1. INTRODUCTION

1.1. Related work. In this section overview related work.

Quantitative topology and persistence. The idea of topological persistence has independently appeared in different settings. In a nutshell, via some functorial constructions one assigns to a topological space $X$: (1) for every $\epsilon > 0$ some space $S_\epsilon(X)$ and (2) for every $\alpha \geq \epsilon$ an equivalence relation $R_\alpha(X)$ on $S_\epsilon(X)$. For example, when $X$ is a metric space, then $S_\epsilon(X)$ could be the collection of $k$-cycles of its Vietoris-Rips complex $VR_\epsilon(X)$ and $R_\alpha(X)$ the equivalence relation arising from two cycles $(c, c') \in R_\alpha(X)$ whenever there exists a $(k + 1)$-chain in $R_\alpha(X)$ such that its boundary is the sum $c + c'$.

Ideas of this type can already be found in the work of Borsuk in the 1940s. For instance, in [9, Section 3] Borsuk studies the transfer of certain scale dependent topological properties of compacta under a suitable metric.

Frosini and collaborators [24, 25] and Robins [43] identified ideas related to concepts nowadays known under the term persistence in the context of applications. From an algorithmic perspective, the study of topological persistence was initiated by Edelsbrunner et al. in [23]. See the overviews [13, 22, 28, 48], for more information.

Scale dependent invariants which blend topology with geometry have also been considered by Gromov [29, 31]. For example, in the late 1990s Gromov suggested the study of homotopy invariants in a scale dependent manner. One question posed by Gromov was: given a $\lambda$-Lipschitz and contractible map $f : X \to Y$ between metric spaces $X$ and $Y$, determine the function $\lambda \mapsto \Lambda(\lambda)$ such that there exists a $\Lambda(\lambda)$ null-homotopy of $f$. This question can be interpreted as a homotopical version of the homological question posed at the beginning of this section.

Homotopy groups and persistence. In the late 1990s Frosini and Mulazzani [27] considered a construction which blended ideas related to persistence with homotopy groups. Their construction dealt with pairs $(M, \varphi)$ where $M$ is a closed manifold and $\varphi = (\varphi_1, \ldots, \varphi_k) : M \to \mathbb{R}^k$ is a continuous function. In this setting, for $\zeta, \eta \in \mathbb{R}^k$ with $\zeta_i \leq \eta_i$ for all $i$ they considered a certain $(\varphi, \zeta, \eta)$-parametrized version of the fundamental group arising from considering equivalence classes of based loops in sublevel sets $M_\zeta := \{x \in M | \varphi_i(x) \leq \zeta_i, \forall i\}$ under the equivalence relation: for $\alpha$ and $\beta$ pointed loops in $M_\zeta$, $\alpha \sim_\eta \beta$ iff there is a (pointed) homotopy whose tracks remain in $M_\eta$. These groups are then used in order to obtain lower bounds for the so called natural pseudo distance between two manifolds. A more comprehensive look at several related ideas is carried out by Frosini in [26].
In [37] in his study of knots, Letscher considered the scenario in which one is given a filtration \( \{X_\varepsilon\}_{\varepsilon>0} \) of a path connected topological space \( X \) and for each \( \varepsilon, \delta > 0 \) he considered the group \( \pi_1^{(\delta)}(X_\varepsilon) \) consisting of equivalence classes of (based) loops contained in \( X_\varepsilon \) under the equivalence relation stating that two loops in \( X_\varepsilon \) are equivalent iff there is a homotopy between them which is fully contained in \( X_{\varepsilon+\delta} \).

In [4] Barceló et al. introduced a certain scale dependent notion of discrete homotopy groups associated to metric spaces via the study of 1-Lipschitz maps from \( n \)-cubes into the metric space in question. Barceló et. al explicitly studied the behaviour of their invariants under scale coarsening.

In his dissertation [49], Wilkins studies a certain notion of discrete fundamental group which he uses to in turn induce a notion of critical values of a metric space. This notion differs from the one introduced in [4] in that the respective notions of homotopies between discrete loops are different.

The notion studied by Wilkins originated in work by Berestovskii and Plaut [6] in the context of topological groups and subsequently extended in [7] to the setting of uniform spaces. In [7] the authors also consider discrete fundamental groups as an inverse system and study its inverse limit. See [40, Page 599, Plaut] for a discussion about the relationship between Vietoris-Rips complex and discrete fundamental groups.

In [8, Section 8.1] Blumberg and Lesnick define persistent homotopy groups of \( \mathbb{R} \)-spaces (in a way somewhat different from Letscher’s) and formulate certain persistent Whitehead conjectures. In [5] Batan, Pamuk and Varli study a certain persistent version of Van-Kampen’s theorem for Letscher’s definition of persistent homotopy groups of \( \mathbb{R} \)-spaces.

In [42] Rieser studies a certain version of discrete homotopy groups of Čech closure spaces. A Čech closure space is a set equipped with a Čech closure operator, which is similar to a topological closure operator (taking the closure of sets) except that it is not required to be idempotent. Given a finite metric space \( X \), a way of obtaining Čech closure operators is the following: for each \( r \geq 0 \) let \( c_r \) be a map between subsets of \( X \) such that \( c_r(A) = \{ x \in X : d(x, A) \leq r \} \) for each \( A \subset X \). The author shows that each \( c_r \) is a Čech closure operator and the identity map \( (X, c_q) \to (X, c_r) \) induces maps \( \iota_q^n : \pi_1^n(X, c_q) \to \pi_1^n(X, c_r) \) for every \( q \leq r \) and \( n \geq 0 \). Then he defines the persistent homotopy groups of \( X \) to be the collection of \( \text{Im}(\iota_q^n) \).

In [33] Jardine utilizes poset theoretic ideas to study Vietoris-Rips complexes (and some variants) associated to data sets and provides explicit conditions for the poset morphism induced by an inclusion of data sets to be quantifiably close to a homotopy equivalence. Jardine also considers persistent fundamental groupoids and higher-dimensional persistent homotopy in the lecture notes [34].

1.2. Overview of our results. We consider three different definitions of persistent fundamental groups. One of them, denoted \( \text{PI}_1^{K^\bullet} \), arises from isometrically embedding a given metric space \( X \), via the so called Kuratowski embedding, into \( L^\infty(X) \) and then applying the \( \pi_1 \) functor to successive thickenings \( X^\varepsilon \) of \( X \) inside \( L^\infty(X) \), cf. Definition 5.5. This definition is similar in spirit to the construction used by Gromov for defining the so-called filling radius invariant [30]. Another definition, denoted \( \text{PI}_1^{VR^\bullet} \), we consider stems from simply considering the geometric realization of nested Vietoris-Rips simplicial complexes for different choices of the scale parameter and then applying the \( \pi_1 \) functor, cf. Definition 5.7. The third, more combinatorial, definition (cf. Definition 5.2) which we consider is one coming from the work
of Plaut and Wilkins \cite{PlautWilkins} (see also Barcelo et al \cite{Barcelo}). This construction, denoted simply \( \Pi^1 \), turns out to be isomorphic to the edge path groups of the nested Vietoris-Rips simplicial complexes used in the previous definition (see Theorem 5.11).

We first observe that these three definitions give rise to isomorphic persistent fundamental groups.

**Theorem 5.11 (Isomorphisms of persistent fundamental groups).** Given a pointed compact metric space \((X, x_0)\), we have

\[
P_{\Pi^1}(X, x_0) \cong P_{\Pi^{VR}}(X, x_0) \cong P_{\Pi^2}(X, x_0).
\]

For a given compact metric space \(X\) and a base point \(x_0 \in X\) denote

\[
P_{\Pi^1}(X, x_0) = \left\{ \pi_1(X, x_0) \xrightarrow{\Phi_{\epsilon, \epsilon'}} \pi'_1(X, x_0) \right\}_{\epsilon \geq \epsilon > 0}.
\]

It is not difficult to see that under fairly mild assumptions, the structure maps \(\Phi_{\epsilon, \epsilon'}\) of persistent fundamental groups of a geodesic space \(X\) are surjective and that for sufficiently small scale parameters the groups involved in the persistent fundamental group of \(X\) are isomorphic to its fundamental group \(\pi_1(X)\). These two facts when combined suggest that as the scale parameter increases homotopy classes in \(X\) can only become equal (no new classes can appear), thus suggesting an existence of a tree-like structure (i.e., a dendrogram) underlying \(P_{\Pi^1}(X)\). For instance, when \(X\) is \(S^1\), the geodesic unit circle, associated to \(P_{\Pi^1}(S^1)\) we have a dendrogram over \(\pi_1(S^1) \cong \mathbb{Z}\) shown in Figure 1. The general situation is stated in the theorem below.

![Figure 1](image.png)

**Figure 1.** The dendrogram associated to \(P_{\Pi^1}(S^1)\). The y-axis represents elements of \(\pi_1(S^1) \cong \mathbb{Z}\), i.e., homotopy classes of continuous loops in \(S^1\) (each corresponds to an integer).

**Theorem 5.14 (Dendrogram over \(\pi_1(X)\)).** Suppose that a compact geodesic metric space \(X\) is both uniformly locally path connected (u.l.p.c.) and uniformly semi-locally simply connected (u.s.l.s.c.). Then there is a dendrogram \(\theta_{\pi_1(X)}\) over \(\pi_1(X)\), given by

\[
\theta_{\pi_1(X)}(\epsilon) := \begin{cases} 
\pi'_1(X), & \text{if } \epsilon > 0 \\
\pi_1(X), & \text{if } \epsilon = 0.
\end{cases}
\]

Dendrograms over a given set can be bijectively associated with an ultrametric over the set. In this sense one can view the map \(X \mapsto \theta_{\pi_1(X)}\) described in the theorem above as a map from Gromov-Hausdorff space into itself. We prove that this endomorphism is 2-Lipschitz.
Theorem 6.2 (\(d_{GH}\)-stability for \(\theta_{\pi_1(\bullet)}\)). If compact geodesic metric spaces \(X\) and \(Y\) are u.l.p.c. and u.s.l.s.c., then

\[
d_{GH}\left(\left(\pi_1(X), \mu_{\theta_{\pi_1(X)}}\right), \left(\pi_1(Y), \mu_{\theta_{\pi_1(Y)}}\right)\right) \leq 2 \cdot d_{GH}(X, Y).
\]

Of the three definitions of persistent fundamental groups given above, two of them can be generalized to the case of general homotopy groups thus giving rise to \(\Pi_n^K\) and \(\Pi_n^{VR}\) as persistent versions of \(\pi_n\). As for the case of \(n = 1\) described in Theorem 5.11, we still have that \(\Pi_1^K(\bullet) \cong \Pi_1^{VR,2}(\bullet)\), as well as the isomorphism of persistent homotopy groups \(\Pi_n^K\cong \Pi_n^{VR}\) (cf. Corollary 5.10). We furthermore have that under the interleaving distance (cf. Definition 3.8) the map from compact metric spaces into persistent groups \(X \mapsto \Pi_n^K(X)\) is 1-Lipschitz.

Theorem 6.1 (\(d_1\)-stability for \(\Pi_n^K(\bullet)\) and \(\Pi_n^{VR}(\bullet)\)). Let \((X, x_0)\) and \((Y, y_0)\) be pointed compact metric spaces. Then, for each \(n \in \mathbb{Z}_{\geq 1}\),

\[
d_1\left(\Pi_1^K(X, x_0), \Pi_1^K(Y, y_0)\right) \leq d_{GH}(\langle X, x_0 \rangle, \langle Y, y_0 \rangle).
\]

If \(X\) and \(Y\) are chain-connected, then

\[
d_1\left(\Pi_1^K(X), \Pi_1^K(Y)\right) \leq d_{GH}(X, Y).
\]

Via the isomorphism \(\Pi_n^K(\bullet) \cong \Pi_n^{VR,2}(\bullet)\), the above two inequalities also hold for \(\Pi_n^{VR}(\bullet)\), up to a factor \(\frac{1}{2}\).

We relate persistent fundamental groups to the standard persistent homology groups via a suitable version of the Hurewicz Theorem.

Theorem 5.29 (Persistent Hurewicz Theorem). Let \(X\) be a chain-connected metric space. Then there is a natural transformation

\[
\Pi_1^K(X) \xrightarrow{\rho} PH_1^K(X),
\]

where for each \(\epsilon > 0\), \(\rho_{\epsilon}\) is surjective and \(\ker(\rho_{\epsilon})\) is the commutator group of \(\Pi_1^{K,\epsilon}(X)\).

The persistent fundamental group of a metric space \(X\) often contains more information than the corresponding first Kuratowski (or Vietoris-Rips) persistent homology group. In Example 6.6 from §6.1, we compare the torus \(S^1 \times S^1\) with the wedge sum \(S^1 \vee S^1\) and obtain that \(PH_1^K(S^1 \times S^1) \cong PH_1^K(S^1 \vee S^1)\), but

\[
d_1\left(\Pi_1^K\left(S^1 \times S^1\right), \Pi_1^K\left(S^1 \vee S^1\right)\right) = \frac{\pi}{6} = \sup_{n \geq 0} d_1\left(\left(\Pi_1^{VR}(S^1 \times S^1), \Pi_1^{VR}(S^1 \vee S^1)\right)\right).
\]

In Example 6.6, we also verify that the supremum on the right hand side is attained for \(n = 2\).

1.3. Organization of the paper. In §2 we provide a notation key to facilitate reading the paper.

In §3 we review elements from category theory, metric geometry, and topology which will be used throughout the paper. In particular §3.4 provides the necessary background about persistent homology, the interleaving distance, and related concepts.

In §4 we review the concept of discrete fundamental groups from the work of Plaut and Wilkins [41] and Barcelo et al. [4], and prove the discretization theorem (cf. Theorem 4.19), which states that the limit of discrete fundamental groups is the classical fundamental group for tame enough spaces. Moreover, §4.4 constructs a stable (under the Gromov-Hausdorff
distance of metric spaces) pseudo-metric $\mu^{(1)}_{X}$ on the set $\mathcal{L}(X, x_0)$ of all discrete chains in a metric space $X$. When $X$ has a discrete and bounded set of critical values (as defined by [49, Definition 2.3.4]), the metric $\mu^{(1)}_{X}$ arises from a generalized subdendrogram over $\mathcal{L}(X, x_0)$.

In §5.1 the definitions of the persistent homotopy groups $\Pi_{\Pi}(\bullet), \Pi_{\Pi}^{VR}(\bullet)$ and $\Pi_{\Pi}^{K}(\bullet)$ are given, together with their main properties and the proof of Theorem 5.11. To handle the high-dimensional homotopy groups of spheres that appear in the calculation of $\Pi_{\Pi}^{K}(S^1)$, we tensor $\Pi_{\Pi}^{K}(S^1)$ with rational numbers $\mathbb{Q}$ to generate computable rational persistent homotopy groups. In §5.2, we prove Theorem 5.14, and show that the ultrametric on $\pi_1(X)$ associated to the dendrogram $\theta_{\pi_1(X)}$ is stable when the underlying spaces are homotopy equivalent, cf. Theorem 5.18, together with an application on Riemannian manifolds. In §5.3 (resp. §5.4), we see that persistent fundamental groups under products (resp. wedge sums) of metric spaces are products (resp. coproducts) of persistent fundamental groups. In §5.5, a persistent version of Hurewicz theorem is proved, cf. Theorem 5.29.

In §6 we address the question of stability of persistent homotopy groups and prove Theorems 6.2 and 6.1. As an application of the stability results, we study three pairs of metric spaces: $S^1 \times S^1$ vs. $S^1 \lor S^1$, $S^1 \times S^m$ vs. $S^1 \lor S^m$ and $S^1 \lor S^1 \lor S^2$, where $S^m$ is the geodesic unit $m$-sphere. In the examples involving $m$-spheres for $m > 1$, $\Pi_{\Pi}^{K}(S^1)$ (or $\Pi_{\Pi}^{K}(m)$) are restricted to some interval $I_m$. While $\Pi_{\Pi}^{K}(S^1)_{I_m}$ fails to separate the two spaces in each case, $\Pi_{\Pi}^{K}(S^1)_{I_m}$ provides a positive lower bound for the Gromov-Hausdorff distance.

In §6.2, an alternative proof, more constructive and independent of the notion of persistent $K$-fundamental groups, of the case $n = 1$ in Theorem 6.1 is given.

