[211]$. In turn, the configuration of the $[f]_O$ and $[f]_{FS}$ can be fixed with the reduction principle of the direct product of the IRREPs of the unitary group.

The obtained possible $[f]_{FS}$ and the corresponding $[f]_O$ are listed in Table I. Corresponding to each IRREP $[f]_{FS}$, the flavor and spin decomposition of the three flavors q^4 state and the $q^4\bar{q}$ state have been given in Ref. [47]. We recall them here in Table II and Table III.

It is obvious that such an orbital and flavor-spin configuration space is very large. Therefore we should pick out the significant ones for the low-lying pentaquark states.

III. INHERENT NODAL STRUCTURE ANALYSIS

From Tables I-III we can notice that, given an IRREP of the orbital wave function, we can deduce the corresponding flavor and spin part of the wave function. Generally, orbital wave function depends on the geometric configuration and the dynamics, or, in present stage, we should say models. In this section, we analyze the structure of the wave functions of the pentaquark states independent of dynamical models.

The zero points for the wave-function are known as nodes. The locus for the nodes is a surface, i.e., the nodal surface, in configuration space. For usual bound states of a quantum system, the fewer nodes the configuration contains, the lower energy the state has. The dynamical nodal surface depends on the dynamics of the system, while the inherent nodal surface relies only on the inherent geometric configuration of the system.

Let \mathcal{A} be a geometric configuration in the coordinate space of a quantum system, \hat{O}_i be an element of the operation on the wave function $F(\mathcal{A})$, we have

$$\hat{O}_i F(\mathcal{A}) = F(\hat{O}_i \mathcal{A}). \quad (2)$$

If the operation \hat{O}_i leaves the configuration \mathcal{A} invariant, i.e., $\hat{O}_i \mathcal{A} = \mathcal{A}$, the above equation becomes

$$\hat{O}_i F(\mathcal{A}) = F(\mathcal{A}). \quad (3)$$

If there do not exist common non-zero solutions for the wave functions governed by Eq. (3), all the $F(\mathcal{A})$ must be zero at the configuration \mathcal{A} , then a nodal surface appears.

The wave function of the four quarks with total angular momentum J and parity π can be written as

$$\Psi = \sum_{L,S,\lambda} \Psi_{L\pi\lambda}^S, \quad (4)$$

with

$$\Psi_{L\pi\lambda}^S = \sum_{i,M,M_S} C_{LM,SM_S}^{J,M_J} F_{LM}^{\pi\lambda_i} \tilde{\chi}_{SM_S}^{\lambda_i}, \quad (5)$$

where $F_{LM}^{\pi\lambda_i}$ is a function of the spatial coordinates, λ denotes an IRREP of the S_4 group, and i index the basis vectors of that IRREP. The L and S is the total orbital angular momentum and the total spin of the four quarks, respectively. They couple to form J via the reduction principle of $SU(2) \otimes SU(2) \supset SU(2)$, i.e., C_{LM,SM_S}^{J,M_J} is the Clebsch-Gordan coefficient where the M , M_S and M_J are the Z-components of L , S and J , respectively. The parity of the

FIG. 1. *Left panel:* body frame illustration of the equilateral tetrahedron (ETH) configuration; *Right panel:* body frame illustration of the square.

four-quark cluster is given by $\pi = (-1)^L$, and the total parity of the pentaquark state $P = -\pi = (-1)^{L+1}$ since the antiquark holds an intrinsic negative parity. $\chi_{SM_S}^{\tilde{\lambda}_i}$ is the wave function of the inner space, belonging to the $\tilde{\lambda}_i$ -representation, the conjugate of λ . $F_{LM}^{\pi\lambda_i}$ spans a representation of the direct product of the rotation group, the space inversion group and the permutation group S_4 . Thus the transformation property of the $F_{LM}^{\pi\lambda_i}$ with respect to the operations in terms of the above groups is prescribed, which will impose a very strong constraint on the $F_{LM}^{\pi\lambda_i}$.

