(Received September 16, 2019)

On the basis of an idea of the electron-hole relation between $f^2$ and $f^4$ states in a $j$-$j$ coupling scheme, we point out a possibility that two-channel Kondo phenomena can be observed even in cubic transuranium compounds including Np and Pu ions with local $\Gamma_3$ non-Kramers doublet ground state. For the purpose, we analyze a seven-orbital impurity Anderson model hybridized with degenerate $\Gamma_8$ conduction electron bands by employing a numerical renormalization group method. From the numerical results for the case of four local $f$ electrons, corresponding to Np$^{3+}$ and Pu$^{4+}$ ions, we confirm that a residual entropy of $0.5 \log 2$, a characteristic of two-channel Kondo phenomena, appears for the case with the local $\Gamma_3$ doublet ground state.

KEYWORDS: Two-channel Kondo effect, transuranium compounds, $j$-$j$ coupling scheme, numerical renormalization group method

1. Introduction

It has been well known that the Kondo effect occurs in a dilute magnetic impurity system [1–3]. For the case in which a single impurity spin $1/2$ is embedded in a single-band conduction electron system, we observe conventional Kondo phenomena and the mechanism has been completely understood both from theoretical and experimental viewpoints [4]. On the other hand, for the case in which plural numbers of electrons with spin-orbital complex degrees of freedom are hybridized with multi-channel conduction electron bands, new and rich phenomena have been actively discussed for a long time, after the clarification of the conventional Kondo effect.

When an impurity spin is hybridized with multi-channel conduction bands, an intriguing concept of multi-channel Kondo effect has been proposed [5]. In particular, for the case of impurity spin $1/2$ and two conduction bands, the appearance of a non-Fermi liquid ground state has been suggested. This is one of the fascinating properties of two-channel Kondo effect. Such a non-Fermi liquid state has been also pointed out in a two-impurity Kondo system [6, 7]. Concerning the reality of the two-channel Kondo effect, Cox has pointed out that two screening channels exist in the case of quadrupole degree of freedom in a cubic uranium compound with $\Gamma_3$ non-Kramers doublet ground state [8, 9]. After this proposal, the stage for the investigation of two-channel Kondo phenomena has been almost fixed as the $f^2$ electron system. First, cubic U compounds have been focused, but recently, cubic Pr compounds have been actively investigated [10].

Although it is important to investigate the $f^2$ electron system to deepen our understanding on the two-channel Kondo effect, we strongly believe that it is also meaningful to expand the research frontier of the two-channel Kondo physics to other rare-earth and actinide compounds. On the basis of our belief, we have examined the Kondo effect for the case of plural numbers of $f$ electrons in rare-earth and actinide compounds by analyzing a seven-orbital impurity Anderson model hybridized with $\Gamma_8$ conduction bands with the use of a numerical renormalization group (NRG) method [11]. First we have reconfirmed the appearance of quadrupole two-channel Kondo effect for the case of $n = 2$ [12], where $n$ denotes the local $f$ electron number per ion. Then, we have moved onto the case of $n = 3$, 

corresponding to Nd ion, in which we have clarified the emergence of magnetic two-channel Kondo effect for the case with a $\Gamma_6$ ground state [13].

In this paper, we analyze the seven-orbital impurity Anderson model hybridized with $\Gamma_8$ conduction electrons by using the NRG method for the case of $n = 4$, corresponding to Np$^{3+}$ and Pu$^{4+}$ ions. We confirm that a residual entropy of $0.5 \log 2$ appears as a clear signal of the quadrupole two-channel Kondo effect for the case with the non-Kramers $\Gamma_3$ doublet ground state. In addition, we also find a quantum critical point (QCP) between local crystalline electric field (CEF) singlet and Kondo-Yosida singlet states for the case of $n = 4$, as has been found in the case of $n = 2$. Finally, we briefly discuss potential materials to observe actually the quadrupole two-channel Kondo effect for the case of $n = 4$. Throughout this paper, we use such units as $\hbar = k_B = 1$.