In §7, we apply stability theorems given in §6 to finite metrics spaces, and give examples of the generalized subdendrograms obtained in §4. We first prove that finite tree metric spaces have the trivial persistent fundamental group. In §7.1, we construct the generalized subdendrograms of cycle graphs $C_m$ and star graphs $S_n$, where the graphs are endowed with the shortest-path distance. We compute $d_{\text{GH}}(C_m, S_n)$ as a function of $m$, which grows at the same rate with $\frac{1}{m}$. Meanwhile, the interleaving distance between $\Pi_{\Pi}(C_m)$ and $\Pi_{\Pi}(S_n)$ grows at rate of $\frac{1}{2m}$, which provides a fair approximation of $d_{\text{GH}}(C_m, S_n)$ and is much easier to calculate. In §7.2, we study the finite metrics spaces $\frac{2\pi}{3}C_3$ and $\frac{2\pi}{4}C_4$ as metric subspaces of $S^1$, by computing several types of distances constructed in this paper. In this particular example, $\mu^{(1)}$ provides a slightly better lower bound of $d_{\text{GH}}\left(\frac{2\pi}{3}C_3, \frac{2\pi}{4}C_4\right)$ than the $d_{I}$ between persistent fundamental (or 1st-homology) groups.

**Acknowledgements.** We thank Prof. C. Plaut for bringing to our attention his results [40] on connecting the discrete fundamental group construction of [49] to the Vietoris-Rips complex (cf. Theorem 5.11). We also thank Prof J. Jardine for sharing his work on persistent fundamental groupoids.

### Persistent Homotopy Groups of Metric Spaces

- **$\mathcal{C}$**: A category.
- **$\text{Top}^*$**: The category of pointed compactly generated weakly Hausdorff topological spaces.
- **$\mathcal{V}_k$**: Free-functor from the category of sets $\text{Set}$ to the category of vector spaces $\text{Vec}$.
- **$\lim A$**: Limit of a family of a diagram $A$, page 8.
- **$\mathcal{M}^{(\text{pt})}$**: The set of (pointed) compact metric spaces, page 10 (12).
- **$d^X_H$**: Hausdorff distance between subsets of the metric space $X$, page 10.
- **$d_{\text{GH}}$**: Gromov-Hausdorff distance between pseudo-metric spaces, page 10.
- **$d_{\text{GH}}^{\text{pt}}$**: Pointed Gromov-Hausdorff distance between pseudo-metric spaces, page 12.
- **$\mathcal{P}C^{(T, \leq)}$**: The category of functors from $(T, \leq)$ to $\mathcal{C}$, for $T \subset \mathbb{R}$, page 12.
- **$\approx$**: Isometry of metric spaces, or Homotopy equivalence of topological spaces, or Isomorphism in $\mathcal{P}C^{(T, \leq)}$ or $\text{Grp}$.
- **$\text{Hom}(V, W)$**: The collection of homorphisms from $V$ to $W$ in $\mathcal{P}C^{(T, \leq)}$, page 12.
- **$\text{Hom}^\delta(V, W)$**: The collection of homorphisms of degree $\delta$ from $V$ to $W$ in $\mathcal{P}C^{(T, \leq)}$, page 13.
- **$d_I$**: Interleaving distance between functors, Definition 3.8.
- **$d_B$**: Bottleneck distance between multisets of points in $\mathbb{R}^2$, page 14.
- **$\text{PH}^{\text{VR}, \epsilon}_k(X)$**: $k$-th (simplicial) homology group of $\text{VR}_\epsilon(X)$ with coefficients in $\mathbb{Z}$, page 14.
- **$\text{PH}^{\text{VR}}_k(X)$**: $k$-th persistent homology of $X$, page 14.
- **$\simeq$**: Weak homotopy equivalence between topological spaces or $\mathbb{R}$-spaces, page 15.
- **$d_{\text{HI}}$**: Homotopy interleaving distance between functors, Definition 3.11.
- **$\mu_{A}$**: Ultrametric induced by the dendrogram $\theta_A$ on a set $A$, page 15.
- **$\mu_{A}^\epsilon$**: Pseudo-ultrametric induced by $\theta_A$ on a set $A$, page 16.
- **$\text{PII}_0(X)$**: The persistent set induced by a metric space $X$ on Page 17.
- **$\{n\}$**: The set $\{0, \cdots, n - 1\}$ for a non-negative set $n$, page 19.
- **$(X, x_0)$**: A pointed metric space.
- **$\mathcal{L}(X, x_0)$**: The set of discrete loops on $(X, x_0)$, Proposition 4.9.
- **$\mathcal{L}^\epsilon(X, x_0)$**: The set of $\epsilon$-loops on $(X, x_0)$, page 20.
- **$\alpha * \alpha'$**: Concatenation of two discrete chains $\alpha$ and $\alpha'$, page 20.
- **$\pi^0_1(X, x_0)$**: Discrete fundamental group at scale $\epsilon$ of $(X, x_0)$, Definition 4.11.
- **$\pi^E_1(K, v_0)$**: Edge-path group of a simplicial complex $K$, page 21.
- **$\text{Cr}(X)$**: The set of critical values of a metric space $X$, page 25.
- **$\text{PII}_1(X, x_0)$**: Persistent fundamental group of $(X, x_0)$, Definition 5.2.
- **$\text{PII}_1^\epsilon(X, x_0)$**: $\pi^\epsilon_1(X, x_0)$, page 21.
## 3. Background

### 3.1. Category Theory.

Let $k$ be a field. We denote the category of sets by $\textbf{Set}$, the category of vector spaces over $k$ by $\textbf{Vec}$, and the category of groups by $\textbf{Grp}$. Also, let $\textbf{Top}$ be the category of compactly generated weakly Hausdorff topological spaces $[8]$, and let $\textbf{Top}^*$ be the category of pointed compactly generated weakly Hausdorff topological spaces. Let $\mathcal{V}_k$ be the free-functor from $\textbf{Set}$ to $\textbf{Vec}$ defined by $\mathcal{V}_k : \mathcal{A} \rightarrow \text{Span}_k(\mathcal{A})$, the linear space spanned by the set $\mathcal{A}$ over $k$.

Now we introduce the definitions of product, coproduct and limit in a category $\mathcal{C}$. The **product** of a family of objects $(A_j)_{j \in J}$ indexed by a set $J$ is an object $\prod_{j \in J} A_j$ of $\mathcal{C}$ together with morphisms $p_j : \prod_{j \in J} A_j \rightarrow A_j$ satisfying the following universal property: for any object $B$ and $J$-indexed family of morphisms $f_j : B \rightarrow A_j$, there exists a unique morphism $f : B \rightarrow \prod_{j \in J} A_j$ such that the diagram

\[
\begin{array}{ccc}
  B & \xrightarrow{f_j} & A_j \\
  \downarrow^{p_j} & & \downarrow^{f_j} \\
  \prod_{j \in J} A_j & & \\
\end{array}
\]

commutes for all $j \in J$.

The **coproduct** of a family of objects $(A_j)_{j \in J}$ indexed by a set $J$ is an object $\coprod_{j \in J} A_j$ of $\mathcal{C}$ together with morphisms $i_j : A_j \rightarrow \coprod_{j \in J} A_j$ satisfying the following universal property: for any object $B$ and $J$-indexed family of morphisms $f_j : A_j \rightarrow B$, there exists a unique morphism $f : \prod_{j \in J} A_j \rightarrow B$ such that the diagram

\[
\begin{array}{ccc}
  \coprod_{j \in J} A_j & \x左下角{i_j} & A_j \\
  \downarrow^{i_j} & & \downarrow^{f_j} \\
  B & & \\
\end{array}
\]

commutes for all $j \in J$.

A **small category** is a category where the class of objects is a set. A functor from a small category $J$ to a category $\mathcal{C}$ is called a $J$-shaped diagram in $\mathcal{C}$. Let $J$ be a small category and let $\mathbb{A}$ be a $J$-shaped diagram. The **limit** of $\mathbb{A}$ is an object $\text{lim} \mathbb{A}$ in $\mathcal{C}$ together with morphisms $p_j : \text{lim} \mathbb{A} \rightarrow \mathbb{A}(j)$ for each $j \in J$ such that $p_j = \mathbb{A}(f_{ij}) \circ p_i$ for each map $f_{ij} : i \rightarrow j$ and the following universal property is satisfied: for any other $(B, (q_j)_{j \in J})$ such that $q_j = \mathbb{A}(f_{ij}) \circ q_i$ for each $f_{ij}$, there exists a unique morphism $u : B \rightarrow \text{lim} \mathbb{A}$ such that the diagram

\[
\begin{array}{ccc}
  \text{lim} \mathbb{A} & \xrightarrow{p_j} & \mathbb{A}(j) \\
  \downarrow^{u} & & \downarrow^{q_j} \\
  B & & \\
\end{array}
\]
commutes for every map $f_{ij}$. For example, when $\mathcal{C} = \text{Grp}$ the limit of a $J$-shaped diagram $\mathbb{A}$ is given by

$$\lim \mathbb{A} = \left\{ (a_j)_{j \in J} \in \prod_{j \in J} \mathbb{A}(j) : a_j = f_{ij}(a_i), \forall i \xrightarrow{f_{ij}} j \right\},$$

equipped with natural projections $p_j : \lim \mathbb{A} \to \mathbb{A}(j)$ by picking out the $j$-th component.

### 3.2. Metric Spaces and General Topology

Given a set $X$, an (extended) pseudo-metric $d$ on $X$ is a function $d : X \times X \to [0, +\infty]$ such that for any $x, y, z \in X$, the following holds:

- $d(x, x) = 0$;
- $d(x, y) = d(y, x)$;
- $d(x, z) \leq d(x, y) + d(y, z)$.

In this paper, the term pseudo-metric will be abused so that when the first condition is not satisfied, we still call it a pseudo-metric. A metric $d$ on $X$ is a pseudo-metric such that $d(x, y) = 0$ if and only if $x = y$. A metric space is a pair $(X, d)$ where $X$ is a set and $d$ is a metric on $X$. A (pseudo) ultrametric $d$ on $X$ is a (pseudo) metric satisfying the strong version of the triangle inequality:

$$d(x, z) \leq \max\{d(x, y), d(y, z)\}, \forall x, y, z \in X.$$

A finite metric space $(X, d_X)$ is called a tree metric space, if $d_X$ satisfies the following condition (called the four-point condition):

$$d_X(x_1, x_3) + d_X(x_2, x_4) \leq \max\{d_X(x_1, x_2) + d_X(x_3, x_4), d_X(x_3, x_2) + d_X(x_1, x_4)\},$$

for any $x_1, x_2, x_3, x_4 \in X$. It is well-known that a metric space $(X, d_X)$ is a tree metric space if and only if there is a tree $T$ with non-negative edge lengths whose nodes contain $X$ such that $d_X(x, y) = d_T(x, y)$, where $d_T(x, y)$ is the length of the shortest path between $x$ and $y$.

For a finite pseudo-metric space, its metric can be represented by a symmetric square matrix containing the pairwise distance between elements, called the distance matrix. The metric space with exactly one point is called the one-point metric space and is denoted by $\ast$. Given two pseudo-metric spaces $(X, d_X)$ and $(Y, d_Y)$, a map $f : (X, d_X) \to (Y, d_Y)$ is called distance-preserving if $d_X(x, x') = d_Y(f(x), f(x'))$ for all $x, x' \in X$. A bijective distance-preserving map is called an isometry. Two pseudo-metric spaces are isometric and denoted by $X \cong Y$, if there exists an isometry between them.

Let $(X, d_X)$ be a metric space. For $A \subset X$, we define the diameter of $A$ to be

$$\text{diam}(A) := \sup\{d_X(x, y) : x, y \in A\}.$$

If $x$ and $\tilde{x}$ are two points in $X$ such that $d_X(x, \tilde{x}) = \text{diam}(X)$, then we say that $\tilde{x}$ is an antipode of $x$. Given $x \in X$, we define the eccentricity of $x$ in $X$ to be

$$\text{ecc}(x) := \sup\{d_X(x, y) : y \in X\}.$$
The \textit{radius} of $X$ is defined to be
\[ \text{rad}(X) := \inf \{ \text{ecc}(x) : x \in X \}. \]
It is not hard to see that \( \text{diam}(X) = \sup \{ \text{ecc}(x) : x \in X \} \) and \( \text{rad}(X) \leq \text{diam}(X) \). We call a point \( x \in X \) a \textit{center} of $X$, if \( \text{ecc}(x) = \text{rad}(X) \). Centers of a metric space may not be unique. When $X$ is compact, the existence of centers is guaranteed.

Let $\mathcal{M}$ be the collection of all compact metric spaces. For $(X, d_X) \in \mathcal{M}$, we denote by $B(x, r)$ the open ball of radius $r$ centered at $x \in X$, and denote by $A^r$ the \textit{r-neighborhood} of a set $A$ in $X$, i.e.,
\[ A^r := \bigcup_{x \in A} B(x, r). \]

Let us recall the following definitions from Vigolo [47]. As a topological space with the metric topology, $X$ is \textit{uniformly locally path connected} (u.l.p.c.) if for each $\epsilon > 0$ there exists $\delta > 0$ such that for every $x \in X$ any two points in $B(x, \delta)$ are connected by a path $\gamma$ with image completely contained in $B(x, \epsilon)$. The space $X$ is \textit{uniformly semi-locally simply connected} (u.s.l.s.c.) if there exists $\epsilon > 0$ small enough so that for every $x \in X$, a loop with image contained in $B(x, \epsilon)$ is null-homotopic in $X$ (but is not necessarily null-homotopic in $B(x, \epsilon)$).

We now review some properties of homology groups and homotopy groups from [32].

Given two connected topological spaces $X$ and $Y$, let $X \vee Y$ denote the wedge sum (cf. [32, Page 10]) and let $X \times Y$ denote the product space. For each $m \geq 1$, denote by $S^m$ the \textit{m-dimensional sphere}.

\textbf{Proposition 3.1.} Let $n \geq 1$. Then, the following is true when homology groups are computed with coefficients $\mathbb{Z}$ or $\mathbb{R}$.

1. $H_n(X \vee Y) \cong H_n(X) \oplus H_n(Y)$;
2. if $X$ and $Y$ are CW complexes, then there are natural short exact sequences
\[ 0 \to \bigoplus_{i+j=n} H_i(X) \otimes H_j(Y) \to H_n(X \times Y) \to \bigoplus_{i+j=n} \text{Tor}(H_i(X), H_{j-1}(Y)) \to 0 \]
and these sequences split.
3. $\pi_n(X \times Y) \cong \pi_n(X) \times \pi_n(Y)$;
4. $\pi_1(X \vee Y) \cong \pi_1(X) * \pi_1(Y)$, as a consequence of the van Kampen’s theorem. For $n \geq 2$,
   (a) $\pi_1(S^1 \vee S^n) \cong \mathbb{Z}[t, t^{-1}]$ the Laurent polynomials in $t$ and $t^{-1}$.
   (b) Let $S^n_\alpha := S^n$ for each $\alpha \in A$ where $A$ is a given set. Then $\pi_n(\bigvee_\alpha S^n_\alpha) \cong \bigoplus_\alpha \mathbb{Z}$.

3.3. \textbf{Gromov-Hausdorff Distance.} We recall the definition of the Gromov-Hausdorff distance [12]. Let $Z_1$ and $Z_2$ be subspaces of a metric space $(X, d)$. The \textit{Hausdorff distance} between $Z_1$ and $Z_2$ is defined to be
\[ d^H_{Z_1}(Z_1, Z_2) := \inf \{ r > 0 : Z_1 \subset Z_1^r \text{ and } Z_2 \subset Z_2^r \} \]
For metric spaces $(X, d_X)$ and $(Y, d_Y)$, the \textit{Gromov-Hausdorff distance} between them is the infimum of $r > 0$ for which there exist a metric spaces $Z$ and two distance preserving maps $\psi_X : X \to Z$ and $\psi_Y : Y \to Z$ such that $d^H_Z(\psi_X(X), \psi_Y(Y)) < r$, i.e.,
\[ d_{GH}(X, Y) := \inf_{Z, \psi_X, \psi_Y} d^H_Z(\psi_X(X), \psi_Y(Y)). \]
Given two metric spaces \((X, d_X)\) and \((Y, d_Y)\), the \textit{distortion} of a map \(\varphi : X \to Y\) is given by
\[
\text{dis}(\varphi) := \sup_{x, x' \in X} |d_X(x, x') - d_Y(\varphi(x), \varphi(x'))|.
\]

For maps \(\varphi : X \to Y\) and \(\psi : Y \to X\), their \textit{co-distortion} is defined to be
\[
\text{codis}(\varphi, \psi) := \sup_{x \in X, y \in Y} |d_X(x, \psi(y)) - d_Y(\varphi(x), y)|.
\]

**Theorem 3.2** (Theorem 2.1, [35]). For two bounded metric spaces \((X, d_X)\) and \((Y, d_Y)\),
\[
d_{\text{GH}}(X, Y) = \inf_{\varphi: X \to Y} \sup_{\psi: Y \to X} \frac{1}{2} \max\{\text{dis}(\varphi), \text{dis}(\psi), \text{codis}(\varphi, \psi)\}.
\]

A \textit{tripod} between two sets \(X\) and \(Y\) is a pair of surjections from another set \(Z\) to \(X\) and \(Y\) respectively. We will express this by the diagram
\[
R: X \xleftarrow{\phi_X} Z \xrightarrow{\phi_Y} Y.
\]

For \(x \in X\) and \(y \in Y\), by \((x, y) \in R\) we mean there exists \(z \in Z\) such that \(\phi_X(z) = x\) and \(\phi_Y(z) = y\). When \((X, d_X)\) and \((Y, d_Y)\) are pseudo-metric spaces, the \textit{distortion} of a tripod \(R\) between \(X\) and \(Y\) is defined to be:
\[
\text{dis}(R) := \sup_{z, z' \in Z} |d_X(\phi_X(z), \phi_X(z')) - d_Y(\phi_Y(z), \phi_Y(z'))|.
\]

Let \(\mathcal{R}(X, Y)\) denote the collection of all tripods between \(X\) and \(Y\). Clearly, a tripod \(R\) satisfies the following property: for any \(x \in X\) there exists at least one \(y \in Y\) such that \((x, y) \in R\) and for any \(y \in Y\) there exists at least one \(x \in X\) such that \((x, y) \in R\).