We assume that the four quarks form an equilateral tetrahedron(ETH) or a square, and the antiquark locates at the center of the four quark cluster, which is illustrated in Fig.1. We determine all the accessible configuration with $L \leq 3$, extending the results of Ref. [48]. For the case of equilateral tetrahedron, we denote O as the center of the four quarks, \hat{i} , \hat{j} , \hat{k} form the frame, and $r_{12} \perp \hat{k}$, $r_{34} \perp \hat{k}$. Referring to $R_{\vec{\delta}}^{\vec{\nu}}$ as a rotation about the axis along the vector $\vec{\nu}$ by an angle δ , p_{ij} as an interchange of the particles i and j , p_{ijk} and p_{ijkl} as permutation among the three and four particles, and \hat{P} as a space inversion, the ETH is

evidently invariant to the operations:

$$\hat{O}_1 = p_{12}p_{34}R_{\pi}^{\hat{k}}, \quad (6)$$

$$\hat{O}_2 = p_{34}R_{\pi}^{\hat{j}}\hat{P}, \quad (7)$$

$$\hat{O}_3 = p_{1423}R_{\pi/2}^{\hat{k}}\hat{P}, \quad (8)$$

$$\hat{O}_4 = p_{243}R_{2\pi/3}^{\hat{n}}. \quad (9)$$

Inserting each of these operators to Eq.(3), we have a set of equations,

$$(\hat{O}_i - E)F_{LM}^{\pi\lambda_j}(\mathcal{A}) = 0. \quad (10)$$

$F_{LM}^{\pi\lambda_j}(\mathcal{A})$ is the orbital wave-function in the body frame, E is the identity matrix, j and M denote the constituent of λ and L . Eqs. (6)-(9) are the equations that $F_{LM}^{\pi\lambda_j}(\mathcal{A})$ has to fulfill. They are homogeneous linear algebraic equations. If they have common non-zero solutions, we have a nodeless structure. The representations of the permutation group S_4 and the rotation group are represented in Table IV and Table V where we just show those for $L = 1$ as an example. The equations can be solved easily. The obtained results are showed in Table VI, where A denotes the accessible configuration (holds nodeless structure) and “-” stands for the inaccessible configuration.

It is believed that the wave functions are strongly constrained at the ETH configuration, however they are less constrained in the neighborhood of the ETH, since the ETH holds the highest symmetry. To check such an idea, we have performed calculations in the case that the shape in the left panel of Fig. 1 is invariant under the operations \hat{O}_1 , \hat{O}_2 and \hat{O}_3 , but not \hat{O}_4 . The obtained results are listed as those marked with ETH₃ in Table VI. It shows apparently that all the configurations accessible to the ETH are definitely accessible to the ETH₃, and more nodeless configurations are allowed for the ETH₃.

For the case of the four quarks forming a square, the operations for the configuration to be invariant are

$$\hat{O}_1 = p_{12}p_{34}\hat{P}, \quad (11)$$

$$\hat{O}_2 = R_{\pi}^{\hat{k}}\hat{P}, \quad (12)$$

$$\hat{O}_3 = p_{34}R_{\pi}^{\hat{j}}, \quad (13)$$

$$\hat{O}_4 = p_{1324}R_{\pi/2}^{\hat{k}}. \quad (14)$$

	3^-	–	A	–	A	–
Square ₃	0^+	A	A	A	A	–
	1^-	–	A	–	A	–
	2^+	A	A	A	A	A
	3^-	–	A	–	A	–

Inserting them into Eq. (3), we get another set of equations as Eq. (10). The obtained accessible configuration of the $(L\pi\lambda)$ and the IRREPs of the S_4 group of the wave functions are listed as those marked as Square in Table VI. In the neighborhood of the square, for example, prolonged along the \hat{j} direction, it is still invariant under \hat{O}_1 , \hat{O}_2 and \hat{O}_3 , but not \hat{O}_4 . The accessible configurations are also given in Table VI with a mark Square₃. It is evident that the square-accessible component is inherently nodeless in the neighborhood of the square.

