Abstract

We formulate the Hartree–Fock method in large-$N$ approximation using a functional integral approach and derive an exact renormalization group equation for the effective action. We consider only a nonperturbative component of the vacuum polarization. For the Dirac–Coulomb operator the renormalization flow of the vacuum polarization is calculated numerically. For the Hartree–Fock operator the polarization is obtained by integrating an appropriately rescaled flow. The text includes a calculation of the vacuum polarization for the Uranium atom.

1 An introduction

One of the most important discoveries that laid a path to the contemporary QED is the Dirac equation. However this discovery introduced a notorious problem of negative energy solutions which led Dirac to the creation of the hole theory. In order to preserve the probabilistic interpretation of the wave function and the particle-hole symmetry he gave a new definition of the density matrix (16). A radical departure from this point of view proposed by R. Feynman. He was the first to realize that negative energy solutions are necessary to describe the motion of the relativistic electrons [4]. A more important difference with the quantum mechanics is the fact that the field operator in QED does not have any probabilistic interpretation. An excellent historical review can be found in ”The Quantum Theory of Fields” by S. Weinberg [7].

The subject of radiative corrections in atoms has a very rich history, see e.g. [45, 21, 44]. In this text we describe the Lamb shift from a QED point of view. As usual we assume that the state of an atom is given by the Slater determinant. We account for many-body environment by putting a valence electron on the Fermi energy level. Of course such an approximation breaks the original symmetry. To restore it we introduce a field multiplet whose component describes an electron and then retain only the invariant term. This yields an action whose semiclassical limit coincides with the Hartree–Fock approximation.
From M. Gell-Mann and F. Low we know however that the parameters of a quantum theory are functions of energy scale [42] and the action obeys the Wilson–Polchinski equation [24]. Furthermore above a sufficiently large infra-red cut-off the Hartree–Fock action can be calculated using the theory of perturbation, i.e. its 1-loop approximation is known analytically. To recover the action below the cut-off we integrate the renormalization group flow. To make our calculations and presentation manageable in size and complexity we consider only the simplest case of the vacuum polarization density.

For a single electron ion the corresponding Green’s function and vacuum polarization have been already studied analytically [21, 33]. Our numerical calculations are in agreement with the exact solution [21]. In the present work we apply the renormalization group method to calculate the vacuum polarization of the Hartree–Fock operator. The computation and numerical analysis are performed using Mathematica [46].

1.1 A short tour of the Dirac theory

To introduce the relativistic propagator it is necessary to clarify the physical meaning of the negative energy solutions of the Dirac equation. In contemporary physics the particle–hole hypothesis has been replaced by the particle–antiparticle formalism. Hence it is appropriate to start with a short exposition of this theory. A reader familiar with QED should rather go to section 2. The essence of the idea is a decomposition of the Klein-Gordon equation using quaternions

$$i(\partial_0 + \sigma_i \partial_i)u = mv,$$

$$i(\partial_0 - \sigma_i \partial_i)v = mu,$$

where $$\sigma_i$$ are the Pauli matrices. If we define a metric $$E = i\sigma_2$$ in the linear space of two-component spinors then for any $$2 \times 2$$ complex matrix $$\Lambda$$ with $$\det \Lambda = 1$$ the bilinear form $$\xi' E \eta'$$ is invariant under the transformation $$\xi' = \Lambda \xi, \eta' = \Lambda \eta$$. Clearly

$$\xi E \eta = \det \| \xi \eta \|, \quad \| \xi \eta \| = \begin{pmatrix} \xi_1 & \eta_1 \\ \xi_2 & \eta_2 \end{pmatrix}, \quad \det \| \xi' \eta' \| = \det (\Lambda \| \xi \eta \|) = \det \Lambda \det \| \xi \eta \|. \quad (3)$$

In the space of anti-hermitian matrices $$M^{\lambda \bar{\mu}}$$

$$M = i \begin{pmatrix} x^0 + x^3 & x^1 \bar{x}^2 \\ x^1 + ix^2 & x^0 - x^3 \end{pmatrix} = i(x^0 + x^3 \sigma_i) \quad (4)$$

the transformation $$M \rightarrow \Lambda M \Lambda^+$$ furnishes an irreducible representation of the proper orthochronous Lorentz group, $$\det M = x^\mu g_{\mu \nu} x^\nu$$. Here $$x^\mu$$ is a contravariant vector in Minkowski space with the metric $$g_{\mu \nu} = (-1, 1, 1, 1)$$. The dot on the top of an index means that the component transforms using the complex conjugate matrix, i.e. $$\xi' = \Lambda^* \xi \bar{\mu}$$. For each element of the Lorentz group we have two matrices $$\pm \Lambda$$. Furthermore it is easy to show that the matrix $$M_{\mu \lambda} = EM^* E^T$$ with covariant indices corresponds to the covariant vector $$x_\mu = g_{\mu \nu} x^\nu$$. Since the partial derivatives transforms as a covariant vector we can write equations (1) and (2) in a form which is explicitly invariant under the spinor transformations

$$i\partial_\mu u^\lambda - mv_\mu = 0, \quad i\partial^{\bar{\mu}} v^\lambda - mu^\lambda = 0. \quad (5)$$
where $\partial^{\lambda\dot{\mu}} = E^{\lambda\sigma} E^{\dot{\mu}\dot{\nu}} \partial_{\nu\sigma}$. We complex conjugate the equation on the right and define a new spinor $u^\mu = v^*\mu$

$$
\iota \partial_\mu \lambda u^\lambda - mw^*_\mu = 0, \quad \iota \partial_\mu \lambda w^\lambda - mu^*_\mu = 0. \tag{6}
$$

With an auxiliary potential $A_{\mu\lambda}$ these equations become $U(1)$ gauge invariant

$$
\iota (\partial_\mu \lambda - i e A_{\mu\lambda}) u^\lambda - mw^*_\mu = 0, \quad \iota (\partial_\mu \lambda + i e A_{\mu\lambda}) w^\lambda - mu^*_\mu = 0. \tag{7}
$$

The gauge transformation has the form

$$
u \rightarrow e^{i e \alpha} \nu, \quad w \rightarrow e^{-i e \alpha} w, \quad A_{\mu\lambda} \rightarrow A_{\mu\lambda} + \partial_\mu \lambda \alpha. \tag{8}
$$

It is clear from equations (7) that the spinors $u$ and $w$ describe particles of opposite charge. Let $b_\mu = u^*_\mu$ and complex conjugate the left equation in (6)

$$
\iota \partial^{\lambda\dot{\mu}} b_\mu - mw^\lambda = 0, \quad \iota \partial_{\mu\lambda} w^\lambda = mb_\mu = 0. \tag{9}
$$

Using the Weyl or chiral representation of the $\gamma$ matrices the equations (1) and (2) yield the Dirac equation

$$
(\bar{\psi} + m)\psi = 0, \quad \psi = \begin{pmatrix} u^\lambda \\ v_\mu \end{pmatrix}, \quad \bar{\psi} = \gamma^\mu \partial_\mu. \tag{10}
$$

Comparing (9) and (5) we see that the Dirac equation is invariant under the transformation of charge conjugation $C$,

$$
C : \begin{pmatrix} u \\ v \end{pmatrix} \rightarrow \begin{pmatrix} w \\ b \end{pmatrix} = \begin{pmatrix} -i \sigma_2 v^* \\ i \sigma_2 u^* \end{pmatrix}, \quad \psi \rightarrow \gamma^2 \psi^*. \tag{11}
$$

Each of the spinors $u$ and $w$ in (6) furnishes an irreducible representation and thus according to the Wigners classification any given solution describes a pair of elementary particles. Clearly the Dirac equation is invariant under the time reversal $T$ and the parity $P$ transformations

$$
T : \psi_{t,\vec{x}} \rightarrow \gamma^1 \gamma^3 \psi^{*}_{-t,\vec{x}}, \quad P : \psi_{t,\vec{x}} \rightarrow i \gamma^0 \psi_{t,-\vec{x}}. \tag{12}
$$

What does a stationary process look like? If the spinor $u_t = e^{-i E t} u_0$ corresponds to a usual particle, i.e. $E > 0$, then $w_t = e^{+i E t} w_0$ describes its opposite charged partner and propagating backwards in time, i.e. with its phase reversed. Due to the particle-antiparticle symmetry $(u, w) \rightarrow (w, u)$ the situation remains the same for $E < 0$. A stationary solution of (6) has the following form

$$
(u_t, w_t) = \begin{cases} 
(e^{-i \omega t} u^{(+)}_0, e^{+i \omega t} u^{(+)}_0) & E > 0, \\
(e^{+i \omega t} u^{(-)}_0, e^{-i \omega t} u^{(-)}_0) & E < 0, 
\end{cases} \quad \omega = |E|. \tag{13}
$$

For $E > 0$ the variables $(u, v)$ in equation (5) describe the propagation of a particle. On the contrary for $E < 0$ the variables $(w, b)$ in equation (9) correspond to the propagation of the antiparticle. Using invariance under the $CPT$-transformation, i.e.

$$
CPT : (u^{(+)}_0, w^{(+)}_0)_x \rightarrow (-u^{(+)}_0, w^{(+)}_0)_{-x} = (u^{(-)}_0, w^{(-)}_0)_x, \quad \psi_{x} \rightarrow -\gamma^5 \psi_{-x}. \tag{14}
$$
we have \((u_0^-, w_0^+) = (-u_0^+, w_0^-)\), \(\vec{x} \in \mathbb{R}^3\). Consequently \(w\) corresponds to the mirror image of the antiparticle. Similarly using invariance of equations (1), (2) under the space inversion \(P\) it is easy to see that a general solution of \(v\) is the mirror image of \(u\). Since \(v\) is the charge conjugate of \(w\) it is natural to identify \(u\) and \(v\) with the chiral components of the particle. In the Dirac representation of the \(\gamma\)-matrices one obtains a different picture such that in the non-relativistic limit one component is dominant, i.e. for \(E > 0\) it corresponds to an electron. However in the Electroweak theory it is more convenient to keep \(u\) and \(v\) independent because, as we all know after the Wu experiment, these two particles interact differently. Using the four component spinor \(\psi\) a positive energy solution describes the chiral components of a particle and, due to the \(CPT\) map (146), a negative energy solution which can not propagate forwards in time corresponds to the mirror image of the antiparticle. In relativistic quantum theory the time direction for virtual particles outside of the light cone depends on the system of coordinates hence the both solutions are necessary to construct the propagator. For a virtual particle evolution of state during a time interval \(\delta t = t_2 - t_1\) is

\[
\psi = \begin{cases} 
  e^{-i E \delta t} \psi_1, & \delta t > 0, \ E > 0, \\
  -e^{-i(-E)\delta t} \psi_2, & \delta t < 0, \ E < 0.
\end{cases}
\]

(15)

The case \(\delta t < 0\) corresponds to the propagation of the antiparticle \(\psi_2 \to \psi_1\) with a positive energy \(-E\), see "The theory of positrons" [4] by R. Feynman where he also proposed that virtual pairs in the vacuum may interact with the real external charges.