**Theorem 3.3** (Theorem 7.3.25, [12]). For any two bounded metric spaces \(X\) and \(Y\),
\[
d_{\text{GH}}(X, Y) = \frac{1}{2} \inf_{R \in \mathcal{R}(X, Y)} \text{dis}(R).
\]

**Remark 3.4.** In this theorem, the formula on the right-hand side applies to pseudo-metric spaces (see [19, 21]) as a generalization of the Gromov-Hausdorff distance. For this reason, we still use the symbol \(d_{\text{GH}}\) to denote this generalized distance.

**Proposition 3.5** (p. 255, [12]). For bounded metric spaces \((X, d_X)\) and \((Y, d_Y)\),
\[
\frac{1}{2} |\text{diam}(X) - \text{diam}(Y)| \leq d_{\text{GH}}(X, Y) \leq \frac{1}{2} \max\{\text{diam}(X), \text{diam}(Y)\}.
\]

In particular, if \(Y\) is the one-point metric space \(*\), then
\[
d_{\text{GH}}(X, *) = \frac{1}{2} \text{diam}(X).
\]

The lower bound in Proposition 3.5 can be improved in the following case:

**Proposition 3.6.** Suppose \((X, d_X) \in \mathcal{M}\) is such that every \(x \in X\) has an antipode. Let \((Y, d_Y) \in \mathcal{M}\) be such that \(\text{rad}(Y) \leq \text{diam}(X)\). Then
\[
\frac{1}{2} (\text{diam}(X) - \text{rad}(Y)) \leq d_{\text{GH}}(X, Y).
\] (1)

**Proof.** Let \(y_0\) be a center of \(Y\). Suppose \(R\) is an arbitrary tripod between \(X\) and \(Y\). Clearly, there exists some \(x \in X\) such that \((x, y_0) \in R\). Let \(\hat{x}\) be an antipode of \(x\), i.e., \(d_X(x, \hat{x}) = \text{diam}(X)\). There exists some \(y \in Y\) such that \((\hat{x}, y) \in R\). Therefore,
\[
\text{diam}(X) - \text{rad}(Y) \leq d_X(x, \hat{x}) - d_Y(y_0, y) \leq \text{dis}(R).
\]

Since \(R\) is arbitrary, we can conclude that Equation (1) is true. \(\square\)
A pointed metric space \((X, x_0, d_X)\) is a metric space \((X, d_X)\) together with a distinguished basepoint \(x_0 \in X\). For the sake of simplicity, we will omit the distance function \(d_X\) and denote a pointed metric space by \((X, x_0)\). Let \(\mathcal{M}^{pt} = \{(X, x_0) | x_0 \in X, (X, d_X) \in \mathcal{M}\}\) be the collection of all pointed compact metric spaces. Given basepoints \(x_0 \in X\) and \(y_0 \in Y\), a **pointed tripod** is a tripod \(R : X \leftarrow \phi_X Z \rightarrow \phi_Y Y\) such that \(\phi_X^{-1}(x_0) \cap \phi_Y^{-1}(y_0)\) is non-empty. Let \(\mathcal{R}^{pt}((X, x_0), (Y, y_0))\) denote the collection of pointed tripods between \((X, x_0)\) and \((Y, y_0)\).

The **pointed Gromov-Hausdorff distance** between \(X\) and \(Y\) is defined to be

\[
d_{\text{GH}}^{pt}((X, x_0), (Y, y_0)) := \frac{1}{2} \inf_{R \in \mathcal{R}^{pt}((X, x_0), (Y, y_0))} \text{dis}(R).
\]

It is clear that

\[
d_{\text{GH}}(X, Y) = \inf_{x_0 \in X, y_0 \in Y} d_{\text{GH}}^{pt}((X, x_0), (Y, y_0)).
\]

### 3.4. Persistence Theory

We recall the definitions of persistence modules and the interleaving distance, as well as the stability theorem for the interleaving distance and the bottleneck distance, from [8, 39].

Let \(T = \mathbb{R}_+, \mathbb{R}_{\geq 0}\) or \(\mathbb{R}\). Note that in any of the three cases there is a canonical poset structure on \(T\), denoted by \((T, \leq)\). Consequently, \((T, \leq)\) can be viewed as a category whose objects are real numbers and the set of morphisms from an object \(a\) to an object \(b\) consists of a single morphism if \(a \leq b\) and is otherwise empty. Let \(\mathcal{C}\) be any arbitrary category. The collections of functors

\[
\mathbb{V} : (T, \leq) \to \mathcal{C},
\]

and natural transformations between functors forms a category denoted by \(\mathbf{PC}^{(T, \leq)}\) (see [11, §2]). Recall that given two objects \(\mathbb{V}\) and \(\mathbb{W}\) of \(\mathbf{PC}^{(T, \leq)}\), a natural transformation from \(\mathbb{V}\) to \(\mathbb{W}\)

\[
f : \mathbb{V} \Rightarrow \mathbb{W},
\]

also called a **homo morphism** from \(\mathbb{V}\) to \(\mathbb{W}\), is a family of morphisms in \(\mathcal{C}\): \(\{f_t : V_t \to W_t\}_{t \in T}\) such that the diagram

\[
\begin{array}{ccc}
V_t & \xrightarrow{v_t} & V_{t'} \\
\downarrow f_t & & \downarrow f_{t'} \\
W_t & \xrightarrow{w_{t,t'}} & W_{t'}
\end{array}
\]

commutes for \(t \leq t'\). If \(f_t\) is an isomorphism in \(\mathcal{C}\) for each \(t \in T\), then the homomorphism \(f\) is called a *(natural) isomorphism* between \(\mathbb{V}\) and \(\mathbb{W}\), in which case we write \(\mathbb{V} \cong \mathbb{W}\). The collection of homomorphisms from \(\mathbb{V}\) to \(\mathbb{W}\) is denoted by \(\text{Hom}(\mathbb{V}, \mathbb{W})\).

For an object \(A \in \mathcal{C}\) and an interval \(I \subset T\), the **interval (generalized) persistence module** \(A[I]\) is defined as follows: \(A[I] = 0\) if \(I\) is empty and otherwise,

\[
(A[I])(t) = \begin{cases} 
A, & \text{if } t \in I, \\
0, & \text{otherwise},
\end{cases}
\]

where \((A[I])(s \leq t) = \text{Id}_A\) when \(s\) and \(t\) are both in \(I\), and \((A[I])(s \leq t) = 0\) otherwise.

Let \(\delta \geq 0\). We define \(S_\delta : (T, \leq) \to (T, \leq)\) to be the functor given by \(S_\delta(t) = t + \delta\) and define \(\eta_\delta : \text{Id}_{(T, \leq)} \Rightarrow S_\delta\) to be the natural transformation given by \(\eta_\delta(t) : t \leq t + \delta\). Note that
\( S_\delta \circ S_{\delta'} = S_{\delta + \delta'} \) and \( \eta_\delta \circ \eta_{\delta'} = \eta_{\delta + \delta'} \). A homomorphism of degree \( \delta \) from \( V \) to \( W \) is a natural transformation
\[
f : V \Rightarrow W \circ S_\delta.
\]
The collection of homomorphisms of degree \( \delta \) from \( V \) to \( W \) is denoted by \( \text{Hom}^\delta(V, W) \).

In this paper, we will consider several choices of \( \mathcal{C} \):

- \( \mathcal{C} = \text{Set} \) yields \( \text{PSet}^{(T, \leq)} \), whose objects are called persistent sets;
- \( \mathcal{C} = \text{Vec} \) yields \( \text{PVec}^{(T, \leq)} \), whose objects are called persistence modules;
- \( \mathcal{C} = \text{Grp} \) yields \( \text{PGrp}^{(T, \leq)} \), whose objects are called persistent groups;
- \( \mathcal{C} = \text{Top} \) yields \( \text{PTop}^{(T, \leq)} \), whose objects are called \( T \)-spaces.

**Definition 3.7** (Definition 3.1, [11]). An \( \delta \)- interleaving of \( V \) and \( W \) consists of natural transformations \( f : V \Rightarrow W \circ S_\delta \) and \( g : W \Rightarrow V \circ S_\delta \) (i.e., \( f \in \text{Hom}^\delta(V, W) \) and \( g \in \text{Hom}^\delta(W, V) \)) such that the following diagrams commute for all \( t \in T \):
\[
(gS_\delta)f = V \eta_{2\delta} \quad \text{and} \quad (fS_\delta)g = W \eta_{2\delta}.
\]

If there exists a \( \delta \)-interleaving \((V, W, f, g)\), then we say that \( V \) and \( W \) are \( \delta \)-interleaved.

In other words, a \( \delta \)-interleaving \((V, W, f, g)\) consists of families of morphisms \( \{f_t : V_t \rightarrow W_{t+\delta}\}_{t \in T} \) and \( \{g_t : W_t \rightarrow V_{t+\delta}\}_{t \in T} \) such that the following diagrams commute for all \( t \leq t' \):

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
V_t \xrightarrow{v_{t,t'}} V_{t'}
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
W_{t+\delta} \xrightarrow{w_{t+\delta,t'+\delta}} W_{t'+\delta}
\end{array}
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
V_{t+\delta} \xrightarrow{v_{t+\delta,t'+\delta}} V_{t'+\delta}
\end{array}
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
W_t \xrightarrow{w_{t,t'}} W_{t'}
\end{array}
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
V_t \xrightarrow{v_{t,t+2\delta}} V_{t+2\delta}
\end{array}
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
W_{t+\delta} \xrightarrow{w_{t+\delta,t+2\delta}} W_{t+2\delta}
\end{array}
\end{array}
\end{array}
\end{array}
\end{array}
\end{array}
\]

and

**Definition 3.8.** Let \( V \) and \( W \) be objects of \( \text{PC}^{(T, \leq)} \). The *interleaving distance* between \( V \) and \( W \) is
\[
d_1(V, W) := \inf\{\delta \geq 0 : V \text{ and } W \text{ are } \delta \text{-interleaved}\}.
\]

Here we follow the convention that \( \inf \emptyset = +\infty \). A quick fact is that \( d_1 \) descends to a distance on isomorphism classes of objects in \( \text{PC}^{(T, \leq)} \).

**Persistence Modules and Persistence Diagrams.** Let \( \mathcal{C} = \text{Vec} \) and let \( T = \mathbb{R}_+ \), unless otherwise specified. Recall from [39] that a persistence module \( V \) is \( q \)-tame if \( \text{rank} (v_{t,t'} : V_t \rightarrow V_{t'}) < \infty \) whenever \( t < t' \). If a persistence module \( V \) can be decomposed as a direct sum of interval modules (e.g. \( V \) is \( q \)-tame), say \( V \cong \bigoplus_{i \in L} k(p_i^*, q_i^*) \) where \( * \) indicates whether the interval is half-open or not (see [17]), then its (undecorated) persistence diagram is the multiset
\[
\text{dgm}(V) := \{(p_l, q_l) : l \in L\} - \Delta,
\]
where \( \Delta := \{(r, r) : r \in \mathbb{R}\} \) is the diagonal in the real plane.
The bottleneck distance between persistence diagrams, and more generally between multisets $A$ and $B$ of points in $\mathbb{R}^2$, where $\mathbb{R}$ are the extended real numbers $\mathbb{R} \cup \{\pm \infty\}$, is defined as follows:

$$d_B(A, B) := \inf \left\{ \sup_{a \in A} \| a - \phi(a) \|_\infty : \phi : A \cup \Delta^\infty \to B \cup \Delta^\infty \text{ a bijection} \right\}.$$ 

Here $\|(p, q) - (p', q')\|_\infty := \max\{|p-p'|, |q-q'|\}$ for each $p, q, p', q' \in \mathbb{R}$ and $\Delta^\infty$ is the multiset consisting of each point on the diagonal $\{(r, r) : r \in \mathbb{R}\}$ in the extended real plane, taken with infinite multiplicity (see [20]).

**Theorem 3.9** (Theorem 5.14, [17]). Let $\mathbb{V}$ and $\mathbb{W}$ be q-tame persistence modules. Then,

$$d_1(\mathbb{V}, \mathbb{W}) = d_B(\text{dgm}(\mathbb{V}), \text{dgm}(\mathbb{W})),$$

where $d_1(\mathbb{V}, \mathbb{W})$ is defined in Definition 3.8 with $\mathcal{C} = \text{Vec}$.

**Vietoris-Rips Complexes.** By first constructing a simplicial filtration out of a metric space and then applying the simplicial homology functor, one obtains a persistence module which encodes computable invariants of the original space. In this paper, we focus on the simplicial filtration given by Vietoris-Rips complexes, and recall the definitions from [2]. Suppose that $(X, d_X)$ is a compact metric space and $\epsilon$ is a non-negative real number. The Vietoris-Rips complex $\text{VR}_\epsilon(X)$ is the simplicial complex with vertex set $X$, where

a finite subset $\sigma \subset X$ is a face of $\text{VR}_\epsilon(X)$ iff $\text{diam}(\sigma) \leq \epsilon$.

The collection $\{\text{VR}_\epsilon(X)\}_{\epsilon \geq 0}$ together with the natural simplicial inclusions forms a filtration of $X$, denoted by $\text{VR}_\bullet(X)$.

Let $G$ be an Abelian group. Given $k \in \mathbb{Z}_{\geq 0}$ and $\epsilon \geq 0$, let $C_k(\text{VR}_\epsilon(X); G)$ be the Abelian group consisting of chains of the form $\sum_i n_i \sigma_i$ where coefficients $n_i$ are taken from $G$ and each $\sigma_i$ is a $k$-simplex in $\text{VR}_\epsilon(X)$. Let $\partial_k : C_k(\text{VR}_\epsilon(X); G) \to C_{k-1}(\text{VR}_\epsilon(X); G)$ be the $k$-th boundary operator. We denote by

$$\text{PH}^\text{VR}_k(\mathbb{V}, \mathbb{W}) := \text{H}_k(\mathbb{V}, \mathbb{W}),$$

the $k$-th (simplicial) homology group of $\text{VR}_\epsilon(X)$ with coefficients in $G$. Then $\{\text{PH}^\text{VR}_k(\mathbb{V}, \mathbb{W})\}_{\epsilon \geq 0}$ together with the maps induced by natural inclusions forms an object in $\text{PGrp}(\mathbb{R}_{\geq 0}, \leq)$, denoted by $\text{PH}^\text{VR}_k(X; G)$. The collection of these modules for $k$ ranging over all dimensions is called the persistent homology of $X$ and denoted by $\text{PH}^\text{VR}(X; G)$. We will omit the coefficient group when $G = \mathbb{Z}$. When $G = \mathbb{K}$ is a field, $\text{PH}^\text{VR}_k(X; \mathbb{K})$ is a persistent module and it is shown in [18] that if $X$ is compact, then $\text{PH}^\text{VR}_k(X; \mathbb{K})$ is q-tame for all $k \in \mathbb{Z}_{\geq 0}$. The persistence diagram corresponding to $\text{PH}^\text{VR}_k(X; \mathbb{K})$ is denoted by $\text{dgm}_k(X)$ for each $k \in \mathbb{Z}_{\geq 0}$.