2. Model and Method

To describe the local $f$-electron model, first we consider one $f$-electron state, which is the eigenstate of spin-orbit and CEF terms. Under the cubic CEF potential, $\Gamma_7$ doublet and $\Gamma_8$ quartet are obtained from $j = 5/2$ sextet, whereas we obtain $\Gamma_6$ doublet, $\Gamma_7$ doublet, and $\Gamma_8$ quartet from $j = 7/2$ octet, where $j$ denotes the total angular momentum of $f$ electron. By using those one-electron states as bases, we express the local $f$-electron Hamiltonian as

$$H_{\text{loc}} = \sum_{j, \mu, \tau} (E_f + \lambda_j + B_{j,\mu}) f^\dagger_{j,\mu,\tau} f_{j,\mu,\tau} + \sum_{j_1 \sim j_4} \sum_{\mu_1 \sim \mu_4} \sum_{\tau_1 \sim \tau_4} f^\dagger_{j_1 j_2 j_3 j_4, \mu_1 \mu_2 \mu_3 \mu_4 \tau_1 \tau_2 \tau_3 \tau_4} f_{j_1 j_2 j_3 j_4, \mu_1 \mu_2 \mu_3 \mu_4 \tau_1 \tau_2 \tau_3 \tau_4},$$

where $E_f$ is the $f$-electron level to control the local $f$-electron number $n$ at an impurity site, $f_{j,\mu,\tau}$ denotes the annihilation operator of a localized $f$ electron in the bases of $(j, \mu, \tau)$, $j = 5/2$ and 7/2 are denoted by "a" and "b", respectively, $\mu$ distinguishes the cubic irreducible representations, $\Gamma_8$ states are distinguished by $\mu = \alpha$ and $\beta$, while $\Gamma_7$ and $\Gamma_6$ states are labeled by $\mu = \gamma$ and $\delta$, respectively, and $\tau$ is the pseudo-spin which distinguishes the degeneracy concerning the time-reversal symmetry. The definitions of $\lambda_j$, $B_{j,\mu}$, and $I$ will be discussed below.

As for the spin-orbit term, we obtain

$$\lambda_a = -2\lambda, \quad \lambda_b = (3/2)\lambda,$$

where $\lambda$ is the spin-orbit coupling of $f$ electron. The magnitude of $\lambda$ depends on the kind of actinide atoms, but in this paper, we set $\lambda = 0.3$ eV, since we consider Np and Pu ions.

Concerning the CEF potential term for $j = 5/2$, we obtain

$$B_{a,\alpha} = B_{a,\beta} = 1320 B_4^0/7, \quad B_{a,\gamma} = -2640 B_4^0/7,$$

where $B_4^0$ denotes the fourth-order CEF parameter in the table of Hutchings for the angular momentum $\ell = 3$ [14, 15]. Here we note that the sixth-order CEF potential term $B_6^0$ does not appear for $j = 5/2$, since the maximum size of the change of the total angular momentum is less than six. On the other hand, for $j = 7/2$, we obtain

$$B_{b,\alpha} = B_{b,\beta} = 360 B_4^0/7 + 2880 B_6^0, \quad B_{b,\gamma} = -3240 B_4^0/7 - 2160 B_6^0,$$

$$B_{b,\delta} = 360 B_4^0 - 3600 B_6^0/7.$$

Note also that $B_6^0$ terms appear in this case. In the present calculations, we treat $B_4^0$ and $B_6^0$ as parameters.
The matrix element of the Coulomb interaction is expressed by \( I \). To save space, we do not show the explicit forms of \( I \) here, but they are expressed by four Slater-Condon parameters \( F^0, F^2, F^4, F^6 \) [16, 17] and Gaunt coefficients [18, 19]. As for the magnitudes of Slater-Condon parameters, first we set \( F^0 = 10 \) eV by hand. Others are determined so as to reproduce excitation spectra of \( U^{4+} \) ion with two \( 5f \) electrons [20]. The results are \( F^2 = 6.4 \) eV, \( F^4 = 5.6 \) eV, and \( F^6 = 4.1 \) eV [21].

Now we include the \( \Gamma_8 \) conduction electron bands hybridized with localized electrons. Since we consider the case of \( n < 7 \), the local \( f \)-electron states are mainly formed by \( j = 5/2 \) electrons and the chemical potential is situated among the \( j = 5/2 \) sextet. Thus, we consider only the hybridization between conduction and \( j = 5/2 \) electrons. The seven-orbital impurity Anderson model is given by

\[
H = \sum_{k,\mu,\tau} \varepsilon_k c^\dagger_{k\mu\tau} c_{k\mu\tau} + \sum_{k,\mu,\tau} V_{\mu} (c^\dagger_{k\mu\tau} f_{a\mu\tau} + \text{h.c.}) + H_{\text{loc}},
\]

where \( \varepsilon_k \) is the dispersion of conduction electron with wave vector \( k \), \( c_{k\gamma\tau} \) denotes an annihilation operator of conduction electron, and we set \( V_\alpha = V_\beta = V \). Here \( V \) denotes the hybridization between \( \Gamma_8 \) conduction and localized electrons.