### 1.2 The Dirac density matrix

We have seen in the previous section that the Dirac theory is a many-body theory. Consequently the probabilistic interpretation of the wave function becomes less obvious. Instead one should consider a transition probability amplitude from one state \(\psi_i\) to another \(\psi_j\), i.e. the scalar product between these states \(\langle \psi_i, \psi_j \rangle_{\mathcal{H}}\). In this sense the kernel of the transition matrix is a density matrix. For sake of simplicity we continue to consider only the case with no external field. An attempt of Dirac to give a probabilistic interpretation of the relativistic wave function leads him to a definition of the density matrix [5],

\[
R_1(x, y) = P_-(x, y) - P_+(x, y),
\]

(16)

where \(P_\pm\) are the projectors on the positive and negative spectrum respectively, i.e. \(P_\pm \mathcal{H} = \mathcal{H}_\pm\). To find these projectors we consider Fourier transform of the Dirac equation

\[
(i\sigma \cdot \mathbf{p} + m)\hat{\psi}(\mathbf{p}) = 0,
\]

\[
\psi(x) = \int \frac{d^4p}{(2\pi)^4} e^{ipx} \hat{\psi}(\mathbf{p}).
\]

(17)

Multiplying the both sides by \((-i\sigma \cdot \mathbf{p} + m)\) one finds that \(\hat{\psi}\) satisfies the Klein–Gordon equation

\[
(p^2 + m^2)\hat{\psi}(\mathbf{p}) = 0,
\]

\[
\hat{\psi}(\mathbf{p}) = \hat{\phi}(\mathbf{p}, \text{sign}(p^0))\delta(p^2 + m^2),
\]

(18)

where \(\hat{\phi} : \mathbb{R}^3 \times \mathbb{Z}_2 \to \mathbb{C}^4\) is a function on the mass shell. Since we restrict the functional space to solutions of the Klein–Gordon equation it is more convenient to use differently
renormalized functions $\hat{\psi}_\pm(\vec{p})$ instead of $\hat{\phi}(\vec{p}, \pm)$

$$\psi_\pm(x) = \int \frac{d^3p}{(2\pi)^\frac{3}{2}} e^{\pm ipx} \hat{\psi}_\pm(\vec{p}), \quad \psi_\pm(x) = \mathcal{F}_\pm^{-1} \hat{\psi}_\pm,$$  \hfill (19)

$$\hat{\psi}_\pm(\vec{p}) = \int \frac{d^3x}{(2\pi)^\frac{3}{2}} e^{\mp ipx} \psi_\pm(x), \quad \hat{\psi}_\pm(\vec{p}) = \mathcal{F}_\pm \psi_\pm.$$  \hfill (20)

Here $p^0 = E$, $E = \sqrt{\vec{p}^2 + m^2}$, $\hat{\psi}_\pm \in \mathcal{H}_\pm$. Let $\psi \in \mathcal{H}_+ \oplus \mathcal{H}_-$ and apply the Fourier transformations

$$(\mathcal{F}_+ \psi)(\vec{p}) = \hat{\psi}_+(\vec{p}) + e^{2iEt} \hat{\psi}_-(\vec{p}), \quad (\mathcal{F}_- \psi)(\vec{p}) = e^{-2iEt} \hat{\psi}_+(\vec{p}) + \hat{\psi}_-(\vec{p}).$$  \hfill (21)

The components $\psi_\pm$ satisfy the Dirac equation

$$(i\partial + m)\hat{\psi}_+(\vec{p}) = 0, \quad (i\partial - m)\hat{\psi}_-(\vec{p}) = 0.$$  \hfill (23)

Similar to (12) the parity transformation gives

$$(i\partial + m)\beta \hat{\psi}_+(\vec{p}) = 0, \quad (i\partial - m)\beta \hat{\psi}_-(\vec{p}) = 0, \quad \beta = i\gamma^0.$$  \hfill (24)

Using (23) we obtain

$$(i\partial - m)\beta \hat{\psi}_+(\vec{p}) = ((i\partial - m)\beta + \beta(i\partial + m))\hat{\psi}_+(\vec{p}) = \beta\{\beta, \vec{p}\} \hat{\psi}_+(\vec{p}) = -2E\hat{\psi}_+(\vec{p}), \quad (i\partial + m)\beta \hat{\psi}_-(\vec{p}) = i\{p, \beta\} \hat{\psi}_-(\vec{p}) = -2E\hat{\psi}_-(\vec{p}).$$  \hfill (25)

We define auxiliary projectors

$$\hat{P}_\pm(\vec{p}) = \frac{-i\partial \pm m}{2E}\beta.$$  \hfill (27)

Then from identities (24)-(26) it follows the following properties

$$\hat{P}_+ \hat{\psi}_+(\vec{p}) = \hat{\psi}_+(\vec{p}), \quad \hat{P}_- \hat{\psi}_+(\vec{p}) = \hat{\psi}_+(\vec{p}), \quad \hat{P}_- \hat{\psi}_-(\vec{p}) = 0.$$  \hfill (28)

Moreover $\hat{P}_+^2 = \hat{P}_+ \neq 0, \hat{P}_-^2 \neq \hat{P}_- \neq 0$. Using (21) and (22) we get $\hat{P}_\pm \mathcal{F} \psi = \hat{\psi}_\pm$ and thus $P_\pm = \mathcal{F}_\pm^{-1} \hat{P}_\pm \mathcal{F}_\pm$

$$P_+(x, y) = \int \frac{d^3p}{(2\pi)^3} \frac{-i\partial + m}{2p^0} \beta e^{ip(x-y)} = (-\delta_x + m)\beta \int \frac{d^3p}{(2\pi)^3 2p^0} e^{ip(x-y)},$$  \hfill (30)

$$P_-(x, y) = \int \frac{d^3p}{(2\pi)^3} \frac{-i\partial - m}{2p^0} \beta e^{-ip(x-y)} = (-\delta_x + m)\beta \int \frac{d^3p}{(2\pi)^3 2p^0} e^{-ip(x-y)}.$$  \hfill (31)

Finally we have

$$P_+(x) + P_-(x) = (-\delta + m)\beta \int \frac{d^3p}{(2\pi)^3 2p^0} (e^{ipx} - e^{-ipx}) = (-\delta + m)\beta \Delta(x),$$  \hfill (32)

$$P_+(x) - P_-(x) = (-\delta + m)\beta \int \frac{d^3p}{(2\pi)^3 2p^0} (e^{ipx} + e^{-ipx}) = (-\delta + m)\beta \Delta_1(x).$$  \hfill (33)
Here $\Delta_1$ is the Hadamard function, known also as the even solution of the Klein–Gordon equation. The odd solution $\Delta$ is the Pauli–Jordan function. A detailed analysis of their singularities can be found in the original paper by Dirac [5].

In non-relativistic quantum mechanics the expectation of an observable $O$ is defined as
\begin{equation}
\langle O \rangle_H = \int_{\mathbb{R}^3 \times \mathbb{R}^3} \psi^*(x) O(x, y) \psi(y), \quad (O \psi)(x) = \int_{\mathbb{R}^3} dy \ O(x, y) \psi(y).
\end{equation}

Consequently the density matrix is $\rho(y, x) = \psi(y) \psi^*(x)$ and the expectation is given by the trace of the observable with the density matrix, i.e. $\langle O \rangle_\rho = Tr(O \rho)$. It follows from (33) that $R_1$ doesn’t vanish at space-like intervals and thus if considered as the density matrix would include non-local contributions to vacuum expectations of observables. In 1927 J. von Neumann defined the density $\rho$ and the expectation of an observable $O$ for a canonical ensemble at temperature $T$, see [8],
\begin{equation}
\rho = \frac{e^{-\beta H}}{Tr(e^{-\beta H})}, \quad \langle O \rangle_\rho = Tr(O \rho), \quad \beta = \frac{1}{\kappa T}.
\end{equation}

This definition has been subsequently extended to the grand canonical ensemble [9, 3]. Using this probability measure one obtains the 2-point Schwinger function (47) which corresponds to the Feynman propagator $\Delta_F$ in Minkowski space [11]. In the quantum field theory there are two equivalent definitions of the propagator [7],
\begin{align}
-ih \Delta_F(x, y) &= \langle T \psi_x \psi_y^+ \rangle_H, \\
-ih \Delta_F(x, y) &= \theta(x^0 - y^0) P_+ - \theta(y^0 - x^0) P_-.
\end{align}

Here $\psi_x$ is a generalized operator on $\mathcal{H}$. Since $P_+ \neq -P_-$ the propagator is not continuous at $x^0 = y^0$. Apparently $R_1$ and $\Delta_F$ have different propagation properties
\begin{equation}
(h \partial + m) R_1 = 0, \quad (h \partial + m) \Delta_F \beta = \delta^4.
\end{equation}

Even if $R_1$ and $\Delta_F$ are distributions we try to consider them at $x^0 = y^0$. The Heaviside function is also a generalized function and its value at zero is not defined. Put $\theta(0) = \theta_0 > 0$ then equation (37) gives
\begin{equation}
ih \Delta_F |_{t=0} = \theta_0 (P_- - P_+) |_{t=0} = \theta_0 R_1 |_{t=0}.
\end{equation}

On the other hand for any space-like intervals
\begin{equation}
\lim_{t \to 0^\pm} ih \Delta_F(t, \vec{x}) = \frac{1}{2} (R_1 |_{t=0} \mp \delta^3_\vec{x}) = \frac{1}{2} R_1 |_{t=0}.
\end{equation}

It follows that $\theta_0 = \frac{1}{2}$ and thus
\begin{equation}
ih \Delta_F |_{t=0} = \frac{1}{2} R_1 |_{t=0}.
\end{equation}

The space-like correlation of the Dirac density matrix $R_1$ is induced by the vacuum fluctuations which are explicitly given by the Feynman–Kac formula in (43) and (46).
The Hartree–Fock action

A usual way to formulate QED is the functional integral formalism, see e.g. L.D. Faddeev [1]. The fundamental formula for constructing Euclidean field theory, see e.g. [3], is

\[ \langle F, e^{-H \tau} G \rangle_{\mathcal{H}} = \langle \theta F, T(\tau) G \rangle, \quad \langle F, G \rangle = \int d\nu_\Phi F^* (\Phi) G(\Phi). \] (42)

Here \( F, G \in \mathcal{E} = \text{span}\{e^{\Phi(f)} : f \in \mathcal{D}\} \) are functionals, i.e. \( F, G : \mathcal{D}' \to \mathbb{C}, \mathcal{D} = C^\infty_0 \); \( \mathcal{H} = \mathcal{E}/\mathcal{N} \) is the Hilbert space where \( \mathcal{N} = \{ A \in \mathcal{E} : \langle A, A \rangle = 0 \} \); \( \theta \) and \( T(\tau) \) are the time reflection and translation where an action \( \varepsilon \) of Euclidean group acts via \( (\varepsilon F)(\Phi) = F(\varepsilon \Phi), (\varepsilon \Phi)(f) = \Phi(\varepsilon f) \). For a wide class of quantum theories \( \int d\nu_\Phi \) denotes a functional integral with a Gaussian measure on \( \mathcal{D}' \).

In particular, the construction of Euclidean QED in the \( \xi \)-gauge leads to a formal path integral in \( \mathcal{D}'(\mathbb{R}^4) \) with the Lagrangian semiclassical density which includes a gauge fixing term

\[ \Gamma_0 = \frac{1}{4} F_{\mu\nu}^2 + \frac{1}{2\xi} (\partial_\mu A_\mu)^2. \] (44)

The Feynman gauge corresponds to \( \xi = 1 \). Calculating the inverse of this bilinear form yields the covariance matrix

\[ C_{\mu\nu}(x) = \int \frac{d^4 p}{(2\pi)^4} e^{ipx} \hat{C}_{\mu\nu}(p), \quad \hat{C}_{\mu\nu}(p) = \frac{\delta_{\mu\nu}}{p^2}. \] (45)

Let \( \mathcal{G}(\mathbb{R}^4) \) denote an infinite dimensional algebra whose generators are maps from \( \mathbb{R}^4 \) to a Grassmann algebra \( \mathcal{G} \). A system with fermions is usually quantized using the Berezin integral [2, 35]

\[ e^{(\bar{\eta} S_0 \eta)} = \int d\nu_\psi \ e^{(\bar{\eta} \psi) + (\bar{\psi} \eta)}. \] (46)

Here \( \bar{\eta}, \eta \in \mathcal{G}(\mathbb{R}^4) \) are smooth function with compact support and \( \bar{\psi}, \psi \in \mathcal{G}'(\mathbb{R}^4) \). For Dirac fermions \( \Gamma_0 = \bar{\psi}(\bar{\phi} + m) \psi \) and thus the covariance matrix is

\[ S_0(x) = \int \frac{d^4 p}{(2\pi)^4} \hat{S}_0(p) e^{ipx}, \quad \hat{S}_0(p) = \frac{-ip + m}{p^2 + m^2}. \] (47)

Here \( \bar{\phi} = p_\mu \gamma_\mu \) and \( \{ \gamma_\nu, \gamma_\mu \} = 2\delta_{\mu\nu}, \gamma_0 = \beta \).

To introduce interaction one substitutes \( \bar{\phi} \) with a covariant derivative wrt local gauge transformations, i.e. \( \bar{\phi} \to \bar{\phi} - ie A, \) and define a generating functional

\[ Z_{\text{qed}}(K) = \int d\nu_\Phi \ e^{-L(\Phi) + (1_\phi \Phi)}, \quad L_0(\Phi) = -ie \int \bar{\psi} A \psi, \] (48)

\[ \Phi \in (A_\mu, \bar{\psi}, \psi), \ K \in (j_\nu, \eta, \bar{\eta}), \quad (1_K)_{\phi \bar{\phi}} = \begin{cases} -1 & K = \phi = \bar{\phi}, \\ \delta_{\phi \bar{\phi}} & \text{otherwise.} \end{cases} \] (49)
In the perturbation theory $L$ is understood as a formal expansion over the Planck constant, i.e. the loop expansion $L = \sum_{l \geq 0} \hbar^l L_l$. The terms $L_l$ with $l > 0$ are the counterterms.