**Theorem 3.10** (Stability Theorem for $d_B$, [16, 18]). Let $(X, d_X)$ and $(Y, d_Y)$ be from $\mathcal{M}$. Then, for any $k \in \mathbb{Z}_{\geq 0},$

$$d_1(\text{PH}^\text{VR}_k(X; \mathbb{K}), \text{PH}^\text{VR}_k(Y; \mathbb{K})) = d_B(\text{dgm}_k(X), \text{dgm}_k(Y)) \leq 2 \cdot d_{\text{GH}}(X, Y).$$

**R-spaces and Homotopy Interleavings.** Recall that $\text{Top}$ is the category of compactly generated weakly Hausdorff topological spaces, and an object in $\text{PTop}(\mathbb{R}, \leq)$ is also called an $\mathbb{R}$-space (see [8]). Let $X$ be an $\mathbb{R}$-space. If for every $t \leq s \in \mathbb{R}$, the map $X_t \to X_s$ is an inclusion, then we call $X$ a filtration. Blumberg and Lesnick showed that the interleaving distance between $\mathbb{R}$-spaces is not homotopy invariant (see [8, Remark 3.3]), and then defined homotopy interleavings between $\mathbb{R}$-spaces as certain homotopy-invariant analogues of interleavings.
Given two $\mathbb{R}$-spaces $X$ and $Y$, a natural transformation $f : X \to Y$ is an \textit{objectwise weak equivalence} if for each $t \in \mathbb{R}$, $f_t : X_t \to Y_t$ is a weak homotopy equivalence, i.e., it induces isomorphisms on all homotopy groups. The $\mathbb{R}$-spaces $X$ and $Y$ are \textit{weakly equivalent}, denoted by $X \simeq Y$, if there exists an $\mathbb{R}$-space $W$ and natural transformations $f : W \to X$ and $g : W \to Y$ that are (objectwise) weak equivalences:

$$X \xrightarrow{f} W \xrightarrow{g} Y.$$

The relation $X \simeq Y$ is an equivalence relation (see [8] for details). Given $T \subset \mathbb{R}$, we can consider the restriction of any given $\mathbb{R}$-space to $T$ and study $T$-spaces in a similar way. For $\delta \geq 0$, two $\mathbb{R}$-spaces $X$ and $Y$ are \textit{$\delta$-homotopy-interleaved} if there exist $\mathbb{R}$-spaces $X' \simeq X$ and $Y' \simeq Y$ such that $X'$ and $Y'$ are $\delta$-interleaved, as in Definition 3.7 with $C = \text{Top}$.

**Definition 3.11** (Homotopy interleaving distance). The \textit{homotopy interleaving distance} between two $\mathbb{R}$-spaces $X$ and $Y$ is given by

$$d_{HI}(X, Y) := \inf \{\delta \geq 0 : X, Y \text{ are } \delta\text{-homotopy-interleaved}\}.$$

**Theorem 3.12** (Theorem 1.6, [8]). Given two compact metric spaces $X$ and $Y$, we have

$$d_B(dgm_k(X), dgm_k(Y)) \leq d_{HI}(|\text{VR}_k(X)|, |\text{VR}_k(Y)|) \leq 2 \cdot d_{GH}(X, Y).$$

Here $|\text{VR}_k(X)|$ denotes the $\mathbb{R}_{\geq 0}$-space given by the geometric realizations of Vietoris-Rips complexes of $X$.

### 3.5. Dendrograms and Generalized Subdendrograms

For this section, we refer to [14]. Let $A$ be a set, and let $\text{Part}(A)$ be the set of partitions of $A$.

**Definition 3.13.** A \textit{dendrogram} over $A$ is a pair $(\theta_A, \theta_B)$, where $\theta_A : \mathbb{R}_{\geq 0} \to \text{Part}(A)$ satisfies:

1. If $t \leq s$, then $\theta_A(t)$ refines $\theta_A(s)$.
2. For all $r$ there exists $\delta > 0$ s.t. $\theta_A(r) = \theta_A(t)$ for all $t \in [r, r + \delta]$.
3. There exists $t_0$ such that $\theta_A(t)$ is the single block partition for all $t \geq t_0$.
4. $\theta_A(0)$ is the partition into singletons.

The following function on $A \times A$ defines an ultrametric on $A$ (see [14]): for any $x, x' \in A$,

$$\mu_{\theta_A}(x, x') := \min \{\delta : x \text{ and } x' \text{ belong to the same block of } \theta_A(\delta)\}.$$ 

Let $(A, \theta_A)$ and $(B, \theta_B)$ be two dendrograms. Given $\delta \geq 0$, we say that the set maps $\phi : A \to B$ and $\psi : B \to A$ provide a $\delta$-\textit{interleaving} between $\theta_A$ and $\theta_B$ iff for all $x \in A, y \in B$ and $t \geq 0$,

$$\phi(\langle x \rangle^A_t) \subset \langle \phi(x) \rangle^B_{t+\delta} \text{ and } \psi(\langle y \rangle^B_t) \subset \langle \psi(y) \rangle^A_{t+\delta},$$

where $\langle x \rangle^A_t$ represents the subset of $A$ containing $x$ in the partition $\theta_A(t)$. If such a $\delta$-interleaving exists, we say that $\theta_A$ and $\theta_B$ are $\delta$-interleaved. The \textit{interleaving distance} between dendrograms $\theta_A$ and $\theta_B$ is defined to be

$$d_I(\theta_A, \theta_B) := \inf \{\delta > 0 : A \text{ and } B \text{ are } \delta\text{-interleaved}\}.$$ 

**Remark 3.14.** Notice that each dendrogram $\theta_A$ can be viewed as an element of $\text{PSet}$, following from the definition of $\theta_A$ and the fact that $\text{Part}(A)$ is a subcategory of $\text{Set}$. Using Definition 3.8, we can construct the interleaving distance, denoted by $d^\text{Set}_I$, between dendrograms $(A, \theta_A)$ and $(B, \theta_B)$. It turns out that $d_I(\theta_A, \theta_B) = d^\text{Set}_I(\theta_A, \theta_B)$. Indeed, each $\delta$-interleaving $(\phi : A \to B, \psi : B \to A)$ clearly induces a $\text{PSet}-\delta$-interleaving. Conversely, given a $\text{PSet}$-$\delta$-interleaving $(\Phi : \text{Part}(A) \to \text{Part}(B), \Psi : \text{Part}(B) \to (A))$, we can define...
map \( \phi : A \to B \) with \( a \mapsto b \in \Phi(0)(\{a\}) \), and similarly define \( \psi : B \to A \). Although \( \phi \) and \( \psi \) are not uniquely defined, it is not hard to see that the resulting \( (\phi, \psi) \) is always a \( \delta \)-interleaving regardless of the choices.

The functor \( \mathcal{V}_k \circ \theta_A : (\mathbb{R}_+, \leq) \to \textbf{Vec} \), with \( \mathcal{V}_k \circ \theta_A(t) = \mathcal{V}_k(\theta_A(t)) \) and \( \mathcal{V}_k \circ \theta_A(t \leq s) = \mathcal{V}_k(\theta_A(t)) \to \mathcal{V}_k(\theta_A(s)) \) induced by refinement of partitions, is then a persistence module.

**Proposition 3.15** (§3.5, [14]). Let \( (A, \theta_A) \) and \( (B, \theta_B) \) be two dendrograms. Then,

\[
\frac{1}{2} \cdot d_1(\mathcal{V}_k \circ \theta_A, \mathcal{V}_k \circ \theta_B) \leq d_{\text{GH}}((A, \mu_{\theta_A}), (B, \mu_{\theta_B})) \leq d_1(\theta_A, \theta_B).
\]

**Proof.** The first inequality follows from an argument in [14]. Assume \( d_{\text{GH}}((X, \mu_{\theta_A}), (Y, \mu_{\theta_B})) \leq \delta/2 \) for some \( \delta \geq 0 \). Then there are maps \( \phi : A \to B \) and \( \psi : B \to A \) such that

- if \( x \) and \( x' \) are in the same block of \( \theta_A(t) \), then \( \phi(x) \) and \( \phi(x') \) belong to the same block of \( \theta_B(t + \delta) \);
- if \( y \) and \( y' \) are in the same block of \( \theta_B(t) \), then \( \psi(y) \) and \( \psi(y') \) belong to the same block of \( \theta_A(t + \delta) \).

In other words, \( \phi \) and \( \psi \) induce homomorphisms of degree \( \delta \) on persistence modules \( \mathcal{V}_k \circ \theta_A \) and \( \mathcal{V}_k \circ \theta_B \), denoted by \( \phi_\delta \) and \( \psi_\delta \), respectively. Given \( t > 0 \), if \( x \) and \( x' \) fall into the same block of \( \theta_A(t) \), then \( \psi \circ \phi(x) \) \( \psi \circ \phi(x') \) belong to the same block of \( \theta_A(t + 2\delta) \). Thus, \( \psi_\delta \circ \phi_\delta = 1_{2^{\mathcal{V}_k \circ \theta_A}} \). Similarly, we have \( \phi_\delta \circ \psi_\delta = 1_{2^{\mathcal{V}_k \circ \theta_B}} \). Therefore, \( \mathcal{V}_k \circ \theta_A \) and \( \mathcal{V}_k \circ \theta_B \) are \( \delta \)-interleaved. Letting \( \delta \leq 2d_{\text{GH}}((A, \mu_{\theta_A}), (B, \mu_{\theta_B})) \), the first inequality follows.

Suppose \( (\phi, \psi) \) is a \( \delta \)-interleaving between \( \theta_A \) and \( \theta_B \). Clearly,

\[
R : A \xleftarrow{\phi} A \sqcup B \xrightarrow{\psi} B
\]

forms a tripod between \( A \) and \( B \), with distortion no larger than \( 2\delta \). Therefore, the second inequality is true. \( \square \)

Given two sets \( A \) and \( B \), let \( P_A := \{A_1, \cdots, A_k\} \) and \( P_B := \{B_1, \cdots, B_l\} \) be partitions of \( A \) and \( B \), respectively. We define the product of \( P_A \) and \( P_B \) to be

\[
P_A \times P_B := \{(A_i, B_j) : 1 \leq i \leq k, 1 \leq j \leq l\},
\]

which is clearly a partition of \( A \times B \). In fact, the map \( (P_A, P_B) \mapsto P_A \times P_B \) gives an embedding \( \text{Part}(A) \times \text{Part}(B) \hookrightarrow \text{Part}(A \times B) \). For two dendrograms \( (A, \theta_A) \) and \( (B, \theta_B) \), we define their product to be \( (A \times B, \theta_A \times \theta_B) \), where

\[
\theta_A \times \theta_B : \mathbb{R}_{\geq 0} \to \text{Part}(A \times B) \text{ with } t \mapsto \theta_A(t) \times \theta_B(t).
\]

It follows directly from Definition 3.13 that \( (A \times B, \theta_A \times \theta_B) \) forms a dendrogram.

A *subpartition* of a set \( A \) is a partition of one of its subsets \( A' \subset A \). Let \( \text{SubPart}(A) \) be the set of subpartitions of \( A \).

**Definition 3.16.** A *generalized subdendrogram* of \( A \) is a pair \( (A, \theta_A^s) \), where \( \theta_A^s : \mathbb{R}_+ \to \text{SubPart}(A) \) satisfies:

1. If \( t \leq s \), then \( \theta_A^s(t) \) and \( \theta_A^s(s) \) are partitions of \( A_t \) and \( A_s \), respectively, where \( A_t \subset A_s \subset A \) and \( \theta_A^s(t) \) refines \( \theta_A^s(s)|_{A_t} := \{B \cap A_t : B \in \theta_A^s(s)\} \).
2. For all \( r \) there exists \( \delta > 0 \) s.t. \( \theta_A^s(r) = \theta_A^s(t) \) for all \( t \in [r, r + \delta] \).
3. There exists \( t_0 \) such that \( \theta_A^s(t) \) is the single block partition for all \( t \geq t_0 \).
Similarly, we consider the following function on $A \times A$: for any $x$ and $x'$ in $A$, 
$$
\mu_{\theta_A}^s(x, x') := \min\{\delta \geq 0 : x, x' \text{ belong to the same block of } \theta_A(\delta)\},
$$
which turns out to be a pseudo-ultrametric.

**Proposition 3.17.** Let $(A, \theta_A^s)$ and $(B, \theta_B^s)$ be two generalized subdendrograms. Then
$$
\frac{1}{4} \cdot d_1(\nu_k \circ \theta_A^s, \nu_k \circ \theta_B^s) \leq d_{\text{GH}}((A, \mu_{\theta_A^s}), (B, \mu_{\theta_B^s})).
$$

**Proof.** This follows from a similar proof with Proposition 3.15. \qed

4. Discrete Fundamental Groups

4.1. Persistent Sets. Given a compact metric space $(X, d_X)$ and $\varepsilon \geq 0$, let $\pi^0_\varepsilon(X) = X/\sim_\varepsilon$, where $x \sim_\varepsilon x'$ if there exists $\{x_0, \ldots, x_n\} \subset X$ such that $x_0 = x, x_n = x'$ and $d_X(x_i, x_{i+1}) \leq \varepsilon$. For simplicity, we will write the sequence $\{x_0, \ldots, x_n\}$ as $x_0 \cdots x_n$. As $\varepsilon' \geq \varepsilon \geq 0$, there is a natural map from $\pi^0_\varepsilon(X)$ to $\pi^0_{\varepsilon'}(X)$ via $[x]_\varepsilon \mapsto [x]_{\varepsilon'}$. The collection $\{\text{PII}_\varepsilon(X) := \pi^0_\varepsilon(X)\}_{\varepsilon \geq 0}$ together with the natural maps forms a persistent set, i.e., an object in $\text{PSet}^{(\mathbb{R} \geq 0; \leq)}$, denoted by $\text{PH}_0(X)$.

**Fact 4.1.** $\nu_k(\text{PII}_0(X)) \cong \text{PH}_0(X; k)$.

**Proof.** Fix an $\varepsilon \geq 0$. Clearly, the boundary operator
$$
\partial_1 : C_1(\text{VR}_\varepsilon(X); k) = \nu_k(\{(x, x') \in X \times X : d_X(x, x') \leq \varepsilon\}) \to C_0(\text{VR}_\varepsilon(X); k) = \nu_k(X)
$$
is given by $(x, x') \mapsto x - x'$. Thus, $\text{Im}(\partial_1) = \nu_k\{x' - x : d_X(x, x') \leq \varepsilon\}$ and
$$
\text{PH}_0(X; k) \cong \text{H}_0(\text{VR}_\varepsilon(X); k) = \nu_k(X)/\nu_k\{x' - x : d_X(x, x') \leq \varepsilon\} \cong \nu_k(X/\sim_\varepsilon) = \nu_k(\text{PII}_\varepsilon(X)).
$$
In addition, the above isomorphisms form a natural isomorphism between $\nu_k(\text{PII}_0(X))$ and $\text{PH}_0(X; k)$ \qed

**Proposition 4.2.** The following defines an ultrametric on $X$: for any $x, x' \in X$,
$$
\mu_X^0(x, x') := \inf \{\varepsilon : x \sim_\varepsilon x'\}
$$
$$
= \inf \{\varepsilon : \exists \{x_0, \ldots, x_n\} \subset X \text{ s.t. } x_0 = x, x_n = x', d_X(x_i, x_{i+1}) \leq \varepsilon\}.
$$

**Proof.** Clearly, $\mu_X^0(x, x) = 0$ and $\mu_X^0(x, x') = \mu_X^0(x', x)$ for all $x$ and $x' \in X$. It remains to prove the strong triangle inequality. Given arbitrary $x, y, z \in X$, suppose $\varepsilon_1 > \mu_X^0(x, y)$ and $\varepsilon_2 > \mu_X^0(y, z)$. Let $x^1_0 \cdots x^1_{n_1}$ and $x^2_0 \cdots x^2_{n_2}$ be the sequences to realize $x \sim_{\varepsilon_1} y$ and $y \sim_{\varepsilon_2} z$, respectively. Then $x^1_0 \cdots x^1_{n_1}, x^2_0, \ldots, x^2_{n_2}$ is such that $x^1_0 = x, x^2_0 = z$ and the distance between adjacent points in that sequence is no larger than $\max\{\varepsilon_1, \varepsilon_2\}$. By the minimality, $\mu_X^0(x, z) \leq \max\{\varepsilon_1, \varepsilon_2\}$. Letting $\varepsilon_1 \searrow \mu_X^0(x, y)$ and $\varepsilon_2 \searrow \mu_X^0(y, z)$, we obtain the strong triangle inequality. \qed

A stability theorem for $\mu^0_*$ can be found in [14]. We include it here together with a proof for pedagogical reasons: our proof of Theorem 4.23 will exhibit a similar pattern.