In this paper, we analyze the model by employing the NRG method [11]. We introduce a cut-off \( \Lambda \) for the logarithmic discretization of the conduction band. Due to the limitation of computer resources, we keep \( M \) low-energy states. Here we use \( \Lambda = 5 \) and \( M = 2,500 \). Note that the temperature \( T \) is defined as \( T = \Lambda^{- (N-1)/2} \) in the NRG calculation, where \( N \) is the number of the renormalization step. In the following calculation, the energy unit is \( D \), which is a half of the conduction band width. Namely, we assume \( D = 1 \) eV in this calculation.

### 3. Calculation Results

First we briefly discuss the \( f \)-electron configurations in a \( j-j \) coupling scheme for \( n = 2 \) and \( n = 4 \). As shown in Fig. 1(a), when we accommodate four \( f \) electrons in the \( j = 5/2 \) sextet, we find two \( f \) holes there. Of course, for the finite value of \( \lambda \), the component of \( j = 7/2 \) octet should be included in the ground-state wave function. Note here that we mention only the main component of the ground and low-energy excited states for \( n = 2 \) and \( n = 4 \) [22, 23]. We emphasize that the electron-hole relation between \( n = 2 \) and \( n = 4 \) on the basis of the \( j-j \) coupling scheme is quite simple, but we expect to observe the quadrupole two-channel Kondo effect even for \( n = 4 \), corresponding to \( \text{Np}^{3+} \) and \( \text{Pu}^{4+} \) ions.

Now we consider the local CEF ground-state phase diagram for \( n = 4 \), obtained from the di-
agonalization of $H_{\text{loc}}$. For $n = 4$, the ground-state multiplet for $B_4^0 = B_6^0 = 0$ is characterized by total angular momentum $J = 4$. Under the cubic CEF potentials, the nonet of $J = 4$ is split into four groups as $\Gamma_1$ singlet, $\Gamma_3$ doublet, $\Gamma_4$ triplet, and $\Gamma_5$ triplet. Among them, $\Gamma_4$ triplet does not appear as a solo ground state under the cubic CEF potential with $O_h$ symmetry.

Then, we obtain three local ground states for $n = 4$, as shown in Fig. 1(b). Roughly speaking, we obtain $\Gamma_1$ singlet for $B_4^0 < 0$, whereas $\Gamma_5$ triplet appears for $B_4^0 > 0$. Here we recall the fact that $f^1$ local ground state is $\Gamma_7$ and $\Gamma_8$ for $B_4^0 > 0$ and $B_4^0 < 0$, respectively, from eq. (3). When we accommodate two holes into this situation, we easily obtain $\Gamma_1$ singlet and $\Gamma_5$ triplet for $B_4^0 < 0$ and $B_4^0 > 0$, respectively, by standard positive Hund’s rule coupling. Note that the results are just reversed in comparison with the the case of $n = 2$, in which we have found $\Gamma_1$ singlet and $\Gamma_5$ triplet for $B_4^0 > 0$ and $B_4^0 < 0$, respectively [12], since the signs in the one-electron potentials are changed between the electron and hole pictures. As for $\Gamma_3$ doublet, it appears for $B_6^0 > 0$ near the region of $B_4^0 \approx 0$. The stabilization of $\Gamma_3$ doublet is understood by effective negative Hund’s rule coupling and the dependence on $B_6^0$ for the hole picture is the same as that for the electron one.

Next we show our NRG results. First we discuss the $V$ dependence of the two-channel Kondo phase for the present parameters. In Fig. 2, we show the results for entropy on the $(V, T)$ plane for $B_4^0 = -0.001$ and $B_6^0 = 0.0002$ with the $\Gamma_3$ local ground state. To visualize precisely the behavior of entropy, we define the color of the entropy between 0 and 1.5, as shown in the right color bar. Note that the green and yellow regions indicate the entropy of log 2 and 0.5 log 2, respectively. We emphasize that 0.5 log 2 entropy does not appear only at a certain value of $V$, but it can be observed in the wider region of $V$ as $0.9 < V < 1.1$ in the present temperature range. This behavior is different from that in the non-Fermi liquid state due to the competition between CEF and Kondo-Yosida singlets, as will be discussed later. Note also that the two-channel Kondo effect appears for relatively large values of $V$ in the present energy scale of $D = 1$ eV. In the following calculations, we set $V = 1$ eV.