In Quantum Mechanics the Hartree–Fock method is an approximation to the quantum many-body problem. One assumes that quantum mechanical $N$-particle state is an anti-symmetric combination of one-particle wave functions $\{ \varphi_i \in H^1 \}$ known as the Slater determinant [16]. The equations of motion are obtained by the variational principle, i.e. they correspond to the stationary points of the energy under the constraint that the $L_2$-norm of the wave functions be one. This leads to the Euler–Lagrange equation $\hat{H}_i \varphi_i = \varepsilon_i \varphi_i$ where $\{ \hat{H}_i \}_{i=1}^N$ are one-particle Hamiltonians. Usually one defines the Fock operator $F$, substitutes one-particle Hamiltonians $\hat{H}_i$ with the Fock operator $F$ and solves the eigenvalue problem $F \varphi_i = \varepsilon_i \varphi_i$. For neutral and positively charged atoms and ions of $N + 1$ electrons the minimiser of the of the Hartree–Fock energy exists [18], and there are infinitely many stationary points of the same non-linear problem with $N$ electrons [17]. The discrete spectrum of the Dirac Hamiltonian with a potential $V$ such that for $r \to \infty$ it behaves as $V = C r^{\alpha - 2}$ where $0 < \alpha < 2$ is also infinite [19]. The one-particle Hamiltonians $\hat{H}_i$ are of this kind, see below (118).

To account for the vacuum polarization it is necessary to add to the method arbitrary number of virtual particles, i.e. we need to make a transition from the representation in the configuration space to a new canonical variable which describes the occupation numbers of quantum states [6]. A further development of this idea led V. Fock to the introduction of the quantized wave function $\psi$ and subsequently to a new form of the non-relativistic energy operator [20]

$$H = \int_{x \in \mathbb{R}^3} \psi_x^+ \left( -\frac{\Delta}{2m} - \frac{e^2}{|x|} \right) \psi_x + \frac{e^2}{2} \int_{x,y \in \mathbb{R}^3} \frac{\psi_x^+ \psi_y^+ \psi_y \psi_x}{|x-y|}. \quad (50)$$

Here the first term is the Hamiltonian of an electron in a Coulomb potential and the second term gives two-particle interaction. This form can be obtained using the generating functional given above in (48) if one integrates out all electromagnetic quantum fluctuations. Indeed given an external current $\mathcal{J}$ and denoting the corresponding background field by $\mathcal{A}$, i.e. $\mathcal{A} = C \mathcal{J}$, we obtain

$$Z_{\text{qed}}(\mathcal{J}, \eta, \bar{\eta}) = e^{\frac{1}{2} \langle \mathcal{J} \mathcal{A} \rangle} e^{W(\eta, \bar{\eta})}, \quad L_{\mathcal{A}} = -i e \langle \bar{\psi} \mathcal{A} \psi \rangle + \frac{e^2}{2} \langle \bar{\psi} \gamma^\mu \psi C_{\mu\nu} \bar{\psi} \gamma^\nu \psi \rangle, \quad (51)$$

$$e^{W(\eta, \bar{\eta})} = \int d\nu \psi \bar{\psi} e^{-L_{\mathcal{A}} + \langle \bar{\eta} \psi \rangle + \langle \bar{\psi} \eta \rangle}. \quad (52)$$

For simplicity we restrict our discussion to the semiclassical approximation and deliberately omit all the counterterms. Let define the classical fields as usual

$$\phi = \frac{\delta W}{\delta \eta}, \quad \bar{\phi} = -\frac{\delta W}{\delta \bar{\eta}}. \quad (53)$$

Each of these vacuum expectations has a non-vanishing value only in the presence of the corresponding external source. Using integration by parts (178) and taking the semiclassical limit, i.e. $\hbar \to 0$, we obtain

$$(\bar{\phi} + m) \phi = \frac{\delta L_{\mathcal{A}}(\bar{\phi}, \phi)}{\delta \phi} + \eta, \quad \bar{\phi}(\phi + m) = \frac{\delta L_{\mathcal{A}}(\phi, \bar{\phi})}{\delta \bar{\phi}} + \bar{\eta}. \quad (54)$$
Solutions of these equations make stationary the following effective action

\[ \Gamma_0 = \langle \bar{\phi}(\varnothing - ie\mathbf{A} + m)\phi \rangle + \frac{e^2}{2} \langle \bar{\phi} \gamma^\mu \phi C_{\mu\nu} \bar{\phi} \gamma^\nu \phi \rangle - \langle \bar{\phi} \eta \rangle - \langle \eta \phi \rangle. \]  

(55)

Defining a quantum state by the Slater determinant and closely following V. Fock [20] we would get a relativistic generalization of the Hartree–Fock equation (50).

Let perform a shift of the Gaussian measure \( d\nu_A \) (43) by a background field \( A_\mu \to A_\mu + A_\mu \)

\[ Z_{\text{qed}}(K) = e^{\frac{1}{2}\left(AC^{-1}A \right) + (A(j-J)) + W(j-J,\bar{\eta},\eta)}, \]

(56)

\[ e^W(K) = \int d\nu_\Phi e^{-L(A + A, \bar{\psi}, \psi) + \langle K \bar{1}_n \Phi \rangle}. \]

(57)

It is also convenient to define a measure \( d\mu_{\bar{\psi}\psi} \)

\[ e^{\langle \bar{\eta}S \eta \rangle} = \int d\mu_{\bar{\psi}\psi} e^{\langle \bar{\eta} \psi \rangle + \langle \bar{\psi} \eta \rangle}, \]

(58)

where \( S \) is a solution of a non-homogeneous Dirac equation with an external potential \( A \), e.g. a Coulomb potential,

\[ \langle \bar{\varnothing} - ie\mathbf{A} + m \rangle S_{xy} = \delta^4_{xy}. \]  

(59)

To uniquely define the propagator \( S \) we shall also specify a walk around the poles.

Given a neutral atom with \( N + 1 \) electrons in a particular quantum state \( \{ \varphi_i \} \) we can single out a valence \( N + 1 \)-th electron and solve the Hartree–Fock problem for the remaining \( N \) electrons. We consider the example in the theory of perturbation up to the first order in the coupling constant of the quartic term in (51) without addressing the convergence of the expansion. A nonperturbative approach will discussed below in section 3. In the Hartree–Fock approximation a \( N \)-particle state in the Hilbert space \( \mathcal{H} \) is a functional \( \Phi_N \in \mathcal{H} \),

\[ \Phi_N = \prod_{i=1}^N \psi^+(f_i), \quad \langle \Phi_N, \Phi_N \rangle_{\mathcal{H}} = 1, \quad f_i = \delta_{ij} \varphi_i, \quad \langle \varphi_i^+ \varphi_j \rangle = \delta_{ij}. \]

(60)

Here \( \varphi_i \in H^1(\mathbb{R}^3, \mathbb{C}^4) \) are wave functions of electrons. The state is invariant under the transformations of a symmetry group, i.e. \( \varphi \mapsto g\varphi \) where \( g \in SU(N) \). We consider the 2-point correlation function of the valence electron in a background state \( \Phi_N \) such that the functions \( \{ \varphi_i \} \) are eigenvectors of the Dirac–Coulomb Hamiltonian

\[ \bar{g}^f(x, y) = \langle \Phi_N, \psi_x \psi^+_y \Phi_N \rangle_{\mathcal{H}}, \quad x, y \in \mathbb{R}^4. \]

(61)

It is not difficult to realize that \( 2(n + 1) \)-point functions \( \langle \Phi_0 \psi_{z_1}^+ \ldots \psi^+_{z_n} \Phi_0 \rangle \) with two points connected to \( x, y \) and with the remaining \( 2n \) points connected to \( \varphi_i(z_i), \varphi_i^+(z'_i) \) describe the screening of the Coulomb potential and the exchange of the valence electron with other \( n \) electrons. The functions at the bottom in Figure 1 can be obtained from the corresponding terms at the top by a suitable modification of the walk around the poles of the propagator (59)

\[ S(x, y) \mapsto S^f(x, y) = S(x, y) + \sum_{i=1}^N S_i(x, y), \quad S_i(x, y) = -e^{-\omega_{ij}(x^0 - y^0)} \varphi_i(x) \varphi_i(y). \]

(62)
However at higher orders we shall account for functions with four and more external lines connected to the background state. Here we do not need to develop the expansion beyond the first order. Performing the Wick rotation to Minkowski space $S^E(it) = -iS^M(t)$, restricting $g^f$ to the hyperplane $t = 0$ and retaining only the leading order we get the result which is similar to equations (36), (41)

\[ i\hbar g^f_0(x, y) = \frac{1}{2} R^f_1(x, y), \quad R^f_1(x, y) = P^f_+(x, y) - P^f_-(x, y), \]  

\[ \bar{g}^f(x, y) = -\sum_{l \geq 0} \hbar^l P^f_+(x, y), \quad P^f_+(x, y) = P^f_+(x, y) \pm \sum_{i=1}^{N} \phi_i(x)\phi^*_i(y). \]  

We come to a representation in which the other electrons define the Fermi energy level, i.e. an appropriate choice of the walk around the poles of the Feynman propagator. It is clear that the connection between the background state and the poles of the propagator is a general property which is independent of QED.

We now obtain one-particle Hamiltonian $\hat{H}$ without resorting to the Feynman diagrams in Figure 1. Assuming the renormalizability of QED we construct a generating functional in such a way that the counterterms preserve the Lorentz invariance and satisfy the Ward identities

\[ Z(K) = \int d\mu_\phi \ e^{-L(K, \psi)}, \quad Z(0) = 1, \]  

\[ \mathcal{L} = -ieZ_2\bar{\psi}\gamma^\mu A_\mu \psi - Z_2\delta m\bar{\psi}\psi + (Z_2 - 1)\bar{\psi}S^{-1}\psi \]  

\[ + (Z_3 - 1)A_\mu C^{-1\mu}A_\nu + \frac{(Z_3 - 1)}{2} A_\mu C^{-1\mu}A_\nu. \]  

Convention used here is clear from the scaling properties of the measure given in appendix A.2. Here we assume that the Ward identities can be restored and intentionally omit all other terms which break the gauge invariance. This point might be needed a further clarification. A mathematically meaningful definition of this integral is rather hopeless without an ultraviolet cutoff. But the introduction of a such cutoff will break the gauge invariance and some nonphysical terms as the photon mass and $A^4$ coupling will appear in our calculations. The latter term is finite but depends on a way we perform the integration, the former is divergent (207). In the course of the renormalization procedure we restore the gauge invariance by normalizing the photon mass to zero. The decomposition given in (66)
preserves the gauge invariance because it reduces to a rescaling of the variables. To see this let assume that the constant $Z_i$ are finite and independent of $\hbar$, then we shall restore the Planck constant in the Feynman–Kac integral and consider the semiclassical limit $\hbar \to 0$

\[ e^{\frac{k}{\hbar}W(K)} = \int d\mu_\Phi \, e^{-\frac{k}{\hbar}L + \frac{k}{\hbar}K_1 + \Phi}. \]  

(67)

Define the corresponding classical fields

\[ a = \hbar \frac{\delta W}{\delta j}, \quad \phi = \hbar \frac{\delta W}{\delta \eta}, \quad \tilde{\phi} = -\hbar \frac{\delta W}{\delta \eta}. \]  

(68)

Using integration by parts (178), (179) we obtain equations of motion in the limit $\hbar \to 0$

\[ C^{-1}a + \frac{\delta L}{\delta a} - j = 0, \quad S^{-1}\phi + \frac{\delta L}{\delta \phi} - \eta = 0, \quad \tilde{\phi}S^{-1} - \frac{\delta L}{\delta \phi} - \tilde{\eta} = 0. \]  

(69)

It follows that the semiclassical action has the form

\[ \Gamma_0 = \frac{1}{2} \langle aC^{-1}a \rangle + \langle \tilde{\phi}S^{-1}\phi \rangle + L - \langle ja \rangle - \langle \tilde{\phi}\eta \rangle - \langle \tilde{\eta}\phi \rangle. \]  

(70)

Substituting $L$ with the decomposition given in (66) we see that this expression is a rescaling of the initial action

\[ \Gamma_0 = \frac{Z_3}{2} \langle (a + A)C^{-1}(a + A) \rangle + Z_2 \langle \tilde{\phi}(\bar{\phi} - ie(\phi + A) + m - \delta m) \phi \rangle \]

\[ - \langle (j + C^{-1}A)a \rangle - \langle \tilde{\phi}\eta \rangle - \langle \tilde{\eta}\phi \rangle - \frac{Z_3}{2} \langle AC^{-1}A \rangle. \]  

(71)

The last term does not appear in equations of motion (69) and can be omitted. In the following we put $Z_i = 1 + O(\hbar)$. The 2-point correlation function is

\[ \langle \bar{\psi}_x \psi_y \rangle_{L_2} = -Z^{\eta \eta}, \quad Z^{\eta \eta} = \frac{\delta^2}{\delta \eta_x \delta \eta_y}Z(0). \]  

(72)

The generating functional of connected Schwinger functions is related to the functional $Z$ by a simple combinatorial relation

\[ e^W = Z. \]  