**Theorem 4.3** (Stability Theorem for $\mu^0_*$). Given $(X, d_X)$ and $(Y, d_Y) \in \mathcal{M}$,
$$
d_{\text{GH}}\left((X, \mu_X^0), (Y, \mu_Y^0)\right) \leq d_{\text{GH}}(X, Y).
$$
Proof. Let $R : X \leftarrow Z \rightarrow Y$ be an arbitrary tripod between $X$ and $Y$. Given $(x, y)$ and $(x', y')$ in $R$, suppose $\varepsilon > \mu_X^{(0)}(x, x')$ and $x_0, \ldots, x_n$ is a sequence to realize $\varepsilon$. For each $0 \leq i \leq n - 1$, there exists some $z_i \in Z$ such that $\phi_X(z_i) = x_i$. Let $y_i = \phi_Y(z_i)$. For $0 \leq i \leq n - 1$,
\[
\begin{align*}
d_Y(y_i, y_{i+1}) & \leq d_X(x_i, x_{i+1}) + |d_Y(y_i, y_{i+1}) - d_X(x_i, x_{i+1})| \\
& \leq \varepsilon + \text{dis}(R),
\end{align*}
\]
where $\text{dis}(R)$ denotes the distortion induced by $d_X$ and $d_Y$. Thus, $\left\{ y = y_0, y_1, \ldots, y_n = y' \right\}$ is an $(\varepsilon + \text{dis}(R))$-homotopy between $y$ and $y'$. As $\varepsilon \land \mu_X^{(0)}(x, x')$, it follows that $\mu_Y^{(0)}(y, y') \leq \mu_X^{(0)}(x, x') + \text{dis}(R)$. Similarly, we can prove $\mu_X^{(0)}(x, x') \leq \mu_Y^{(0)}(y, y') + \text{dis}(R)$. Therefore,
\[
\begin{align*}
d_{\text{GH}}((X, \mu_X^{(0)}), (Y, \mu_Y^{(0)})) & = \frac{1}{2} \inf_{R \in \mathcal{R}(X,Y)} \max_{(x,y),(x',y') \in R} |\mu_X^{(0)}(x, x') - \mu_Y^{(0)}(y, y')| \\
& \leq \frac{1}{2} \inf_{R \in \mathcal{R}(X,Y)} \text{dis}(R) \\
& = d_{\text{GH}}(X, Y).
\end{align*}
\]
\[\square\]

The following example is a case where $\mu^{(0)}$ gives a better approximation of the Gromov-Hausdorff distance, compared to the bottleneck distance lower bound given by Theorem 3.10.

**Example 4.4.** Let $X_\varepsilon := (\{0,1\}, d_\varepsilon)$ be a metric space consisting of two points, where $d_\varepsilon(0,1) = 1 + \varepsilon$. Since $\mu_X^{(0)} = d_\varepsilon$, we have
\[
\begin{align*}
d_{\text{GH}}((X_\varepsilon, \mu_X^{(0)}), (X_0, \mu_X^{(0)})) & = d_{\text{GH}}(X_\varepsilon, X_0) = \frac{\varepsilon}{2},
\end{align*}
\]
for all $\varepsilon \geq 0$. On the other hand, it is not hard to verify that $\text{dgm}_0(X_\varepsilon) = \{(0, 1+\varepsilon), (0, +\infty)\}$, and thus,
\[
\frac{1}{2}d_B(\text{dgm}_0(X_\varepsilon), \text{dgm}_0(X_0)) = \min \left\{ \frac{\varepsilon}{2}, \frac{1+\varepsilon}{4} \right\} \leq \frac{\varepsilon}{2},
\]
where the inequality is strict when $\varepsilon > 1$.

4.2. Discrete Fundamental Groups. Let us fix a parameter $\varepsilon > 0$, and adopt the construction of discrete fundamental groups from [49]. An $\varepsilon$-chain in $(X, d_X)$ is a finite sequence of points $\gamma = x_0 \cdots x_n$ such that $d_X(x_i, x_{i+1}) \leq \varepsilon$ for $i = 0, \ldots, n - 1$. When $x_0 = x_n$, we say that $\gamma$ is an $\varepsilon$-loop. The integer $n$ is called the size of $\gamma$, and written as $\text{size}(\gamma)$. The reversal of $\gamma$ is the $\varepsilon$-chain $\gamma^{-1} := x_n, x_{n-1}, \ldots, x_0$. The terms discrete chains (resp. discrete loops) will refer to $\varepsilon$-chains (resp. $\varepsilon$-loops) for all $\varepsilon > 0$. A subdivision of a discrete chain $\gamma$ is a discrete chain which can be written as
\[
\alpha' = (x_0^0 \cdots x_{m_0}^0) \cdots (x_i^0 \cdots x_{m_i}^0) \cdots (x_{n-1}^0 \cdots x_{m_{n-1}}^0),
\]
where $x_i^0 = x_i, x_i^{m_i} = x_{i+1}$ and $x_i^{j_i} \in X$ for any $i$ and $j_i = 1, \ldots, m_i - 1$. In this case, we denote $\alpha' \supset \alpha$ or $\alpha \subseteq \alpha'$.

A space $X$ is $\varepsilon$-connected if any two points $x, y \in X$ can be joined by an $\varepsilon$-chain. If $X$ is $\varepsilon$-connected for all $\varepsilon > 0$, we say that $X$ is chain-connected.

**Lemma 4.5** (Lemma 2.1.1, [49]). Let $X$ be a metric space.

- If $X$ is connected, then $X$ is chain-connected.
• If $X$ is chain-connected and compact, then $X$ is connected.

In [49], Wilkins defined a basic move on an $\epsilon$-chain as the addition or removal of a point which is not an endpoint, so that the resulting path is still an $\epsilon$-chain. In our paper, in order to avoid tedious arguments, basic moves also include the case when there are no changes.

Definition 4.6. Two chains $\alpha$ and $\beta$ are $\epsilon$-homotopic, denoted by $\alpha \sim^\epsilon \beta$, if there is a finite sequence of $\epsilon$-chains

$$H = \{\alpha = \gamma_0, \gamma_1, \ldots, \gamma_{k-1}, \gamma_k = \beta\}$$

such that each $\gamma_i$ differs from $\gamma_{i-1}$ by a basic move. We call $H$ an $\epsilon$-homotopy and denote the $\epsilon$-homotopy class of an $\epsilon$-chain $\alpha$ by $[\alpha]_\epsilon$.

The following reformulation (see [4]) will be useful in the sequel. For a non-negative integer $n$, let $[n] := \{0, \ldots, n-1\}$. Note that an $\epsilon$-chain in $X$ can also be regarded as an $\epsilon$-Lipschitz map $\gamma : ([n], \ell^\infty) \to (X, d_X)$ for some $n \in \mathbb{Z}_{>0}$, i.e., $d_X(\gamma(i), \gamma(i+1)) \leq \epsilon$ for all $i \in [n-1]$. A lazification of an $\epsilon$-path $\gamma : [n] \to X$ is an $\epsilon$-chain $\tilde{\gamma} : [m] \to X$ such that $m \geq n$ and $\tilde{\gamma} = \gamma \circ p$ where $p : [m] \to [n]$ is surjective and monotone.

Proposition 4.7. Two chains $\alpha$ and $\beta$ are $\epsilon$-homotopic if and only if there exists a triple $(\tilde{\alpha}, \tilde{\beta}, \tilde{H})$ where

- $\tilde{\alpha}$ and $\tilde{\beta}$, of the same size $n$, are lazifications of $\alpha$ and $\beta$, respectively;
- $\tilde{H} : ([n] \times [m], \ell^\infty) \to (X, d_X)$ is an $\epsilon$-Lipschitz map such that $\tilde{H}(\cdot, 0) = \alpha$, $\tilde{H}(\cdot, m) = \beta$, $\tilde{H}(0, t) = \alpha(0) = \beta(0)$ and $\tilde{H}(n, t) = \alpha(n) = \beta(n)$ for all $t \in [m]$.

Proof. We prove the ‘if’ part by induction on the number of basic moves. For the base case, we suppose $\alpha = x_0 \cdots x_n$ and $\{\alpha = \gamma_0, \gamma_1 = \beta\}$ is an $\epsilon$-homotopy. If there is no change between $\alpha$ and $\beta$, we take $\tilde{H}(\cdot, 0) = \gamma_0$ and $\tilde{H}(\cdot, 1) = \gamma_1$.

Otherwise, there is a removal or addition of a point from $\alpha$ to $\beta$. Define two maps $p_i : [n] \to [n-1]$ and $p^i : [n+1] \to [n]$ as

$$p_i(j) = \begin{cases} j, & \text{if } j \neq i \\ i-1, & \text{if } j = i \end{cases} \quad \text{and} \quad p^i(j) = \begin{cases} j, & \text{if } j < i \\ i-1, & \text{if } j \geq i \end{cases}$$

If $\gamma_1$ is obtained from $\gamma_0$ by removing some point $x_i$, we set $\tilde{\gamma}_1 = \gamma_1 \circ p_i$ and

$$\tilde{H}(\cdot, 0) = \gamma_0 \quad \text{and} \quad \tilde{H}(\cdot, 1) = \tilde{\gamma}_1.$$ 

If $\gamma_1$ is obtained from $\gamma_0$ by adding some point between $x_{i-1}$ and $x_i$, we take $\tilde{\gamma}_0 = \gamma_0 \circ p^i$

$$\tilde{H}(\cdot, 0) = \tilde{\gamma}_0 \quad \text{and} \quad \tilde{H}(\cdot, 1) = \gamma_1.$$ 

Now suppose the statement is true for any two $\epsilon$-chains which differ by $k-1$ basic moves. Assume that $H = \{\alpha = \gamma_0, \gamma_1, \ldots, \gamma_{k-1}, \gamma_k = \beta\}$ is an $\epsilon$-homotopy between $\alpha$ and $\beta$. By the induction hypothesis, there exists a required triple $(\tilde{\gamma}_0, \tilde{\gamma}_{k-1}, \tilde{H}_1)$. Since $\gamma_{k-1}$ and $\gamma_k$ differ by one basic move, we need to discuss three cases as before. Notice that $\tilde{H}_1$ is essentially a matrix with entries from $X$. If there is no change, we append one more row $\gamma_k$ to $\tilde{H}_1$ to obtain $\tilde{H}$. If $\gamma_{k-1}$ and $\gamma_k$ differ by the removal of the point $\gamma_{k-1}(i)$, we compose $\gamma_k$ with some $p_i : [\text{size}(\gamma_{k-1})] \to [\text{size}(\gamma_k)]$ and append $\gamma_k \circ p_i$ as a new row to $\tilde{H}_1$. If they differ by the addition of the point $\gamma_k(i)$, we compose each row of $\tilde{H}_1$ with some $p^i : [\text{size}(\gamma_k)] \to [\text{size}(\gamma_{k-1})]$ and append one more row $\gamma_k$ to $\tilde{H}_1$. 

For the ‘only if’ part, it suffices to establish it for the case \( m = 1 \). Suppose \( \beta = x_0'x_1' \cdots x_{n-1}'x_n' \), where \( x_0' = x_0 \) and \( x_n' = x_n \). For each \( i = 0, \ldots, n-1 \), we have \( d_X(x_i, x_{i+1}) \leq \epsilon \). Thus, \( x_i' \) can be inserted between \( x_{i-1} \) and \( x_i \) into \( \alpha \) for each \( i = 1, \ldots, n \), after which \( x_i \) can be removed for each \( i = 1, \ldots, n \). Therefore, we can obtain \( \beta \) from \( \alpha \) via \( 2n \) basic moves. \( \square \)

The following fact will be used repeatedly.

Remark 4.8. Let \( p_j : [n_j] \to [n] \) for \( j = 1, 2 \) be surjective monotone maps. There exists an integer \( N \), and surjective monotone maps \( q_j : [N] \to [n_j] \) for \( j = 1, 2 \) such that \( p_1 \circ q_1 = p_2 \circ q_2 \).

Fix a basepoint \( x_0 \in X \) and \( \epsilon > 0 \).

Proposition 4.9. The relation \( \sim_1^\epsilon \) defines an equivalence relation on the set of discrete chains based at \( x_0 \), denoted by \( \mathcal{L}(X, x_0) \).

Proof. Clearly, \( \sim_1^\epsilon \) is reflexive and symmetric. Let \( \alpha, \beta \) and \( \gamma \) be any three chains such that \( \alpha \sim_1^\epsilon \beta \) and \( \beta \sim_1^\epsilon \gamma \). Then, there exists two sequences of \( \epsilon \)-chains \( H_1 = \{\alpha = \gamma_0, \gamma_1, \ldots, \gamma_{k-1}, \gamma_k = \beta\} \) and \( H_2 = \{\beta = \gamma_{k+1}, \gamma_{k+2}, \ldots, \gamma_{k+l-1}, \gamma_{k+l} = \gamma\} \) such that each \( \gamma_i \) differs from \( \gamma_{i-1} \) by a basic move. Then \( H = \{\alpha = \gamma_0, \gamma_1, \ldots, \gamma_{k+l-1}, \gamma_{k+l} = \gamma\} \) is a sequence of \( \epsilon \)-chains, where each adjacent two differ by a basic move. Thus, \( \alpha \sim_1^\epsilon \gamma \). \( \square \)

An \( \epsilon \)-loop based at \( x_0 \) is an \( \epsilon \)-chain \( \gamma = x_0x_1 \cdots x_n \) such that \( x_n = x_0 \). If an \( \epsilon \)-loop \( \gamma \) is \( \epsilon \)-homotopic to the trivial loop \( \{x_0\} \), we say that \( \gamma \) is \( \epsilon \)-null. Let \( \mathcal{L}^\epsilon(X, x_0) \) be the collection of all \( \epsilon \)-loops based at \( x_0 \). Given two \( \epsilon \)-loops \( \gamma = x_0x_1 \cdots x_{n-1}x_0 \) and \( \gamma' = x_0y_1 \cdots y_{m-1}x_0 \), define their \textit{concatenation} by

\[
\gamma * \gamma' = x_0x_1 \cdots x_{n-1}x_0y_1 \cdots y_{m-1}x_0.
\]

The \textit{birth time} of a discrete loop \( \gamma = x_0x_1 \cdots x_n \) is defined to be

\[
\text{birth}(\gamma) := \max_{0 \leq i \leq n-1} d_X(x_i, x_{i+1}).
\]

The \textit{death time} of \( \gamma \) is defined to be

\[
\text{death}(\gamma) := \inf\{\epsilon > 0 : \gamma \sim_1^\epsilon \{x_0\}\}.
\]

When \( X \) is compact, it is clear that both birth(\( \gamma \)) and death(\( \gamma \)) are no larger than diam(\( X \)).

Remark 4.10. Because \( \mathcal{L}^\epsilon(X, x_0) \) is a subset of \( \mathcal{L}(X, x_0) \), it follows from Proposition 4.9 that \( \sim_1^\epsilon \) defines an equivalence relation on \( \mathcal{L}^\epsilon(X, x_0) \). By Lemma 2.1.2 of [49], \( \mathcal{L}^\epsilon(X, x_0)/\sim_1^\epsilon \) is a group under the operation of concatenation, where the identity element is \( [x_0]_\epsilon \) and \( \gamma_1^{-1} = [\gamma_1]_\epsilon^{-1} \).

Definition 4.11 (Discrete fundamental group). The \textit{discrete fundamental group at scale} \( \epsilon \) \textit{of a metric space} \( X \), based at \( x_0 \), is

\[
\pi_1^\epsilon(X, x_0) := \mathcal{L}^\epsilon(X, x_0)/\sim_1^\epsilon.
\]

Proposition 4.12 (Lemma 2.2.9, [49]). For \( \epsilon > 0 \), suppose \( x_0 \) and \( x_1 \) are points in \( X \) such that there is an \( \epsilon \)-chain \( \lambda \) from \( x_0 \) to \( x_1 \). Then

\[
\pi_1^\epsilon(X, x_0) \xrightarrow{\sim} \pi_1^\epsilon(X, x_1) \text{ via } [\gamma]_\epsilon \mapsto [\lambda^{-1} * \gamma * \lambda]_\epsilon.
\]
Thus, if $X$ is an $\epsilon$-connected metric space, we have $\pi_1^1(X, x_0) \cong \pi_1^1(X, x_1)$ for any two points $x_0$ and $x_1$ in $X$. In this case, the discrete fundamental groups at scale $\epsilon$ are independent of choices of basepoints, up to isomorphism, so we can omit the basepoints and simply write $\pi_1^1(X)$.

**Example 4.13** (Example 2.2.6, [49]). Let $S^1(r)$ be a circle of radius $r > 0$, equipped with the geodesic metric. When $r = 1$, we simply write $S^1$ for $S^1(1)$. Then

$$
\pi_1^1(S^1(r)) = \begin{cases} 
\mathbb{Z}, & \text{if } 0 < \epsilon < \frac{2\pi}{3}r, \\
0, & \text{if } \epsilon \geq \frac{2\pi}{3}r.
\end{cases}
$$

In Theorem 4.15, we will see that discrete fundamental groups of a compact metric space are in fact isomorphic to fundamental groups of its successive Vietoris-Rips complexes.