Combining Table II and Table VI one can get the number of the accessible (nodeless) states $J_4^\pi = L^\pi \oplus S$ with orbital angular momentum $L \leq 3$. The obtained result is listed in Table VII.

Considering the fact that, for usual bound states of quantum system, the fewer nodes

TABLE VII. Obtained number of the accessible (nodeless) states J^P with orbital angular momentum $L \leq 3$ of the ETH configuration and square configuration of the four quark system.

Configuration	0^+	0^-	1^+	1^-	2^+	2^-	3^+	3^-	4^+	4^-	5^+	5^-
ETH	7	10	19	22	25	28	15	26	4	15	0	4
square	7	7	18	15	25	19	15	17	4	10	0	2
ETH ₃	9	10	21	22	26	28	15	26	4	15	0	4
square ₃	11	7	25	15	27	19	15	17	4	10	0	2

the configuration contains, the lower energy the state has. One can recognize that the J^π of the lowest energy state involving four quarks with three flavors is $J_4^\pi = 2^+$ (the accessible number is 50). While that of the second, the third lowest state is 2^- , 3^- (the accessible number is 47, 43, respectively). If the symmetry of the configurations are less constrained, such as those for ETH₃ and square₃, the result almost maintains the same (the accessible number becomes 53, 47, 46, respectively, but the J_4^π of the third lowest changes to 1^+).

In our scheme regarding pentaquark states, we notice that the P_c^+ states are composed of a four quark cluster involving a c -quark ($uudc$) and an antiquark \bar{c} at the ground state. The total spin and the parity of the P_c^+ states should be $J^P(P_c^+) = J_4^\pi(uudc) \oplus \frac{1}{2}^-(\bar{c}) \in \{\frac{3}{2}^-, \frac{5}{2}^-, \frac{3}{2}^+, \frac{5}{2}^+\}$. Since the c -quark is much heavier than the u - and d -quarks, we can assume that the interaction between the cluster and the \bar{c} -quark is similar to that between the c - and \bar{c} -quarks. In view of heavy quark interaction, the energy sequence (from lower to higher) of the doublet with mainly $J_4^\pi = 2^\pm$, is $\{\frac{3}{2}^-, \frac{5}{2}^-\}$, $\{\frac{3}{2}^+, \frac{5}{2}^+\}$, respectively. Taking the fact that the spin-orbital splitting is proportional to the orbital angular momentum into consideration, one can assign the energy sequence of the J^P states to $\frac{3}{2}^-, \frac{5}{2}^-, \frac{3}{2}^+, \frac{5}{2}^+$.

IV. SUMMARY AND REMARKS

In summary, by analyzing the symmetry, more concretely the inherent nodal structure, of the system including four quarks involving three flavors, we propose dynamical model independently that the quantum numbers of the lowest-lying pentaquark states P_c^+ could be $J^P = \frac{3}{2}^-$ with orbital angular momentum $L = 2$ mainly. The quantum numbers of the other two low-lying pentaquark states P_c could be $J^P = \frac{3}{2}^+, \frac{5}{2}^+$. And there may exist another P_c

pentaquark state with $J^P = \frac{5}{2}^-$, which may be observed by analyzing the structure of the peak around 4312 MeV. More experiments or analyzing the existing experiments with more broad viewpoints (see, e.g., Refs. [49, 50]) are then expected.

It is finally remarkable that our present result is only valid for the pentaquark states without molecular structure, namely no color singlet three-quark states and meson-like states. Of course, such a result is only a qualitative result. However, taking the presently assigned configuration into dynamical model calculations can apparently help to reduce the load of numerical calculation tasks. In addition, the work analyzing the inherent nodal structure of the pentaquark states with molecular configurations will be given in a sequel.
