Natural Actor-Critic Converges Globally for Hierarchical Linear Quadratic Regulator

Yuwei Luo∗ Zhuoran Yang† Zhaoran Wang‡ Mladen Kolar§

Abstract

Multi-agent reinforcement learning has been successfully applied to a number of challenging problems. Despite these empirical successes, theoretical understanding of different algorithms is lacking, primarily due to the curse of dimensionality caused by the exponential growth of the state-action space with the number of agents. We study a fundamental problem of multi-agent linear quadratic regulator in a setting where the agents are partially exchangeable. In this setting, we develop a hierarchical actor-critic algorithm, whose computational complexity is independent of the total number of agents, and prove its global linear convergence to the optimal policy. As linear quadratic regulators are often used to approximate general dynamic systems, this paper provided an important step towards better understanding of general hierarchical mean-field multi-agent reinforcement learning.

1 Introduction

Multi-agent reinforcement learning (MARL) (Bu et al., 2008) combined with deep neural networks has recently been applied successfully to problems ranging from self-driving cars (Shalev-Shwartz et al., 2016) and robotics (Yang and Gu, 2004) to E-sports (Vinyals et al., 2019; OpenAI, 2018) and Go (Silver et al., 2016, 2017). Despite promising empirical results in few specific domains, MARL remains challenging both in theory and practice as the state-action space grows exponentially with the number of agents (Menda et al., 2019). This curse

of dimensionality makes developing computationally tractable and statistically consistent procedures difficult. When the agents are homogeneous, the curse of dimensionality can be avoided by exploiting symmetries in the problem, which gives rise to mean-field multi-agent reinforcement learning (Huang et al., 2012; Carmona et al., 2013; Fornasier and Solombrino, 2014). Mean-field algorithms rely on the assumption that the agents are exchangeable, in which case the optimal policy that maximizes the expected total reward symmetrically decomposes across agents. As a consequence, the optimal policy can be found by solving a single-agent reinforcement learning problem while additionally accounting for the mass effect induced by all other agents, which is summarized by a mean field. Through this reduction to a single-agent reinforcement learning problem one can again obtain computationally tractable procedures for which the statistical error does not grow exponentially with the number of agents (Yang et al., 2018).

The assumption that the agents are exchangeable is often violated in practical problems, such as real-time strategy gaming with different kinds of units (OpenAI, 2018; Vinyals et al., 2019) and urban traffic control (UTC) with heterogeneous junctions (El-Tantawy and Abdulhai, 2012; Chu and Wang, 2017), which makes practical application of the mean-field algorithms difficult. One approach to relaxing the exchangeability assumption is through the notion of partial exchangeability (Arabneydi and Mahajan, 2016), which allows for exploitation of the symmetry among possibly heterogeneous agents. The key to partial exchangeability is the hierarchical structure of agents, which is often observed in practice. Within a subpopulation of exchangeable agents, the symmetry is exploited as in mean-field multi-agent reinforcement learning through decoupling, while the heterogeneity across different subpopulations of agents is accounted for by tracking multiple mean fields. In particular, within each subpopulation of agents it suffices to solve a single-agent reinforcement learning problem. Due to partial exchangeability, one can escape the curse of dimensionality, while allowing for the heterogeneity among agents.

Our contribution is three-fold. First, we motivate hierarchical LQR model via decoupling the dynamics of agents in the system with the notion of partial exchangeability, thus decomposing the multi-agent LQR control problem into computationally tractable control problems on subpopulation systems. Second, we extend MARL approaches for hierarchical LQR model by proposing hierarchical actor-critic algorithm that is model-free, with computational complexity independent of the number of agents in each subpopulation, thus breaking the curse of dimensionality. Third, we establish non-asymptotic global rate of convergence of our algorithm for multi-agent LQR control problem, which is fundamental in MARL and optimal control.
1.1 Related Work

We contribute to several strands of the literature, including development of actor-critic algorithms, linear quadratic regulators, and mean-field multi-agent reinforcement learning.

Our algorithm belongs to the family of actor-critic algorithms. Konda and Tsitsiklis (1999) proposed the first actor-critic algorithm, which was later extended to the natural actor-critic algorithm (Peters and Schaal, 2008) using the natural policy gradient (Kakade, 2002). Convergence analysis of actor-critic and natural actor-critic algorithms with linear function approximation was studied in Kakade (2002), Bhatnagar et al. (2009), Bhatnagar et al. (2008), Castro and Meir (2010), and Bhatnagar (2010). Compared to the policy gradient algorithm (Williams, 1992), the online (critic) update of the action-value function in an actor-critic algorithm reduces the variance of the policy gradient and leads to faster convergence, which was rigorously shown for linear quadratic regulator problem (Yang et al., 2019). Due to its favorable properties, in this paper we develop a hierarchical natural actor-critic algorithm for multi-agent linear quadratic regulator setting and establish linear global convergence to the optimal policy.

We establish our theoretical results in the setting of linear quadratic regulator (LQR) problem, which is a fundamental problem in reinforcement learning and control theory. The policy in the LQR setting takes a linear form (Zhou et al., 1996; Anderson and Moore, 2007; Bertsekas, 2012) and a number of properties of reinforcement learning algorithms were established in this setting (Bradtke, 1993; Recht, 2018; Tu and Recht, 2017, 2018; Dean et al., 2018a,b; Simchowitz et al., 2018; Dean et al., 2017; Hardt et al., 2018). See Recht (2019) for a recent review. We contribute to this literature by studying multi-agent LQR problem with partial exchangeability. In particular, our convergence analysis is inspired by the optimization landscape of LQR characterized by Fazel et al. (2018), where they show the global convergence of policy gradient algorithm, and the global convergence analysis of the natural actor-critic algorithm established in the single agent LQR problem (Yang et al., 2019). Instead, we establish the global convergence of actor-critic algorithm for the multi-agent LQR control problem, while at the same time still being computationally tractable.

We further contribute to the literature on MARL in the framework of Markov games (Littman, 1994). A number of authors have tried to address the curse of dimensionality in MARL. Wang and Sandholm (2003) and Arslan and Yüksel (2016) assume that all the rewards are identical among agents and, as a result, no interaction needs to be considered. Linear function approximation methods were studied in Lee et al. (2018) and Zhang et al. (2018), while function approximation with deep neural networks was explored in Foerster et al. (2016), Gupta et al. (2017), Lowe et al. (2017), Omidshafiei et al. (2017),
and Foerster et al. (2017). These papers primarily focus on empirical performance of the algorithms or establish asymptotic results, leaving the theoretical understanding and rigorous convergence analysis for MARL largely open.

Model-based approaches to the mean-field approximation require knowledge of model parameters (see, for example, Elliott et al., 2013; Arabneydi and Mahajan, 2015, 2016; Li et al., 2017), while model-free methods (Yang et al., 2017, 2018) only come with algorithms with asymptotic analysis. In contrast, our method is model-free and comes with provable global non-asymptotic convergence analysis. Mean-field MARL problem in a collaborative setting, known as team games (Tan, 1993; Panait and Luke, 2005; Wang and Sandholm, 2003; Claus and Boutilier, 1998), can be regarded as a centralized mean-field control problem (Huang et al., 2012; Carmona et al., 2013; Fornasier and Solombrino, 2014) with infinitely many homogeneous agents. Our work extends this model by allowing potential heterogeneity among agents.

Our method relies on the notion of partial exchangeability (Arabneydi and Mahajan, 2016). A different notion with the same name was used to construct the joint state-action statistic which can be combined with local state-action to predict the agent’s next state (Nguyen et al., 2018). As such, it can be viewed as a generalization of homogeneity of all agents. In contrast, partial exchangeability in our work only assume homogeneity within each subpopulation, thus allowing for the heterogeneity across different subpopulations of agents.

1.2 Notation

For a vector $v$, we use $\|v\|_2$ to denote its $\ell_2$-norm. For a matrix $A$, we denote by $\|A\|$ and $\|A\|_F$ its operator norm and Frobenius norm respectively. For a square matrix $X$, we use $\sigma_{\text{min}}(X)$ and $\rho(X)$ to denote its minimal singular value and spectral radius respectively. For vectors $x$, $y$ and $z$, we denote by vec$(x, y, z)$ the vector obtained by stacking all the vectors, i.e. $[x^\top, y^\top, z^\top]^\top$. We denote by rows$(A, B, C)$ the matrix $[A^\top, B^\top, C^\top]^\top$ for matrices $A$, $B$ and $C$ with the same number of columns. Also, we denote by cols$(A, B, C)$ the matrix $[A, B, C]$ for matrices $A$, $B$ and $C$ with the same number of rows. For a symmetric matrix $Z$, we denote by svec$(Z)$ the vectorization of the upper triangular submatrix of $Z$, with the off-diagonal entries weighted by $\sqrt{2}$. Also, its inverse operation is denoted by smat$(\cdot)$.
2 Background

In this section we provide necessary background. In Section 2.1, we describe actor-critic algorithm. Linear quadratic regulator is introduced in Section 2.2. Section 2.3 presents multi-agent reinforcement learning.

2.1 Actor-Critic Algorithm

In reinforcement learning, a system is described by a Markov decision process \( \{X, U, c, T, D_0\} \), where starting with initial state \( x_0 \sim D_0 \), at each time step, an agent interacts with the environment by selecting an action \( u_t \sim \pi(\cdot \mid x_t) \in U \) based on its current state \( x_t \in X \). Then the environment gives feedback with cost \( c(x_t, u_t) \), and the agent moves to the next state by the transition kernel \( x_{t+1} = T(x_t, u_t) \). The agent aims to find the policy that minimizes the expected time-average cost

\[
C(\pi) = \lim_{T \to \infty} \sup_{x_0, u_0} \frac{1}{T} \sum_{t=0}^{T-1} E_{x_{t}, u_{t} \sim \pi(\cdot \mid x)} [c(x_t, u_t)].
\]  

Given any policy \( \pi \), the action- and state-value functions are defined respectively as

\[
Q_\pi(x, u) = \sum_t E_{u_t \sim \pi(\cdot \mid x_t)} [c(x_t, u_t) - C(\pi) \mid x_0 = x, u_0 = u],
\]

\[
V_\pi(x) = E_{u \sim \pi(\cdot \mid x)} [Q_\pi(x, u)].
\]

In practice, the policy \( \pi \) is parameterized as \( \pi_\theta \). We denote the corresponding cost and action-value by \( C(\theta) \) and \( Q_\theta \), respectively. By the policy gradient theorem (Sutton et al., 2009a), the gradient with respect to the parameter \( \theta \) can be computed as

\[
\nabla_\theta C(\theta) = E_{x \sim D_\theta, u \sim \pi_\theta(\cdot \mid x)} [\nabla_\theta \log \pi_\theta(u \mid x) \cdot Q_\theta(x, u)],
\]

where \( D_\theta \) is the stationary distribution of the Markov chain \( \{x_t\}_{t \geq 0} \) under policy \( \pi_\theta \).

An actor-critic algorithm consists of a critic step that approximates the action-value function \( Q_\theta \) with a parameterized function \( Q(\cdot, \cdot, \omega) \) by estimating the parameter \( \omega \), and an actor step where the policy \( \pi_\theta \) is updated with a stochastic version of the policy gradient. The natural actor-critic algorithm (Peters and Schaal, 2008) updates the policy with the natural policy gradient \( [\mathcal{I}_\theta]^{-1} \nabla_\theta C(\theta) \) (Kakade, 2002), where

\[
\mathcal{I}_\theta = E_{x \sim D_\theta, u \sim \pi_\theta(\cdot \mid x)} [\nabla \log \pi_\theta(u \mid x) \cdot \nabla \log \pi_\theta(u \mid x)^\top]
\]

is the Fisher information of the policy \( \pi_\theta \).
2.2 Linear Quadratic Regulator

Linear Quadratic Regulator is a fundamental problem in optimal control. In reinforcement learning, the LQR setting is used to develop theoretical understanding of different methods and serves as a performance benchmark (Fazel et al., 2018; Tu and Recht, 2017; Hardt et al., 2018). The state space is specified as $X = \mathbb{R}^d$ and action space as $U = \mathbb{R}^k$. The transition dynamics takes a linear form and the cost function takes a quadratic form, specified by

$$x_{t+1} = Ax_t + Bu_t + \epsilon_t, \quad c(x_t, u_t) = x_t^\top Q x_t + u_t^\top R u_t,$$

where $A$, $B$, $Q$ and $R$ are matrices of proper dimensions, and noise $\epsilon_t \sim N(0, \Phi)$, with $Q, R, \Phi \succ 0$.

The policy $\pi^*$ that minimizes $C(\pi)$ in (2.1) is static and takes a linear form (Anderson and Moore, 2007) $\pi^*(x_t) = -K^*x_t$, where

$$K^* = (R + B^\top P^* B)^{-1} B^\top P^* A,$$

and $P^*$ is the solution to a discrete algebraic Riccati equation (Zhou et al., 1996). In the model-free setting, where reinforcement learning methods do not have access to model parameters, it is known that policy gradient (Fazel et al., 2018; Tu and Recht, 2018; Malik et al., 2018) and actor-critic (Kakade, 2002) are guaranteed to find the optimal policy $\pi^*$.

2.3 Multi-Agent Reinforcement Learning

A multi-agent system with the set of agents $\mathcal{N}$ can be described by a Markov Decision Process (MDP) characterized by the tuple $(X, \{U^i\}_{i \in \mathcal{N}}, T, \{c_i\}_{i \in \mathcal{N}})$ (Littman, 1994), where each agent in the system takes an individual action $u_i \in U^i$, observes its individual cost $c_i : X \times U^i \rightarrow \mathbb{R}$, and moves to the next state by the global transition kernel $T : X \times U \rightarrow X$, with $U = \prod_i U^i$ denoting the joint action space.

We are interested in the team optimal control problem where the goal is to find a parameterized policy $\pi = \pi_\theta : X \times U \rightarrow U$ that minimizes the global total expected time-average cost of all agents, defined by

$$\min_{\theta} \quad C(\theta) = \limsup_{T \rightarrow \infty} T^{-1} \sum_{t=0}^{T-1} \mathbb{E} \left[ \sum_{i \in \mathcal{N}} c_i(x_t, u_t) \right] = \limsup_{T \rightarrow \infty} T^{-1} \sum_{t=0}^{T-1} \mathbb{E} [c_{gt}(x_t, u_t)].$$

Here $c_{gt}(x_t, u_t) = \sum_{i \in \mathcal{N}} c_i(x_t, u_t)$ is the global total cost, while $x_t = (x^1_t, \ldots, x^N_t) = (x^i_t)_{i \in \mathcal{N}}$ and $u_t = (u^1_t, \ldots, u^N_t) = (u^i_t)_{i \in \mathcal{N}}$ denote the joint state and action tuples, respectively. The
corresponding action-value function is defined as
\[
Q_\theta(x, u) = \sum_t \mathbb{E}_{\theta} [c_{gt}(x_t, u_t) - C(\theta) \mid x_0 = x, u_0 = u]
\]
and the state-value function is given by \(V_\theta(x) = \mathbb{E}_{u \sim \pi_\theta(\cdot \mid x)}[Q_\theta(x, u)]\). The action- and state-value functions are coupled across agents since the transition dynamics and costs depend on the joint state and action of the entire system. As the number of agents increases, it becomes infeasible to learn \(Q_\theta(\cdot, \cdot)\) due to the coupling structure and the exponentially increasing interactions.

3 Hierarchical Mean-Field Multi-Agent Reinforcement Learning

We introduce Hierarchical Mean-Field Multi-Agent Reinforcement Learning as a way for accounting for the heterogeneity of agents and dealing with the curse of dimensionality. We partition the population of agents \(N\) into disjoint subpopulations \(N = \bigsqcup_l^L N_l\) and approximate interactions of agents by each agent interacting with mean-field effects of subpopulations. In Section 3.1, we define system with partial exchangeability. Hierarchical Actor-Critic Algorithm is introduced in Section 3.2.

3.1 Partial Exchangeability

Consider a multi-agent dynamical system with agents \(N\). The state, action, and noise spaces for each agent are specified by \(X^i = \mathbb{R}^{d_i}, U^i = \mathbb{R}^{k_i},\) and \(W^i = \mathbb{R}^{d_i}\). Let \(x_t = \text{vec}\left((x^i_t)_{i \in N}\right)\), \(u_t = \text{vec}\left((u^i_t)_{i \in N}\right)\), and \(w_t = \text{vec}\left((w^i_t)_{i \in N}\right)\) denote respectively the global state, action, and noise vectors of the whole system at time \(t\). The system transition dynamics is given by

\[
x_{t+1} = f(x_t, u_t, w_t).
\]

Let \(c_t(x_t, u_t)\) denote the per-step cost at time \(t\) and \(\sigma_{i,j}\) denote the permutation transformation. For example, \(\sigma_{1,3}((x_1, x_2, x_3)) = (x_3, x_2, x_1)\). We first give the definition of partial exchangeability (Arabneydi and Mahajan, 2016).

Definition 3.1 (Exchangeable agents). A pair \((i, j)\) of agents is called exchangeable if \(X^i = X^j, U^i = U^j,\) and \(W^i = W^j\), that is, the dimensions of states, actions and disturbances are the same, and, moreover, the dynamics and cost satisfy

\[
f(\sigma_{i,j}x_t, \sigma_{i,j}u_t, \sigma_{i,j}w_t) = \sigma_{i,j}(f(x_t, u_t, w_t)),
\]

\[
\mathbb{P}(x_{t+1} \mid x_t, u_{t}, w_{t}) = \mathbb{P}(x_{t+1} \mid x_{t}, \sigma_{i,j}u_t, \sigma_{i,j}w_t).
\]
\[ c(\sigma_{i,j}x_t, \sigma_{i,j}u_t) = c(x_t, u_t), \]

that is, exchanging agent \( i \) and \( j \) does not affect the dynamics and cost.