(73)

Since $\bar{\psi}, \psi$ are odd elements of $G'(\mathbb{R}^4)$ their expectations vanish, $\langle \bar{\psi} \rangle_{L_2} = \langle \psi \rangle_{L_2} = 0$. Consequently we have $W^{\eta \eta} = Z^{\eta \eta}$, and thus the leading order of $W^{\eta \eta}$ in the loop expansion coincides with the covariance $-S$. Using integration by parts (178) we obtain an identity

\[ \int d\mu_\Phi \, e^{-L} \langle \bar{\eta}\psi \rangle \langle \bar{\psi}\eta \rangle = \langle \bar{\eta}S\eta \rangle + \int d\mu_\Phi \, e^{-L} \left( \langle \bar{\eta}S \frac{\delta^2 L}{\delta \psi \delta \psi} S \eta \rangle - \langle \bar{\eta}S \frac{\delta L}{\delta \psi} \langle \frac{\delta L}{\delta \psi} S \eta \rangle \right). \]  

(74)

The propagators at the endpoints suggest the introduction of the connected amputated Schwinger functions. We define its generating functional $L$

\[ W(K) = \frac{1}{2} \langle jCj \rangle + \langle \bar{\eta}S\eta \rangle - L(Cj, \bar{\eta}S, S\eta), \]  

(75)

\[ e^{-L(a, \tilde{\phi}, \phi)} = \int d\mu_\Phi \, e^{-L(A + a, \bar{\psi} + \bar{\phi}, \psi + \phi)}. \]  

(76)
In particular for 2-point correlators all these definitions yield
\[
\langle \psi_x \psi_y \rangle_{L_2} = -Z^n(x)\eta(y) = -W^{\eta(x)\eta(y)} = S_{xy} + S_{x\bar{x}}L\tilde{\phi}(x')\tilde{\phi}(y') S_{y'y}.
\] (77)

Hence identity (74) has the form
\[
L\tilde{\phi} = \int d\mu \phi e^{-L} \left( \frac{\delta^2 L}{\delta \tilde{\psi} \delta \psi} - \frac{\delta L \delta L}{\delta \tilde{\psi} \delta \psi} \right),
\] (78)

where
\[
\frac{\delta L}{\delta \psi} = Z_2 i e \bar{\psi} A + Z_2 \delta m \bar{\psi} - (Z_2 - 1) \bar{\psi} S^{-1},
\] (79)
\[
\frac{\delta L}{\delta \bar{\psi}} = -Z_2 i e A \psi - Z_2 \delta m \psi + (Z_2 - 1) S^{-1} \psi,
\] (80)
\[
\frac{\delta^2 L}{\delta \psi \delta \bar{\psi}} = Z_2 i e A \delta_{xy} + Z_2 \delta m \delta_{xy} - (Z_2 - 1) S^{-1} \delta_{xy}.
\] (81)

One can obtain this equation directly from definition (76) using the fact that odd fermionic correlators vanish. Using integration by parts (79) for linear and quadratic functions on \(L_2(D', d\mu e^{-L})\) we have
\[
\int d\mu \phi e^{-L} \langle fA \rangle = \int d\mu \phi e^{-L} \langle f\Pi \rangle,
\] (82)
\[
\int d\mu \phi e^{-L} \langle fA \rangle \langle Ag \rangle = \int d\mu \phi e^{-L} \left( \frac{1}{Z_3} \langle fC \rangle + \langle f\Pi \rangle \langle \Pi g \rangle \right),
\] (83)

where
\[
\Pi_\alpha = i e \frac{Z_2}{Z_3} C_{\alpha\beta} \bar{\psi} \gamma^\beta \psi - \frac{Z_3 - 1}{Z_3} A_\alpha.
\] (84)

Substituting these identities into (78) we obtain
\[
L\tilde{\phi}(x') = i e Z_2 \delta_{xy}[\bar{\psi}]_{L_2} - \frac{Z_2^2 e^2}{Z_3^2} (\bar{\gamma}^\nu \psi_{\nu\mu}(x, y) \bar{\psi} \gamma^\mu)_{L_2} + Z_2 \delta m \delta_{xy} - (Z_2 - 1) S^{-1} \delta_{xy}^4
\]
\[
+ \langle (Z_2 i e \bar{\psi} + Z_2 \delta m \psi - (Z_2 - 1) S^{-1} \psi_x Z_2 i e \bar{\psi} \Pi + Z_2 \delta m \bar{\psi} - (Z_2 - 1) \bar{\psi} S^{-1}) y \rangle_{L_2},
\] (85)

where the last term is a correction of the second order in the Planck constant. Retaining only the leading order we get
\[
L^\tilde{\phi}(x') = e^2 \delta_{xy}^4 \gamma^\nu C_{\nu\mu} T(r(S^\gamma\mu)) - i e (Z_3 - 1) \delta_{xy}^4 A
\]
\[
- e^2 \gamma^\nu C_{\nu\mu}(x, y) S(x, y) \gamma^\mu + \delta m \delta_{xy}^4 - (Z_2 - 1) S^{-1} \delta_{xy}^4.
\] (86)

Each of constants \(Z_2, Z_3, \delta m\) has divergent and finite parts. The finite part is fixed by the renormalization conditions. Retaining in equation (77) terms up to the first order in the Planck constant we obtain the Dirac equation
\[
(\bar{\psi} - i e A + m - L^\tilde{\phi}) W^{\eta \eta} = -\delta^4.
\] (87)
Expression on the right hand in (86) can be written in a more concise form using 1PI functions. The generating functional of 1PI functions is the effective action \( \Gamma \) which is defined by the Legendre transform (68)

\[
\Gamma(\Phi) = \langle K \hat{1}_1 \hat{1}_\eta \rangle - W(K).
\]

From this definition one can derive the following identity

\[
\frac{\delta^2 \Gamma}{\delta \Phi \delta \Phi} \frac{\delta^2 W}{\delta K \delta K} \hat{1}_\eta = \delta^4.
\]

(89)

We substitute into this equation the expansion of \( \Gamma \) over the Planck constant

\[
\Gamma(\Phi) = \frac{1}{2} \langle AC^{-1} A \rangle + \langle \bar{\psi} (\partial - ie(\mathcal{A} + \mathcal{A}) + m) \psi \rangle + \sum_{l \geq 1} h^l \Gamma_l(\Phi),
\]

(90)

restrict it to \( K = 0 \) and retain only first order corrections. This yields

\[
(\partial - ie(\mathcal{A} + \Sigma + ie\hat{\mathcal{G}} \Gamma^A_1)) W^{\eta \eta} = - \delta^4.
\]

(91)

Subtracting equation (87) we obtain

\[
L_1 \hat{\phi} = \Sigma_1 - ie\hat{\mathcal{G}} \Gamma^A_1.
\]

(92)

Let perform the Wick rotation back to Minkowski space-time. Recall that the Schwinger functions \( S_n \) is a restriction of an analytic extension of the Wightman functions \( W_n \) to Euclidean points [11]

\[
\mathcal{R} : x \mapsto \left( \begin{array}{cc} -i & 0 \\ 0 & 1 \end{array} \right) x,
\]

\[
\mathcal{R} : S_n(x_1, \ldots x_n) = W_n(\mathcal{R} x_1, \ldots \mathcal{R} x_n), \quad x_j > x_{j+1}.
\]

(93)

(94)

The covariance matrix of the vector field \( A \) transforms respectively under \( SO(4) \) and \( SO(1, 3) \). For \( x_1 > x_2 \) let \( -iC^\mathcal{M} = W_{AA} = \langle AA \rangle_\mathcal{H} \) and \( C^\mathcal{E} = S_{AA} \). Consequently we have

\[
\mathcal{R} : iC^\mathcal{E}(x_1, x_2) = \mathcal{R} C^\mathcal{M}(\mathcal{R} x_1, \mathcal{R} x_2) \mathcal{R}.
\]

(95)

Indeed for \( t > 0 \)

\[
C^\mathcal{E}(t, \vec{x}) = \int \frac{d^3 p}{(2\pi)^3} \frac{e^{-i\vec{p}t + i\vec{p}\vec{x}}}{2|\vec{p}|} \delta_{\mu\nu},
\]

(96)

and thus

\[
\mathcal{R}^{-1} C^\mathcal{E}(\mathcal{R}^{-1} x) \mathcal{R}^{-1} = -i \int \frac{d^4 p}{(2\pi)^4} e^{ipx} \hat{C}_\mu^\mathcal{M}(p), \quad \hat{C}_\mu^\mathcal{M}(p) = \frac{g_{\mu\nu}}{p^2 - i\epsilon}.
\]

(97)

The propagator in the Coulomb gauge can be obtained using a gauge transformation [12]

\[
\hat{C}_{\mu\nu}(p) = \frac{g_{\mu\nu} + p_\mu f_\nu(p) + p_\nu f_\mu(p)}{p^2 - i \epsilon}, \quad f_\mu = -\frac{p_\mu}{2p^2}, \quad f_0 = \frac{p_0}{2p^2}.
\]

(98)
This has the form

\[
\hat{C}^0(p) = \frac{1}{p^2 - i\varepsilon} \left( \begin{array}{cc} -\frac{\varepsilon^2}{p^2} & 0 \\ 0 & \delta_{ij} - \frac{p_i p_j}{p^2} \end{array} \right) + \frac{\xi p_\mu p_\nu}{(p^2)^2}, \quad \varepsilon \to 0, \quad \xi \to 0, \tag{99}
\]

where \(\xi\) is a device to obtain the inverse operator, see e.g. (44). Similarly for \(x_1^0 > x_2^0\) let

\[-iS^M_0 = W_{\psi\bar{\psi}} = \langle \psi\bar{\psi} \rangle_0 \text{ and } S^E_0 = S_{\psi\bar{\psi}}.\]

Furthermore there is a group homomorphism, i.e. \(\forall g \in SL(2, \mathbb{C})\) and \(\forall h \in SU(2) \times SU(2)\)

\[
h : S^E \rightarrow U_h S^E U_h^{-1}, \quad g : S^M \rightarrow V_g S^M V_g^{-1}. \tag{100}
\]

Consequently for the 2-point function of spinor fields in (47) we have

\[
S^E_0(\mathcal{R}^{-1} x) = -i S^M_0(x), \quad \hat{S}^M_0(p) = \frac{-i\phi + m}{p^2 + m^2 - i\varepsilon}. \tag{101}
\]

Let \(L^E\phi(\mathcal{R}^{-1} x) = L^M\phi(x)\phi(y)\). Then equation (86) has the form

\[
iL^4_{\phi(x)\phi(y)} = e^2 \delta^4_{xy} \gamma^\mu C^M_{\mu\nu} T_r(-iS^M \gamma^\nu) + ic(Z_3 - 1)\delta^4_{xy}A - e^2 C^M(x, y) \gamma^\mu (iS^M(x, y)) \gamma^\nu + \delta m \delta^4_{xy} - (Z_2 - 1)S^{-1}\delta^4_{xy}. \tag{102}
\]

The divergent constants calculated by several authors, see e.g. [10, 7]

\[
Z_2 = 1 - \frac{\alpha}{4\pi} D_2, \quad Z_3 = 1 - \frac{\alpha}{3\pi} D_3, \quad \delta m = m \frac{3\alpha}{4\pi} D_m, \quad D_a = \log \frac{\Lambda_0^2}{c_a m^2}, \quad \alpha = \frac{e^2}{4\pi}, \tag{103}
\]

where \(\Lambda_0\) is an ultraviolet cut-off in the momentum space and \(\{c_a\}\) are some finite constants.

Using equation (77) we obtain that the 2-point Green function \(-ig^f(x, y) = W_{\psi\bar{\psi}}(x, y)\) satisfies the Dirac equation with first order radiative corrections,

\[
(\hat{\phi} - icA + m - iL^4_1)g^f = \delta^4. \tag{104}
\]

Since the Green function \(S\) coincides with \(g^f\) at the leading order in the loop expansion we can substitute \(S\) with \(g^f\) in equation (102). Furthermore because the quantities are invariant under the time translation we can perform the Fourier transform

\[
g^f_\omega = \int dt e^{i\omega t} g^f(t), \quad \hat{L}^f_\omega = \int dt e^{i\omega t} \hat{L}^f(t). \tag{105}
\]

Put \(V_\omega = -i\beta L^f_0\), \(V_\omega \in \mathcal{D}'(\mathbb{R}^3, \mathbb{R}^3)\). From equation (104) we read off that \(g^f_\omega\) is the resolvent of the Hamiltonian

\[
(\hat{H} - \omega)g^f_\omega = \delta^3, \quad \hat{g}^f = g^f \beta, \quad \hat{H} = \alpha^k (\partial_k - icA_k) - cA_0 + \beta m + V_\omega, \tag{106}
\]

where \(\alpha^k = \beta \gamma^k\) are the Dirac \(\alpha\)-matrices. Here \(g^f\) depends on the external potential \(A\) which we shall restrict to the Coulomb potential of the nuclear charge \(-Ze\). The resolvent can also be written using the bilinear formula

\[
g^f_\omega(\bar{x}, y) = \int dz \frac{\varphi_z(\bar{x})\varphi^+_z(y)}{z_+ - \omega}, \quad z_+ = \begin{cases} z - i\varepsilon & z \in \sigma_+(\hat{H}), \\ z + i\varepsilon & otherwise, \end{cases} \quad \hat{H}\varphi_z = z\varphi_z, \tag{107}
\]
where $\sigma_+(H)$ is the essential and discrete spectra of unoccupied orbitals. The position of the residues has been chosen such that $\lim_{t \to 0^\pm} -i\bar{g}(t) = \pm P_\pm$, see also (64).