**Edge-path Groups of Vietoris-Rips Complexes.** Given a simplicial complex $K$, an **edge** in $K$ is an ordered pair $e = v_1v_2$ for vertices of $K$, such that $v_1$ and $v_2$ are in the same simplex. An **edge path** in $K$ is a sequence of vertices connected by edges. The concatenation of two edge paths can be defined in a natural way and called the **product** of two edge paths. If $e = v_1v_2$ and $f = v_2v_3$ are such that $v_1, v_2$ and $v_3$ are vertices of a simplex, then the product $ef$ is **edge equivalent** to $v_1v_3$. Two edge paths are **edge equivalent** if one can be obtained from another by a sequence of such elementary edge equivalences. Let $v_0$ be a vertex of $K$. When an edge starts and ends at the same vertex $v_0$, we call it an **edge loop** at $v_0$. We define $\pi_1^E(K, v_0)$ to be the set of edge equivalence classes of edge loops at $v_0$, called the **edge-path group** of $K$ (see [46, p. 87]). Let $|K|$ denote the geometric realization of $K$.

**Theorem 4.14** (Theorem 4 and 5, §4.4, [46]). With the notations above, $\pi_1^E(K, v_0)$ is a group, with identity $v_0v_0$, under the operation of product defined above. Furthermore,

$$
\pi_1^E(K, v_0) \cong \pi_1(|K|, v_0).
$$

It is an interesting fact that the following groups are isomorphic.

**Theorem 4.15** (Isomorphisms). Let $(X, x_0)$ be a pointed compact metric space and let $\epsilon \geq 0$. Then

$$
\pi_1^1(X, x_0) \cong \pi_1^E(\text{VR}_\epsilon(X), x_0) \cong \pi_1(|\text{VR}_\epsilon(X)|, x_0).
$$

**Proof.** The rightmost isomorphism follows directly from Theorem 4.14. The leftmost isomorphism is straightforward from the definitions. Indeed, if we write $\mathcal{L}^E(\text{VR}_\epsilon(X), x_0)$ as the set of loops at $x_0$ in $\text{VR}_\epsilon(X)$, it is clear that $\mathcal{L}^E(X, x_0) = \mathcal{L}^E(\text{VR}_\epsilon(X), x_0)$ as sets. It remains to check that $\epsilon$-homotopy equivalence is the same as the edge equivalence in $\mathcal{L}^E(\text{VR}_\epsilon(X), x_0)$, which can be done by proving that basic moves are equivalent to elementary edge equivalences. Indeed, for $x_1, x_3 \in X$ such that $d_1(x_1, x_3) \leq \epsilon$, $x_1x_2x_3 \sim_1 x_1x_3$ iff $x_1, x_2$ and $x_3$ form a 2-simplex in $\text{VR}_\epsilon(X, x_0)$, iff $x_1x_2x_3 \sim_1 x_1x_3$. \[\square\]

Given $\epsilon' > \epsilon$, an $\epsilon$-chain is also an $\epsilon'$-chain and an $\epsilon$-homotopy is also an $\epsilon'$-homotopy. Thus, there is a natural group homomorphism

$$
\Phi_{\epsilon, \epsilon'} : \pi_1^1(X, x_0) \to \pi_1^1(X, x_0) \text{ with } [\alpha]_\epsilon \mapsto [\alpha]_{\epsilon'}.
$$

The collection $\{\pi_1^1(X, x_0) : \epsilon \geq 0\}$ together with the natural group homomorphisms $\{\Phi_{\epsilon, \epsilon'}\}_{\epsilon' \geq \epsilon > 0}$ forms a persistent group, denoted by $\Pi_1^1(X, x_0)$, or $\Pi_1(X, x_0)$ for simplicity.
Remark 4.16. The leftmost isomorphism in Theorem 4.15 was first established in [40, Page 599].

4.3. Discretization Homomorphism. Let \( \gamma : [0,1] \to X \) be a continuous path and \( \epsilon > 0 \). An \( \epsilon \)-chain along \( \gamma \) is an \( \epsilon \)-chain \( x_0 \cdots x_n \) where there exists a partition \( \{0 = t_0, \ldots, t_n = 1\} \) of \([0,1]\) such that each \( x_i = \gamma(t_i) \). A strong \( \epsilon \)-chain along \( \gamma \) is an \( \epsilon \)-chain along \( \gamma \) such that \( \gamma([t_{i-1}, t_i]) \subset B(\gamma(t_{i-1}), \epsilon) \) for each \( i \). When \( \gamma \) is a continuous loop, a (strong) \( \epsilon \)-chain along \( \gamma \) is also called a (strong) \( \epsilon \)-loop along \( \gamma \).

The following lemma permits relating the fundamental group of a space to its discrete fundamental groups.

Lemma 4.17 (Lemma 3.1.7, [49]). Let \( X \) be a chain-connected metric space, and let \( \epsilon > 0 \) be given. Then the following map is a well-defined homomorphism (called the \( \epsilon \)-discretization homomorphism)
\[
\Phi_\epsilon : \pi_1(X) \to \pi_1^\epsilon(X) \text{ with } [\gamma] \mapsto [\alpha]_\epsilon,
\]
where \( \alpha \) is a strong \( \epsilon \)-loop along \( \gamma \). If the \( \epsilon \)-balls of \( X \) are path-connected (e.g. \( X \) is geodesic or locally simply connected), then \( \Phi_\epsilon \) is surjective.

Example 4.18. Let \( Y \) be any simply connected (thus, geodesic) compact space. By Lemma 4.17 and the fact \( \pi_1(Y) = 0 \), we have
\[
\pi_1^\epsilon(Y) = 0, \forall \epsilon > 0.
\]

The well-definedness of \( \Phi_\epsilon \) indicates that any two \( \epsilon \)-discretizations of a continuous loop are \( \epsilon \)-homotopic. It follows that \( \Phi_{\epsilon,\epsilon'} \circ \Phi_\epsilon = \Phi_{\epsilon'} \) for all \( \epsilon \leq \epsilon' \). By the universal property of limit, there is a natural group homomorphism
\[
\Phi : \pi_1(X) \to \lim \mathbb{P}_1(X) \text{ with } [\gamma] \mapsto \lim [\alpha]_\epsilon.
\]

Vigolo proved in [47, Theorem 3.2] that for u.l.p.c. and u.s.l.s.c. metric spaces the discretization homomorphism is in fact an isomorphism, albeit using a slightly different definition for \( \epsilon \)-homotopy. It turns out a similar result and proof can be applied to our case as well.

Theorem 4.19 (Discretization Theorem). When a metric space \((X,d_X)\) is u.l.p.c. and u.s.l.s.c., the \( \epsilon \)-discretization homomorphism \( \Phi_\epsilon \) is an isomorphism for \( \epsilon \) small enough. In particular, the discretization homomorphism \( \Phi : \pi_1(X,x_0) \to \lim \mathbb{P}_1(X,x_0) \) is an isomorphism.

Proof. We first prove that \( \Phi_\epsilon \) is injective for \( \epsilon \) small enough. Since \( X \) is u.s.l.s.c., there exists \( \delta' > 0 \) such that a loop in \( B(x,\delta') \) is null-homotopic for any \( x \in X \). Because \( X \) is u.l.p.c., there exists \( \delta < \delta'/2 \) so that any two points in \( B(x,\delta) \) can be connected by a path with image completely contained in \( B(x,\delta'/2) \), for any \( x \in X \). Fix a parameter \( 0 < \epsilon < \delta \) and let \( \gamma \) be a continuous loop based at \( x_0 \) whose \( \epsilon \)-discretization \( \alpha = x_0 \cdots x_n \) is trivial. Recall that \( \alpha \) is a strong \( \epsilon \)-path along \( \gamma \), i.e., there exists a partition \( \{t_0, \ldots, t_n\} \) of \([0,1]\) such that each \( x_i = \gamma(t_i) \) and \( \gamma([t_i,t_{i+1}]) \subset B(\gamma(t_i),\epsilon) \) for each \( i \). We want to show \( \gamma \) is null-homotopic.

Suppose \( \alpha \sim^1_{\epsilon} x_0 \) via an \( \epsilon \)-homotopy \( H : [n] \times [m] \to X \) with \( H(\cdot,0) = \alpha \) and \( H(\cdot,m) = x_0 \). Let \( 0 \leq i \leq n-1 \) and \( 0 \leq j \leq m \). Since \( d_X(H(i, j), H(i + 1, j)) \leq \epsilon < \delta \), there exists a path \( \alpha_{i,j} \) joining them with image in \( B(H(i, j),\delta'/2) \). Similarly, for \( 0 \leq i \leq n \) and \( 0 \leq j \leq m-1 \), there exists a path \( \beta_{i,j} \) joining \( H(i, j) \) and \( H(i, j + 1) \) with image in \( B(H(i, j),\delta'/2) \). It follows that the concatenations \( \beta_{i,j} \alpha_{i,j+1} \) and \( \alpha_{i,j} \beta_{i+1,j} \) are both contained in \( B(H(i, j),\delta') \).
Since $\alpha_{i,j}^{-1}$ is a loop in $B(H(i,j), \delta')$, it is null-homotopic. For $0 \leq i \leq n-1$ and $0 \leq j \leq m-1$, let $\xi_{i,j} := \alpha_{0,0} \cdot \alpha_{1,0,0} \cdot \alpha_{-1,0} \cdot \beta_i^{-1} \alpha_i^{1} \beta_{i+1} \alpha_{i+1}^{-1} \beta_{i+1} \alpha_{i+1}^{-1} \eta_i^{-1}$, which is a null-homotopic loop at $x_0$ based on construction. Notice that
\[
\gamma_i := \eta_i \cdot \eta_{n,m-1} \sim (\alpha_{0,0} \cdot \cdots \alpha_{i,0}) (\beta_{i+1,0} \cdot \cdots \beta_{i+1,m-1}) \alpha_{i,m}^{-1} (\beta_{i+1,m-1} \cdot \cdots \beta_{i+1,0})^{-1} \alpha_{0,0} \cdots \alpha_{i,0}^{-1}
\]
and
\[
\gamma_{n-1} \cdot \gamma_0 \sim (\alpha_{0,0} \cdots \alpha_{n-1,0}) (\beta_{n,0} \cdots \beta_{n,m-1}) (\alpha_{n,m}^{-1} \cdots \alpha_{0,0}^{-1}) (\beta_{n,m-1} \cdots \beta_{0,0}) \sim \alpha_{0,0} \cdots \alpha_{n-1,0}.
\]
Since $\gamma([t_i, t_{i+1}]) * \alpha_{i,m}^{-1} \subset B(\gamma(t_i), \epsilon) \subset B(\gamma(t_i), \delta')$, $\gamma([t_i, t_{i+1}])$ must be a null-homotopic loop. Therefore, $\gamma \sim \alpha_{0,0} \cdots \alpha_{n-1,0} \sim x_0$. It follows that $\Phi_\epsilon$ is injective for all $0 < \epsilon < \delta$, and $\Phi$ is injective as well.

Because $X$ is u.i.p.c., its $\epsilon$-balls are path connected. By Lemma 4.17, $\Phi_\epsilon$ is surjective, and thus an isomorphism. It remains to show $\Phi$ is surjective. A generic element of $\lim \pi_\theta^\theta(X)$ can be represented by a family $[\alpha_\theta]_{\theta > 0}$, where $\alpha_\theta$ is an $\theta$-loop based at $x_0$ such that for every $\theta < \theta'$ we have $\alpha_\theta \sim _{\theta} ^{\theta'} \alpha_{\theta'}$. Take a real number $\epsilon$ such that $0 < \epsilon < \delta$. The surjectivity of $\Phi$ shows us that there is a continuous loop $\gamma_\epsilon$ such that $\alpha_\epsilon$ is $\epsilon$-homotopic to a strong $\epsilon$-path along $\gamma_\epsilon$. Since $[\alpha_{\epsilon'}]_{\epsilon'} = [\alpha_\epsilon]_{\epsilon'}$ for $0 < \epsilon < \epsilon'$ $< \delta$, the injectivity of $\Phi_{\epsilon'}$ implies that $\gamma_\epsilon$ and $\gamma_{\epsilon'}$ are homotopic. When $\theta \geq \epsilon$, we always have $[\alpha_\theta]_{\theta} = [\alpha_{\theta}]_{\theta}$. Thus, for $([\alpha_\theta]_{\theta})_{\theta > 0}$, we have found a continuous loop $\gamma_\epsilon$ such that
\[
\Phi([\gamma_\epsilon]) = ([\gamma_\epsilon]_{\theta})_{\theta > 0} = ([\alpha_\theta]_{\theta})_{\theta > 0},
\]
where $[\gamma_\epsilon]_{\theta}$ denotes the $\theta$-homotopy class of a strong $\theta$-path along $\gamma_\epsilon$.

4.4. Generalized Subendodroms and a Pseudo-metric on $L(X, x_0)$. By analogy with the ultrametric $\mu^{(0)}$ discussed in §4.1, we introduce a pseudo-ultrametric on the set of all discrete loops on a given metric space. This will allow us to view the discrete loop space of a metric space as a metric space in itself.

Proposition 4.20. Given a pointed metric space $(X, x_0)$, the following defines a pseudo-ultrametric on $L(X, x_0)$: for any $\gamma, \gamma' \in L(X, x_0)$,
\[
\mu_X^{(1)}(\gamma, \gamma') := \inf\{\epsilon > 0 : \gamma \sim _{\epsilon} ^{\epsilon} \gamma'\}.
\]

Proof. Clearly, $\mu_X^{(1)}(\gamma, \gamma') = \mu_X^{(1)}(\gamma', \gamma)$ for all $\gamma, \gamma' \in L(X, x_0)$. It remains to prove the strong triangle inequality. Given arbitrary $\alpha, \beta, \gamma \in L(X, x_0)$, let $\epsilon_1 = \mu_X^{(1)}(\alpha, \beta)$ and $\epsilon_2 = \mu_X^{(1)}(\beta, \gamma)$. For each $\delta_1 > \epsilon_1$ and $\delta_2 > \epsilon_2$, there exist a sequence of $\delta_1$-paths $H_1 = \{\alpha = \gamma_0, \gamma_1, \cdots, \gamma_{k-1}, \gamma_k = \beta\}$ and a sequence of $\delta_2$-paths $H_2 = \{\beta = \gamma_{k+1}, \gamma_{k+2}, \cdots, \gamma_{k+t-1}, \gamma_{k+t} = \gamma\}$ such that each $\gamma_i$ differs from $\gamma_{i-1}$ by a basic move. Then $H = \{\alpha = \gamma_0, \cdots, \gamma_{k+t-1}, \gamma_{k+t} = \gamma\}$ is a sequence of $\max\{\delta_1, \delta_2\}$-paths, where each adjacent two differ by a basic move. Then $\alpha$ and $\gamma$ are $\max\{\delta_1, \delta_2\}$-homotopic via $H$. By the minimality, $\mu_X^{(1)}(\alpha, \gamma) \leq \max\{\delta_1, \delta_2\}$.

Letting $\delta_1 \setminus \epsilon_1$ ($i = 1, 2$), we obtain $\mu_X^{(1)}(\alpha, \gamma) \leq \max\{\epsilon_1, \epsilon_2\}$. \hfill $\square$

Remark 4.21. For any $\gamma \in L(X, x_0)$, note that
\[
\text{birth}(\gamma) = \mu_X^{(1)}(\gamma, \gamma) \text{ and death}(\gamma) = \mu_X^{(1)}(\gamma, \{x_0\}).
\]
Suppose $\alpha$ and $\beta$ are two discrete loops in $X$. Let $\epsilon = \max\{\text{birth}(\alpha), \text{birth}(\beta)\}$. Then, for any $\gamma \in L^\epsilon(X, x_0)$, we have
\[
\mu_X^{(1)}(\alpha * \gamma, \beta * \gamma) = \mu_X^{(1)}(\alpha, \beta).
\]
This is because when $\delta \geq \epsilon$, there is a $\delta$-homotopy $H = \{\alpha, \cdots, \beta\}$ iff there is a $\delta$-homotopy $H \ast \gamma := \{\alpha \ast \gamma, \cdots, \beta \ast \gamma\}$.

**Stability for $\mu_\ast^{(i)}$.** Let $(X, x_0)$ and $(Y, y_0)$ be in $\mathcal{M}^{pt}$. Let $R : X \xleftarrow{\phi_X} Z \xrightarrow{\phi_Y} Y$ be a pointed tripod between $X$ and $Y$. Note that $\phi_X$ and $\phi_Y$ induce surjective maps
\[
\mathcal{L}(Z, z_0) \to \mathcal{L}(X, x_0) \text{ and } \mathcal{L}(Z, z_0) \to \mathcal{L}(Y, y_0)
\]
respectively, still denoted by $\phi_X$ and $\phi_Y$. Thus, we have a tripod between $\left(\mathcal{L}(X, x_0), \mu_X^{(1)}\right)$ and $\left(\mathcal{L}(Y, y_0), \mu_Y^{(1)}\right)$:
\[
R_{\mathcal{L}} := \mathcal{L}(X, x_0) \xleftarrow{\phi_X} \mathcal{L}(Z, z_0) \xrightarrow{\phi_Y} \mathcal{L}(Y, y_0).
\]

**Lemma 4.22.** Let $(X, x_0)$ and $(Y, y_0)$ be in $\mathcal{M}^{pt}$. Then each $R \in \mathfrak{R}^{pt}(\{(X, x_0), (Y, y_0)\})$ induces a tripod $R_{\mathcal{L}} \in \mathfrak{R}(\mathcal{L}(X, x_0), \mathcal{L}(Y, y_0))$ with $\text{dis}(R_{\mathcal{L}}) \leq \text{dis}(R)$. In particular, if $\alpha_X$ is an $\epsilon$-chain in $X$ and $(\alpha_X, \alpha_Y) \in R_{\mathcal{L}}$ (see Page 11), then $\alpha_Y$ is an $(\epsilon + \text{dis}(R))$-chain in $Y$.