**Definition 3.2** (Multi-agent system with partial exchangeability). A multi-agent system is called a system with *partial exchangeability* if the agents \( \mathcal{N} \) can be partitioned into \( L \) disjoint exchangeable subpopulations \( \mathcal{N}^l, l \in \mathcal{L} := \{1, \ldots, L\} \), such that each pair of agents in \( \mathcal{N}^l \) is exchangeable.

Partial exchangeability assumes that agents in the system can be partitioned into subpopulations and exchanging agents in the same subpopulation does not affect the system dynamics and cost. This definition accounts for the heterogeneity among agents across subpopulations and, thus, applies to a broader range of settings compared to vanilla mean-field MARL methods, which assume homogeneous agents. With partial exchangeability, we can define the mean-field of each subpopulation, which serves as a good summary of the information of that subpopulation.

**Definition 3.3** (Mean-fields of states and actions). The mean-field state and action of each subpopulation are defined respectively as the empirical means

\[ \bar{x}^l_t := \frac{1}{|\mathcal{N}^l|} \sum_{i \in \mathcal{N}^l} x^i_t, \quad \bar{u}^l_t := \frac{1}{|\mathcal{N}^l|} \sum_{i \in \mathcal{N}^l} u^i_t, \quad l \in \mathcal{L}. \]

The global mean-field of the system are defined by stacking all the mean-field value vectors:

\[ \bar{x}_t := \text{vec} \left( \bar{x}^1_t, \ldots, \bar{x}^L_t \right), \quad \bar{u}_t := \text{vec} \left( \bar{u}^1_t, \ldots, \bar{u}^L_t \right). \quad (3.2) \]

In Section 4 we show that in the LQR setting, partial exchangeability makes the global mean-field values \( \bar{x}_t \) and \( \bar{u}_t \) sufficient to characterize the interactions of agents.

### 3.2 Hierarchical Actor-Critic Algorithm

In this section, we propose the hierarchical actor-critic algorithm. We start by utilizing partial exchangeability to decompose the original optimal control problem in a multi-agent system into optimal control problems of \( L + 1 \) auxiliary systems: \( L \) for the subpopulations, denoted as \( \{S^l\}_{l \in \mathcal{L}} \), and one for the mean fields, denoted as \( \bar{S} \). The construction of auxiliary systems relies on a coordinate transformation. We also need to define the cost function of each auxiliary system. We specify them in the following definitions.
Definition 3.4 (Coordinate transformation). For each agent $i \in \mathcal{N}^l$, we define the coordinate transformation as

$$\tilde{x}_i^t = x_i^t - \bar{x}_t^l, \quad \tilde{u}_i^t = u_i^t - \bar{u}_t^l.$$ 

The coordinate of auxiliary system $\mathcal{S}_l$ is defined to be the tuples $\tilde{x}_l^t = (\tilde{x}_i^t)_{i \in \mathcal{N}^l}$ and $\tilde{u}_l^t = (\tilde{u}_i^t)_{i \in \mathcal{N}^l}$. For the mean-field auxiliary system $\mathcal{S}$, the coordinate is given by the mean-field values $\tilde{x}_t$ and $\tilde{u}_t$ defined in Definition 3.3.

Definition 3.5 (Cost functions). The global total cost of $\mathcal{S}_l$ is given by

$$\tilde{c}_l^t = c_{gt}(x_t^l, u_t^l) - c_{gt}(\tilde{x}_l^t, \tilde{u}_l^t),$$

where $\tilde{x}_l^t$ denotes the joint state obtained by replacing each individual state $(x_i^t)_{i \in \mathcal{N}^l}$ in $x_t$ with the mean-field states $\bar{x}_t^l$, and $\tilde{u}_l^t$ is defined similarly. With slight abuse of notation, $\tilde{x}_l^t$ and $\tilde{u}_l^t$ are defined respectively by

$$\tilde{x}_l^t = \left(\text{rep}(\bar{x}_t^l, |\mathcal{N}^l|), (x_i^t)_{j \in \mathcal{N}^l} \right), \quad \tilde{u}_l^t = \left(\text{rep}(\bar{u}_t^l, |\mathcal{N}^l|), (u_i^t)_{j \in \mathcal{N}^l} \right),$$

where we use $\text{rep}(\bar{x}_t^l, |\mathcal{N}^l|)$ to denote the tuple obtained by replicating the vector $\bar{x}_t^l |\mathcal{N}^l|$ times and we denote by $\mathcal{N}^l$ all subpopulations other than $\mathcal{N}^l$. The cost of $\mathcal{S}$ is given by

$$\tilde{c} = c_{gt}(\tilde{x}_t, \tilde{u}_t),$$

where $\tilde{x}_t$ is obtained by replacing all individual states in $x_t$ with their corresponding subpopulation mean-field states, and $\tilde{u}_t$ is defined similarly. In particular, $\tilde{x}_t$ and $\tilde{u}_t$ are defined respectively by

$$\tilde{x}_t = \left(\text{rep}(\bar{x}_t^l, |\mathcal{N}^l|)\right)_{i \in \mathcal{L}}, \quad \tilde{u}_t = \left(\text{rep}(\bar{u}_t^l, |\mathcal{N}^l|)\right)_{i \in \mathcal{L}}. \quad (3.3)$$

We remark that the state-action pairs of the auxiliary systems are induced by the state-action pairs of the original system through coordinate transformation, as is shown in Definition 3.4. The costs of the auxiliary systems are calculated with costs of the original system, as is shown in Definition 3.5, and in Section 4.1 we show that they can be calculated directly by matrix computation in the LQR setting. However, the policies are defined in the auxiliary systems. After choosing actions with the states and policies of the auxiliary systems, we can recover the states and policies of the original system, and proceed with its transition dynamics.

For the auxiliary system $\mathcal{S}_l$, we assume that all agents share a common policy $\bar{\pi}_{\theta_l}$ due to homogeneity within a subpopulation $\mathcal{N}^l$. Thus it reduces to a single-agent system with state-action pairs $\{(\tilde{x}_t^l, \tilde{u}_t^l)\}_{t \geq 0}$ induced by $\bar{\pi}_{\theta_l}$ and cost $\tilde{c}_l^t$ at time step $t$. Agents in $\mathcal{S}_l$ aim to
Algorithm 1 Hierarchical (Natural) Actor-Critic

**Input:** Number of iteration $N$, the partition $\{N^l : l \in \mathcal{L} := \{1, \ldots, L\}\}$, stepsizes $\{\eta_l: l \in L\}$ and $\bar{\eta}$.

**Initialization:** Initialize policies $\{\tilde{\pi}^0_l\}_{l \in \mathcal{L}}$ and $\bar{\pi}^0$ for the auxiliary systems $\{\mathcal{S}_l\}_{l \in \mathcal{L}}$ and $\bar{\mathcal{S}}$ respectively.

for $n = 0, \ldots, N$ do

**Critic step.**

Initialize states $x_0 = (x^i_0)_{i \in \mathcal{N}}$, do coordinate transformation to obtain initial states $\{\tilde{x}_0^l\}_{l \in \mathcal{L}}$ and $x_0$ of auxiliary systems.

for $t = 0, \ldots, T$ do

Take actions $\{\tilde{u}_t^l\}_{l \in \mathcal{L}}$ and $\bar{u}_t$ in each auxiliary system respectively based on current states $\{\tilde{x}_t^l\}_{l \in \mathcal{L}}$, $x_t$ and policies $\{\tilde{\pi}_l^n\}_{l \in \mathcal{L}}, \bar{\pi}^n$.

Recover original coordinates $x_t$ and $u_t$. Calculate the costs $\tilde{c}_t^l$ and $\bar{c}_t$ based on the original cost $c_{gl}$. Observe the next state $x_{t+1} = T(x_t, u_t)$.

Do coordinate transformation to obtain the next auxiliary states $\{\tilde{x}_{t+1}^l\}_{l \in \mathcal{L}}$ and $\bar{x}_{t+1}$.

end for

Obtain estimators of the action-value functions $\{\hat{Q}_{\pi_l}^l\}_{l \in \mathcal{L}}$ and $\hat{Q}_{\bar{\pi}}$ via a policy evaluation algorithm in the auxiliary systems. For online algorithms, the estimation is implemented during the simulation (for example, Algorithm 3 in §A).

**Actor step.**

Update the auxiliary policies by (natural) policy gradient decent with gradients estimated by $\{\hat{Q}_{\pi_l}^l\}_{l \in \mathcal{L}}$ and $\hat{Q}_{\bar{\pi}}$ and step sizes $\{\eta_l: l \in L\}$ and $\bar{\eta}$.

end for

**Output:** The final policies $\{\tilde{\pi}_N^l\}_{l \in \mathcal{L}}$ and $\bar{\pi}_N$.

search for a common optimal policy that minimizes the corresponding expected time-average cost $\bar{C}^\bar{l}$. Similarly, $\bar{\mathcal{S}}$ is a single-agent system with state-action pairs $\{(\bar{x}_t, \bar{u}_t)\}_{t \geq 0}$ induced by current policy $\bar{\pi}_{\bar{\theta}}$ and cost $\bar{c}$. The agent aims to search for an optimal policy that minimizes the corresponding expected time-average cost $\bar{C}$.

The resulting action-value functions $\{\hat{Q}_{\pi_l}^l\}_{l \in \mathcal{L}}$ and $\hat{Q}_{\bar{\pi}}$ are still coupled since the costs $\bar{c}_t^l$, $\bar{c}_t$ and the dynamics depend on the joint state $x_t$ and action $u_t$. We address this by assuming that for each auxiliary system, the action-value function has either a decoupled form or can be approximated by a decoupled function that only depends on the coordinates of that auxiliary system. This assumption allows us to update policies separately. While we are interested in methods for a general MDP setting, in this work we establish prove global
linear convergence for our method in the context of LQR.

Algorithm 1 provides a summary of the hierarchical actor-critic algorithm. We are evaluating and updating policies with actor-critic algorithm in the auxiliary systems, and observe the dynamics transition and costs in the origin system. We provide a rigorous justification of this algorithm in the LQR setting in Section 4.1 and establish global convergence in Section 4.3.

4 Main Results

In Section 4.1 we provide rigorous justification of Algorithm 1 in the LQR setting. The hierarchical natural actor-critic algorithm for the LQR problem is specified in Section 4.2. In Section 4.3 we establish the provable global convergence for hierarchical natural actor-critic algorithm.

4.1 Decomposition of LQR with Partial Exchangeability

We focus on the multi-agent LQR optimal control problem defined as

$$\min_{K} C(K) = \limsup_{T \to \infty} T^{-1} \sum_{t=0}^{T-1} \mathbb{E}_{x_t \sim D_0, u_t \sim \pi_K(\cdot|x_t)} \left[ c_{gt}(x_t, u_t) \right]$$

subject to

$$x_{t+1} = Ax_t + Bu_t + w_t, \quad c_{gt}(x_t, u_t) = x_t^T Q x_t + u_t^T R u_t,$$

where $x_t = \text{vec} \left( (x_{it})_{i \in \mathcal{N}} \right)$ and $u_t = \text{vec} \left( (u_{it})_{i \in \mathcal{N}} \right)$ denote the global joint state and action at time $t$ of all agents. Recall that the optimal control takes a linear form and we use the matrix $K$ to parameterize the policy $\pi$ such that $u_t = -Kx_t + \sigma z_t, z_t \sim N(0, I_d)$. In addition to being of fundamental importance, the LQR problem is frequently used in practice to approximate the original problem in (3.1).

We focus on the case where the system satisfies partial exchangeability with partition $\mathcal{N} = \bigsqcup_{i \in L} \mathcal{N}^i$. We consider the information structure where each agent $i$ can perfectly observe its local state $x_{it}$, action $u_{it}$, and the global mean-field state $\bar{x}_t$ defined in (3.2). Furthermore, each agent can recall its entire observation history perfectly. Such an information structure is called mean-field sharing (Arabneydi and Mahajan, 2016).

We show that after the coordinate transformation, optimization problem (4.1) can be decomposed into $L + 1$ control problems that correspond to the $L + 1$ auxiliary systems $\{S_l\}_{l \in L}$ and $\bar{S}$. This is established by proving that in the auxiliary systems, the dynamics, costs and thus the action-value functions take decoupled forms. As a result, each of the
control problems can be controlled separately with a linear policy. Finally, the observation that minimizing the decoupled objectives separately for all auxiliary systems decreases the global total expected time-average cost $C(K)$ concludes validity of Algorithm 1 in the LQR setting.

We first introduce Lemma 4.1, adapted from Arabneydi and Mahajan (2016), that expresses the agent’s individual dynamic and cost with respect to the mean-field and individual state-action pairs.

**Lemma 4.1.** Suppose the LQR problem specified in (4.1) satisfies partial exchangeability with exchangeable partition $\mathcal{N} = \{\mathcal{N}^l\}_{l \in \mathcal{L} := [L]}$. There exist matrices $A_l, B_l, \bar{A}_l, \bar{B}_l, \bar{Q}, \bar{R}, Q_l$ and $R_l$ explicitly defined by $A, B, Q$ and $R$ with dimensions independent of the number of agents in each subpopulation, such that the individual dynamics and cost function in (4.1) decompose as

$$x_{t+1}^i = A_l x_t^i + B_l u_t^i + \bar{A}_l \bar{x}_t + \bar{B}_l \bar{u}_t + w_t^i,$$

$$c(x_t, u_t) = \bar{x}_t^\top \bar{Q} \bar{x}_t + \bar{u}_t^\top \bar{R} \bar{u}_t + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} \left( (x_t^i)^\top Q_l x_t^i + (u_t^i)^\top R_l u_t^i \right).$$

A proof is given in Section 5.1, where we also provide explicit definitions of $A_l, B_l, \bar{A}_l, \bar{B}_l, Q_l, R_l, \bar{Q}, \bar{R}, Q$ and $R$.

Based on the matrices defined in Lemma 4.1, we further define the following matrices that turn out to be useful in defining the auxiliary systems. Specifically, we define matrices $\bar{A}$ and $\bar{B}$ as

$$\bar{A} := \text{diag} (A_1, \ldots, A_L) + \text{rows} (\bar{A}_1, \ldots, \bar{A}_L),$$

$$\bar{B} := \text{diag} (B_1, \ldots, B_L) + \text{rows} (\bar{B}_1, \ldots, \bar{B}_L),$$

and matrices $\bar{Q}$ and $\bar{R}$ as

$$\bar{Q} := \text{diag} (|\mathcal{N}_1^i| \cdot Q_1, \ldots, |\mathcal{N}_L^i| \cdot Q_L),$$

$$\bar{R} := \text{diag} (|\mathcal{N}_1^i| \cdot R_1, \ldots, |\mathcal{N}_L^i| \cdot R_L).$$

The following standard assumption (Fazel et al., 2018; Arabneydi and Mahajan, 2016) ensures that the cost functions of the auxiliary systems are well-defined.

**Assumption 4.2.** Matrices $\{Q_l\}_{l \in \mathcal{L}}$, $\{R_l\}_{l \in \mathcal{L}}$, $(\bar{Q} + \bar{Q})$ and $(\bar{R} + \bar{R})$ are positive semi-definite.

Now we are ready to give the dynamics and the cost functions of the auxiliary systems. The following proposition tells us the dynamics and costs of the auxiliary systems take decoupled forms. Note that we also apply coordinate transformation to the noise terms.
Proposition 4.3 (Auxiliary systems with decoupled dynamics and costs). Suppose the assumptions of Lemma 4.1 and Assumption 4.2 hold. After an application of the coordinate transformation (3.4), the dynamics of the auxiliary systems $S_l$ and $\bar{S}$ induced by the original dynamics in (4.1) can be written as

$$\begin{align*}
\bar{x}_{t+1}^i &= A_t \bar{x}_t^i + B_t \bar{u}_t^i + \bar{w}_t^i, \quad \bar{w}_t^i \sim N(0, \Phi_t), \\
\bar{x}_{t+1} &= \bar{A}_t \bar{x}_t + \bar{B}_t \bar{u}_t + \bar{w}_t, \quad \bar{w}_t \sim N(0, \bar{\Phi}).
\end{align*}$$

Furthermore, the global total costs of $S_l$ and the cost of $\bar{S}$, defined in Definition 3.5, only depend on state-action pairs $(\bar{x}_t^i, \bar{u}_t^i)$ and $(\bar{x}_t, \bar{u}_t)$ respectively, and can be written as

$$\begin{align*}
\bar{c}^l(\bar{x}_t^i, \bar{u}_t^i) &= \sum_{i \in \mathcal{N}^l} \left[ (\bar{x}_t^i)^\top Q_l \bar{x}_t^i + (\bar{u}_t^i)^\top R_l \bar{u}_t^i \right], \\
\bar{c}(\bar{x}_t, \bar{u}_t) &= \bar{x}_t^\top \left( \bar{Q} + \bar{Q} \right) \bar{x}_t + \bar{u}_t^\top \left( \bar{R} + \bar{R} \right) \bar{u}_t.
\end{align*}$$

Moreover, the original global total cost function decomposes as

$$c_{gt}(x_t, u_t) = \bar{c}(x_t, u_t) + \sum_{l \in \mathcal{L}} \bar{c}^l(x_t^l, u_t^l).$$

Note that by Proposition 4.3, the original system decomposes into $L + 1$ auxiliary systems: $L$ for each subpopulation $\{\mathcal{N}^l\}_{l \in \mathcal{L}}$, and one for the mean-field system. The auxiliary systems have decoupled dynamics and costs, hence they can be controlled with separate policies. Moreover, as is shown in (4.6), the individual cost (also denoted by $\bar{c}^l(\cdot, \cdot)$ with a slight abuse of notation) in $S_l$ takes the identical form

$$\bar{c}^l(\bar{x}_t^i, \bar{u}_t^i) = (\bar{x}_t^i)^\top Q_l \bar{x}_t^i + (\bar{u}_t^i)^\top R_l \bar{u}_t^i.$$ 

Therefore, their optimal policies are identical, which justifies usage of a common policy $\bar{\pi}_l$ in Algorithm 1.