Let us define the instantaneous density matrix $\rho^f$ as the restriction of the Green function to $t = 0$, i.e. $\rho^f = i\bar{g}(t = 0)$. Performing the inverse Fourier transform and applying the Cauchy contour integration theorem we have

$$
\rho^f(x, y) = i\bar{g}(x, y)
$$

$$
R^f_1(x, y) = P^f_1(x, y) - P^f_+(x, y), \quad P^f_\pm(x, y) = \sum_{\omega \in \sigma_\pm(H)} \varphi_\omega(x) \varphi_\omega^+(y).
$$

Similar to equation (63) for the density with a non-trivial propagator we have

$$
\rho^f(x, y) = \rho(x, y) + \sum_{i=1}^N \varphi_i(x) \varphi_i^+(y).
$$

Because we have changed the definition of $S$ by putting the valence electron on a non-trivial Fermi energy level then at the leading order for $t \neq 0$ we also have

$$
i\bar{g}(t, x, y) = i\bar{g}(t, x, y) + \sum_{i=1}^N e^{-i\omega_i t} \varphi_i(x) \varphi_i^+(y).
$$

In the following we make a crude approximation by assuming the external magnetic field vanishes and omitting the magnetic interaction of electrons, i.e. we restrict the photon propagator to the Coulomb term

$$
C_{\mu\nu}(t, r) = \left( \begin{array}{cc} -\frac{\delta_{\mu\nu}}{4\pi r} & 0 \\ 0 & 0 \end{array} \right), \quad \tilde{C}_{\mu\nu}(p) = \left( \begin{array}{cc} -\frac{1}{p_\mu} & 0 \\ 0 & 0 \end{array} \right).
$$

However to calculate the self-energy of electron one should use the complete photon propagator. Finally omitting the delta function $\delta_{xy}$ in the diagonal terms the kernel of the Hamiltonian (106) has the form

$$
\hat{H}_{xy} = \alpha^k \partial_k - \frac{\alpha Z}{r} + \beta m + \alpha \int_{\mathbb{R}^3} \frac{Tr \sum_{i=1}^N \varphi_i(\bar{z}) \varphi_i^+(\bar{z})}{|\bar{x} - \bar{z}|} - \alpha \sum_{i=1}^N \frac{\varphi_i(x) \varphi_i^+(y)}{|x - y|} - \alpha \frac{Z}{r} (Z_3 - 1) + \beta m \beta - \frac{\alpha Z}{r} - \omega - \delta m \beta - e^2 \beta (C_{\mu\nu} \gamma^\mu i\bar{g} \gamma^\nu)\omega.
$$

The fourth and fifth terms are the direct and exchange terms respectively.

The above argument motivates us to obtain the Hartree–Fock approximation from the QED Lagrangian by modifying the propagator. The additive terms to the propagator (62) are equivalent to $2N$-dimensional Grassmann integral over a set of auxiliary variables $\{\bar{\psi}_i, \psi_i\}_{i=1}^N$ with the covariance $S_\psi$. The variables $\bar{\psi}_i, \psi_i$ of each color have nonvanishing vacuum expectations $\bar{\varphi}_i, \varphi_i$. The color can not be observed. There is only one particle of each color.
Definition 1 We define a $SU(N)$ invariant generating functional of connected Schwinger functions as follows

$$e^{W(n,n)} = \int d\mu_{\phi\phi} e^{\frac{1}{2}\left(\bar{\psi}\gamma^\mu\psi\right)c_{\mu\nu}(\bar{\psi}\gamma^\nu\psi)F^{\mu\nu} + (\bar{\psi}\eta_0 + (\bar{\psi}\phi_i)}$$

Here we omit the counterterms. The definition of the classical fields literally repeats expression (53). As above these fields satisfy the Euler–Lagrange equations (54) with the following action

$$\Gamma_0 = \langle \phi(\phi - ieA + m)\phi \rangle + \frac{e^2}{2N}\sum_{ij=1}^N\left\langle (\bar{\phi}_i\gamma^\mu\phi_i)C_{\mu\nu}(\bar{\phi}_j\gamma^\nu\phi_j) + (\phi_i\gamma^\mu\phi_j)C_{\mu\nu}(\bar{\phi}_j\gamma^\nu\phi_i)\right\rangle.$$

Omitting the magnetic interaction (112) we obtain an identity $\hat{H}_{\phi_i} = \alpha N\phi_i$, i.e.

$$\hat{H}_{xG} = \alpha^k \partial_k - \frac{\alpha Z}{r} + \beta m + \alpha N \int_{z \in \mathbb{R}^3} \frac{Tr(-\phi_i\phi_j\beta)}{|x - y|} + \alpha N\frac{\phi_i(x)\phi_j(y)\beta}{|x - y|}, \quad \alpha N = \frac{\alpha}{N}.$$

The kernel of one-particle Hamiltonian is $\hat{H}_{xG} = \langle \phi_{n-1}, \phi_{n-1}\rangle$, i.e.

$$\hat{H}_{xG} = \alpha^k \partial_k - \frac{\alpha Z}{r} + \beta m + \alpha N \int_{z \in \mathbb{R}^3} \frac{\sum_{i \neq a}Tr(\phi_i^+\phi_i)}{|x - y|} - \alpha N\frac{\sum_{i \neq a}\phi_i(x)\phi_i^+(y)}{|x - y|}.$$

Usually one solves Dirac–Coulomb eigenvalue problem using the spherical coordinates system. Using the Dirac representation of the $\gamma$-matrices by separation of variables one obtains the radial Dirac equation

$$-G^\gamma + \frac{\kappa}{x}G = (z - 1 + \frac{\gamma}{x})F, \quad F' + \frac{\kappa}{x}F = (z + 1 + \frac{\gamma}{x})G,$$

$$z = \frac{\lambda}{m}, \quad \gamma = \frac{Z}{m}, \quad x = rm, \quad \kappa \in \mathbb{Z}\setminus\{0\}, \quad \varphi_\lambda(r) = \frac{1}{r} \left( F^m_{Y^{\kappa \pm\frac{1}{2}} - \frac{\gamma_\lambda}{m}} iG_{r^m_{\kappa \pm\frac{1}{2}} - \frac{\gamma_\lambda}{m}} \right).$$

Here $F, G$ are the radial wave functions and $Y^m_{\kappa \pm\frac{1}{2}}$ are the spin spherical harmonics, for notation see e.g. [32, 14, 13]. Note that these equations are invariant under the charge conjugation $F \leftrightarrow G, \gamma \leftrightarrow -\gamma, z \leftrightarrow -z, \kappa \leftrightarrow -\kappa$. For $0 < z < 1$ there exists a discrete set of eigenvectors $\{G_n, F_n\}$ which is dense in $H^1(\mathbb{R})$. For $-1 < z \leq 0$ there are no solutions in $H^1(\mathbb{R})$, see [13]. For $|z| > 1$ every solution is bounded for $x \to \infty$ [15].

We now consider a map between solutions of the radial Dirac equation under a dilatation of $Z$. Let denote these solutions by $F_{Z}^{\kappa j}$ and $G_{Z}^{\kappa j}$ where $\kappa \in \mathbb{Z}\setminus\{0\}$ and $j \in \mathbb{N}_+$. Put $m = j + |\kappa|$. Since $z_m - 1 \sim \frac{\kappa^2}{x} \sim \frac{Z^2 z^2}{2m^2}$ and $z_m + 1 \sim 2$ then for $x > 1$ we get the following scaling property

$$F_{Z}^{\kappa j}(x) = Z^{\frac{1}{2}}F_{1}^{\kappa j}(Zx) + O(\log Z), \quad G_{Z}^{\kappa j}(x) = Z^{\frac{1}{2}}G_{1}^{\kappa j}(Zx) + O(\log Z).$$
3 The Wilson–Polchinski equation

To account for radiative corrections one needs to add the vacuum polarization and self-energy terms to the Hamiltonian. In this section we derive the renormalization group (RG) equation of the Hartree–Fock action. As an introduction to the RG theory the reader might consider the original review written by K. Wilson [22]. There is an extensive list of references on the subject with applications to condensed matter physics [23], the field theory [24, 25, 26, 27, 28] and stochastic pdes [29].

We restrict the solution to the leading contribution in the $1/N$-expansion which is a meaningful approximation for large atoms and molecules. The calculation of radiative corrections on non-trivial backgrounds in this approximation considered already by many authors, see e.g. [40, 34, 30]. Distribution over energy levels of a large number of bosons is described by the Bose–Einstein statistics. At zero temperature such systems create a condensate. Distribution of electrons in large atoms is described by the Fermi–Dirac statistics, i.e. at zero temperature all orbitals below the Fermi energy are occupied and all orbitals above are free. Furthermore in the large-$N$ limit all $n$-point irreducible functions with $n > 4$ are negligible in the vacuum [38, 39] and thus we will omit these terms in the effective action.

It is important to observe how the Green function changes from one energy level to another one. At very higher energy scale the Coulomb interaction can be considered as a perturbation of free particle motion. For the electrons of inner shells the exchange term balances the screening of the direct term. Hence for such orbitals the Coulomb potential is of the foremost importance. For orbitals with higher quantum numbers the exchange term is weak compared with the direct term. Given a Hartree–Fock state an orbital can also be obtained by a non-trivial dilatation of the Coulomb solution (121). This induces a deformation of the spectrum. The spectrum can be computed by a variety of methods, e.g. [47]. At the leading order we need only the spectral dilatation of $s$-orbitals. Here we use a multiscale expansion in order to continuously follow up the corresponding deformation of the effective action as the infra-red cut-off decreases down to zero. A proof of convergence for a similar expansion can be found, for example, in V. Mastropietro [31].

At the leading order in the $1/N$ expansion all one-particle Hamiltonians $\hat{H}_i$ are equivalent. Let denote by $\Lambda_0$ and $\Lambda$ the ultraviolet and infra-red cut-offs which restrict the space of distributions on $H^1$ to a subset

$$\mathcal{D}'_{\Lambda_0}(\mathbb{R}^3) = \{ \varphi_z \in H^{-1} : \hat{H}\varphi_z = z\varphi_z, |z^2 - m^2| > \Lambda^2, |z| \leq \Lambda_0 \}.$$  \hspace{1cm} (122)

The generating functional (114) with the both cut-offs has the form

$$e^{W^{\Lambda_0\Lambda_0}(\eta, \bar{\eta})} = \int d\mu_{\hat{\psi}\psi}^{\Lambda_0\Lambda_0} e^{-L^{\Lambda_0\Lambda_0} + \langle \hat{\psi} \eta \rangle + \langle \eta \psi \rangle},$$  \hspace{1cm} (123)

where $L^{\Lambda_0\Lambda_0}$ includes the counterterms. Since the Lagrangian is time translation invariant the Legendre transform (53) gives the Hartree–Fock $\mathcal{E}_{HF}^{0\Lambda_0}$ energy multiplied by a time interval $T$ [41]. Here we are interested in the limit $\Lambda \to 0$,

$$\Gamma^{0\Lambda_0}(\bar{\psi}, \psi) = T\mathcal{E}_{HF}^{0\Lambda_0} - \langle \bar{\psi} \beta \omega \psi \rangle = \langle \bar{\psi} \eta \rangle + \langle \eta \psi \rangle - W^{0\Lambda_0}(\eta, \bar{\eta}),$$  \hspace{1cm} (124)

where the orbital energies $\omega$ are Lagrange multipliers. Furthermore since our goal is an effective low energy theory we restrict generating functionals to the low energy components,
In the semiclassical approximation the auxiliary tensors are e.g. $\eta, \bar{\eta} \in \mathcal{G}_{0\Lambda}$. Using the background field method we translate the integration variables $\psi \rightarrow \psi + \phi$ by a field $\phi \in \mathcal{G}_{0\Lambda}$ and then obtain

$$e^{W_{\Lambda_0}(\eta, \bar{\eta})} = e^{-\langle \bar{\phi} S_{0\Lambda_0}^{-1} \phi \rangle + \langle \bar{\phi} \eta \rangle + \langle \eta \phi \rangle} \int d\mu_{\psi_{\Phi}} e^{-L_{\Lambda_0}(\psi_{\bar{\Phi}} \psi + \phi) + \bar{\psi}(\eta - S_{0\Lambda_0}^{-1} \phi) + \langle \eta - \bar{\phi} S_{0\Lambda_0}^{-1} \psi \rangle}. \quad (125)$$