**Proof.** Let $R : X \xleftarrow{\phi_X} Z \xrightarrow{\phi_Y} Y$ be a pointed tripod between $X$ and $Y$. If $\alpha = x_0 \cdots x_n$ is an $\epsilon$-loop in $X$, then there exists a discrete loop $\gamma = z_0 \cdots z_n$ in $Z$ such that $\alpha = \phi_X(\gamma)$. Note that $\phi_Y(\gamma)$ is an $(\epsilon + \text{dis}(R))$-loop in $Y$, because for $0 \leq i \leq n - 1$,
\[
d_Y(\phi_Y(z_i), \phi_Y(z_{i+1})) \leq d_X(\phi_X(z_i), \phi_X(z_{i+1})) + |d_Y(\phi_Y(z_i), \phi_Y(z_{i+1})) - d_X(\phi_X(z_i), \phi_X(z_{i+1}))| \\
\leq \epsilon + \text{dis}(R).
\]

Let $(\alpha, \beta), (\alpha', \beta') \in R_{\mathcal{L}}$ and $\delta > \mu_X^{(1)}(\alpha, \beta)$. Then there is a finite sequence of $\delta$-loops in $X$
\[
H_X = \{\alpha = \alpha_0, \alpha_1, \cdots, \alpha_{k-1}, \alpha_k = \alpha'\}
\]
such that each $\alpha_j$ differs from $\alpha_{j-1}$ by a basic move. For each $\alpha_j$, let $\beta_j = \phi_Y(\gamma_j)$ where $\gamma_j$ is such that $\alpha_j = \phi_X(\gamma_j)$. Then each $\beta_j$ differs from $\beta_{j-1}$ by a basic move. In particular,
\[
H_Y = \{\beta = \beta_0, \beta_1, \cdots, \beta_{k-1}, \beta_k = \beta'\}
\]
is a $(\delta + \text{dis}(R))$-homotopy between $\beta$ and $\beta'$. Therefore, $\mu_Y^{(1)}(\alpha', \beta') \leq \delta + \text{dis}(R)$. Letting $\delta \searrow \mu_X^{(1)}(\alpha, \beta)$, we obtain $\mu_Y^{(1)}(\alpha', \beta') \leq \mu_X^{(1)}(\alpha, \beta) + \text{dis}(R)$. Similarly, $\mu_X^{(1)}(\alpha, \beta) \leq \mu_Y^{(1)}(\alpha', \beta') + \text{dis}(R)$. This is true for all $(\alpha, \beta), (\alpha', \beta') \in R_{\mathcal{L}}$, implying that $\text{dis}(R_{\mathcal{L}}) \leq \text{dis}(R)$. \hfill $\Box$

**Theorem 4.23 (Stability Theorem for $\mu_\ast^{(1)}$).** Given $(X, x_0)$ and $(Y, y_0)$ in $\mathcal{M}^{pt}$,
\[
d_{\mathcal{L}}(\mathcal{L}(X, x_0), \mathcal{L}(Y, y_0)) \leq d_{\mathcal{L}}^{pt}(\{(X, x_0), (Y, y_0)\}).
\]

**Proof.** By Lemma 4.22,
\[
d_{\mathcal{L}}(\mathcal{L}(X, x_0), \mathcal{L}(Y, y_0)) = \frac{1}{2} \inf \{\text{dis}(R_{\mathcal{L}}) : R_{\mathcal{L}} \in \mathfrak{R}(\mathcal{L}(X, x_0), \mathcal{L}(Y, y_0))\} \\
\leq \frac{1}{2} \inf \{\text{dis}(R_{\mathcal{L}}) : R_{\mathcal{L}} \text{ induced by } R, R \in \mathfrak{R}(X, Y)\} \\
\leq \frac{1}{2} \inf \{\text{dis}(R) : R \in \mathfrak{R}(X, Y)\} \\
= d_{\mathcal{L}}(X, Y).
\]

**Corollary 4.24.** Given $(X, d_X)$ and $(Y, d_Y) \in \mathcal{M}$,
\[
\inf_{R \in \mathfrak{R}(X, Y)} \sup_{(x_0, y_0) \in R} d_{\mathcal{L}}(\mathcal{L}(X, x_0), \mathcal{L}(Y, y_0)) \leq d_{\mathcal{L}}(X, Y).
\]
Critical Values. Let $X$ be a chain-connected metric space. A non-critical interval of $X$ is a non-empty open interval $I \subset \mathbb{R}_+$, such that for $\epsilon, \epsilon' \in I$ with $\epsilon < \epsilon'$, the map $\Phi_{\epsilon, \epsilon'}$ is bijective. We call a positive number $\epsilon$ a critical value of $X$ if it is not contained in any non-critical interval. We denote the subset of $\mathbb{R}_+$ consisting of all critical values of $X$ by $\text{Cr}(X)$, and call this the critical spectrum of $X$ (see [49]).

**Theorem 4.25** (Theorem 3.1.11, [49]). Let $X$ be a compact geodesic space. Then $\text{Cr}(X)$ is discrete and bounded above in $\mathbb{R}_+$.

**Remark 4.26.** For a finite metric space $X$, it is straightforward to check that $\text{Cr}(X)$ is discrete and bounded above in $\mathbb{R}_+$.

Given $(X, x_0) \in \mathcal{M}^\text{pt}$ and $\epsilon > 0$, $\pi_1^i(X, x_0) = \mathcal{L}(X, x_0)/\sim_i^\epsilon$ forms a partition of $\mathcal{L}(X, x_0)$, i.e., a subpartition of $\mathcal{L}(X, x_0)$.

**Lemma 4.27.** Let $X$ be either a compact geodesic space or a finite metric space. The map $\epsilon \mapsto \pi_1^i(X, x_0)$ induces a generalized subendodrogram over $\mathcal{L}(X, x_0)$, denoted by $\theta_{\mathcal{L}(X, x_0)}^\epsilon$.

**Proof.** We want to check that conditions (1'), (2) and (3) in Definition 3.16 are satisfied. For $\epsilon \leq \epsilon'$, $\mathcal{L}(X, x_0) \subseteq \mathcal{L}(X, x_0)$ and $\theta_{\mathcal{L}(X, x_0)}(\epsilon)$ refines $\theta_{\mathcal{L}(X, x_0)}(\epsilon')|_{\mathcal{L}(X, x_0)}$, i.e., condition (1') is satisfied. For condition (3), we notice that whenever $\epsilon \geq \text{diam}(X)$, $\theta_{\mathcal{L}(X, x_0)}(\epsilon)$ is the single block partition. The semi-continuity, i.e., condition (2): for all $r$ there exists $\epsilon > 0$ s.t. $\theta_{\mathcal{L}(X, x_0)}(r) = \theta_{\mathcal{L}(X, x_0)}(t)$ for all $t \in [r, r + \epsilon]$, follows from Theorem 4.25 and Remark 4.26.

Examples of generalized subendodograms arising from discrete fundamental groups will be presented in §7. It is not hard to see that $\mu^{(1)}(X) = \mu_{\theta_{\mathcal{L}(X, x_0)}^\epsilon}$, so we can apply Proposition 3.17 to conclude:

**Corollary 4.28.** Given $(X, d_X)$ and $(Y, d_Y) \in \mathcal{M}$, 

$$\inf_{R \in \mathbb{R}(X, Y)} \sup_{(x_0, y_0) \in R} d_I(\nu_k \circ \theta_{\mathcal{L}(X, x_0)}^\epsilon, \nu_k \circ \theta_{\mathcal{L}(Y, y_0)}^\epsilon) \leq d_{\text{GH}}(X, Y).$$

In general, the computation of Gromov-Hausdorff distance is NP-hard [44], while in the left-hand-side $d_I(\nu_k \circ \theta_{\mathcal{L}(X, x_0)}^\epsilon, \nu_k \circ \theta_{\mathcal{L}(Y, y_0)}^\epsilon)$, as the interleaving distance between 1-dimensional persistence modules, is computable in polynomial time.

5. **Persistent Homotopy Groups**

We assume $T = \mathbb{R}_+$ in this section unless otherwise specified. In §3.4, we have defined persistent groups as objects in $\text{PGrp}^{(T, \leq)}$, as well as homomorphisms and homomorphisms of degree $\delta$ between persistent groups. In this section, we study persistent homotopy groups, which are persistent groups given by homotopy groups of some spaces.

**Persistent Groups.** Recall from §3.4 that the set of homomorphisms from the persistent group $\mathbb{G}$ to the persistent group $\mathbb{H}$ is denoted by $\text{Hom}(\mathbb{G}, \mathbb{H})$, and the collection of homomorphisms of degree $\delta$ is written as $\text{Hom}^\delta(\mathbb{G}, \mathbb{H})$. By isomorphisms between persistent groups, we will mean isomorphisms in the category $\text{PGrp}^{(T, \leq)}$, denoted by $\cong$. We denote by $\langle 0 \rangle$ the trivial group containing exactly one element 0, the addition identity element. The trivial persistent group is given by $\mathbb{0} := \langle 0 \rangle [T]$. 

For a group $G$ and an interval $I \subset T$, the interval generalized persistence module $G[I]$ (see Page 12) is also called the interval persistent group.

From the definitions of product and coproduct given in §3.1, we immediately obtain the following proposition.

**Proposition 5.1** (Product and coproduct). In $\mathbf{PGrp}^{(T, \leq)}$, for any two objects $G$ and $H$,

- the product is given by component-wise direct products and denoted by $G \times H$; and
- the coproduct is given by component-wise free products and denoted by $G \ast H$.

### 5.1 Persistent Homotopy Groups

Given a pointed metric space $(X, x_0)$, there are different approaches to construct persistent groups using homotopy information from the metric space, such as the persistent group $\Pi_1(X, x_0)$ constructed on Page 21.

**Definition 5.2** (Persistent fundamental group). Given a pointed metric space $(X, x_0)$, the persistent group $\Pi_1(X, x_0)$, given by $\{\pi_1(X, x_0)\}_{i > 0}$ together with the natural group homomorphisms $\{\Phi_{\epsilon, \delta}\}_{\epsilon, \delta > 0}$, is called the persistent fundamental group of $X$.

Let us examine some properties of persistent fundamental groups here.

**Proposition 5.3** (Induced Homomorphisms). Let $X$ and $Y$ be chain-connected metric spaces, and let $\varphi : (X, x_0) \to (Y, y_0)$ be any pointed set map.

1. For any $\delta \geq \text{dis}(\varphi)$ and $\epsilon > 0$, the map
   $\varphi^\epsilon : \pi_1^\epsilon(X) \to \pi_1^\epsilon(Y)$ with $[\alpha]_\epsilon \mapsto [\varphi(\alpha)]_\epsilon$
   is a well-defined group homomorphism, and $(\varphi^\epsilon)_{\epsilon > 0} \in \text{Hom}^\delta(\Pi_1(X), \Pi_1(Y))$.

2. If $\varphi$ is 1-Lipschitz, then for each $\epsilon > 0$, the map
   $\varphi : \pi_1^\epsilon(X) \to \pi_1^\epsilon(Y)$ with $[\alpha]_\epsilon \mapsto [\varphi(\alpha)]_\epsilon$
   is a well-defined group homomorphism, and $(\varphi)_{\epsilon > 0} \in \text{Hom}(\Pi_1(X), \Pi_1(Y))$.

**Proof.** Given an $\epsilon$-loop $\alpha = x_0 \cdots x_n$ in $X$, $\varphi(\alpha) = \varphi(x_0) \cdots \varphi(x_n)$ is an $(\epsilon + \delta)$-loop in $Y$, because for $0 \leq i \leq n - 1$,

$$d_Y(\varphi(x_i), \varphi(x_{i+1})) \leq d_X(x_i, x_{i+1}) + |d_Y(\varphi(x_i), \varphi(x_{i+1})) - d_X(x_i, x_{i+1})| \leq \epsilon + \delta.$$  

Since $\varphi$ preserves basic moves, given an $\epsilon$-homotopy $H = \{\alpha = \alpha_0, \cdots, \alpha_k = \beta\}$, $\varphi(H) := \{\varphi(\alpha) = \varphi(\alpha_0), \cdots, \varphi(\alpha_k) = \varphi(\beta)\}$ is an $(\epsilon + \delta)$-homotopy in $Y$. Thus, $\varphi^\epsilon$ is well-defined. In addition, $\varphi^\epsilon$ is a group homomorphism, because for any $\alpha, \beta \in L(X, x_0),$

$$\varphi^\epsilon([\alpha \ast \beta]_\epsilon) = [\varphi(\alpha \ast \beta)]_{\epsilon + \delta} = [\varphi(\alpha) \ast \varphi(\beta)]_{\epsilon + \delta} = [\varphi(\alpha)]_{\epsilon + \delta} \ast [\varphi(\beta)]_{\epsilon + \delta} = \varphi^\epsilon([\alpha]_\epsilon) \ast \varphi^\epsilon([\beta]_{\epsilon + \delta}).$$

Here $\ast$ denote the concatenation of discrete chains.

The statement $(\varphi^\epsilon)_{\epsilon > 0} \in \text{Hom}^\delta(\Pi_1(X), \Pi_1(Y))$ follows from the following commutative diagram (for all $\epsilon' > \epsilon$):

$$
\begin{array}{ccc}
[\alpha]_\epsilon & \longrightarrow & [\varphi(\alpha)]_{\epsilon + \delta} \\
\downarrow & & \downarrow \\
[\alpha]_{\epsilon'} & \longrightarrow & [\varphi(\alpha)]_{\epsilon' + \delta}.
\end{array}
$$

Similar arguments can be applied to prove Part (2), so we omit them. \( \square \)
5.1.1. Persistent K-homotopy Groups and Persistent VR-homotopy Groups. For \( n \in \mathbb{Z}_{\geq 1} \), assigning the \( n \)-dimensional homotopy group to a pointed topological space forms a functor from the category of pointed spaces to the category of groups, called the homotopy group functor and denoted by \( \pi_n : \text{Top}^\ast \rightarrow \text{Grp} \). In particular, when \( n = 1 \), we call it the fundamental group functor. In analogy to persistent homology theory, one could apply the homotopy group functor to filtrations of a given metric space to obtain a persistent group.

**Kuratowski Filtration and Persistent K-homotopy Groups.** Let \((X, d_X)\) be a bounded metric space. We recall from [10] a method to embed \( X \) isometrically as a subset of some Banach space, which will eventually allow us to enlarge \( X \). Let \( K(X) := (L^\infty(X), \| \cdot \|_\infty) \), where \( L^\infty(X) \) is the space of bounded functions \( f : X \rightarrow \mathbb{R} \) and \( \| f \|_\infty := \sup_{x \in X} |f(x)| \). For a bounded metric space \((X, d_X)\), the Kuratowski embedding is given by:

\[
K_X : X \rightarrow L^\infty(X), \quad x \mapsto d_X(x, \cdot).
\]

By the Kuratowski–Wojdyslawski Theorem (see [10, Theorem III.8.1]), the Kuratowski embedding \( K_X \) is distance-preserving.

**Definition 5.4** (\( \epsilon \)-thickening). The \( \epsilon \)-thickening of a compact metric space \((X, d_X)\) is the \( \epsilon \)-neighborhood of \( K_X(X) \) in \( K(X) \) (see Page 10), henceforth denoted by \( X^\epsilon \).

Let \((X, x_0)\) be a pointed compact metric space. For any \( 0 \leq \epsilon < \epsilon' \), there is a natural embedding \( i_{\epsilon, \epsilon'}^X : X^\epsilon \rightarrow X^{\epsilon'} \), which forms a filtration in \( \text{Top} \), called the Kuratowski filtration and denoted by \( \mathbb{X} \). When there is no danger of confusion, we simply write \( i_X^\epsilon \) for \( i_{\epsilon, \epsilon'}^X \). Under the map \( K_X, x_0 \) can be viewed as a point in \( X^\epsilon \) for each \( \epsilon > 0 \), which induces a functor \( (\mathbb{X}, x_0) : (\mathbb{R}_{\geq 0}, \leq) \rightarrow \text{Top}^\ast \) such that \((\mathbb{X}, x_0)(\epsilon) = (X^\epsilon, x_0) \) and \((\mathbb{X}, x_0)(\epsilon \leq \epsilon') = i_{\epsilon, \epsilon'}^X \).