We parameterize the policies of auxiliary systems by matrices $K_l \in \mathbb{R}^{k_l \times d_l}$ and $\bar{K} \in \mathbb{R}^{\bar{k} \times \bar{d}}$. By adding Gaussian noise to allow for exploration, the policies can be written as

$$\begin{align*}
\bar{u}_t^i &= -K_l \bar{x}_t^i + \sigma_l \cdot \bar{z}_t^i, \quad \bar{z}_t^i \sim N(0, I_{d_l}), \quad i \in \mathcal{N}^l, \quad l \in \mathcal{L}, \\
\bar{u}_t &= -\bar{K} \bar{x}_t + \bar{\sigma} \cdot \bar{z}_t, \quad \bar{z}_t \sim N(0, I_{\bar{d}}),
\end{align*}$$

with the corresponding distributions denoted as $\pi_{K_l}(\cdot | \bar{x}_t^i)$ and $\pi_{\bar{K}}(\cdot | \bar{x}_t)$. Our next results states that minimizing the original objective $C(K)$ can be done separately with respect to $\bar{K}$ and $K_l$, $l \in \mathcal{L}$.
**Proposition 4.4.** The objective $C(K)$ can be decomposed as $C(K) = \bar{C}(\bar{K}) + \sum_{l \in \mathcal{L}} \tilde{C}(\tilde{K}_l)$, where

$$\bar{C}(\bar{K}) := \lim_{T \to \infty} \mathbb{E}_{x_0 \sim \mathcal{D}_0, u_t \sim \pi_{\bar{K}}(\cdot|x_t)} \left[ \frac{1}{T} \sum_{t=0}^{T-1} \bar{c}(\bar{x}_t, \bar{u}_t) \right], \quad (4.10)$$

$$\tilde{C}(\tilde{K}_l) := \lim_{T \to \infty} \mathbb{E}_{x_0 \sim \mathcal{D}_0, u_t \sim \pi_{\tilde{K}_l}(\cdot|x_t)} \left[ \frac{1}{T} \sum_{t=0}^{T-1} \tilde{c}(\tilde{x}_l^t, \tilde{u}_l^t) \right], \quad i \in \mathcal{N}^l, \ l \in \mathcal{L}. \quad (4.11)$$

The result follows by direct computation and is given in Section 5.3. Note that $\bar{C}(\bar{K})$ and $\tilde{C}(\tilde{K}_l)$ are exact objectives of the optimal control problems defined in the auxiliary systems and minimizing them separately yields the minimum of the original objective $C(K)$. With the decoupled dynamics and cost functions, as well as, the linearly parameterized policies described above, the corresponding action-value functions $\{\bar{Q}_{K_i}\}_{l \in \mathcal{L}}$ and $\bar{Q}_{\bar{K}}$ indeed have decoupled structures, which justifies Algorithm 1 in the LQR setting.

### 4.2 Hierarchical Natural Actor-Critic in LQR Setting

In this section we develop the hierarchical natural actor-critic algorithm for the LQR problem. With the action distribution defined in (4.9), the state dynamics defined by (4.4) take respectively the forms

$$\bar{x}_{l+1} = (A_l - B_l K_l) \bar{x}_l + \bar{e}_t, \quad \bar{e}_t \sim N(0, \bar{\Phi}_l), \quad i \in \mathcal{N}^l, \ l \in \mathcal{L}, \quad \bar{x}_{l+1} = (\bar{A} - \bar{B} \bar{K}) \bar{x}_l + \bar{e}_t, \quad \bar{e}_t \sim N(0, \bar{\Phi}_l), \quad (4.12)$$

where $\Phi_{l_{\sigma_l}} := \Phi_l + \sigma_l^2 \cdot B_l B_l^\top$ and $\bar{\Phi}_l := \bar{\Phi} + \sigma_l^2 \cdot \bar{B} \bar{B}^\top$. Let $\{\Sigma_{K_l}\}_{l \in \mathcal{L}}$ and $\Sigma_{\bar{K}}$ denote the unique positive definite solutions to the Lyapunov equations

$$\Sigma_{K_i} = \Phi_{\sigma_l} + (A_l - B_l K_l) \Sigma_{K_l} (A_l - B_l K_l)^\top, \quad \Sigma_{\bar{K}} = \bar{\Phi} + (\bar{A} - \bar{B} \bar{K}) \Sigma_{\bar{K}} (\bar{A} - \bar{B} \bar{K})^\top. \quad \Sigma_{\bar{K}}$$

Under the condition that $\rho(A_l - B_l K_l) < 1$ and $\rho(\bar{A} - \bar{B} \bar{K}) < 1$, the Markov chains introduced by (4.12) have stationary distributions $N(0, \Sigma_{K_l})$ and $N(0, \Sigma_{\bar{K}})$, denoted by $\mathcal{D}_{K_l}$ and $\mathcal{D}_{\bar{K}}$.

The following lemma establishes functional forms of costs $\tilde{C}(\tilde{K}_l)$ and $\bar{C}(\bar{K})$ as well as their gradients.

**Lemma 4.5.** The ergodic costs are given by

$$\tilde{C}(\tilde{K}_l) = \text{Tr} \left[ (Q_l + K_l^\top R_l K_l) \Sigma_{K_l} \right] + \sigma_l^2 \cdot \text{Tr}(R_l)$$

$$\bar{C}(\bar{K}) = \text{Tr} \left[ (Q_l + K_l^\top R_l K_l) \Sigma_{\bar{K}} \right] + \sigma_l^2 \cdot \text{Tr}(R_l), \quad (4.13)$$
\[ \bar{C}(\bar{K}) = \text{Tr} \left[ \left( (\bar{Q} + \bar{Q}) + \bar{K}^\top (\bar{R} + \bar{R}) \bar{K} \right) \Sigma_{\bar{K}} \right] + \sigma^2 \cdot \text{Tr}(\bar{R} + \bar{R}) \]
\[ = \text{Tr} \left( P_K \bar{\Phi}_\sigma \right) + \sigma^2 \cdot \text{Tr}(\bar{R} + \bar{R}), \] (4.14)

with gradients
\[ \nabla_{K_i} \bar{C}(K_i) = 2 \left[ \left( R_i + B_i^\top P_{K_i} B_i \right) K_i - B_i^\top P_{K_i} A_i \right] \Sigma_{K_i} = 2 E_{K_i} \Sigma_{K_i}, \] (4.15)
\[ \nabla_{\bar{K}} \bar{C}(\bar{K}) = 2 \left[ \left( \bar{R} + \bar{R} + \bar{B}^\top P_{\bar{K}} \bar{B} \right) \bar{K} - \bar{B}^\top P_{\bar{K}} A \right] \Sigma_{\bar{K}} = 2 E_{\bar{K}} \Sigma_{\bar{K}}, \] (4.16)

where \( P_{K_i} \) and \( P_{\bar{K}} \) are obtained as the solution to
\[ P_{K_i} = (Q_i + K_i^\top R_i K_i) + (A_i - B_i K_i)^\top P_{K_i} (A_i - B_i K_i), \]
\[ P_{\bar{K}} = \left( \bar{Q} + \bar{Q} + \bar{K}^\top (\bar{R} + \bar{R}) \bar{K} \right) + (\bar{A} - \bar{B} \bar{K})^\top P_{\bar{K}} (\bar{A} - \bar{B} \bar{K}), \]

and \( E_{K_i} \) and \( E_{\bar{K}} \) are defined as
\[ E_{K_i} = (R_i + B_i^\top P_{K_i} B_i) K_i - B_i^\top P_{K_i} A_i, \]
\[ E_{\bar{K}} = \left( \bar{R} + \bar{R} + \bar{B}^\top P_{\bar{K}} \bar{B} \right) \bar{K} - \bar{B}^\top P_{\bar{K}} \bar{A}. \]

The lemma directly follows from Lemma C.1 applied to each LQR problem of the auxiliary systems.

To see how natural policy gradient is related to \( E_{K_i} \), observe that \( \mathcal{I}(K_i) \) has block diagonal structure with \( k_i \) blocks of size \( d_i \times d_i \). Each block contains entries with coordinates of the form \((i, \cdot) \times (i, \cdot)\), where \( i \in \{1 \ldots k_i\} \). All of the blocks are identical to \( \Sigma_{K_i} \). Hence, the natural policy gradient algorithm updates the policy in the direction of
\[ [\mathcal{I}(K_i)]^{-1} \nabla_{K_i} C(K_i) = \nabla_{K_i} C(K_i) \Sigma_{K_i}^{-1} = 2 E_{K_i}. \]

Similarly, the natural gradient for mean-field system is \( 2 E_{\bar{K}} \). In the critic step, the model-free estimates \( \{ \hat{E}_{K_i} \}_{i \in \mathcal{L}} \) and \( \hat{E}_{K_i} \) can be obtained with an online gradient-based temporal-difference algorithm (Sutton et al., 2009b). In the actor step, the policies are updated with \( \{ \hat{E}_{K_i} \}_{i \in \mathcal{L}} \) and \( \hat{E}_{K_i} \). Thus, we obtain the hierarchical natural actor critic algorithm for LQR problem, as is summarized in Algorithm 2.

### 4.3 Global Convergence

In this section, we prove that the hierarchical natural actor critic algorithm, described in the previous section, converges globally to the optimal policy at a linear rate for LQR problems. We start by making some mild assumptions.
### Algorithm 2 Hierarchical Natural Actor-Critic for LQR Problem

**Input:** Number of iteration $N$, the partition ${\mathcal N}^l : l \in \mathcal L := \{1, \ldots, L\}$, stepsizes \{\eta_l : l \in \mathcal L\} and \(\bar{\eta}\).

**Initialization:** Initialize policies \{\pi_{K_{l,0}} : l \in \mathcal L\} and \(\bar{\pi}_{K_0}\).

for $n = 0, \ldots, N$ do

**Critic step.** Simulate current policies \{\pi_{K_{l,n}}\}_{l \in \mathcal L} and \(\bar{\pi}_{K_n}\) following the same steps in Algorithm 1. Update estimators \{\hat{E}_{K_{l,n}} : l \in \mathcal L\} and \(\hat{E}_{\bar{K}_n}\) via online GTD algorithm (Algorithm 3 in §A) at each simulating iteration.

**Actor step.** Update the policy parameter by

\[
K_{l,n+1} = K_{l,n} - \eta_l \cdot \hat{E}_{K_{l,n}} \quad \text{and} \quad \bar{K}_{n+1} = \bar{K}_n - \bar{\eta} \cdot \hat{E}_{\bar{K}_n}.
\]

end for

**Output:** The final policies \{\pi_{K_{l,N}} : l \in \mathcal L\} and \(\bar{\pi}_{K_N}\).

---

**Assumption 4.6.** The initial policies \{\pi_{K_{l,0}} : l \in \mathcal L\} satisfy $\rho(A_l - B_l K_{l,0}) < 1$ and \(\bar{\pi}_{K_0}\) satisfies $\rho(A - B \bar{K}_0) < 1$.

**Assumption 4.7.** The stepsizes are sufficiently small and satisfy

\[
\eta_l \leq \left[\|R_l\| + \sigma_{\min}^{-1}(\Phi_l) \cdot \|B_l\|^2 \cdot C(K_{l,0})\right]^{-1}, \forall l \in \mathcal L,
\]

\[
\bar{\eta} \leq \left[\|\hat{R}\| + \sigma_{\min}^{-1}(\hat{\Phi}) \cdot \|\hat{B}\|^2 \cdot C(\bar{K}_0)\right]^{-1}.
\]

At iteration $n$, the algorithm produces the policy $K_n$ for the multi-agent system with \{\pi_{K_{l,n}}\}_{l \in \mathcal L} and \(\bar{\pi}_{K_n}\). We denote by \{\pi^*_l\}_{l \in \mathcal L} and $\pi^*$ the optimal policies for the subpopulations and the mean-field agent respectively. They induce the optimal policy for the multi-agent system, denoted by $K^*$. With this notation, We make the following assumption.

**Assumption 4.8.** The estimates of natural gradients given by the critic step satisfy

\[
\left\|\hat{E}_{K_{l,n}} - E_{K_{l,n}}\right\| \leq \delta_{l,n} \quad \text{and} \quad \left\|\hat{E}_{\bar{K}_n} - E_{\bar{K}_n}\right\| \leq \bar{\delta}_n,
\]

where \{\delta_{l,n}\}_{l \in \mathcal L} and \(\bar{\delta}_n\) are sufficiently small positive values satisfying

\[
\delta_{l,n} \leq c_1 \cdot \epsilon \cdot \eta_l \cdot \sigma_{\min}^{-1}(\Phi_l) \cdot \sigma_{\min}(R) \cdot \left\|\Sigma_{K^*_l}\right\|^{-1} \cdot 1/\Lambda(\|K_{l,n}\|, C(K_{l,0})) \cdot 1/(L + 1),
\]

\[
\bar{\delta}_n \leq \bar{c} \cdot \epsilon \cdot \bar{\eta} \cdot \sigma_{\min}^{-1}(\hat{\Phi}) \cdot \sigma_{\min}(R) \cdot \left\|\Sigma_{\bar{K}^*}\right\|^{-1} \cdot 1/\Lambda(\|\bar{K}_n\|, C(\bar{K}_0)) \cdot 1/(L + 1).
\]

Here \{c_1\}_{l \in \mathcal L} and \(\bar{c}\) are some constants, $\Lambda(\cdot, \cdot)$ is a polynomial, and $\epsilon$ is the error level we want to achieve, that is, $C(K_N) - C(K^*) \leq \epsilon$. 

---

16
Assumption 4.6 is a standard assumption for the model-free LQR problem (Fazel et al., 2018; Malik et al., 2018; Tu and Recht, 2017). Assumptions 4.7 and 4.8 are technical assumptions on the relative updating steps of the natural gradient decent in the actor step and the GTD algorithm in the critic step (see Algorithm 3 proposed in appendix). In particular, Assumption 4.8 states that the critic is updated at a faster pace than the actor. Under these assumptions we can prove non-asymptotic convergence results in contrast to asymptotic results of classical actor-critic algorithms (Konda and Tsitsiklis, 2000; Bhatnagar et al., 2009; Grondman et al., 2012). Note that Assumption 4.8 is rather weak and can be satisfied by setting the number of iterations in GTD Algorithm 3 sufficiently large. See Theorem A.2 in Appendix A. Now we are ready to present the main theorem.

**Theorem 4.9** (Global convergence of hierarchical actor-critic algorithm). Suppose Assumptions 4.6 - 4.8 hold. Then \( \{ C(K_n) \}_{n \geq 0} \) is a monotonously decreasing sequence. Moreover, for any \( \epsilon > 0 \), if \( N > 2M \log \{ [C(K_0) - C(K^*)] \cdot (L + 1)/\epsilon \} \) where constant \( M \) is defined as

\[
M = \max \left\{ \{ \| \Sigma_{\bar{K}l} \| \cdot \eta_l^{-1} \cdot \sigma_{\min}^{-1}(\Phi_l) \cdot \sigma_{\min}^{-1}(R_l) \} \right\}_{l \in \mathcal{L}} \cdot \| \Sigma_{\bar{K}^*} \| \cdot \eta^* \cdot \sigma_{\min}^{-1}(\bar{\Phi}) \cdot \sigma_{\min}^{-1}(\bar{R}) \}
\]

then \( C(K_N) - C(K^*) \leq \epsilon \).

Theorem 4.9 establishes that Algorithm 2 converges globally to the optimal policy \( K^* \) at a linear rate. Moreover, note that our algorithm involves \( L + 1 \) decoupled optimal control problems whose complexity does not depend on the number of agents in each subpopulation. This feature and Theorem 4.9 together guarantee the computational efficiency of our algorithm, allowing us to escape the curse of dimensionality. In the next subsection, we prove our main result.

**4.4 Proof of Theorem 4.9**

By Propositions 4.3 and 4.4, the original LQR problem defined in (4.1) decomposes into optimal control problems for each auxiliary system. Therefore, it is sufficient to prove the global convergence for each auxiliary system. Note that, since agents in \( \mathcal{S}_l \) share a common policy \( \pi_{K_l} \) in the algorithm, the optimal control problem reduces to single agent case. In particular, we need to prove the convergence theorem for a single agent LQR problem. In the rest of this section, we no longer distinguish each LQR problem and remove all the notations that indicate the subpopulations and the mean field. We first present the global convergence result of the hierarchical natural actor-critic algorithm for the single agent LQR problem.