Next we decompose the measure $d\mu_{\psi_{\Phi}}$ into $d\mu_{\psi_{\Phi_1}} d\mu_{\psi_{\Phi_2}}$. Since $\phi, \eta \in \mathcal{G}_{0\Lambda}$ the integrand depends on $\psi_2$ and $\bar{\psi}_2$ only via the term $L_{\Lambda_0}(\psi_1 + \bar{\psi}_2 + \phi, \psi_1 + \bar{\psi}_2 + \phi)$. Consequently the integration over $d\mu_{\psi_{\Phi_2}}$ yields the generating functional of connected amputated Schwinger functions with the infra-red cut-off $L_{\Lambda_0}$,

$$e^{W_{\Lambda_0}(\eta, \bar{\eta})} = e^{-\langle \bar{\phi} S_{0\Lambda_0}^{-1} \phi \rangle + \langle \bar{\phi} \eta \rangle + \langle \eta \phi \rangle} \int d\mu_{\psi_{\Phi}} e^{-L_{\Lambda_0}(\psi_{\bar{\Phi}} \psi + \phi) + \bar{\psi}(\eta - S_{0\Lambda_0}^{-1} \phi) + \langle \eta - \bar{\phi} S_{0\Lambda_0}^{-1} \psi \rangle}. \quad (126)$$

The functional $L_{\Lambda_0}$ is free of any ultraviolet divergences when $\Lambda_0 \rightarrow \infty$ and contains the radiative corrections of perturbative QED. This functional can be obtained from the semiclassical Hartree–Fock action by substituting the constants $e$ and $m$ with its 1-loop approximation. By expanding $L_{\Lambda_0}$ at the point $\phi$ we get

$$e^{W_{\phi}(\eta, \bar{\eta})} = e^{-I_{\phi}(\phi, \bar{\phi}) + \langle \bar{\phi} \eta \rangle + \langle \eta \phi \rangle + W_{\phi}(\eta - \delta_{\phi} I_{\phi}(\phi, \bar{\phi}), \bar{\phi} + \delta_{\phi} I_{\phi}(\phi, \bar{\phi}))}, \quad (127)$$

$$e^{W_{\Lambda}(\eta, \bar{\eta})} = \int d\mu_{\Phi} e^{-\sum_{n \geq 2} L_{\Lambda}^n(\bar{\psi}) + \langle \eta \phi \rangle + \langle \psi \bar{\phi} \rangle}, \quad (128)$$

$$L_{\Lambda}^n(\bar{\psi}, \psi) = \sum_{j + i = n} \langle \psi \delta_{\phi} \rangle^i \langle \bar{\psi} \delta_{\phi} \rangle^j L_{\Lambda}^{0\Lambda}(\bar{\phi}, \phi), \quad (129)$$

$$I_{\Lambda}(\bar{\phi}, \phi) = \langle \bar{\phi} S_{0\Lambda_0}^{-1} \phi \rangle + L_{\Lambda}(\bar{\phi}, \phi). \quad (130)$$

The action $I_{\Lambda}$ includes all radiative corrections above the infra-red cut-off $\Lambda$. The bilinear term $L_{2\Lambda}^{0\Lambda}(\bar{\psi}, \psi)$ can be decomposed in the form

$$L_{2\Lambda}^{0\Lambda}(\bar{\psi}, \psi) = \langle \bar{\psi} (V - \Sigma) \psi \rangle - \frac{1}{2} \langle \bar{\psi}_s \bar{\psi}_r Q^{sk} + \bar{Q}_{sr} \bar{\psi}_s \psi_r \rangle. \quad (131)$$

In the semiclassical approximation the auxiliary tensors are

$$V_{sk} = F_{sk} \delta_{xy} \gamma^{\mu} C_{\mu \nu} Tr(-\phi_r \bar{\phi}_s \gamma^\nu), \quad Q_{sk} = F_{sk} \gamma^\mu \phi_s(x) C_{\mu \nu} (x, y) \gamma^\nu \phi_r(y), \quad (132)$$

$$\Sigma_{sk} = F_{sk} C_{\mu \nu} (x, y) \gamma^{\mu} (-\phi_r(x) \bar{\phi}_s(y) \gamma^\nu), \quad \bar{Q}_{sr} = F_{sr} \bar{\phi}_s(x) \gamma^{\mu} C_{\mu \nu} (x, y) \bar{\phi}_r(y) \gamma^\nu. \quad (133)$$

We can account for the bilinear form by defining a new measure $d\bar{\mu}_s$

$$e^{\frac{1}{2}(K_1 G_1 K_1 K_1)} = \int d\mu_{\Phi} e^{(K_1 \Phi)}, \quad K = (\eta, \bar{\eta}), \quad \Phi = (\bar{\psi}, \psi). \quad (134)$$

Here $G$ is the propagator of the particles at the point $\phi$

$$G = \begin{pmatrix} -G_{QQ} & -G_{QG}^t \\ G_{GQ} & G_{GG} \end{pmatrix}, \quad G = (1 + GQQ^t Q)^{-1} G, \quad (135)$$
where $G$ is the Green function of the Hartree–Fock operator with the standard walk around the poles
\[
(\hat{\phi} - ie\mathcal{A} + m + V - \Sigma)G = \delta_{xy}.
\] (136)

Using the measure $d\tilde{\mu}_\phi$ we can write
\[
\int d\mu_{\phi}^A e^{-L_{\Lambda}^\infty(\psi,\psi)+\langle K\psi,\psi \rangle} = \left(\frac{\det S_{0\Lambda}}{\det G_{0\Lambda}}\right)^{1/2} \int d\tilde{\mu}_{\psi}^A e^{\langle K\psi,\psi \rangle}.
\] (137)

It follows that the generating functional $W_{\phi}^{0\Lambda}$ has the form
\[
e^{W_{\phi}^{0\Lambda}(\eta,\eta)} = e^{\frac{1}{2} Tr \log G_{0\Lambda}^{-1} S_{0\Lambda} e^{\bar{W}_{\phi}^{0\Lambda}(\eta,\eta)}},
\] (138)

\[
e^{\bar{W}_{\phi}^{0\Lambda}(\eta,\eta)} = \int d\tilde{\mu}_{\phi} A e^{-\sum_{n>2} L_{\Lambda}^\infty(\psi,\psi)+\langle \delta \psi \rangle + \langle \eta \rangle + \langle \eta \rangle}.
\]

Substituting (127) into (124) and denoting $\delta \psi = \bar{\psi} - \bar{\phi}$, $\delta \psi = \psi - \phi$ we get an expansion
\[
\Gamma_{0\infty}(\phi, \psi) = I_{\Lambda}^{\phi}(\phi, \phi) + \langle \delta \psi \frac{\delta I_{\Lambda}^{\phi}(\phi, \phi)}{\delta \phi} \rangle + \langle \delta \psi \frac{\delta I_{\Lambda}(\phi, \phi)}{\delta \phi} \rangle + \Gamma_{0A}(0).
\] (140)

Here $\Gamma_{0A}(0)$ is the Legendre transform of $W_{\phi}^{0\Lambda}$. Furthermore using equation (138) we have
\[
\Gamma_{0A}(\phi, \psi) = -\frac{\hbar}{2} Tr \log G_{0\Lambda}^{-1} S_{0\Lambda} + \bar{W}_{\phi}^{0\Lambda}(\bar{\psi}, \psi).
\] (141)

We choose the background fields to coincide with the classical fields, i.e. $\phi = \psi, \bar{\phi} = \bar{\psi}$ and
\[
\Gamma_{0\infty}(\bar{\phi}, \bar{\psi}) = I_{\Lambda}^{\phi}(\bar{\phi}, \bar{\phi}) + \Gamma_{0A}(0).
\] (142)

Using (141) we have
\[
\Gamma_{0\infty}(\bar{\phi}, \bar{\psi}) = I_{\Lambda}^{\phi}(\bar{\phi}, \bar{\phi}) - \frac{\hbar}{2} Tr \log(G_{0\Lambda}^{-1} S_{0\Lambda}) + \bar{W}_{\phi}^{0\Lambda}(0).
\] (139)

Since $\bar{W}_{\phi}^{0\Lambda}(0) = O(\hbar^2)$ this equation gives the well known result of 1-loop approximation, see e.g. [30, 40]. The Hartree–Fock energy $\mathcal{E}_{HF}^{0\infty}$ has the following form
\[
\mathcal{E}_{HF}^{0\infty}(\bar{\phi}, \bar{\psi}) = \mathcal{E}_{HF}^{0\infty}(\bar{\phi}, \bar{\psi}) - \frac{\hbar}{2} Tr \log(G_{0\Lambda}^{-1} S_{0\Lambda})_{0 \times \mathbb{R}^3} + O(\hbar^2).
\] (144)

We have used the time translation symmetry, i.e. $I_{\Lambda} = T \mathcal{E}_{HF}^{0\infty} - (\bar{\phi} \beta \omega \phi)$. The Taylor expansion of the logarithm yields the perturbative result (113). In addition to the effective action $\bar{\Gamma}_{0A}$ we also define the corresponding reduced action $\Gamma_{0A}$
\[
\bar{\Gamma}_{0A}(\bar{\phi}) = \frac{1}{2} \langle \bar{\phi} G_{0\Lambda}^{-1} \bar{\phi} \rangle + \bar{\Gamma}_{0A}(\bar{\phi}).
\] (145)

Let $\lambda \in (0, \Lambda]$ be a floating infra-red cut-off. Here $G_{\lambda\Lambda}$ is the propagator with the floating infra-red cut-off, i.e. $G_{\lambda\Lambda} = \sigma_{\lambda\lambda} G$. In the following we will omit the subscript and the tilde in
the notation for the effective action $\hat{\Gamma}_\phi$. Furthermore, $\hat{G}_{\lambda\Lambda}$ is a shorthand for $\partial_\lambda G_{\lambda\Lambda}$; $\Gamma''$ stands for $\Delta \Gamma$ where $\Delta_{ij} = \delta_{\phi_i} \delta_{\phi_j}$ and $\Phi_i \in (\bar{\psi}, \psi)$; $L'' = \Delta L$ where $\Delta_{ij} = \delta_{\Phi_i} \delta_{\Phi_j}$ and $\Phi_i \in (\bar{\phi}, \phi)$. Let assume that $\Gamma''^{-1}$ is a Neumann series expansion on the interval of energy scales $(0, \Lambda]$

\[ \Gamma''^{-1} = -\sum_{n=0}^{\infty} (G_{\lambda\Lambda} \Gamma''^{-1})^n G_{\lambda\Lambda} \]  

(146)

**Theorem 1** The RG equation for the effective action has the form [37, 36]

\[ \dot{\Gamma}^{\lambda\Lambda} = \frac{\hbar}{2} (\hat{G}_{\lambda\Lambda} \Gamma'' (1 - G_{\lambda\Lambda} \Gamma'')^{-1}). \]  

(147)

**Proof.** Using the definition of the Grassmann measure (134) it is straightforward to obtain the derivative $d\mu$ wrt the infra-red cut-off

\[ \int d\mu_\phi e^{\langle K \hat{1}_\eta \phi \rangle} = -\frac{\hbar}{2} \int d\mu_\phi \langle \delta_\phi \hat{G} \delta_\phi \rangle e^{\langle K \hat{1}_\eta \phi \rangle}. \]  

(148)

This yields the Wilson–Polchinski equation for the functional $L$ defined in (76)

\[ \dot{L} = \frac{\hbar}{2} \left( \langle \hat{G} L'' \rangle + \langle L' \hat{G} L' \rangle \right). \]  

(149)

The Legendre transform (88) of the free energy $W(K) = \frac{1}{2} \langle K \hat{1}_\eta G \hat{1}_\eta K \rangle - L(\hat{G} \hat{1}_\eta K)$ gives

\[ \Gamma(\Psi) = L(\Phi) - \frac{1}{2} \langle (\Psi - \Phi) G^{-1} (\Psi - \Phi) \rangle. \]  

(150)

Applying the derivative $\partial_\Lambda$ and using equation (149) we have

\[ \dot{\Gamma} = \frac{\hbar}{2} \langle \hat{G} L'' \rangle. \]  

(151)

Equation (89) gives the identity

\[ L'' = \Gamma'' (1 - G \Gamma''). \]  

(152)

Together with (151) this yields the RG equation (147).