In Fig. 3, we show the contour color map of the entropy on the plane of $(B_4^0, B_6^0)$ for $V = 1.0$ and $T = 2.6 \times 10^{-6}$. The definition of the color is the same as that in Fig. 2. We immediately notice that a region with an entropy of $0.5 \log 2$ (yellow region) almost corresponds to that of the $\Gamma_3$ ground state in comparison with Fig. 1(b). Note that for large $B_6^0$, the color becomes green, but when we decrease the temperature, we find the entropy of $0.5 \log 2$ even for large $B_6^0$. The results strongly suggest the emergence of quadrupole two-channel Kondo effect for the case of $n = 4$. Note that in the present model, we have observed the discontinuous change in entropy behavior between yellow ($\Gamma_3$) and red ($\Gamma_1$ or $\Gamma_5$) regions. Quantum critical behavior which may occur between non-Fermi-liquid and
Fig. 3. Color contour map of the entropy for \( n = 4 \) on the plane of \((B_4^0, B_6^0)\) for \( V=1.0 \) and \( T = 2.6 \times 10^{-6} \). White curves denote the boundaries among local CEF ground states shown in Fig. 1. Note that yellow spots appear along the boundary curve between \( \Gamma_1 \) and \( \Gamma_5 \) regions.

Fermi-liquid phases will be discussed elsewhere in future.

Here we remark that there exists a blue region corresponding to \( \log 3 \) in the local \( \Gamma_5 \) state. This is quite natural, since the local \( \Gamma_5 \) state is triply degenerate. The \( \Gamma_5 \) moment is screened by \( \Gamma_8 \) conduction electrons and thus, it is expected that the conventional Kondo effect occurs in the \( \Gamma_5 \) region, although the magnitude of the Kondo temperature significantly depends on the hybridization and excitation energy.

Note also that in the region of \( B_6^0 < 0 \), we observe some blurry yellow spots along the boundary curve between \( \Gamma_1 \) singlet and \( \Gamma_5 \) triplet local ground states. The QCP is known to appear between the local CEF and Kondo singlet states for \( n = 2 \) [12]. Thus, we deduce that those spots form a QCP curve, although we could not obtain enough amounts of numerical results to depict the smooth curve.

In Fig. 4, we show the curves of entropy vs. temperature for the points near \( B_6^0 = 0.0 \) and \( B_6^0 = -0.0002 \). For \( B_6^0 = -0.0001 \) (CEF singlet) and \(-0.0003 \) (Kondo singlet), entropies are found to be zero around at \( T = 10^{-4} \), while we find a residual entropy of \( 0.5 \log 2 \) even at \( T = 10^{-10} \) for \( B_6^0 = -0.000190226 \). When \( B_6^0 \) deviates even slightly from this value, we find that \( 0.5 \log 2 \) entropy

Fig. 4. Entropies on the line of \( B_4^0 = 0 \) for \( B_6^0 = -0.0001, -0.000190226, \) and \(-0.0003 \).
immediately disappears. The present results are quite similar to those for \( n = 2 \), which we have actually found in the same model [12]. In this sense, we highly expect the existence of QCP between CEF and Kondo singlet states even in the \( f^4 \) system.

4. Summary and Discussion

In this paper, we have analyzed the seven-orbital impurity Anderson model hybridized with \( \Gamma_8 \) conduction bands by using the NRG technique. For the case of \( n = 4 \), we have confirmed the emergence of two-channel Kondo effect. As for the mechanism of quadrupole two-channel Kondo effect for the case of \( n = 4 \), we deduce that it is essentially the same as that for the case of \( n = 2 \) from the viewpoint of the electron-hole relation between \( f^2 \) and \( f^4 \) states on the basis of the \( j-j \) coupling.

We have also observed the QCP curve running in the \( \Gamma_1 \) region near the boundary between the CEF singlet and Kondo-Yosida singlet states. Here readers may have some questions on this QCP curve. For instance, the curve seems to merge into the two-channel Kondo state in the local \( \Gamma_3 \) region, but the property of the state at the merging point is unclear. The details on the properties of the QCP curve will be discussed elsewhere in future.

Finally, we provide a brief comment on actual materials to observe the two-channel Kondo effect for the case of \( n = 4 \). In rare-earth ions, the case of \( n = 4 \) corresponds to \( \text{Pr}^{3+} \), but unfortunately, there exist no stable isotopes for \( \text{Pm} \). Thus, we turn our attention to actinide ions such as \( \text{Np}^{3+} \) and \( \text{Pu}^{4+} \) with \( 5f^4 \) configurations. It may be difficult to synthesize new \( \text{Np} \) and \( \text{Pu} \) compounds, but we expect that \( \text{Np 1-2-20} \) compound will be synthesized in future.