17
**Theorem 4.10** (Global convergence of actor-critic algorithm). Suppose Assumptions 4.6 - 4.8 hold. Then \( \{C(K_n)\}_{n \geq 0} \) is a monotonously decreasing sequence. Moreover, for any \( \epsilon > 0 \), if the iteration number \( N \) is large enough such that

\[
N > 2 \|\Sigma_K\| \cdot \eta^{-1} \cdot \sigma_{\min}^{-1}(\Phi) \cdot \sigma_{\min}^{-1}(R) \cdot \log \left\{ \frac{[C(K_0) - C(K^*)]}{\epsilon} \right\},
\]

we have \( C(K_N) - C(K^*) \leq \epsilon \).

We remark that by setting number of iterations in the GTD Algorithm 3 sufficiently large, we can make \( \delta_n \) sufficiently small so that Assumption 4.8 is satisfied. Using Theorem 4.10, Theorem 4.9 directly follows with Propositions 4.3 and 4.4. In the reminder of the section, we prove Theorem 4.10.

Our proof can be decomposed into three steps. In the first step, we study the geometry of \( C(K) \) as a function of \( K \). In general, natural gradient decent methods are not guaranteed to converge to the global optimal due to non-convexity of the LQR optimization problem (Fazel et al., 2018). However, we can establish the geometric condition called gradient domination in the LQR setting that allows us to prove convergence. In the second step, we show that the policy is improved at a linear rate along the direction of the oracle natural policy gradient at each iteration. In the third step, we show the policy updated with the estimated natural policy gradient has cost close to that of the policy updated with the oracle natural policy gradient, thus we can show linear convergence for it as well.

The following lemma establishes the gradient domination condition.

**Lemma 4.11** (Gradient domination). Let \( K^* \) be an optimal policy for agents in \( \mathcal{N} \). Suppose \( K \) has finite cost in the sense that \( \rho(A - BK) < 1 \). Then it holds that

\[
\sigma_{\min}(\Phi) \cdot \|R + B^\top P_K B\|^{-1} \cdot \text{Tr} \left( E_K^\top E_K \right) \leq C(K) - C(K^*) \leq 1/\sigma_{\min}(R) \cdot \|\Sigma_K\cdot\| \cdot \text{Tr} \left( E_K^\top E_K \right). \tag{4.17}
\]

Note that the upper bound in (4.17) takes the form \( 1/\sigma_{\min}(R) \cdot \|\Sigma_K\cdot\| \cdot \langle E_K, E_K \rangle \). Therefore, updating policy \( K \) with the natural gradient \( E_K \) in the actor step of Algorithm 2 minimizes the upper bound of the difference \( C(K) - C(K^*) \). Moreover, the natural gradient will not vanish before reaching the optimum. The following lemma that shows the policy is improved at a linear rate along the direction of the true natural policy gradient, provided that the step size is small enough.

**Lemma 4.12.** Suppose Assumption 4.6 and 4.7 hold. Let \( \{K_n\} \) be the sequence induced by the natural policy gradient algorithm started at the initial policy \( K_0 \). Let \( K_{n+1}' = K_n - \eta \cdot E_{K_n} \)
be a single update along the direction of the true natural policy gradient. Then we have

\[ C(K'_{n+1}) - C(K_n) \leq -\eta \cdot \sigma_{\min}(\Phi) \cdot \sigma_{\min}(R) \cdot \|\Sigma_{K^*}\|^{-1} \cdot [C(K_n) - C(K^*)] \]  

(4.18)

and

\[ C(K'_{n+1}) - C(K^*) \leq [1 - \eta \cdot \sigma_{\min}(\Phi) \cdot \sigma_{\min}(R) \cdot \|\Sigma_{K^*}\|^{-1}] \cdot [C(K_n) - C(K^*)]. \]  

(4.19)

To draw a similar conclusion on the update \( K_{t+1} = K_t - \eta \cdot \hat{E}_{K_t} \), we need to link the objectives \( C(K'_{t+1}) \) and \( C(K_{t+1}) \). The following lemma bounds the difference between \( C(K'_{n+1}) \) and \( C(K_n) \) by problem parameters.

**Lemma 4.13.** Suppose Assumptions 4.6 - 4.8 hold. Furthermore, suppose \( C(K_n) < C(K_0) \). Let \( K'_{n+1} = K_n - \eta \cdot E_{K_n} \) and \( K_{n+1} = K_n - \eta \cdot \hat{E}_{K_n} \) be updates along the exact and estimated natural policy gradient at time \( t \). Then, for any fixed \( \epsilon > 0 \), it holds that

\[ |C(K_{n+1}) - C(K'_{n+1})| \leq \epsilon / 2 \cdot \eta \cdot \sigma_{\min}(\Phi) \cdot \sigma_{\min}(R) \cdot \|\Sigma_{K^*}\|^{-1}. \]  

(4.20)

When \( C(K_n) - C(K^*) \geq \epsilon \), combining (4.18) and (4.20), we have

\[ C(K_{n+1}) - C(K_n) \leq -\epsilon / 2 \cdot \eta \cdot \sigma_{\min}(\Phi) \cdot \sigma_{\min}(R) \cdot \|\Sigma_{K^*}\|^{-1} < 0. \]

This shows that \( \{C(K_n)\}_{n \geq 0} \) is monotonically decreasing. Moreover, combining (4.19) with (4.20), we further conclude that

\[ C(K_{n+1}) - C(K^*) \leq [1 - \eta / 2 \cdot \sigma_{\min}(\Phi) \cdot \sigma_{\min}(R) \cdot \|\Sigma_{K^*}\|^{-1}] \cdot [C(K_n) - C(K^*)], \]

which shows a linear convergence in terms of the policy parameter. By direct computation, if the iteration number \( N \) is large enough such that

\[ N > 2 \|\Sigma_{K^*}\| \cdot \eta^{-1} \cdot \sigma_{\min}^{-1}(\Phi) \cdot \sigma_{\min}^{-1}(R) \cdot \log \{[C(K_0) - C(K^*)] / \epsilon\}, \]

it holds that \( C(K_N) - C(K^*) \leq \epsilon \). This concludes the proof of Theorem 4.10.

## 5 Technical Proofs

In this section, we present the proofs of our technical results in Section 4. Proofs of the supporting lemmas are deferred to Appendix C.
5.1 Proof of Proposition 4.1

Recall the dynamics and cost function of the LQR problem specified in (4.1) are given as
\[ x_{t+1} = Ax_t + Bu_t + w_t, \quad c_{gt}(x_t, u_t) = x_t^\top Q x_t + u_t^\top R u_t, \] (5.1)
and satisfy the partial exchangeability with exchangeable partition \( \mathcal{N} = \{\mathcal{N}^l\}_{l \in \mathcal{L} = [L]} \).

In the following, let \( A^{i,j} \) denote the \((i, j)\)-th block of \( A \). Fix a subpopulation \( l \in \mathcal{L} \). For agents \( i, j \in \mathcal{N}^l \), the exchangeability in Definition 3.1 implies \( A^{i,i} = A^{j,j} \) and \( B^{i,i} = B^{j,j} \), denoted by \( a^l \) and \( b^l \), respectively. For \( i, j \in \mathcal{N}^l \) and \( n, m \in \mathcal{N}^k, l \neq k \), we have \( A^{i,n} = A^{j,m} \) and \( B^{i,n} = B^{j,m} \), denoted by \( a^{l,k} \) and \( b^{l,k} \), respectively. For \( i, j \in \mathcal{N}^l \), we have \( Q^{i,i} = Q^{j,j} \) and \( R^{i,j} = R^{j,i} \), denoted by \( q^l \) and \( r^l \), respectively. For \( i, j \in \mathcal{N}^l \) and \( n, m \in \mathcal{N}^k, l \neq k \), we have \( Q^{i,n} = Q^{j,m} \) and \( R^{i,n} = R^{j,m} \), denoted by \( q^{l,k} \) and \( r^{l,k} \), respectively. With this notation we provide the explicit forms for \( A_l, B_l, \bar{A}_l, \bar{B}_l, Q_l, R_l, \bar{Q} \) and \( \bar{R} \).

First, we define \( A_l \) and \( B_l \) as
\[ A_l := a^l - \bar{a}^{l,l}, \quad B_l := b^l - \bar{b}^{l,l}. \]
We also define \( \bar{A}_l, \bar{B}_l, Q_l, \) and \( R_l \) as
\[
\begin{align*}
\bar{A}_l &:= \text{cols} \left( |\mathcal{N}^l| \bar{a}^{l,1}, \ldots, |\mathcal{N}^l| \bar{a}^{l,L} \right), \\
\bar{B}_l &:= \text{cols} \left( |\mathcal{N}^l| \bar{b}^{l,1}, \ldots, |\mathcal{N}^l| \bar{b}^{l,L} \right), \\
Q_l &:= (q^l - \bar{q}^{l,l}), \\
R_l &:= (r^l - \bar{r}^{l,l}).
\end{align*}
\]
Finally, we define \( \bar{Q} \) and \( \bar{R} \) by specifying each block as
\[ \bar{Q}^{l,k} := |\mathcal{N}^k| |\mathcal{N}^l| \bar{q}^{l,k}, \quad \bar{R}^{l,k} := |\mathcal{N}^l| |\mathcal{N}^k| \bar{r}^{l,k}. \]
We remark that the dimensions of \( A_l, B_l, \bar{A}_l, \bar{B}_l, Q_l, R_l, \bar{Q} \) and \( \bar{R} \) do not depend on the size of each subpopulation. Instead, they are determined by the subpopulations’ state- and action-dimensions.

With the definitions above, we are ready to present the proof. The dynamics of agent \( i \) of subpopulation \( k \) is
\[ x_{t+1}^i = A^i x_t^i + B^i u_t^i + w_t^i, \]
where \( A^i \) and \( B^i \) denote respectively the rows corresponding to the \( i \)-th block of \( A \) and \( B \).

By direct computation, we have
\[
A^i x_t^i = A^{i,i} x_t^i + \sum_{j \in \mathcal{N}^l, j \neq i} A^{i,j} x_t^j + \sum_{k \in \mathcal{L}, k \neq l} \sum_{n \in \mathcal{N}^k} A^{i,n} x_t^n \\
= a^l x_t^i + \bar{a}^{l,l} \sum_{j \in \mathcal{N}^l, j \neq i} x_t^j + \sum_{k \in \mathcal{L}, k \neq l} \bar{a}^{l,k} \sum_{n \in \mathcal{N}^k} x_t^n
\]
\[20\]
Similarly, we have

\[ B^i \mathbf{u}_t = B_t u_t^i + \bar{B}_t \bar{u}_t. \]

Moreover, we have

\[
x_t^i Q x_t = \sum_{l \in \mathcal{L}} \sum_{k \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} \sum_{j \in \mathcal{N}^k} (x_t^i)^\top Q_{i,j} x_t^j
\]

\[= \sum_{l \in \mathcal{L}} \sum_{k \in \mathcal{L}, k \neq l} \sum_{i \in \mathcal{N}^l} \sum_{j \in \mathcal{N}^k} (x_t^i)^\top \bar{q}^{l,k} x_t^j
\]

\[+ \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} \sum_{j \in \mathcal{N}^l, j \neq i} (x_t^i)^\top q_{i,j} x_t^j + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} (x_t^i)^\top q^l x_t^i
\]

\[= \sum_{l \in \mathcal{L}} \sum_{k \in \mathcal{L}, k \neq l} |\mathcal{N}^l| |\mathcal{N}^k| \left( \bar{x}_t^l \right)^\top \bar{q}^{l,k} \bar{x}_t^k + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} |\mathcal{N}^l|^2 \left( \bar{x}_t^i \right)^\top q^l \bar{x}_t^i
\]

\[\quad - \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} (x_t^i)^\top \bar{q}^l x_t^i + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} (x_t^i)^\top q^l x_t^i
\]

\[= \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} |\mathcal{N}^l| |\mathcal{N}^k| \left( \bar{x}_t^i \right)^\top \bar{q}^{l,k} \bar{x}_t^k + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} (x_t^i)^\top (q^l - \bar{q}^l) x_t^i
\]

\[= x_t^i Q x_t + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} (x_t^i)^\top Q_l x_t^i,
\]

Similarly, we have

\[
\mathbf{u}_t^\top R \mathbf{u}_t = \mathbf{u}_t^\top \bar{R} \mathbf{u}_t + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^l} (u_t^i)^\top R_l u_t^i.
\]

Thus, we conclude the proof.

### 5.2 Proof of Proposition 4.3

From the coordinate transformation

\[ \bar{x}_t^i = x_t^i - \bar{x}_t, \quad \bar{u}_t^i = u_t^i - \bar{u}_t, \quad \bar{w}_t^i = w_t^i - \bar{w}_t, \]

we have that the subpopulation mean fields vanish in (4.2). Therefore, we have

\[
\ddot{x}_{t+1}^i = A_t \ddot{x}_t^i + B_t \bar{u}_t^i + \bar{w}_t^i, \quad (5.2)
\]
and

\[ \ddot{x}_t^i + \dot{x}_t^i = A_i \ddot{x}_t^i + A_i \dot{x}_t^i + B_i \ddot{u}_t^i + B_i \dot{u}_t^i + \ddot{\bar{x}}_t + \dot{\bar{u}}_t + \ddot{\bar{w}}_t + \bar{w}_t. \]  

Combining (5.2) and (5.3), we have

\[ \dot{x}_{t+1} = \dot{A} \bar{x}_t + B \dot{\bar{u}}_t + \bar{w}_t, \]  

where

\[ \dot{x}_t := \text{vec} \left( \bar{x}_t^1, \ldots, \bar{x}_t^L \right), \quad \dot{u}_t := \text{vec} \left( \bar{u}_t^1, \ldots, \bar{u}_t^L \right), \quad \dot{w}_t := \text{vec} \left( \bar{w}_t^1, \ldots, \bar{w}_t^L \right). \]

To prove the decomposition shown by (4.6), (4.7) and (4.8), observe that for any \( i \in \mathcal{N}^t \) and \( l \in \mathcal{L} \), we have

\[ \sum_{i=1}^{N^t} (x^i) \top Q_l x^i = \sum_{i=1}^{N^t} \left[ (\ddot{x}_t) \top Q_l \ddot{x}_t^i + |\mathcal{N}^t| \cdot (\dot{x}_t) \top Q_l \dot{x}_t^i \right]. \]

Similar relationship holds for \( R_l^i \) as well. By direct computation, we conclude that

\[ c_{gt} (x_t, u_t) = \ddot{x}_t^\top(Q + \ddot{Q})\ddot{x}_t + \dot{u}_t^\top(R + \ddot{R})\dot{u}_t + \sum_{l \in \mathcal{L}} \sum_{i \in \mathcal{N}^t} \left[ (\ddot{x}_t) \top Q_l \ddot{x}_t^i + (\dot{u}_t) \top R_l \dot{u}_t^i \right]. \]  

After replacing individual states \( \{x_i^t\}_{i \in \mathcal{N}^t} \) in \( x_t \) with \( \ddot{x}_t^i \), and similarly for actions, as is shown in (3.5), we have

\[ c_{gt}(\ddot{x}_t^l, \dot{u}_t^l) = \ddot{x}_t^\top(Q + \ddot{Q})\ddot{x}_t + \dot{u}_t^\top(R + \ddot{R})\dot{u}_t + \sum_{k \in \mathcal{L}, k \neq l} \sum_{i \in \mathcal{N}^t} \left[ (\ddot{x}_t^i) \top Q_k \ddot{x}_t^i + (\dot{u}_t^i) \top R_k \dot{u}_t^i \right]. \]

Therefore, we have

\[ c^l = c_{gt}(x_t, u_t) - c_{gt}(\ddot{x}_t^l, \dot{u}_t^l) = \sum_{i \in \mathcal{N}^t} \left[ (\ddot{x}_t^i) \top Q_l \ddot{x}_t^i + (\dot{u}_t^i) \top R_l \dot{u}_t^i \right] \]  

and \( c^l(\ddot{x}_t^l, \dot{u}_t^l) \) only depends on coordinates in \( \mathcal{S}_t \), which shows (4.6).