The reduced action $\Gamma$ is proportional to the fine-structure constant which is small. Furthermore the integration path $(0, \Lambda]$ is short. Therefore we omit all nonlinear terms in the renormalization group equation (147). Finally we perform the Wick rotation to Minkowski space (93), i.e. $\Gamma^\varepsilon = i \Gamma^M$. At the leading order this gives us a flow equation

\[ \dot{\Gamma}^{\lambda\Lambda} = \frac{\hbar}{2} \langle i \dot{G}_{\lambda\Lambda} \Delta \rangle \Gamma^{\lambda\Lambda} \]  

\[ G_{\lambda\Lambda} = \begin{pmatrix} 0 & -G_{\lambda\Lambda}^c \varepsilon \\ G_{\lambda\Lambda}^c & 0 \end{pmatrix}. \]  

(153)

Using notations of (132) and (133) in 1-loop approximation the flow equation has the form

\[ \dot{\Gamma}^{\lambda\Lambda} = \hbar \langle i \hat{G}_{\lambda\Lambda} (V - \Sigma) \rangle. \]  

(154)

Clearly the equation is nontrivial only for 2-point function $\Gamma^{\bar{\psi} \psi} = \delta_{\bar{\psi}} \delta_{\psi} \Gamma(0)$. In the limit $N \to \infty$ only the diagonal terms of the color indices remain

\[ \dot{\Gamma}^{\bar{\psi} \psi}_{xy} = -\frac{\hbar e^2}{N} \left( \delta_{xy} \gamma^\nu C_{\mu\nu} Tr(i \hat{G}_{\lambda\Lambda} \gamma^\mu) - \gamma^\mu i \hat{G}_{\lambda\Lambda}(x, y) C_{\mu\nu}(x, y) \gamma^\nu \right). \]  

(155)
4 The vacuum polarization

We will consider only the vacuum polarization, i.e. the first term in (155), and will also omit
the magnetic interaction, see (112). It follows from definition (145) that $\Gamma^{\psi\psi}$ vanishes at
zero order in $\hbar$. At the leading order we make the following decomposition

$$\Gamma^{\Lambda\Lambda} = T \langle \bar{\psi} x \alpha \beta \int_{x \in R^3} \frac{\hbar \rho^{\Lambda\Lambda}_{\bar{x} x}}{|\bar{x} - x|} \psi x \rangle_{0 \times R^3}.$$  

(156)

Here $T$ is a finite time interval. It is convenient also to define the Dirac density matrix

$$\frac{1}{2} R^\Lambda_N = i G^\Lambda_{0 \times R^3, 0 \times R^3} \beta.$$  

(157)

Substituting these definitions into equation (155) and omitting the second term we obtain

$$\rho^{\Lambda\Lambda} = \rho^{\Lambda_1 \Lambda} - \sum_{\{\lambda_n\} > \Lambda} \frac{1}{2N} \int_{\lambda_n}^{\lambda_{n+1}} \mathcal{D} \omega \, \text{Tr} \, \dot{R}_N^{\Omega x \Lambda} \rho^{\omega \Lambda}, \quad \forall \lambda \leq \lambda_1.$$  

(158)

Here the trace runs over the color and spinor indices. The vacuum polarization $R_N$ becomes
negligible at long distances. At shorter distances, e.g. the wavelength of 1s orbital, the
Hartree–Fock operator (136) is a perturbation of the Dirac–Coulomb operator (59). Below
this scale the dilatation of eigenfunctions (121) is negligible and one can use the reduced
Green functions $\rho^{\Lambda}$ to find them. However there is a significant dilatation of the spectrum,
in other words, a rescaling of the measure $d\omega$ (108). For each spectral interval $(\lambda_{n+1}, \lambda_n]$, i.e. for each $x \in (\frac{1}{n+1}, \frac{1}{n}]$, we replace the flow $\partial_x R_N^{x \Lambda} = \dot{R}_N^{x \Lambda} \omega$ by a linear dilatation of the
flow $\partial_x R_{1,1}^{x \Lambda}$ which corresponds to the Dirac–Coulomb operator,

$$\partial_x R_N^{x \Lambda} \mapsto \sum_{\frac{\lambda_n - \lambda_{n+1}}{\delta \omega_n}} \partial_x R_{1,1}^{x \omega(\Lambda)}, \quad \delta \omega_n = \frac{\gamma}{n(n+1)},$$  

(159)

$$x(\omega) = \frac{1}{n} \left( 1 - \frac{1}{n+1} \frac{\lambda_n - \omega}{\lambda_n - \lambda_{n+1}} \right), \quad \omega \in (\lambda_{n+1}, \lambda_n].$$  

(160)

At very short distances, e.g. below one Compton length, the Uehling’s induced charge $U$
becomes dominant. It follows from (127) that $\rho^{\Lambda\Lambda} = U^{\Lambda}$ assuming that $\Lambda$ is sufficiently
large, e.g. $\Lambda > 5$. In the flow equation (158) we omit the interval $(\lambda_1, \Lambda]$. For $\lambda > \lambda_1$ the
direct and exchange terms are small perturbation of the Coulomb potential. Primary we
are interested in scales where the perturbative theory is not feasible. The nonperturbative
component of the vacuum polarization is the difference between $\rho$ and the Fourier transform
of the Uehling’s running coupling (206),

$$\nu(r) = \rho(r) - U(r), \quad r \in R^3 \quad |r| > 1;$$  

(161)

$$U(r) = e^2 Z \int \frac{d^3 \bar{p}}{(2\pi)^3} e^{-i\bar{p}r} \pi(0, \bar{p}), \quad \int d^3 x U(x) = 0.$$  

(162)
The running coupling \( \pi(0, \cdot) \) is not a function in \( L_1(\mathbb{R}^3) \) and the Fourier transform does not exist in the usual sense. One needs to rescale the charge of nuclei (113) by adding a counterterm and to use the renormalization condition above in order to extract a finite part.

First we consider one electron in the potential of the Uranium nuclei, i.e. \( Z = 92 \). To calculate \( R_{11}^{A\Lambda_0} \) we use definition of the density matrix (16), the spherical decomposition (120) and the solutions of the radial Dirac equation given in appendix C,

\[
\frac{1}{2} Tr R_{11}^{A\Lambda_0}(r) = \frac{y^{A\Lambda_0}(|r|)}{8\pi r^2},
\]

\[
y^{A\Lambda_0} = \sum_{|\kappa| \leq K} 2|\kappa| \left( y^{A\Lambda_0}_{-\kappa} - y^{A\Lambda_0}_{+\kappa} - \tilde{y}^{\Lambda}_{\kappa} \right),
\]

\[
y^{A\Lambda_0}_{\pm\kappa} = \int_{A} dp \left( |F^{\pm\kappa}_{\pm}|^2 + |G^{\pm\kappa}_{\pm}|^2 \right), \quad \tilde{y}^{\Lambda}_{\kappa} = \sum_{|\kappa| + j \leq M_{\Lambda}} (|\tilde{F}^{\kappa j}|^2 + |\tilde{G}^{\kappa j}|^2).
\]

The sum over \( \kappa \) is a finite sum of \( 2K \) terms where the radial cut-off \( K \) is fixed \( K = 55 \). The last sum runs over the principal quantum numbers \( m = |\kappa| + j \) such that \( p_m \geq \Lambda \) where \( p_m \) is the corresponding momentum, for details see (196). Because of the spherical symmetry we use the radial scaling. For a fixed \( M_{\Lambda} \) we calculate the vacuum polarization \( y^{A\Lambda_0} \) with different cut-offs \( \Lambda_0 \). We do these calculations on bounded intervals \([a_{\Lambda_0}, b_{\Lambda_0}K]\) because the cut-offs \( \Lambda_0 \) and \( K \) are finite.

Next we compute the Laplace transform (188) and perform the following decomposition

\[
y^{A\Lambda_0}(x) = c_1^{A_0} x + u(x) + c_2^{A_0} \delta(x) + \frac{w^{A\Lambda_0}_1}{x} + \frac{s^{A\Lambda_0}}{x^5} + O(x),
\]

\[
u(x) = 8\pi x^2 U(x), \quad s^{A\Lambda_0}(x) = \sum_{\omega \in \Omega^{A\Lambda_0}} c_{\omega}^{A\Lambda_0} e^{i\omega x}.
\]

The first component is divergent and must be subtracted, see also (207). The second and third components are the Uehling’s charge density and finite charge renormalization, respectively. The fourth constant \( w^{A\Lambda_0}_1 \) is a nonphysical \( A^4 \) coupling, i.e. an artifact. This artifact depends on the way one defines the momentum integration and it vanishes in the limit \( \Lambda \to 0 \) and \( \Lambda_0 \to \infty \). The sixth constant \( w^{A\Lambda_0}_5 \) gives a nonperturbative vacuum polarization. The oscillations \( s^{A\Lambda_0} \) are another artifact appearing as a result of the finite cut-offs,
i.e. $\Lambda, \Lambda_0, K$. The oscillations become larger outside the interval $[a^{\Lambda_0}, b^{\Lambda_0 K}]$. To calculate a frequency $\omega$ we perform the decomposition, restrict the Laplace transform to the imaginary axis, choose a neighborhood $\mathcal{B}$ of the highest spike, then find the maximum $\omega \in \mathcal{B}$ of the convolution $\hat{O} \ast (c_1 \sin + c_2 \cos)_{\mathcal{B}}$ where $c_1^2 + c_2^2 = 1$. We add the frequencies $\pm \omega$ to the set $\Omega^{\Lambda_0}$ and repeat the decomposition until the remainder $O$ is sufficiently small. We perform these calculations with 10% of accuracy. To measure the remainder and oscillations we define two norms

$$
\|O\|_2^2 = \frac{1}{(b - a)^2} \int_a^b dx O^2(x), \quad \|s\|_2^2 = \frac{1}{a^2} \sum_{\omega \in \Omega^+} |c^{\Lambda_0 \omega} s\omega(0) + c^{\Lambda \omega} \tilde{s}\omega(0)|^2.
$$

(167)

For a fixed upper bound of the remainder we choose a decomposition that minimizes the oscillations. An example of the decomposition is shown in Figure 2. We omit the linear term in the figure. In the left panel we have the original $y^{\Lambda_0}$ which is calculated numerically (163), the oscillations $s^{\Lambda_0}$, the Uehling’s density $u$ and fourth component combined. In the right panel we have the last two terms of the decomposition. The oscillations vanish only in the limit $\Lambda \to 0$ and $\Lambda_0 \to \infty$. They do not vanish at a finite $\Lambda > 0$ even in the limit $\Lambda_0 \to \infty$.

In order to calculate the limits $\{w_5^{\infty}\}$ we define an objective function $f$ and use the gradient descent to find the minimiser

$$
f(\{w_5^{\infty}\}, \beta, \eta, ) = \sum_{\{\Lambda_0\}} (w_5^{\infty} + \beta \Lambda_0^{-\eta} - w_5^{\Lambda_0})^2.
$$

(168)

This yields $\beta = 22.72, \eta = 2.35$ and the limits $\{w_5^{\infty}\}$. To simplify the notation let us put $w_5(x) = w_5^{2\pi \infty}$. Using a similar minimization method we find a piecewise differentiable approximation

$$
w_5(x) = \nu x^{\xi_i} + \chi, \quad x \in (0, t_i],
$$

(169)

$$
\frac{\partial \log w_5(x)}{\partial \log x} = \xi_i, \quad x \in (t_i-1, t_i],
$$

(170)

where

$$
\begin{array}{ccc}
\xi_i & t_{i-1} & t_i \\
1.36 & 0 & 0.13 \\
1.35 & 0.13 & 0.20 \\
1.24 & 0.2 & 0.23 \\
0.84 & 0.23 & 1 \\
\end{array}
$$

(171)

For $x > 1$ the running constant $w_5(x)$ steeply approaches zero, i.e. $w_5^{\infty} = 0$. The coupling is generated at the scale of $1s$ orbital and then decreases as we integrate the flow (158),

$$
\nu_5(x) = w_5(1) - \sum_{n=1}^{x < x_n} \frac{\lambda_n - \lambda_{n+1}}{\delta \omega_n} \int_{\max(x_{n+1}, x)}^{x_n} dx w_5', \quad \delta \omega_n = \frac{\gamma}{n(n + 1)}, \quad x_n = \frac{1}{n}.
$$

(172)

where $\nu_5(x(\omega)) = \nu_5^\Lambda$, see (160). In the leading order we have substituted $\nu_5(1)$ with $w_5(1)$. The nonperturbative component at large distances is

$$
\nu_5^\Lambda(r) = \frac{\nu_5^{\Lambda}}{8\pi|r|^2}, \quad r \in \mathbb{R}^3 \quad |r| > 1.
$$

(173)
For Uranium atom we use only a small interval of the spectrum. This part corresponds to the occupied $s$-orbitals. The remainder can be estimated as follows

\[
\sum_{n>7}^{\infty} \frac{1}{Z} \int_{x_{n+1}}^{x_n} dx \frac{w_5'}{w_5} = \frac{1}{Z} \int_0^{\frac{1}{Z}} dx \frac{w_5(\frac{1}{Z}) - w_5(0)}{Z} = \frac{0.043}{Z} = 4.7 \times 10^{-4}. \quad (174)
\]

Summing over first six spectral intervals in equation (172) we obtain $\nu_5^{\Lambda} = 0.015$. In the left panel of Figure 3 we show the corresponding flows of the running coupling for the atom of Uranium $\nu_5^{\Lambda}$ and its ion with one electron $w_5^{\Lambda}$. The right panel contains the difference between two running couplings $\nu_5^{\Lambda} - w_5^{\Lambda}$. Finally, the density (173) has the form

\[
\nu_0^{\Lambda}(r) = \frac{1}{|r|^7} \begin{cases} 6 \times 10^{-4} & \text{92 electrons}, \\ 1.2 \times 10^{-3} & \text{one electron}, \end{cases} |r| > 1. \quad (175)
\]

Here $r$ is in Compton length units. For one electron ion the exact result is known. The corresponding density at one Compton length is $1.3 \times 10^{-3}$ [21].

We have performed the calculation with $Z = 92$. For other $Z$ one can appropriately rescale the leading term in the Taylor expansion: $\xi_i(\gamma) = \xi_i^{(0)}$, $\nu(\gamma) = \gamma^3 \nu^{(3)}$, $\chi(\gamma) = \gamma^3 \chi^{(3)}$. Furthermore for light elements one would need to sum over a wide interval of the spectrum and also retain the remainder (174).

5 Acknowledgments

The work has been realized for the project ANR-17-CE29-0004 founded by the French National Research Agency. We are grateful to T. Leininger for providing us with an access to a dedicated computational node and T. Saue for calculating the spectrum of Uranium.
Appendices

A  Functional integral

A.1  Integration by parts

Let \( f, \bar{f} \in G(\mathbb{R}^4) \) Grassmann smooth functions with compact support; \( \psi, \bar{\psi} \in G'(\mathbb{R}^4) \); and denote by \( S \) the covariance of the measure \( d\mu \), see e.g. (46), (58).

\[
\int d\mu \langle \bar{f}\psi \rangle e^{\langle \eta\psi \rangle + \langle \bar{\psi}\eta \rangle} = \langle \bar{f} \delta \rangle e^{\langle \eta\delta \rangle + \langle \bar{\psi}\delta \rangle} \bigg|_{\delta = 0} = \langle \bar{f} \delta \rangle e^{\langle \eta\delta \rangle + \langle \bar{\psi}\delta \rangle}.
\]

(176)

\[
\int d\mu \langle \bar{\psi}f \rangle e^{\langle \eta\psi \rangle + \langle \bar{\psi}\eta \rangle} = -\langle \delta f \rangle e^{\langle \eta\psi \rangle + \langle \bar{\psi}\eta \rangle} \bigg|_{\eta = 0} = -\langle \delta f \rangle e^{\langle \eta\psi \rangle + \langle \bar{\psi}\eta \rangle}.
\]

(177)

It follows that for Grassmann valued functionals \( F_{\psi\bar{\psi}} \in L_2(G'(\mathbb{R}^4), d\mu) \) we get

\[
\langle \bar{f}\psi \rangle = \langle \bar{f} \delta \rangle F_{\psi\bar{\psi}} , \quad \langle \bar{\psi}f \rangle = -\langle \delta f \rangle F_{\psi\bar{\psi}}.
\]

(178)

A similar formula holds for the Gaussian measure (43). For \( F_A \in L_2(D', d\nu_A) \) one obtains

\[
\langle jA \rangle F_A = \langle jC \delta \rangle F_A.
\]

(179)

For details see [3].

A.2  Scaling properties

Let \( d\mu_C \) denote a Gaussian measure with covariance \( C \), see (43),

\[
Z(j) = \int d\mu_C e^{-\frac{1}{2}(Z_3-1)(AC^{-1}A)+(jA)} , \quad Z'_j(j) = \frac{\delta Z(j)}{\delta j}.
\]

(180)

Using integration by parts (179) we obtain

\[
Z'_j(j) = \int d\mu_C \left( -(Z_3-1)A + Cj \right) e^{-\frac{1}{2}(Z_3-1)(AC^{-1}A)+(jA)} - (Z_3-1)Z'_j(j) + Cj Z(j).
\]

(181)

It follows that \( Z(j) \) is the characteristic function of the measure \( d\mu_{Z_3^{-1}C} \)

\[
Z'_j(j) = Z_3^{-1}Cj Z(j) \implies Z(j) = Z(0) e^{\frac{1}{2}(jZ_3^{-1}Cj)}.
\]

(182)
Similarly let $d\mu_S$ denote a Grassmann measure with covariance $S$, see (46),
\[
Z(\bar{\eta}, \eta) = \int d\mu_S e^{-(Z_2-1)(\bar{\psi}S^{-1}\psi) + (\bar{\psi}\eta) + (\eta\bar{\psi})}, \quad Z'_\eta(\bar{\eta}, \eta) = \frac{\delta Z(\bar{\eta}, \eta)}{\delta \bar{\eta}}. \tag{183}
\]

Using integration by parts (178) we have
\[
Z'_\eta(\bar{\eta}, \eta) = \int d\mu_S ((Z_2-1)\bar{\psi} - \bar{\eta}) e^{-(Z_2-1)(\bar{\psi}S^{-1}\psi) + (\bar{\psi}\eta) + (\eta\bar{\psi})}
= -(Z_2-1)Z'_\eta(\bar{\eta}, \eta) - \bar{\eta}S\bar{\eta}Z(\bar{\eta}, \eta). \tag{184}
\]

This yields
\[
Z'_\eta(\bar{\eta}, \eta) = Z_2^{-1}S\eta Z(\bar{\eta}, \eta), \quad Z'_\bar{\eta}(\bar{\eta}, \eta) = -\bar{\eta}Z_2^{-1}SZ(\bar{\eta}, \eta). \tag{185}
\]

Consequently $Z(\bar{\eta}, \eta)$ is the characteristic function of the measure $d\mu_{Z_2^{-1}S}$
\[
Z(\bar{\eta}, \eta) = Z(0)e^{(\bar{\eta}Z_2^{-1}S\eta)}. \tag{186}
\]

**B  The Laplace transform**

The Laplace transform restricted to an interval $[a, b]$ is the following map
\[
f(x) \mapsto \hat{f}(p) = \int_a^b dx \, f(x)e^{-px}. \tag{188}
\]

We use the following transformations:
\[
e^{iwx} \mapsto \hat{s}_\omega(p) = \frac{e^{-(p- iw)} - e^{-(p+ iw)}}{p - iw}, \tag{189}
\]
\[
\frac{1}{x^{m+1}} \mapsto \hat{e}_m(p) = a^{-m}E_{m+1}(ap) - b^{-m}E_{m+1}(pb), \tag{190}
\]
\[
x \mapsto \left(\frac{e^{-bp} - e^{-ap}}{p}\right)', \tag{191}
\]
\[
u(x) \mapsto \hat{u}(p) = -\frac{8\gamma}{3\pi} \int_1^\infty d\zeta \sqrt{\zeta^2 - 1} \left(1 + \frac{1}{2\zeta}\right) \left(\frac{e^{-(2\zeta+p)b} - e^{-(2\zeta+p)a}}{p+2\zeta}\right)', \tag{192}
\]

where $E_n$ is the exponential integral function, the definition of $u$ see in (166).
C Solutions of the radial Dirac equation

For \((\kappa, n) \in \mathbb{Z}_+ \cup \mathbb{Z}_-\) the eigenfunctions of the radial Dirac equation (119) are

\[
\tilde{F}^{\kappa n}(r) = (1 + z)^{\frac{1}{2}}(2pr)^s u_1 \sqrt{p} e^{-pr} \tilde{H}_-(r),
\]
\[
\tilde{G}^{\kappa n}(r) = -(1 - z)^{\frac{1}{2}}(2pr)^s u_1 \sqrt{p} e^{-pr} \tilde{H}_+(r),
\]
\[
\tilde{H}_\pm = \left(\frac{n + s}{z} - \kappa\right) F_1(-n, 2s + 1, 2pr) \pm n F_1(1 - n, 2s + 1, 2pr),
\]

(193) \hspace{1cm} (194) \hspace{1cm} (195)

\[
p = (1 - z^2)^{\frac{1}{2}}, \quad z = \left(1 + \frac{\gamma^2}{(n + s)^2}\right)^{-\frac{1}{2}},
\]
\[
s = (\kappa^2 - \gamma^2)^{\frac{1}{2}}, \quad u_1 = \frac{1}{\Gamma(2s + 1)} \left(\frac{\Gamma(2s + n + 1)}{2^{n+s}(n+s) - \kappa n!}\right)^{\frac{1}{2}}.
\]

(196) \hspace{1cm} (197)

For \(\kappa \in \mathbb{Z}\setminus\{0\}, p > 0\) solutions of the radial equation in \(L_\infty\) are

\[
\tilde{F}^{\kappa p}(r) = \left(\frac{z + 1}{z}\right)^{\frac{1}{2}} (2pr)^s u_2 \text{Re}H(2ipr),
\]
\[
\tilde{G}^{\kappa p}(r) = \mp \left(\frac{z - 1}{z}\right)^{\frac{1}{2}} (2pr)^s u_2 \text{Im}H(2ipr),
\]
\[
H(x) = e^{-\frac{x}{2}} \left((-\kappa + \frac{i}{z}) (s + iy)\right)^{\frac{1}{2}} F_1(s + 1 + iy, 2s + 1, x),
\]

(198) \hspace{1cm} (199) \hspace{1cm} (200)

\[
u_2 = \frac{e^{\frac{i\pi}{2}} |\Gamma(s + iy)|}{\sqrt{\pi} \Gamma(1 + 2s)}, \quad y = \frac{\gamma z}{p}, \quad z = \pm(1 + p^2)^{\frac{1}{2}}, \quad s = (\kappa^2 - \gamma^2)^{\frac{1}{2}}.
\]

(201)

For details of calculations see [32, 48, 49].

D The vacuum polarization at short distances

In Minkowski space the vacuum polarization at 1-loop is given by the following expression

\[
\hat{\Pi}^{\mu\nu}(p) = i \int_\Omega \frac{d^4 k}{(2\pi)^4} \frac{\text{Tr}\{-i k + m\gamma^\mu(-i(k + p) + m)\gamma^\nu\}}{(k^2 + m^2 - i\epsilon)((k + p)^2 + m^2 - i\epsilon)}, \quad \Omega = \{k \in \mathbb{R}^4 : k^2 < \Lambda_0^2\}.
\]

(202)

One usually performs the Wick rotation to Euclidean space, calculates the traces and uses the Feynman parameterization

\[
\frac{1}{a_1 \ldots a_n} = (n - 1)! \int_0^1 dx_1 \ldots dx_n \frac{\delta(1 - \sum_{i=1}^n x_i)}{(\sum_{i=1}^n a_i x_i)^n}.
\]

(203)
These steps yield the following form

\[
\hat{\Pi}^{\mu\nu}(p) = 4\pi^2 \int_0^1 dx \left( -2 I_x^{\mu\nu} - (p^\nu I_x^\mu + p^\mu I_x^\nu) + \delta^{\mu\nu}(I_x^2 + p_0 I_x^0 + m^2 I_x^0) \right)
\]

where

\[
I_x^{\mu\nu} = \int_{\Omega} \frac{d^4k}{(2\pi)^4} \frac{k^\mu k^{\nu}}{(k^2 + 2kp_x + M_x^2)^2}, \quad p_x = p(1-x), \quad M_x^2 = p^2(1-x) + m^2.
\]

The calculation of all integrals in (204) is lengthy but straightforward. Eventually we obtain the following result

\[
\pi(p) = \frac{1}{12\pi^2} \log \frac{\Lambda_0^2}{m^2} - \frac{1}{36\pi^2} - \frac{1}{2\pi^2} \int_0^1 dx \frac{x(1-x)}{\log \frac{M_x^2}{m^2}},
\]

\[
\hat{\Pi}^{\mu\nu}(p) = (p^2 g^{\mu\nu} - p^\mu p^\nu)\pi(p) + \frac{g^{\mu\nu}}{8\pi^2} \left( m^2 - \Lambda_0^2 \right) + \frac{p^\mu p^\nu}{24\pi^2}.
\]