After replacing all individual states and actions with the corresponding mean fields, as is shown in (3.3), the last term in (5.5) vanishes, and we have

\[ \ddot{c} = c_{gt}(\ddot{x}_t, \dot{u}_t) = \ddot{x}_t^\top(Q + \ddot{Q})\ddot{x}_t + \dot{u}_t^\top(R + \ddot{R})\dot{u}_t. \]  

Thus \( \ddot{c} = \ddot{c}(\ddot{x}_t, \dot{u}_t) \) only depends on the mean-fields \( \ddot{x}_t \) and \( \dot{u}_t \). This shows (4.7). Finally, (4.8) follows directly from (5.6) and (5.7).
5.3 Proof of Proposition 4.4

By direct computation, we have

\[
C(K) = \lim_{T \to \infty} \mathbb{E}_{x_0 \sim D_0, u_t \sim \pi_K(\cdot|x_t)} \left[ \frac{1}{T} \sum_{t=0}^{T-1} c_{gt} (x_t, u_t) \right]
\]

\[
= \lim_{T \to \infty} \mathbb{E}_{x_0 \sim D_0, u_t \sim \pi_K(\cdot|x_t)} \left[ \frac{1}{T} \sum_{t=0}^{T-1} \bar{c} (x_t, u_t) + \frac{1}{T} \sum_{t=0}^{T-1} \sum_{l \in L} \sum_{i \in N^l} \bar{c} \left( \tilde{x}_t, \tilde{u}_t \right) \right]
\]

\[
+ \sum_{l \in L} \sum_{i \in N^l} \mathbb{E}_{x_0 \sim D_0, \bar{u}_t \sim \pi_{K_l}(\cdot|x_t)} \left[ \frac{1}{T} \sum_{t=0}^{T-1} \tilde{c} \left( \tilde{x}_t, \tilde{u}_t \right) \right].
\]

\[
=: \bar{C}(K) + \sum_{l \in L} \bar{C}(K_l).
\]

5.4 Proof of Lemma 4.11

Lemma C.1 shows that

\[
C(K) = \text{Tr} (P_K \Phi) + \sigma^2 \cdot \text{Tr}(R) = \mathbb{E}_{x \sim \mathcal{N}(0, \Phi)} (x^\top P_K x) + \sigma^2 \cdot \text{Tr}(R).
\]

Let \(x^*\) and \(u^*\) denote the states and actions induced by \(K^*\), respectively. Lemma C.2 then gives us

\[
C(K) - C(K^*) = -\mathbb{E}_{x \sim \mathcal{N}(0, \Phi)} \sum_{t \geq 0} A_{K, K^*} (x_t^*) \leq \text{Tr} \left[ \Sigma_{K^*} E_K^\top (R + B^\top P_K B)^{-1} E_K \right].
\] (5.8)

Since \(R + B^\top P_K B \succeq R\), we have

\[
\text{Tr} \left[ \Sigma_{K^*} E_K^\top (R + B^\top P_K B)^{-1} E_K \right] \leq \| \Sigma_{K^*} \| \cdot \| (R + B^\top P_K B)^{-1} \| \cdot \text{Tr} (E_K^\top E_K)
\]

\[
\leq \frac{\| \Sigma_{K^*} \|}{\sigma_{\text{min}}(R)} \text{Tr} (E_K^\top E_K),
\]

which completes the upper bound proof.

Next, we establish a lower bound. Since the policy \(K' := K - (R + B^\top P_K B)^{-1} E_K\) attains the equality in (5.8), we have

\[
C(K) - C(K^*) \geq C(K) - C(K')
\]
\[
\begin{align*}
&= -\mathbb{E}_{x \sim N(0, \Psi_\sigma)} \sum_{t \geq 0} A_{K, K'} (x_t') \\
&= \text{Tr} \left[ \Sigma_{K'} E_{K}^T (R + B^T P_K B)^{-1} E_K \right] \\
&\geq \sigma_{\text{min}}(\Phi) \cdot \| R + B^T P_K B \|^{-1} \cdot \text{Tr} \left( E_{K}^T E_K \right).
\end{align*}
\]

This completes the proof.

### 5.5 Proof of Lemma 4.12

We first make the induction assumption \( C(K_n) \leq C(K_0) \). Applying Lemma C.2 to policies \( K_n \) and \( K'_{n+1} = K_n - \eta \cdot E_{K_n} \), we have

\[
C \left( K'_{n+1} \right) - C \left( K_n \right) \\
= -2\eta \cdot \text{Tr} \left( \Sigma_{K'_{n+1}} \cdot E_{K_n}^T E_{K_n} \right) + \eta^2 \cdot \text{Tr} \left[ \Sigma_{K'_{n+1}} \cdot E_{K_n}^T (R + B^T P_K B) E_K \right] \\
\leq -2\eta \cdot \text{Tr} \left( \Sigma_{K'_{n+1}} \cdot E_{K_n}^T E_{K_n} \right) + \eta^2 \cdot \| R + B^T P_K B \| \cdot \text{Tr} \left( \Sigma_{K'_{n+1}} \cdot E_{K_n}^T E_{K_n} \right). \tag{5.9}
\]

Note that we also have

\[
\text{Tr} \left[ \Sigma_{K'_{n+1}} \cdot E_{K_n}^T (R + B^T P_K B) E_{K_n} \right] \leq \| R + B^T P_K B \| \cdot \text{Tr} \left( \Sigma_{K'_{n+1}} \cdot E_{K_n}^T E_{K_n} \right). \tag{5.10}
\]

Furthermore by Lemma C.4 and the induction assumption \( C(K_n) \leq C(K_0) \), we have

\[
\| R + B^T P_K B \| \leq \| R \| + \| B \|^2 \cdot \| P_K \| \leq \| R \| + \sigma_{\text{min}}^{-1}(\Phi) \cdot \| B \|^2 \cdot C \left( K_0 \right).
\]

Since the step size \( \eta \) satisfies \( \eta \leq \left[ \| R \| + \sigma_{\text{min}}^{-1}(\Phi) \cdot \| B \|^2 \cdot C \left( K_0 \right) \right]^{-1} \), combining (5.9) and (5.10), we conclude

\[
C \left( K'_{n+1} \right) - C \left( K_n \right) \leq -\eta \cdot \text{Tr} \left( \Sigma_{K'_{n+1}} \cdot E_{K_n}^T E_{K_n} \right) \leq -\eta \cdot \sigma_{\text{min}}(\Phi) \cdot \text{Tr} \left( E_{K_n}^T E_{K_n} \right), \tag{5.11}
\]

where we use the fact that \( \Sigma_{K'_{n+1}} \succeq \Phi \). Combining (5.11) and (4.17) in Lemma 4.11, we conclude (4.18). Then (4.19) follows directly by adding \( C(K_n) - C(K^*) \) to both sides of (4.18). Thus, we concludes the proof.

### 5.6 Proof of Lemma 4.13

We will use Lemma C.3 in the proof. We first show that its condition (C.15) holds, which is equivalent to

\[
4 \left( 1 + \| A - B K'_{n+1} \| \right) \cdot \| B \| \cdot \| \Sigma_{K'_{n+1}} \| \cdot \| K_{n+1} - K'_{n+1} \| \leq \sigma_{\text{min}}(\Phi). \tag{5.12}
\]

24
By direct computation, we have
\[ \|A - BK'_{n+1}\| \leq \|A - BK_n\| + \eta \cdot \|B\| \cdot \|E_{K_n}\|. \] (5.13)

In the following, we bound \(\|E_{K_n}\|\) and \(\|\Sigma_{K_{n+1}}\|\) with problem parameters. For \(\|E_{K_n}\|\), we have
\[
\|E_{K_n}\| = \|(R + B^TP_nB)K_n - B^TP_nA\|
\leq \|R + B^TP_nB\| \cdot \|K_n\| + \|B^T\| \cdot \|P_n\| \cdot \|A\|
\leq \left(\|R\| + \|B\|^2 \cdot \frac{C(K_0)}{\sigma_{\min}(\Phi)}\right) \cdot \|K_n\| + \|B\| \cdot \|A\| \cdot \frac{C(K_0)}{\sigma_{\min}(\Phi)},
\] (5.14)

where in the last inequality we have used Lemma C.4 and the induction assumption. For \(\|\Sigma_{K_{n+1}}\|\), by Lemma C.4 again and the induction assumption again, we have
\[
\|\Sigma_{K_{n+1}}\| \leq \frac{C(K'_{n+1})}{\sigma_{\min}(Q)} \leq \frac{C(K_0)}{\sigma_{\min}(Q)}.
\] (5.15)

Furthermore, with Assumption 4.8, we can bound \(\|K_{n+1} - K'_{n+1}\|\) as
\[
\|K_{n+1} - K'_{n+1}\| = \eta \|\widehat{E}_{K_n} - E_{K_n}\| \leq \eta \cdot \delta_n.
\] (5.16)

Combining (5.13), (5.14), (5.15) and (5.16), we conclude that
\[
4 \left(1 + \|A - BK'_{n+1}\|\right) \cdot \|B\| \cdot \|\Sigma_{K_{n+1}}\| \cdot \|K_{n+1} - K'_{n+1}\| \leq \Lambda_1(\|K_n\|, C(K_0)) \cdot \delta_n,
\] (5.17)

where \(\Lambda_1(\cdot, \cdot)\) is a polynomial of \(\|K_n\|\) and \(C(K_0)\). Here we regard \(A\), \(B\) and \(K_0\) as fixed parameters. Under the assumptions, \(\delta_n\) satisfies
\[
0 < \delta_n \leq \sigma_{\min}(\Phi) \cdot 1/\Lambda_1(\|K_n\|, C(K_0)),
\] (5.18)

and, therefore, the condition (5.12) holds. Then by Lemma C.3, we have
\[
\|C(K_{n+1}) - C(K'_{n+1})\| \leq 6 \left(\|\Phi\| \cdot \sigma^2 \cdot \|B\|^2 \cdot \sigma_{\min}(\Phi) \cdot \|\Sigma_{K_{n+1}}\| \cdot \|K'_{n+1}\| \cdot \|R\|
\cdot \|K'_{n+1}\| \cdot \|B\| \cdot \|A - BK'_{n+1}\| + \|K'_{n+1}\| \cdot \|B\| + 1\right) \cdot \|K_{n+1} - K'_{n+1}\|.
\] (5.19)

Note that we can further bound \(\|K'_{n+1}\|\) by
\[
\|K'_{n+1}\| = \|K_n - \eta \cdot E_{K_n}\| \leq \|K_n\| + \eta \cdot \|E_{K_n}\|.
\] (5.20)
Combining (5.13), (5.14), (5.16), (5.19) and (5.20), we conclude that

\[ |C(K_{n+1}) - C(K'_{n+1})| \leq \Lambda_2(\|K_n\|, C(K_0)) \cdot \delta_n \]  

(5.21)

where \( \Lambda_2(\|K_n\|, C(K_0)) \) is a polynomial of \( \|K_n\| \) and \( C(K_0) \). Again, here we regard \( A, B, R, K_0, \Phi \) and \( \sigma^2 \) as fixed parameters. Under the assumptions on \( \delta_n \), we have

\[ 0 < \delta_n \leq \frac{\epsilon}{2} \cdot \eta \cdot \sigma_{\text{min}}(\Phi) \cdot \sigma_{\text{min}}(R) \cdot \|\Sigma_{K^*}\|^{-1} \cdot 1/\Lambda_2(\|K_n\|, C(K_0)), \]  

(5.22)

and, hence,

\[ |C(K_{n+1}) - C(K'_{n+1})| \leq \frac{\epsilon}{2} \cdot \eta \cdot \sigma_{\text{min}}(\Phi) \cdot \sigma_{\text{min}}(R) \cdot \|\Sigma_{K^*}\|^{-1}. \]  

This concludes the proof.

A Policy Evaluation Algorithm

For completeness, we introduce a policy evaluation algorithm based on gradient-based temporal difference learning (Algorithm 2 in Yang et al. (2019)) that can be implemented in Algorithm 2.

In the LQR setting, the state- and action-value functions of policy $\pi_K$ take respectively the forms

$$V_K(x) = \sum_{t=0}^{\infty} \{ \mathbb{E} [c(x_t, u_t) | x_0 = x] - C(K) \}, \quad Q_K(x, u) = c(x, u) - C(K) + \mathbb{E}_{x'} [V_K(x')] ,$$

(A.1)

where $\{(x_t, u_t)\}_{t \geq 0}$ is the sequence of state-action pairs generated by policy $\pi_K$ with initial state $x_0 = x$. Here we use $x'$ to denote the next state generated by $(x, u)$, i.e. $x' = Ax + Bu + w$, where the noise $w \sim N(0, \Phi)$ for some positive definite matrix $\Phi$.

The following lemma establishes functional forms of the state- and action-value functions.

**Lemma A.1.** The state and action value functions (A.1) are given respectively by

$$V_K(x) = x^\top P_K x - \text{tr} (P_K \Sigma_K) ,$$

(A.2)

$$Q_K(x, u) = \varphi(v)^\top \delta^*_K - \sigma^2 \cdot \text{Tr}(R + P_K BB^\top) - \text{Tr}(P_K \Sigma_K) ,$$

(A.3)

where $v = \text{vec}(x, u)$ and $\varphi(v) = \text{svec}(vu^\top)$. The vector $\delta^*_K$ is called value vector and is related to matrices $A, B, Q, R$ and matrix $P_K$ defined in Lemma C.1. Moreover, $E_K$ can be recovered with $\delta^*_K$ and $K$. The explicit form of $\delta^*_K$ is given in the proof in §B.1.

By Lemma A.1, estimating action-value function $Q_K(x, u)$ is equivalent to estimating $\delta^*_K$ and thus gives estimator of $E_K$ as we desired.

Lemma C.5 tells us that $v = [x^\top, u^\top]^\top \sim N(0, \tilde{\Sigma}_K)$ is a Markov chain. Hereafter we use $c(v)$ to denote $c(x, u)$. Similar notations are also used for other functions.

Note that $V_K(x) = \mathbb{E}_{v \sim \pi_K(\cdot | x)} [Q_K(v)]$, which indicates that for any $v \in \mathbb{R}^{d+2}$, we have

$$\langle \varphi(v), \delta^*_K \rangle = c(v) - C(K) + \langle \mathbb{E}_{\varphi(v')} \varphi(v') , \delta^*_K \rangle ,$$

(A.4)

where $v' = \text{vec}(x', u')$ is the next state-action pair generated by $v = \text{vec}(x, u)$. Denote the expectation with respect to $v \sim N(0, \tilde{\Sigma}_K)$ by $\mathbb{E}_{v}$. We let

$$b_k = (C(K) d_K)^\top , \quad \Theta_K = \mathbb{E}_v \left\{ \varphi(v) [\varphi(v) - \varphi(v')]^\top \right\} , \quad \text{and} \quad d_K = \mathbb{E}_{v} [c(v) \varphi(v)] .$$

We also let $\gamma_K = (C(K), \delta^*_K)^\top$. It is shown in Yang et al. (2019) that $(\gamma_K^*, 0)^\top$ is the unique saddle point to the minimax optimization problem:

$$\min_{\gamma \in \mathcal{A}_T} \max_{\xi \in \mathcal{A}_\Xi} G(\gamma, \xi) = [\gamma^1 - C(K)] \cdot \xi^1 + \langle \gamma^1 \cdot \mathbb{E}_{v} [\varphi(v)] + \Theta_K \gamma^2 - d_K, \xi^2 \rangle - 1/2 \cdot \|\xi\|_2^2 ,$$

(A.5)
Algorithm 3 Gradient-Based Temporal-Difference (Algorithm 2 in Yang et al. (2019))

Input: Current policy $\pi_K$, number of iterations $T$, and step sizes $\{\alpha_t = \alpha/\sqrt{t}\}_{t \in \{1, 2, \ldots, T\}}$.

Initialization: Initialize $\gamma_0 \in \mathcal{X}_T$ and $\xi_0 \in \mathcal{X}_\Xi$. Sample the initial state-action pairs $x_0 \sim \mathcal{D}_K$, $u_0 \sim \pi_K (\cdot | x_0)$, and construct $v_0$. Observe the cost $c_0$ and the next state $x_1$.

for $t = 1, 2, \ldots, T$ do

Take action $u_t \sim \pi_K (\cdot | x_t)$, set $v_t = \text{vec}(x_t, u_t)$, observe the cost $c_t$ and the next state $x_{t+1}$.

Update primal-dual parameters $\gamma_{t-1}$ and $\xi_{t-1}$ with gradient decent to obtain $\gamma_t$ and $\xi_t$.

Project $\gamma_t$ and $\xi_t$ to $\mathcal{X}_T$ and $\mathcal{X}_\Xi$.

end for

Obtain $\hat{\gamma} = (\hat{\gamma}^1, \hat{\gamma}^2) = (\sum_{t=1}^{T} \alpha_t \cdot \gamma_t)/(\sum_{t=1}^{T} \alpha_t)$ and $\hat{\xi} = (\sum_{t=1}^{T} \alpha_t \cdot \xi_t)/(\sum_{t=1}^{T} \alpha_t)$.

Output: Estimators $\hat{C} = \hat{\gamma}^1$ of cost $C(K)$ and $\hat{\delta}_K = \hat{\gamma}^2$ of $\delta_K$.

where $\mathcal{X}_T$ and $\mathcal{X}_\Xi$ are compact sets and $\gamma = (\gamma^1, \gamma^2)$ and $\xi = (\xi^1, \xi^2)$ are primal and dual variables.

We solve (A.5) with stochastic gradient method, and return $\hat{\delta}_K = \hat{\gamma}^2$ as the estimator of $\delta_K$. Algorithm 3 details the Gradient-Based Temporal Difference (GTD) Algorithm.

To present the theoretical result of the policy evaluation algorithm using GTD, we make the following assumptions. First, we specify the compact sets $\mathcal{X}_T$ and $\mathcal{X}_\Xi$ defined in (A.5) to be

$$
\mathcal{X}_T = \{\gamma : 0 \leq \gamma^1 \leq \Gamma^1, \|\gamma^2\|_2 \leq \Gamma^2\},
$$

$$
\mathcal{X}_\Xi = \{\xi : 0 \leq |\xi^1| \leq \Xi^1 = C(K_0), \|\xi^2\|_2 \leq \Xi^2\},
$$

where $\Gamma^1 = C(K_0)$, $\Gamma^2 = \|Q\|_F + \|R\|_F + \sqrt{d}/\sigma_{\min}(\Phi) \cdot (\|A\|_F^2 + \|B\|_F^2) \cdot C(K_0)$, $\Xi^1 = C(K_0)$, and $\Xi^2 = C \cdot (1 + \|K\|_F^2) \cdot \Gamma^2 \cdot \sigma_{\min}^2(Q) \cdot |C(K_0)|^2$. Here $C$ is a constant that does not depend on $K$. Moreover, we set the step size in Algorithm 3 to be $\alpha_t = \alpha/\sqrt{t}$.

Theorem A.2 (Policy evaluation algorithm using GTD). Let initial policy $\pi_{K_0}$ be stable in the sense that $\rho(A - BK_0) < 1$. Let $\mathcal{X}_T$ and $\mathcal{X}_\Xi$ be compact sets specified in (A.6). For any $\rho \in (\rho(A - BK), 1)$, there exists sufficiently large iteration number $T$, so that with probability at least $1 - T^{-4}$, we have

$$
\|\hat{\delta}_K - \delta_K\|_2^2 \leq \Lambda (\Gamma^2, \Xi^2, C(K_0), \|K\|_F, \Sigma_K, \sigma_{\min}^{-1}(Q)) \cdot \frac{\log^6 T}{(1 - \rho)\tau_K^2 \sqrt{T}},
$$

where $\Lambda$ is a polynomial of $\Gamma^2$, $\Xi^2$, $C(K_0)$, $\|K\|_F$, $\Sigma_K$ and $\sigma_{\min}^{-1}(Q)$, and constant $\tau_K > 0$ solely depends on $\rho(A - BK)$, $\sigma$, and $\sigma_{\min}(\Phi)$.
A.1 Proof Sketch of Theorem A.2

We will use Lemma D.3 to establish the result. We start by verifying the conditions of Lemma D.3.

The following lemma shows that \((\gamma^*_K, 0)\) is the solution to the optimization problem (A.5).

**Lemma A.3.** It holds that \(\gamma^*_K \in \mathcal{X}_T\). Let \(\xi(\gamma)\) be the solution to the unconstrained problem \(\max_\xi G(\gamma, \xi)\). Then for any \(\gamma \in \mathcal{X}_T\), we have \(\xi(\gamma) \in \mathcal{X}_\xi\).

**Proof.** See §B.2 for a detailed proof.

For fixed values \(\hat{\gamma} \in \Gamma\) and \(\hat{\xi} \in \Xi\), we let

\[
G_{\hat{\gamma}} = \max_{\xi \in \Xi} G(\hat{\gamma}, \xi), \quad G_{\hat{\xi}} = \min_{\gamma \in \Gamma} G(\gamma, \hat{\xi}),
\]

and the primal-dual gap with respect to \(\hat{\gamma}\) and \(\hat{\xi}\) is defined as \(G_{\hat{\gamma}} - G_{\hat{\xi}}\), which measures the closeness between \((\hat{\gamma}, \hat{\xi})\) and the saddle point \((\delta^*_K, 0)\). The rate of convergence of estimators obtained by the primal-dual problem (A.5) is controlled by the primal-dual gap \(G_{\hat{\gamma}} - G_{\hat{\xi}}\) as shown by the following lemma.

**Lemma A.4.** It holds that

\[
\tau^2_K \left( |\gamma_1 - C(K)|^2 + \|\tilde{\delta}_K - \delta^*_K\|_2^2 \right) \leq G_{\hat{\gamma}} - G_{\hat{\xi}}, \tag{A.9}
\]

where \(\tau^*_K > 0\) is a constant that depends only on \(\rho(A - BK), \sigma\), and \(\sigma_{\text{min}}(\Phi)\).

**Proof.** See §B.3 for a detailed proof.

Next, we construct an upper bound on \(G_{\hat{\gamma}} - G_{\hat{\xi}}\). For technical reasons, it is convenient to consider the case where \(\|v_t\|^2 = \|x_t\|^2 + \|u_t\|^2\) is bounded by some value that depends on \(T\), for \(0 \leq t \leq T\). This will guarantee better Lipschitz properties of \(G(\gamma, \xi)\) and thus enable us to bound the primal-dual gap. We use the following lemma to characterize the tail distribution of \(v\).

**Lemma A.5.** Consider the event

\[
\mathcal{A} = \left\{ \|v\|_2^2 - \text{Tr} \left( \Sigma_K \right) \leq C' \cdot \log T \cdot \|\hat{\Sigma}_K\| \right\},
\]

where \(v \sim N(0, \hat{\Sigma}_K)\) and \(\hat{\Sigma}_K\) is defined in Lemma C.5. We have \(\mathbb{P}(\mathcal{A}^c) \leq T^{-6}\) when \(C'\) is large enough.

**Proof.** See §B.4 for a detailed proof.
Hereafter we consider the optimization problem in (A.5) conditioned on event $A$ defined in Lemma A.5. Define the truncated feature vector by $\tilde{\varphi}(v) = \varphi(v) \cdot 1_A$. Let $\tilde{\Theta}_K$ and $\tilde{d}_K$ be defined as $\Theta_K$ and $d_K$, but with $\varphi(v)$ and $\varphi(v')$ replaced with $\tilde{\varphi}(v)$ and $\tilde{\varphi}(v')$, respectively. Consider the new optimization problem

$$\min_{\gamma \in \mathcal{X}_T} \max_{\xi \in \mathcal{X}_T} \bar{G}(\gamma, \xi) = [\gamma^1 - C(K)] \cdot \xi^1 + \left\langle \gamma^1 \cdot \mathbb{E}_v[\tilde{\varphi}(v)] + \tilde{\Theta}_K \gamma^2 - \tilde{d}_K, \xi^2 \right\rangle - 1/2 \cdot \|\xi\|^2_2.$$  

(A.10)

For sufficiently large $T$, the objectives in (A.5) and (A.10) are close.

**Lemma A.6.** When $T$ is sufficiently large, it holds that

$$|G(\gamma, \xi) - \bar{G}(\gamma, \xi)| \leq \frac{1}{T}$$

(A.11)

for any $\gamma \in \mathcal{X}_T$, $\xi \in \mathcal{X}_T$.

*Proof.* See §B.5 for a detailed proof.

A direct corollary is that the difference of primal-dual gaps between optimization problems (A.5) and (A.10) can be bounded as

$$|(G_{\tilde{\gamma}} - G_\gamma) - (\tilde{G}_{\tilde{\gamma}} - \tilde{G}_\gamma)| \leq \frac{2}{T}. $$

(A.12)

The objective function of the truncated optimization problem (A.10) has good properties as characterized by the following lemma.

**Lemma A.7.** As a function of $\gamma$ and $\xi$, the norm of $\nabla \tilde{G}(\gamma, \xi)$ can be bounded by

$$3(\Gamma^2 + \Xi^2) \cdot (C' \cdot \log T + d + k)^2[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|^2] =: L_1,$$

(A.13)

for a sufficiently large $C'$. Thus, $\tilde{G}(\gamma, \xi)$ is Lipschitz for both $\gamma$ and $\xi$ with finite a constant $L_1$. Moreover, we have $\nabla^2_{\gamma\gamma} \tilde{G}(\gamma, \xi) = 0$ and $\nabla^2_{\xi\xi} \tilde{G}(\gamma, \xi) = -I$, where $I$ is the identity matrix of proper dimension.

*Proof.* See §B.6 for a detailed proof.

Finally, Lemma C.5 shows that $\{v_t\}_{t \geq 0}$ is a geometrically $\beta$-mixing stochastic process with a parameter $\rho \in (\rho(A - BK), 1)$ and thus mixes rapidly. Therefore, we have verified the conditions of Lemma D.3, which gives an upper bound on the primal-dual gap in (A.10). We have the following result.
Lemma A.8. When $T$ is sufficiently large, it holds with probability at least $1 - T^{-5}$ that
\[ \tilde{G}_{\gamma} - \tilde{G}_{\xi} \leq \Lambda_3 \frac{\log^2 T + \log(T^5)}{\log(1/\rho) \cdot \sqrt{T}} + \Lambda_4 \frac{\log^6 T}{(1 - \rho)T}, \] (A.14)
where $\Lambda_3$ and $\Lambda_4$ are polynomials of $\Gamma^2, \Xi^2, C(K_0), \|K\|_F, \Sigma_K$, and $\sigma_{\min}^{-1}(Q)$.

Proof. See §B.7 for a detailed proof. \qed

Recall that for the event $\mathcal{A}_t = \{\|v_t\|^2 - \text{Tr} \left( \tilde{\Sigma}_K \right) > C' \cdot \log T \cdot \|\tilde{\Sigma}_K\|\}$, we have $P(\mathcal{A}) \leq T^{-6}$ for $C_1$ large enough. Then the event $\bigcap_{t=1}^T \mathcal{A}_t$ holds with probability at least $1 - T^{-5}$.

Combining (A.14) and (A.12), it holds with probability at least $1 - 2T^{-5} > 1 - T^{-4}$ that the primal-dual gap of the original optimization problem A.5 can be bounded as
\[ G_{\gamma} - G_{\xi} \leq \Lambda_3 \frac{\log^2 T + \log(T^5)}{\log(1/\rho) \cdot \sqrt{T}} + \Lambda_4 \frac{\log^6 T}{(1 - \rho)T} + \frac{2}{T}. \] (A.15)
This concludes the proof.

The formula above is dominated by the first term on the right-hand side. Combining (A.15) and Lemma (A.9), we establish Theorem A.2.

\section{B Technical Proofs of Lemmas in §A.1}

\subsection{B.1 Proof of Lemma A.1}

Since the dynamic is linear, $V_K(x)$ has a quadratic form in $x$ specified as
\[ V_K(x) = \sum_{t=0}^{\infty} \{\mathbb{E} [c(x_t, u_t) | x_0 = x] - C(K)\} \]
\[ = \sum_{t=0}^{\infty} \{\mathbb{E} [x_t^T (Q + K^T R K) x_t] + \sigma^2 \cdot \text{Tr}(R) - C(K)\}. \] (B.1)
By definition, we have $E_{x \sim \mathcal{D}_K}[V_K(x)] = 0$, so $V_K(x) = x^T P_K x - E_{x \sim \mathcal{D}_K}[x^T P_K x]$, for some matrix $P_K \in \mathbb{R}^{d \times d}$. We also have
\[ V_K(x) = \mathbb{E}_{x' \sim \pi_K}[c(x, u)] - C(K) + \mathbb{E}_{x'}[V_K(x')], \] (B.2)
where $x'$ is the next state generated by $(x, u)$. Therefore, we find that $P_K$ is a solution to the equation
\[ x^T P_K x = x (Q + K^T R K) x + x^T (A - BK)^T P_K (A - BK)x \] (B.3)
and the functional form of $V_K(x)$ follows from computing
\[
\mathbb{E}_{x \sim D_K} [x^T P_K x] = \text{Tr} \left[ (Q + K^T R K) \Sigma_K \right] + \text{Tr} \left[ (A - BK)^T P_K (A - BK) \Sigma_K \right] \\
= \text{Tr} [P_K \Phi] + \text{Tr} \left[ P_K (A - BK) \Sigma_K (A - BK)^T \right] \\
= \text{Tr} \left( P_K \Sigma_K \right). \tag{B.4}
\]

Direct computation yields the functional form of $Q_K(x, u)$:
\[
Q_K(x, u) = c(x, u) - C(K) + \mathbb{E}_{x'} [V_K(x') | x] \\
= x^T Q x + u^T R u + (Ax + Bu)^T P_K (Ax + Bu) + \text{Tr} (P_K \Phi) - C(K) - \text{Tr} (P_K \Sigma_K) \\
= v^T \Delta_K v - \sigma^2 \text{Tr} (P + P_K BB^T) - \text{Tr} (P_K \Sigma_K), \tag{B.5}
\]
where the last equation follows from (4.13), $\Phi\sigma = \Phi + \sigma^2 \cdot BB^T$, and the matrix $\Delta_K$ is given by
\[
\Delta_K = \begin{pmatrix}
\Delta_{11}^K & \Delta_{12}^K \\
\Delta_{21}^K & \Delta_{22}^K
\end{pmatrix} = \begin{pmatrix}
Q + A^T P_K A & A^T P_K B \\
B^T P_K A & R + B^T P_K B
\end{pmatrix} \tag{B.6}
\]
We define $\delta^*_K = \text{svec}(\Delta_K)$. Then $\Delta_K$ can be recovered by $\Delta_K = \text{smat}(\delta^*_K)$. We can check that $E_K = \Delta_{22}^K K - \Delta_{21}^K$, thus estimating $\delta^*_K$ is equivalent to estimating $E_K$.

### B.2 Proof of Lemma A.3

To prove $\gamma^*_K \in \mathcal{X}_\Gamma$, we just need to show $\|\delta^*_K\|_2 = \|\Delta_K\|_F \leq \Gamma^2$. Note that we have
\[
\Delta_K = \begin{pmatrix}
Q + A^T P_K A & A^T P_K B \\
B^T P_K A & R + B^T P_K B
\end{pmatrix} = \text{diag}(Q, R) + (A B)^T P_K (A B). \tag{B.7}
\]
We have $\|\Delta_K\|_F \leq \Gamma^2 \leq \|Q\|_F + \|R\|_F + (\|A\|^2_F + \|B\|^2_F) \cdot \|P_K\|_F$. From Lemma C.4, we have $\|P_K\| \leq C(K)/\sigma_{\text{min}}(\Phi)$. Therefore, it holds that
\[
\|P_K\|_F \leq \sqrt{d}/\sigma_{\text{min}}(\Phi) \cdot C(K) \leq \sqrt{d}/\sigma_{\text{min}}(\Phi) \cdot C(K_0).
\]
Hence we conclude
\[
\|\Delta_K\| \leq \Gamma^2 \leq \|Q\|_F + \|R\|_F + (\|A\|^2_F + \|B\|^2_F) \cdot \|P_K\|_F \\
\leq \|Q\|_F + \|R\|_F + (\|A\|^2_F + \|B\|^2_F) \cdot \sqrt{d}/\sigma_{\text{min}}(\Phi) \cdot C(K_0), \tag{B.8}
\]
and thus we have $\gamma^*_K \in \mathcal{X}_\Gamma$.

To prove the second statement, observe that $\xi(\gamma)$ has components
\[
\xi(\gamma)^1 = \gamma^1 - C(K), \\
\xi(\gamma)^2 = \gamma^1 \cdot \mathbb{E}_v [\varphi(v)] + \Theta_K \gamma^2 - d_K.
\]
We bound $|\gamma^1 - C(K)|$, $\|\gamma^1 \cdot E(x,u)[\varphi(v)]\|_2$, $\|\Theta K \gamma^2\|_2$ and $\|d_K\|_2$ separately. From the fact that $0 \leq \gamma^1 \leq \Gamma^1 = C(K_0)$, we have $|\gamma^1 - C(K)| \leq C(K_0)$ and $0 \leq |\xi^1| \leq \Xi^1$. From Lemma C.5, we have

$$\|\gamma^1 \cdot E_v[\varphi(x,u)]\|_2 \leq C(K_0)\|\tilde{\Sigma}_K\|_F \leq C(K_0) [k\sigma^2 + (d + \|K\|_F^2) \cdot \|\Sigma_K\|] \cdot$$  

(B.9)

From Lemma D.2, we have $\|\Theta K \gamma^2\|_2 \leq \|\Theta K\|\|\gamma^2\|_2 \leq 4 (1 + \|K\|_F^2) \cdot \|\Sigma_K\| \cdot \Gamma^2$. To bound $\|d_K\|_2$, note that for any positive definite matrix $\Sigma'$, we can rewrite $d_K^T \text{svec}(\Sigma')$ by

$$d_K^T \text{svec}(\Sigma') = E_v \{ \langle \phi(v), \text{smat}([\text{diag}(Q,R)]) \rangle \cdot \langle \phi(v), \text{smat}(\Gamma) \rangle \}
= 2 \left( \tilde{\Sigma}_K \text{diag}(Q,R) \tilde{\Sigma}_K \right) \cdot \left( \tilde{\Sigma}_K, \text{diag}(Q,R) \right) \cdot \left( \tilde{\Sigma}_K, \Gamma \right),$$  

(B.10)

where the second equation follows from Lemma D.5 and $\tilde{\Sigma}_K$ is defined in Lemma C.5. Thus we conclude $\|d_K\|_2 \leq 3 (\|Q\|_F + \|R\|_F) \cdot \|\tilde{\Sigma}_K\|_2^2$. Combining the bounds above and (5.14), we conclude that

$$\|\xi^2\|_2 \leq C(K_0) \left[ k\sigma^2 + (d + \|K\|_F^2) \cdot \|\Sigma_K\| \right] + 4 (1 + \|K\|_F^2)^2 \cdot \|\Sigma_K\| \cdot \Gamma^2 + 12 \left( \|Q\|_F + \|R\|_F \right) \cdot \left( d + \|K\|_F^2 \right)^2 \cdot \|\Sigma_K\| \cdot \Gamma^2
\leq C \cdot (1 + \|K\|_F^2)^2 \cdot \Gamma^2 \cdot \sigma_{\min}(Q) \cdot [C(K_0)]^2$$  

(B.11)

for some constant $C$.

### B.3 Proof of Lemma A.4

Note that the optimal value of the dual problem satisfies

$$G_{\tilde{\gamma}} = \max_{\xi \in \Xi} G(\hat{\gamma}, \xi) = \|\hat{\gamma}^1 - C(K)\|^2 + \|\hat{\gamma}^1 \cdot E(x,u)[\varphi(x,u)] + \Theta_K \hat{\gamma}^2 - d_K\|_2^2 = \|\Omega_K \hat{\gamma} - b_K\|_2^2,$$

where we define

$$\Omega_K = \begin{pmatrix} 1 & 0 \\ E_v[\varphi(v)] & \Theta_K \end{pmatrix}, \quad \gamma^*_K = (C(K), \delta^*_K)^T.$$  

(B.13)

The optimal value of the primal problem satisfies

$$G_{\hat{\gamma}} = \min_{\gamma \in \mathcal{X}_r} G(\gamma, \hat{\xi}) \leq \min_{\gamma \in \mathcal{X}_r} G_{\tilde{\gamma}} = \min_{\gamma \in \mathcal{X}_r} \|\Omega_K \hat{\gamma} - b_K\|_2^2 = 0.$$  

(B.14)

39
Therefore \( \|\Omega_K(\hat{\gamma} - \gamma_K^*)\|^2 \leq G_{\hat{\gamma}} - G_{\hat{\xi}} \). Moreover, by Lemma D.2, we have \( \|\Omega_K\| \geq \tau_K^* > 0 \) for some constant \( \tau_K^* \) that only depends on \( \rho(A - BK), \sigma \), and \( \sigma_{\min}(\Phi) \). Hence we have

\[
(\tau_K^*)^2 \left( \|\gamma^1 - C(K)\|^2 + \|\tilde{\Delta}_K - \Delta_K\|^2_F \right) \leq \tau_K^* \|\hat{\gamma} - \gamma_K^*\|^2 \leq \|\Omega_K(\hat{\gamma} - \gamma_K^*)\|^2 \leq G_{\hat{\gamma}} - G_{\hat{\xi}}.
\]

(B.15)

### B.4 Proof of Lemma A.5

Set \( s = C' \cdot \log T \cdot \|\tilde{\Sigma}_K\| \) with \( C' \) sufficiently large so that \( s^2 \cdot \|\tilde{\Sigma}_K\|^{-2} \geq s \cdot \|\tilde{\Sigma}_K\|^{-1} \). Applying Lemma D.1 to \( v \sim N\left(0, \tilde{\Sigma}_K\right) \), we get

\[
\mathbb{P} \left[ \|v\|^2_2 - \text{Tr}(\tilde{\Sigma}_K) > s \right] \leq 2 \cdot \exp[-C \cdot \min(s^2 \cdot \|\tilde{\Sigma}_K\|^{-2}, s \cdot \|\tilde{\Sigma}_K\|^{-1})]
\]

\[
= 2 \cdot \exp[-C \cdot \|\tilde{\Sigma}_K\|^{-1} \cdot s]
\]

\[
= 2 \cdot \exp[-C \cdot C' \cdot \log T].
\]

(B.16)

When \( C' \) is sufficiently large, we have \( \mathbb{P}(A^c) \leq T^{-6} \).

### B.5 Proof of Lemma A.6

By direct computation, we have

\[
G(\gamma, \xi) - \tilde{G}(\gamma, \xi) = [\gamma^1 - \mathbb{E}_v[c(v)]] \cdot \xi^1 - [\gamma^1 - \mathbb{E}_v[c(v) \cdot 1_{A^c}] \cdot \xi^1
\]

\[
+ \left\langle \gamma^1 \cdot \mathbb{E}_v[\varphi(v)] + \Theta_K \gamma^2 - d_K, \xi^2 \right\rangle - \left\langle \gamma^1 \cdot \mathbb{E}_v[\varphi(v)] + \tilde{\Theta}_K \gamma^2 - \tilde{d}_K, \xi^2 \right\rangle
\]

\[
= \mathbb{E}_v [c(v) \cdot 1_{A^c}] \cdot \xi^1 - \left\langle \mathbb{E}_v \left[\varphi(v)\varphi(v')^T 1_A 1_{A^c}\right] \cdot \gamma^2, \xi^2 \right\rangle
\]

\[
+ \left\langle \mathbb{E}_v \left[\gamma^1 \cdot \varphi(v) 1_{A^c} + \varphi(v) \cdot \varphi(v')^T 1_A \gamma^2 - c(v) \varphi(v) 1_{A^c}\right], \xi^2 \right\rangle
\]

\[
= \mathbb{E}_v [c(v) \cdot 1_{A^c}] \cdot \xi^1 - \left\langle \mathbb{E}_v \left[\varphi(v)\varphi(v')^T 1_A 1_{A^c}\right] \cdot \gamma^2, \xi^2 \right\rangle
\]

\[
+ \left\langle \mathbb{E}_v \left[\varphi(v)[\gamma^1 - c(v) + \varphi(v)^T \gamma^2] 1_{A^c} - \varphi(v)\varphi(v')^T \gamma^2 1_{A^c}\right], \xi^2 \right\rangle
\]

(B.17)

and

\[
|G(\gamma, \xi) - \tilde{G}(\gamma, \xi)| \leq \mathbb{E}_v [c(v) \cdot 1_{A^c}] \cdot C'(K_0) + \left\| \mathbb{E}_v \left[\varphi(v)\varphi(v')^T 1_A 1_{A^c}\right] \cdot \gamma^2 \right\| \cdot \Xi^2
\]

\[
+ \left\| \mathbb{E}_v \left[\gamma^1 \cdot \varphi(v) 1_{A^c} + \varphi(v) \cdot \varphi(v')^T 1_A \gamma^2 - c(v) \varphi(v) 1_{A^c}\right] \right\| \cdot \Xi^2.
\]

(B.18)

We can bound each term on the right-hand side separately with

\[
\left( \mathbb{E}_v [c(v) \cdot 1_{A^c}] \right)^2 \cdot \mathbb{P}(A^c) \leq \mathbb{E} \left[ c^2(v) \right] \cdot \mathbb{P}(A^c) \leq \mathbb{P}(A^c) \leq T^{-6},
\]

(B.19)
\[
\| \mathbb{E}_v [\varphi(v)\varphi(v')^\top \mathbb{1}_{\mathcal{A}} \mathbb{1}_{\mathcal{A}^c}] \gamma^2 \| \leq (\mathbb{E}_v [\|\varphi(v)\varphi(v')^\top\|_2^2])^{\frac{1}{2}} \cdot \mathbb{P}(\mathcal{A}^c)^{\frac{1}{2}}, \tag{B.20}
\]

where
\[
\mathbb{E}_v [\|\varphi(v)\varphi(v')^\top\gamma^2\|_2^2] \leq \left( \mathbb{E} [\|\varphi(v')^\top\gamma^2\|^4] \cdot \mathbb{E} [\|\varphi(v)\|_2^4] \right)^{\frac{1}{2}}. \tag{B.21}
\]

Furthermore,
\[
\| \mathbb{E}_v [\varphi(v)[\gamma^1 - c(v) + \varphi(v)^\top\gamma^2] \mathbb{1}_{\mathcal{A}^c} - \varphi(v)\varphi(v')^\top\gamma^2 \mathbb{1}_{\mathcal{A}^c}] \|
\leq \left( \mathbb{E}_v [\|\varphi(v)[\gamma^1 - c(v) + \varphi(v)^\top\gamma^2] - \varphi(v)\varphi(v')^\top\gamma^2\|_2^2] \right)^{\frac{1}{2}} \cdot \mathbb{P}(\mathcal{A}^c)^{\frac{1}{2}}, \tag{B.22}
\]

where
\[
\mathbb{E}_v [\|\varphi(v)[\gamma^1 - c(v) + \varphi(v)^\top\gamma^2] - \varphi(v)\varphi(v')^\top\gamma^2\|_2^2]
\leq 2\mathbb{E}_v \left[ |\gamma^1 - c(v) + \varphi(v)^\top\gamma^2|^2 \|\varphi(v)\|^2 + \|\varphi(v)\varphi(v')^\top\gamma^2\|^2 \right]
\leq 2 \left( \mathbb{E}_v [|\gamma^1 - c(v) + \varphi(v)^\top\gamma^2|^4] \cdot \mathbb{E}_v [\|\varphi(v)\|^4] \right)^{\frac{1}{2}} + 2 \left( \mathbb{E}_v [\|\varphi(v')^\top\gamma^2\|^4] \cdot \mathbb{E}_v [\|\varphi(v)\|_2^4] \right)^{\frac{1}{2}}. \tag{B.23}
\]

Note that (B.21) and (B.23) can be bounded by the fourth moments of \(N \left( 0, \tilde{\Sigma}_K \right)\). Since \(P(\mathcal{A}^c) \leq T^{-6}\), when \(T\) is sufficiently large, it holds that \(|G(\gamma, \xi) - \tilde{G}(\gamma, \xi)| \leq 1/T\).

### B.6 Proof of Lemma A.7

By direct computation, we have
\[
\nabla_{\gamma} G(\gamma, \xi) = \xi^1 + \mathbb{E}_v [\tilde{\varphi}(v)^\top] \xi^2, \tag{B.24}
\]
\[
\nabla_{\gamma^2} G(\gamma, \xi) = \mathbb{E}_v [\tilde{\varphi}(v)^\top \xi^2 \cdot [\tilde{\varphi}(v) - \tilde{\varphi}(v')]], \tag{B.25}
\]
\[
\nabla_{\xi^1} G(\gamma, \xi) = \gamma^1 - \mathbb{E}_v [\tilde{c}(v)] - \xi^1, \tag{B.26}
\]
\[
\nabla_{\xi^2} G(\gamma, \xi) = \mathbb{E}_v \left[ \gamma^1 \tilde{\varphi}(v) + \tilde{\varphi}(v)(\tilde{\varphi}(v) - \tilde{\varphi}(v'))^\top \gamma^2 - \tilde{c}(v)\tilde{\varphi}(v) \right] - \xi^2. \tag{B.27}
\]

By definition, we have the bound
\[
\|\tilde{\varphi}(v)\|_2 \leq C' \cdot \log T \cdot \|\tilde{\Sigma}_K\| + \text{Tr}(\tilde{\Sigma}_K)
\leq (C' \cdot \log T + d + k)\|\tilde{\Sigma}_K\|
\leq (C' \cdot \log T + d + k)[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|], \tag{B.28}
\]

where the last inequality follows from (C.30). The same bound holds for \(\|\tilde{\varphi}(v')\|_2\).
Combining (B.28) and definitions of $\mathcal{X}_T$ and $\mathcal{X}_\Xi$, by direct computation, we have
\[
\|\nabla_\xi \tilde{G}(\gamma, \xi)\|_2 \leq C(K_0) + \|\tilde{\varphi}(v)\|_2 \cdot \|\xi\|_2 + \|\tilde{\varphi}(v)\|_2 \cdot \|\xi\|_2 \cdot \|\tilde{\varphi}(v) + \tilde{\varphi}(v')\|_2
\leq C(K_0) + \Xi^2 \cdot (C' \cdot \log T + d + k)[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|]
+ 2 \cdot \Xi^2 \cdot (C' \cdot \log T + d + k)[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|]^2.
\]  
(B.29)

Similarly, we have
\[
\|\nabla_\gamma \tilde{G}(\gamma, \xi)\|_2 \leq 2C(K_0) + C(K_0)(C' \cdot \log T + d + k)[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|]
+ 2 \cdot \Gamma^2 \cdot (C' \cdot \log T + d + k)[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|]^2.
\]  
(B.30)

Using that fact that $\sqrt{x+y} < x+y$ when $x > 0$ and $y > 0$, we have
\[
\|\nabla \tilde{G}(\gamma, \xi)\|_2 \leq \|\nabla_\gamma \tilde{G}(\gamma, \xi)\|_2 + \|\nabla_\xi \tilde{G}(\gamma, \xi)\|_2
\leq 3(\Gamma^2 + \Xi^2) \cdot (C' \cdot \log T + d + k)[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|]^2,
\]  
(B.31)

where $C_1$ is sufficiently large.

### B.7 Proof of Lemma A.8

We can further specify $L_1$, $L_2$, $D$ and $C_\zeta$. By Lemma A.7, we can set
\[
L_1 = 3(\Gamma^2 + \Xi^2) \cdot (C' \cdot \log T + d + k)[\sigma^2 + (1 + \|K\|_F^2)\|\Sigma_K\|]^2, \quad L_2 = 1.
\]  
(B.32)

By (A.6), we can set $D$ to be
\[
D = (2C(K_0)^2 + (\Gamma^2)^2 + (\Xi^2)^2)^{1/2}.
\]  
(B.33)

By Lemma C.5 and D.4, we can set
\[
C_\zeta = C_{\rho, \kappa} \cdot \left[\text{Tr} \left(\tilde{\Sigma}_K\right) + (d + k) \cdot (1 - \rho)^{-2}\right]^{1/2}.
\]  
(B.34)

Set $\delta = T^{-5}$ and note that $\log x < x + 1$ for $\forall x > 0$. We conclude that with probability at least $1 - T^{-5}$ the primal-dual gap conditioned on $\bigcap_{t=1}^T A_t$ is bounded by
\[
\tilde{G}_{\gamma'} - \tilde{G}_{\xi'} \leq \Lambda_3 \frac{\log^2 T + \log(T^5)}{\log(1/\rho) \cdot \sqrt{T}} + \Lambda_4 \frac{\log^6 T}{(1 - \rho)T},
\]  
(B.35)

when $T$ is sufficiently large, where $\Lambda_3$ and $\Lambda_4$ are polynomials of $\Gamma^2$, $\Xi^2$, $C(K_0)$, $\|K\|_F$, $\Sigma_K$, and $\sigma^{-1}_{\text{min}}(Q)$.  

42
Proof of Supporting Lemmas

In this section, we lay out the proofs of supporting lemmas.

**Lemma C.1.** Consider the LQR problem specified by

\[ x_{t+1} = Ax_t + Bu_t + \epsilon_t, \quad c(x_t, u_t) = x_t^\top Q x_t + u_t^\top R u_t, \]

where \( A, B, Q \) and \( R \) are matrices of proper dimensions, and noise \( \epsilon_t \sim N(0, \Phi) \), with matrices \( Q, R, \Phi \succ 0 \). Under policy \( \pi_K \) satisfying \( \rho(A - BK) < 1 \), action \( u_t \) is written as

\[ -Kx_t + \sigma \cdot z_t, \quad z_t \sim N(0, I_d). \]

By direct computation, the state dynamic is given by

\[ x_{t+1} = (A - BK)x_t + \epsilon_t, \quad \epsilon_t \sim N(0, \Phi_\sigma), \]

where \( \Phi_\sigma := \Phi + \sigma^2 \cdot BB^\top \). We denote by \( \Sigma_K \) the unique positive definite solution to the Lyapunov equation

\[ \Sigma_K = \Phi_\sigma + (A - BK)\Sigma_K(A - BK)^\top, \]

then (C.1) has stationary state distribution \( N(0; \Sigma_K) \). We further denote by \( P_K \) the unique positive definite solution to the Bellman equation

\[ P_K = (Q + K^\top RK) + (A - BK)^\top P_K(A - BK). \]

Then the corresponding time-average cost and its gradient under policy \( \pi_K \) are given respectively by

\[
\begin{align*}
C(K) &= \text{Tr} \left[ (Q + K^\top RK) \Sigma_K \right] + \sigma^2 \cdot \text{Tr}(R) = \text{Tr} \left( P_K \Phi_\sigma \right) + \sigma^2 \cdot \text{Tr}(R), \\
\nabla_K C(K) &= 2 \left[ (R + B^\top P_K B) K - B^\top P_K A \right] \Sigma_K = 2E_K \Sigma_K.
\end{align*}
\]

where we define \( E_K = (R + B^\top P_K B) K - B^\top P_K A. \)

*Proof.* For all \( t \geq 0 \), we have

\[
\begin{align*}
\mathbb{E} [c(x_t, u_t) | x_t] &= x_t^\top Q x_t + \mathbb{E}_{z_t \sim N(0, I_d)} \left[ (-Kx_t + \sigma \cdot z_t)^\top R (-Kx_t + \sigma \cdot z_t) \right] \\
 &= x_t^\top (Q + K^\top RK) x_t + \sigma^2 \cdot \text{Tr}(R).
\end{align*}
\]

Then the time-average cost is given by

\[
\begin{align*}
C(K) &= \mathbb{E}_{x_0 \sim D_K} \left[ x_0^\top (Q + K^\top RK) x_0 \right] + \sigma^2 \cdot \text{Tr}(R) \\
 &= \text{Tr} \left[ (Q + K^\top RK) \Sigma_K \right] + \sigma^2 \cdot \text{Tr}(R), \quad (C.8)
\end{align*}
\]
where \( \mathcal{D}_K \) is the stationary distribution of the Markov chain \( \{x_t\}_{t \geq 0} \).

To see why the second equation in (C.5) holds, consider operators \( \mathcal{T}_K \) and \( \mathcal{T}_K^\top \) defined by

\[
\mathcal{T}_K(X) = \sum_{t \geq 0} (A - BK)^t X [(A - BK)^t]^\top, \quad \mathcal{T}_K^\top(X) = \sum_{t \geq 0} [(A - BK)^t]^\top X (A - BK)^t,
\]

where \( X \) is a positive definite matrix of proper dimension. By direct computation, we have \( \operatorname{Tr} [X_1 \cdot \mathcal{T}_K (X_2)] = \operatorname{Tr} [\mathcal{T}_K^\top (X_1) \cdot X_2] \) for positive definite matrices \( X_1 \) and \( X_2 \). Then the proof is concluded by observing that \( \Sigma_K = \mathcal{T}_K (\Phi_a) \) and \( P_K = \mathcal{T}_K^\top (Q + K^\top R K) \).

Let \( x \) be the state sequence induced by \( x_{t+1} = (A - BK)x_t \) with \( x_0 = x \in \mathbb{R}^d \). Then we have

\[
x^\top P_{K'} x - x^\top P_K x = \sum_{t \geq 0} A_{K,K'} (x_t'),
\]

where we define the advantage as

\[
A_{K,K'}(x) = 2x^\top (K' - K)^\top E_K x + x^\top (K' - K)^\top (R + B^\top P_K B) (K' - K) x.
\]

Moreover, it holds that

\[
A_{K,K'}(x) \geq -\operatorname{Tr} \left[ xx^\top E_K^\top \left( R + B^\top P_K B \right)^{-1} E_K \right].
\]

**Proof.** The inequality (C.11) follows by direct computation:

\[
A_{K,K'}(x) = \operatorname{Tr} \left\{ xx^\top \left[ K' - K + (R + B^\top P_K B)^{-1} E_K \right]^\top (R + B^\top P_K B) \right\} - \operatorname{Tr} \left[ xx^\top E_K^\top \left( R + B^\top P_K B \right)^{-1} E_K \right]
\]

\[
\geq -\operatorname{Tr} \left[ xx^\top E_K^\top \left( R + B^\top P_K B \right)^{-1} E_K \right].
\]

To prove (C.10), note that \( P_{K'} \) satisfies the equation

\[
P_{K'} = (Q + K'^\top R K'^\top) + (A - BK'^\top)^\top P_{K'} (A - BK'^\top).
\]

By direct computation, we have

\[
x^\top P_{K'} x - x^\top P_K x = \sum_{t \geq 0} x^\top [(A - BK')^t]^\top \left( Q + K'^\top R K' \right) [(A - BK')^t] x - x^\top P_K x
\]
\[= \sum_{t \geq 0} x_t^T \left( Q + K'^T RK' \right) x_t' - x_t^T P_K x \]
\[= \sum_{t \geq 0} \left[ x_t^T \left( Q + K'^T RK' \right) x_t' + x_t^T P_K x_t' - x_t^T P_K x_t' \right] - x_0^T P_K x_0 \]
\[= \sum_{t \geq 0} \left[ x_t^T \left( Q + K'^T RK' \right) x_t' + x_{t+1}^T P_K x_{t+1}' - x_t^T P_K x_t' \right]. \quad \text{(C.13)} \]

To see how the last line is related to the value \( \sum_{t \geq 0} A_{K,K'} (x_t') \), we have
\[
x^T Q x + (-K' x)^T \left( R - K' x \right) + \left[ (A - BK') x \right]^T P_K \left[ (A - BK') x \right] - x^T P_K x
\[= x^T \left[ Q + (K' - K + K)^T R (K' - K + K) \right] x
+ x^T \left[ A - BK - B (K' - K) \right]^T P_K \left[ A - BK - B (K' - K) \right] x - x^T P_K x
= 2 x^T (K' - K)^T \left[ (R + B^T P_K B) K - B^T P_K A \right] x
+ x^T (K' - K)^T (R + B^T P_K B) (K' - K) x. \quad \text{(C.14)} \]

Recalling that \( E_K = (R + B^T P_K B) K - B^T P_K A \), we conclude (C.10).

**Lemma C.3** (Perturbation of \( C(K) \)). Suppose \( K' \) is a perturbation of \( K \) and satisfies
\[
\|K' - K\| \leq \sigma_{\text{min}}(\Phi)/4 \cdot \|\Sigma_K\|^{-1} \|B\|^{-1} \cdot (\|A - BK\| + 1)^{-1}. \quad \text{(C.15)}
\]

Then it holds that
\[
\|C(K') - C(K)\| \leq 6 \left( \|\Phi\| \cdot +\sigma^2 \cdot \|B\|^2 \right) \cdot \sigma_{\text{min}}^{-1}(\Phi) \cdot \|\Sigma_K\| \cdot \|K\| \cdot \|R\| \cdot (\|K\| \cdot \|B\| \cdot \|A - BK\| + \|K\| \cdot \|B\| + 1) \cdot \|K' - K\|. \quad \text{(C.16)}
\]

**Proof.** This lemma is obtained by combining Lemmas 17 and 24 in Fazel et al. (2018). We sketch the proof below. First we have the inequality
\[
|C(K) - C(K')| = |\text{Tr} \left[ (P_K - P_{K'}) \cdot \Phi_{\sigma} \right]| \leq \|\Phi_{\sigma}\| \cdot \|P_K - P_{K'}\|
\[\leq \left[ \|\Phi\| \cdot +\sigma^2 \cdot \|B\|^2 \right] \cdot \|P_K - P_{K'}\|. \quad \text{(C.17)} \]

Under condition (C.15), by Lemma 24 in Fazel et al. (2018), we can bound \( \|P_K - P_{K'}\| \) as
\[
\|P_{K'} - P_K\| \leq 6 \|\mathcal{T}_K\| \cdot \|K\| \cdot \|R\| \cdot \|B\| \cdot \|A - BK\| + \|K\| \cdot \|B\| + 1) \cdot \|K' - K\|, \quad \text{(C.18)}
\]
where the operator $\mathcal{T}_K$ is defined in (C.9). By Lemma 17 in Fazel et al. (2018), we can further bound $\|\mathcal{T}_K\|$ as

$$\|\mathcal{T}_K\| \leq \sigma_{\min}^{-1}(\Phi) \cdot \|\Sigma_K\|. \quad (C.19)$$

Combining (C.17), (C.18) and (C.19) completes the proof.

Lemma C.4. Let $\pi_K$ be a stable policy such that $\rho(A - BK) < 1$. Then it holds that

$$\|\Sigma_K\| \leq C(K)/\sigma_{\min}(Q), \quad \|P_K\| \leq C(K)/\sigma_{\min}(\Phi). \quad (C.20)$$

Proof. This follows from Lemma 4.5 and direct computation

$$C(K) \geq \text{Tr} \left[ (Q + K^\top R K) \Sigma_K \right] \geq \sigma_{\min}(Q) \cdot \text{Tr} (\Sigma_K) \geq \sigma_{\min}(Q) \cdot \|\Sigma_K\|, \quad (C.21)$$

$$C(K) \geq \text{Tr} (P_K \Phi_\sigma) \geq \sigma_{\min}(\Phi_\sigma) \cdot \text{Tr} (P_K) \geq \sigma_{\min}(\Phi_\sigma) \|P_K\|. \quad (C.22)$$

Lemma C.5 (Characterization of $v$). Let $v = [x^\top, u^\top]^\top$ be defined as in Lemma A.1. Then $\{v_t\}_{t \geq 0}$ is a linear system with transition equation $v' = \hat{K}v + \hat{\epsilon}$, where

$$\hat{K} = \begin{pmatrix} A & B \\ -KA & -KB \end{pmatrix}, \quad \hat{\epsilon} = \begin{pmatrix} \epsilon \\ -K\epsilon + \sigma \cdot z \end{pmatrix}.$$

Moreover, $v$ has stationary distribution $N \left(0, \hat{\Sigma}_K\right)$, where

$$\hat{\Sigma}_K = \begin{pmatrix} \Sigma_K & -\Sigma_K K^\top \\ -K\Sigma_K & K\Sigma_K K^\top + \sigma_2 \cdot I_k \end{pmatrix} \quad (C.23)$$

with

$$\|\hat{\Sigma}_K\|_F \leq k\sigma^2 + (d + \|K\|_F^2) \cdot \|\Sigma_K\|, \quad (C.24)$$

$$\|\hat{\Sigma}_K\| \leq \sigma^2 + (1 + \|K\|_F^2) \cdot \|\Sigma_K\|. \quad (C.25)$$

Furthermore, $\{v_t\}_{t \geq 0}$ is a geometrically $\beta$-mixing stochastic process with parameter $\rho \in (\rho(A - BK), 1)$.

Proof. Let $v' = [x'^\top, u'^\top]^\top$ be the next states and actions. The transition is given by

$$x' = Ax + Bu + \epsilon, \quad (C.26)$$
\[ u' = -Kx' + \sigma \cdot z = -KAx - KBu - K\epsilon + \sigma \cdot z. \quad (C.27) \]

Then \( v' = \hat{K}v + \hat{\epsilon} \) and \( v \) has Gaussian distribution with covariance matrix

\[ \hat{\Phi}_K = \begin{pmatrix} \Phi & -\Phi K^\top \\ -K\Phi & K\Phi K^\top + \sigma^2 \cdot I_k \end{pmatrix}. \quad (C.28) \]

Moreover, note that

\[ \hat{K} = \begin{pmatrix} A & B \\ -KA & -KB \end{pmatrix} = \begin{pmatrix} I_d & -K \end{pmatrix} \begin{pmatrix} A & B \end{pmatrix} \]

with the spectral norm bounded as \( \rho(\hat{K}) = \rho(A - BK) < 1 \).

We can find the stationary distribution of \( v \) by solving the Lyapunov equation. By direct computation, we can check that \( \hat{\Sigma}_K \) is the unique solution to the Lyapunov equation \( \hat{\Sigma}_K = \hat{K} \hat{\Sigma}_K \hat{K}^\top + \hat{\Phi}_K \). Therefore, \( v \) has stationary distribution \( N(0, \hat{\Sigma}_K) \).

To bound \( \|\hat{\Sigma}_K\| \), note that we have

\[ \hat{\Sigma}_K = \begin{pmatrix} 0 & 0 \\ 0 & \sigma^2 I_k \end{pmatrix} + (I_d - K)^\top \Sigma_K (I_d - K). \]

By direct computation, we have

\[ \|\Sigma_K\| \leq k\sigma^2 + (d + \|K\|_F^2) \cdot \|\Sigma_K\|, \quad (C.29) \]
\[ \|\hat{\Sigma}_K\| \leq \sigma^2 + (1 + \|K\|_F^2) \cdot \|\Sigma_K\|, \quad (C.30) \]

Furthermore, since \( \rho(\hat{K}) < 1 \), Lemma D.4 from (Tu and Recht, 2017) implies \( \{v_t\}_{t\geq0} \) is a geometrically \( \beta \)-mixing stochastic process with parameter \( \rho \in (\rho(\hat{K}), 1) \).

\[ \square \]

D Auxiliary Lemmas

**Lemma D.1** (Hansen-Wright Inequality (Rudelson et al., 2013)). Let \( X = (X_1, \ldots, X_n) \sim N(0, I_n) \in \mathbb{R}^n \) and \( A \in \mathbb{R}^{n \times n} \) a fixed matrix. Then it holds that

\[ \Pr \{ |X^\top AX - \mathbb{E}X^\top AX| > s \} \leq 2 \exp \left[ -C \min \left( s^2 \|A\|^{-2}_F, s \|A\|^{-1} \right) \right], \quad (D.1) \]

where \( C \) is an absolute constant.

**Proof.** See Rudelson et al. (2013) for a detailed proof. \[ \square \]
**Lemma D.2.** Suppose \( \rho(A - BK) < 1 \). Let \( N(0, \hat{\Sigma}_K) \) be the stationary distribution of \( v \) specified in Lemma C.5. Then \( \Theta_K = \mathbb{E}_v \left\{ \varphi(v) [\varphi(v) - \varphi(v')]^\top \right\} \) is invertible and can be written as

\[
\Theta_K = \left( \hat{\Sigma}_K \otimes_s \hat{\Sigma}_K \right) - \left( \hat{\Sigma}_K \hat{\Sigma}^\top \right) \otimes_s \left( \hat{\Sigma}_K \hat{\Sigma}^\top \right) = \left( \hat{\Sigma}_K \otimes_s \hat{\Sigma}_K \right) \left( I - \hat{K}^\top \otimes_s \hat{K}^\top \right),
\]

(D.2)

where we use \( A \otimes_s B \) to denote the symmetric Kronecker product of matrices \( A \) and \( B \). Furthermore, we have \( \| \Theta_K \| \leq 4 \left( 1 + \| K \|_F^2 \right)^2 \| \Sigma_K \|^2 \), and the matrix \( \Omega_K \), defined in (B.13), has the minimum singular value lower bounded by a constant \( \tau_K^* > 0 \) that only depends on \( \rho(A - BK), \sigma, \) and \( \sigma_{\min}(\Phi) \).

**Proof.** See Lemma B.2 in Yang et al. (2019) for a detailed proof. \( \square \)

**Lemma D.3** (Lemma 5.4 in Yang et al. (2019)). Consider the minimax stochastic optimization problem with convex-concave objective function \( H(x, y) \) defined by

\[
\min_{x \in \mathcal{X}_x} \max_{y \in \mathcal{X}_y} H(x, y) = \mathbb{E}_{\zeta \sim \pi_\zeta} [\Psi(x, y; \zeta)].
\]

(D.3)

Assume \( \mathcal{X}_x \) and \( \mathcal{X}_y \) are convex, \( \| x - x' \|_2 \leq D \) for all \( x, x' \in \mathcal{X}_x \) and \( \| y - y' \|_2 \leq D \) for all \( y, y' \in \mathcal{X}_y \), when \( D > 0 \) is a constant. Moreover, assume the stationary distribution \( \pi_\zeta \) of \( \zeta \) corresponds to a Markov chain that has a mixing coefficients satisfying \( \beta(k) \leq C_\zeta \cdot \rho^k \) for some constant \( C_\zeta \), where \( \beta(k) \) is the \( k \)-th mixing coefficient. In addition, we assume for all \( \zeta \sim \pi_\zeta \), the objective function \( \Psi(x, y; \zeta) \) is \( L_1 \)-Lipschitz in both \( x \) and \( y \) almost surely, \( \nabla_x \Psi(x, y; \zeta) \) is \( L_2 \)-Lipschitz in \( y \) for all \( x \in \mathcal{X}_x \), and \( \nabla_y \Psi(x, y; \zeta) \) is \( L_2 \)-Lipschitz in \( x \) for all \( y \in \mathcal{X}_y \) for some constant \( L_1 \) and \( L_2 \). Without loss of generality, we consider the case where the constants \( D, L_1, \) and \( L_2 \) are all greater than 1.

Let \( \mathcal{P}_{\mathcal{X}_x} \) and \( \mathcal{P}_{\mathcal{X}_y} \) be the projection operators. Consider the Gradient-based TD (GTD) algorithm with iterates

\[
x_t = \mathcal{P}_{\mathcal{X}_x} \left[ x_{t-1} - \alpha_t \nabla_x \Psi \left( x_{t-1}, y_{t-1}; \zeta_{t-1} \right) \right],
\]

(D.4)

\[
y_t = \mathcal{P}_{\mathcal{X}_y} \left[ y_{t-1} + \alpha_t \cdot \nabla_y \Psi \left( x_{t-1}, y_{t-1}; \zeta_{t-1} \right) \right],
\]

(D.5)

where step sizes \( \alpha_t = \alpha / \sqrt{T} \), for \( t \in [T] \), that returns

\[
\hat{x} = \frac{\sum_{t=1}^T \alpha_t \cdot x_t}{\sum_{t=1}^T \alpha_t}, \quad \hat{y} = \frac{\sum_{t=1}^T \alpha_t \cdot y_t}{\sum_{t=1}^T \alpha_t}
\]

(D.6)

as the final output. Then there exists an absolute constant \( M > 0 \) such that for any \( \delta \in (0, 1) \), with probability at least \( 1 - \delta \), the primal-dual gap can be bounded as

\[
\max_{y \in \mathcal{X}_y} \hat{G}(\hat{x}, y) - \min_{x \in \mathcal{X}_x} \hat{G}(x, \hat{y}) \leq M \cdot \left( D^2 + L_1^2 + L_2 D \right) \frac{\log^2 T + \log(1/\delta)}{\sqrt{T}} + \frac{M \cdot C_\zeta L_1 D}{T}.
\]

(D.7)
Proof. See Yang et al. (2019) for a detailed proof.

Lemma D.4 (Proposition 3.1 in Tu and Recht (2017)). Let $X_{t+1} = AX_t + \epsilon_t$ be a linear dynamic system, where noise $\epsilon_t$ has a Gaussian distribution, and $A \in \mathbb{R}^{n \times n}$ has spectral norm $\rho(A) < 1$. Denote the stationary distribution of $\{X_t\}_{t \geq 0}$ by $N(0, \Sigma_A)$. For any integer $k \geq 0$, the $k$-th $\beta$-mixing coefficient is defined as

$$\beta(k) = \sup_{t \geq 0} \mathbb{E}_{x \sim D_t} \left[ \| \mathbb{P}_{X_k} (\cdot | X_0 = x) - \mathbb{P}_{N(0, \Sigma_A)} (\cdot) \|_{TV} \right], \quad (D.8)$$

where the expectation is taken with respect to the marginal distribution $D_t$ of $X_t$. Then it holds that for any $k \geq 0$ and $\rho \in (\rho(A), 1)$,

$$\beta(k) \leq C_{\rho, A} \cdot \left[ \text{Tr} (\Sigma_A) + n \cdot (1 - \rho)^{-2} \right]^{1/2} \cdot \rho^k, \quad (D.9)$$

where $C_{\rho, A}$ is a constant that depends on $\rho$ and $A$ only. Therefore, $\{X_t\}_{t \geq 0}$ is geometrically $\beta$-mixing.

Proof. See Tu and Recht (2017) for a detailed proof.

Lemma D.5. Let $x \sim N(0, I_n)$, and let $M, N$ be two symmetric matrices in $\mathbb{R}^{n \times n}$. It holds that,

$$\mathbb{E} \left[ x^\top M x \cdot x^\top N x \right] = 2 \text{Tr} (MN) + \text{Tr} (M) \cdot \text{Tr} (N). \quad (D.10)$$

Proof. See Nagar (1959) for a detailed proof.