**Definition 5.5** (Persistent K-homotopy group\(^1\)). Let \((X, x_0)\) be a pointed compact metric space. By \((\mathbb{X}, x_0)\), composing the homotopy group functor \( \pi_n \) with \((\mathbb{X}, x_0)\) induces a persistent group

\[
\Pi_n^K(X, x_0) := \{ \pi_n(X^\epsilon, x_0) \}_{\epsilon \geq 0},
\]

together with the induced homomorphisms on homotopy groups. We call it the \( n \)-th persistent K-homotopy group.

**Remark 5.6.** Composing the homology functor \( H_n \) with \( \mathbb{X} \) results into the persistent K-homology group \( \Pi^n_n^K(X, x_0) \).

Similarly, we can apply homotopy group functors to the geometric realizations of Vietoris-Rips complexes.

**Definition 5.7** (Persistent VR-homotopy group). Let \((X, x_0)\) be a pointed compact metric space. For each \( n \in \mathbb{Z}_{\geq 1} \), we have the persistent group

\[
\Pi_n^{VR}(X, x_0) := \{ \pi_n(|\text{VR}_\epsilon(X)|, x_0) \}_{\epsilon \geq 0},
\]

together with the induced homomorphisms. We call it the \( n \)-th persistent VR-homotopy group.

\(^1\)K is for Kuratowski.
As Vietoris-Rips complexes are simplicial complexes, one can also apply the edge-path group (see Page 21) functor to obtain a persistent group

\[ \Pi_1^E(X, x_0) := \{ \pi_1^E(\text{VR}_\epsilon(X), x_0) \}_{\epsilon \geq 0}, \]

together with the induced homomorphisms edge-path groups. We have seen in Theorem 4.15 that

\[ \Pi_1^\text{VR}(X, x_0) \cong \Pi_1^E(X, x_0) \cong \Pi_1(X, x_0). \]

It will be seen in Theorem 5.11 that Definition \( \Pi_1^K(X, x_0) \) is isomorphic to the others as well.

**Remark 5.8.** One advantage of persistent \( K \)-homotopy groups and persistent \( \text{VR} \)-homotopy groups is that they can be defined for \( n \)-dimensional homotopy groups. However, it does not appear to be trivial to generalize the idea of persistent fundamental group or \( \Pi_1^E(X, x_0) \) to higher dimensions.

**Theorem 5.9** (Theorem 3.1, [38]). Let \( X \in \mathcal{M} \) and \( \epsilon \geq 0 \). Then,

\[ X^* \cong |\text{VR}_\epsilon(X)|. \]

**Corollary 5.10.** Let \( (X, x_0) \) be a pointed compact metric space. Then,

\[ \Pi^n_1^K(X, x_0) \cong \Pi^n_1^\text{VR}(X, x_0) \) and \( \Pi^n_2^\mathcal{K}^*(X, x_0) \) isomorphic to \( \Pi^n_2^\mathcal{R}^*(X, x_0) \)

Now we are ready to prove the following isomorphism theorem of persistent fundamental groups.

**Theorem 5.11** (Isomorphisms of persistent fundamental groups). Given a pointed compact metric space \( (X, x_0) \), we have

\[ \Pi_1^\mathcal{K}^*(X, x_0) \cong \Pi_1^\text{VR}\mathcal{R}^*(X, x_0) \cong \Pi_1^2^*(X, x_0). \quad (2) \]

**Proof.** The first isomorphism in Equation (2) follows from Corollary 5.10 directly. The second isomorphism is derived from Theorem 4.15, by checking the following collection of group isomorphisms

\[ \pi_1(X, x_0) \cong \pi_1(\text{VR}_\epsilon(X), x_0), \forall \epsilon \geq 0 \]

forms an isomorphism between persistent groups. \( \square \)

**Example 5.12** (Unit circle \( S^1 \)). Recall from [2, Theorem 7.6] that we have homotopy equivalence

\[ |\text{VR}_\epsilon(S^1)| \cong \begin{cases} \mathbb{S}^{2l+1}, & \text{if } \frac{l}{2l+1} 2\pi < r < \frac{l+1}{2l+3} 2\pi \text{ for some } l = 0, 1, \ldots, \\ \vee^r \mathbb{S}^{2l}, & \text{if } r = \frac{l}{2l+1} 2\pi \text{ for some } l = 0, 1, \ldots, \\ \ast, & \text{if } r \geq \pi. \end{cases} \]

Here \( \epsilon \) is the cardinality of the continuum (i.e. the cardinality of \( \mathbb{R} \)), and \( \ast \) is the one-point space.

Let \( k \in \mathbb{Z}_{>1} \). As \( \vee^\epsilon \mathbb{S}^{2k} \) is \((2k - 1)\)-connected, it follows from the Hurewicz theorem (cf. [32, Theorem 4.32]) that

\[ \pi_{2k} \left( \vee^\epsilon \mathbb{S}^{2k} \right) \cong H_{2k} \left( \vee^\epsilon \mathbb{S}^{2k} \right) \cong \mathbb{Z}^\times. \]
Then the persistent homology groups of $S^1$ are

$$PH^\text{VR}_n(S^1) \cong \begin{cases} \mathbb{Z} \left( \frac{k-1}{2k-1} 2\pi, \frac{k}{2k+1} 2\pi \right), & \text{if } n = 2k - 1, \\ \mathbb{Z}^\times \left[ \frac{k}{2k+1} 2\pi, \frac{k}{2k+1} 2\pi \right], & \text{if } n = 2k. \end{cases}$$

Because $\pi_n(S^m)$ is not totally known for the case $n > m$, the calculation of $\Pi^\text{VR}_n(S^1)$ can only be done for some choices of $n$. For example, we have

$$\Pi^\text{VR}_n(S^1) \cong \begin{cases} \mathbb{Z} \left( 0, \frac{2\pi}{3} \right), & \text{if } n = 1, \\ \mathbb{Z}^\times \left[ \frac{2\pi}{3}, \frac{2\pi}{3} \right], & \text{if } n = 2. \end{cases}$$

5.1.2. Persistent Rational Homotopy Groups. The rational homotopy groups $\pi_n(X, x_0) \otimes \mathbb{Q}$ of a pointed topological space $(X, x_0)$ are the standard homotopy group $\pi_n(X, x_0)$ tensored with the rational numbers $\mathbb{Q}$, for each $n \geq 0$. We assume that all topological spaces are path-connected and denote the rational homotopy groups by $\pi_n(X) \otimes \mathbb{Q}$ for simplicity of notation. Compared with the difficulty of calculating homotopy groups of spheres, the computation of rational homotopy groups of spheres is substantially easier and was done by Serre in 1951 (see [45]):

$$\pi_n(S^{2k-1}) \otimes \mathbb{Q} \cong \begin{cases} \mathbb{Q}, & n = 2k - 1, \\ 0, & \text{otherwise}, \end{cases} \quad \text{and} \quad \pi_n(S^{2k}) \otimes \mathbb{Q} \cong \begin{cases} \mathbb{Q}, & n = 2k \text{ or } n = 4k - 1, \\ 0, & \text{otherwise}. \end{cases}$$

This inspires us to consider the notion of persistent rational homotopy groups, by tensoring persistent homotopy groups with rational numbers $\mathbb{Q}$ in the following sense.

Let the field $k = \mathbb{Q}$. Then the category $\text{Vec}$ represents the category of vector spaces over $\mathbb{Q}$. Let $\text{Ab}$ be the category of Abelian groups, and let $\mathsf{PAb}^{(\mathbb{R}, \leq)}$ denote the category of functors $G : (\mathbb{R}, \leq) \to \text{Ab}$. Because $\text{Ab}$ and $\text{Vec}$ are categories of $\mathbb{Z}$-modules and $\mathbb{Q}$-modules respectively, the following defines a functor from $\text{Ab}$ to $\text{Vec}$:

$$- \otimes \mathbb{Q} : G \to G \otimes \mathbb{Q} \quad \text{and} \quad f \otimes \mathbb{Q} = f \otimes \text{Id}_\mathbb{Q} : G \otimes \mathbb{Q} \to H \otimes \mathbb{Q},$$

for each group homomorphism $f : G \to H$ of Abelian groups. Moreover, the functor $- \otimes \mathbb{Q}$ induces a functor from $\mathsf{PAb}^{(\mathbb{R}, \leq)}$ to $\mathsf{PVec}^{(\mathbb{R}, \leq)}$ such that for each $G \in \mathsf{PAb}^{(\mathbb{R}, \leq)}$, $G \otimes \mathbb{Q}$ is the composition of the following two functors:

$$(\mathbb{R}, \leq) \xrightarrow{G} \text{Ab} \xrightarrow{- \otimes \mathbb{Q}} \text{Vec}.$$
The leftmost isomorphism in Equation (3) follows from the universal coefficient theorem for homology (cf. [32, Theorem 3A.3]). In addition, it can be directly checked that
\[ d_1 \left( \Pi_1^{VR}(S^1) \otimes \mathbb{Q}, \Pi_1^{VR}(S^1; \mathbb{Q}) \right) = 0. \]
Note that in the case of \( n = 4k - 1 \), because persistent modules \( \Pi_1^{VR}(S^1) \otimes \mathbb{Q} \) and \( \Pi_1^{VR}(S^1; \mathbb{Q}) \) contain different types of indecomposables, they are not isomorphic to each other.

Notice that any \( \delta \)-interleaving between two persistent Abelian groups \( G \) and \( H \) induces a \( \delta \)-interleaving between the persistent modules \( G \otimes \mathbb{Q} \) and \( H \otimes \mathbb{Q} \). Thus,
\[ d_1 (G \otimes \mathbb{Q}, H \otimes \mathbb{Q}) \leq d_1 (G, H). \]
In addition, we have the following corollary of Theorem 4.1.

**Corollary 5.13.** Let \( X \) and \( Y \) be compact chain-connected metric spaces. Then for each \( n \in \mathbb{Z}_{\geq 2}, \)
\[ d_1 \left( \Pi_1^K(X) \otimes \mathbb{Q}, \Pi_1^K(Y) \otimes \mathbb{Q} \right) \leq d_{GH}(X,Y). \]
When \( \Pi_1^K(X), \Pi_1^K(Y) \in \mathcal{PA} \), we also have
\[ d_1 \left( \Pi_1^K(X) \otimes \mathbb{Q}, \Pi_1^K(Y) \otimes \mathbb{Q} \right) \leq d_{GH}(X,Y). \]

### 5.2. Dendrograms and a Metric on \( \pi_1(X,x_0) \)

Let \( G = \{ \{G_t\}_{t>0}, \{f_{ts}\}_{t<s} \} \) be a persistent group, which is naturally an \((\mathbb{R}_+, \leq)\)-shaped diagram in \( \text{Grp} \). We can consider its limit, i.e., the group
\[ G_0 := \lim G = \left\{ (a_t)_{t>0} \in \prod_{t>0} G_t : a_s = f_{ts}(a_t), \forall t \leq s \right\}, \]
endowed with natural projections \( p_t : G_0 \to G_t \) picking out the \( t \)-th component. Since \( p_s = f_{ts} \circ p_t \) for \( t \leq s \), we have \( \ker(p_t) \subset \ker(p_s) \). If \( p_t \) is surjective, then \( G_t \cong G_0/\ker(p_t) \) can be regarded as a partition of the limit \( G_0 \). If \( p_t \) and \( p_s \) are both surjective for some \( t \leq s \), then, as partitions of \( G_0 \), \( G_t \) refines \( G_s \).

By Theorem 4.19, if a metric space \((X, d_X)\) is both u.l.p.c. and u.s.l.s.c., then each \( \Phi^X \) is surjective and \( \pi_1(X) \cong \lim \pi_1^t(X) \), in which case each \( \pi_1^t \) can be regarded as a partition of \( \pi_1(X) \). Furthermore, applying Theorem 4.25 we obtain the following theorem:

**Theorem 5.14 (Dendrogram over \( \pi_1(X) \)).** Suppose that a compact geodesic metric space \( X \) is both uniformly locally path connected (u.l.p.c.) and uniformly semi-locally simply connected (u.s.l.s.c.). Then there is a dendrogram \( \theta_{\pi_1(X)} \) over \( \pi_1(X) \), given by
\[ \theta_{\pi_1(X)}(\epsilon) := \begin{cases} \pi_1^t(X), & \text{if } \epsilon > 0 \\ \pi_1(X), & \text{if } \epsilon = 0. \end{cases} \]

As an example, let us look at the dendrogram associated to \( S^1 \) and understand the induced metric \( \mu_{\theta_{\pi_1(S^1)}} \).

**Example 5.15.** When \( r = 1 \) in Example 4.13, associated to \( \Pi_1(S^1) \) we have a dendrogram over \( \pi_1(S^1) \cong \mathbb{Z} \) shown in Figure 1 on Page 4. The metric \( \mu_{\theta_{\pi_1(S^1)}} \) induces an ultrametric \( d \) on \( \mathbb{Z} \) given by
\[ d(n,m) = \begin{cases} \frac{2\pi}{3}, & \text{if } n \neq m \\ 0, & \text{if } n = m. \end{cases} \]
In Example 4.18, a simply connected compact space (e.g. the unit sphere $S^2$) has a trivial associated dendrogram. Thus, the metric space $\left(\pi_1(S^2), \mu_\theta_{\pi_1(S^2)}\right)$ is (isometric to) the one-point metric space $\ast$. It follows from Proposition 3.5 that

$$d_{GH}\left(\left(\pi_1(S^1), \mu_\theta_{\pi_1(S^1)}\right), \left(\pi_1(S^2), \mu_\theta_{\pi_1(S^2)}\right)\right) = \frac{1}{2}\text{diam}(\pi_1(S^1)) = \frac{\pi}{3}.$$

By the same argument, we conclude:

**Corollary 5.16.** If $X$ is an u.l.p.c. and u.s.l.s.c. compact geodesic space and $Y$ is a simply connected compact space, then

$$d_{GH}\left(\left(\pi_1(X), \mu_\theta_{\pi_1(X)}\right), \left(\pi_1(Y), \mu_\theta_{\pi_1(Y)}\right)\right) = \frac{1}{2}\text{diam}(\pi_1(X)).$$

The next theorem, following immediately from Theorem 5.14, Proposition 3.15 and Theorem 4.19, shows that the Gromov-Hausdorff distance between fundamental groups can be estimated by the interleaving distance between dendrograms.

**Theorem 5.17.** If compact geodesic metric spaces $X$ and $Y$ are u.l.p.c. and u.s.l.s.c., then

$$\frac{1}{2} \cdot d_1(V_k \circ \theta_{\pi_1(X)}, V_k \circ \theta_{\pi_1(Y)}) \leq d_{GH}\left(\left(\pi_1(X), \mu_\theta_{\pi_1(X)}\right), \left(\pi_1(Y), \mu_\theta_{\pi_1(Y)}\right)\right) \leq d_1(\theta_{\pi_1(X)}, \theta_{\pi_1(Y)}).$$

We finish this section with a stability result for $\mu_{\theta_{\pi_1(\ast)}}$.

**Theorem 5.18 (ℓ∞-stability for dendrograms over $\pi_1(\ast)$).** Let compact geodesic metric spaces $(X, d_X)$ and $(Y, d_Y)$ be u.l.p.c. and u.s.l.s.c. Suppose $X$ and $Y$ are homotopy equivalent, i.e., there exists continuous maps $f : X \to Y$ and $g : Y \to X$ such that $f \circ g$ is homotopic to $\text{Id}_Y$ and $g \circ f$ is homotopic to $\text{Id}_X$. Then

$$\left\|\mu_{\theta_{\pi_1(X)}} - \mu_{\theta_{\pi_1(Y)}} \circ (\pi_1 f, \pi_1 f)\right\|_\infty \leq \max\{\text{dis}(f), \text{dis}(g)\},$$

where $\pi_1 f : \pi_1(X) \to \pi_1(Y)$ is the induced homomorphism. In particular, when $X = Y$ and $d_X$ and $d_Y$ induce the same topology on $X$, we can take $f$ and $g$ to be the identity map. In this case,

$$\left\|\mu_{\theta_{\pi_1(X)}} - \mu_{\theta_{\pi_1(Y)}}\right\|_\infty \leq \|d_X - d_Y\|_\infty.$$

**Proof.** Note that the induced homomorphisms $\pi_1 f : \pi_1(X) \to \pi_1(Y)$ and $\pi_1 g : \pi_1(Y) \to \pi_1(X)$ are isomorphisms, and these isomorphisms are inverses of each other. Since $\text{dis}(\pi_1 f) = \text{codis}(\pi_1 f, \pi_1 g) = \text{dis}(\pi_1 g)$, we have

$$\max\{\text{dis}(\pi_1 f), \text{codis}(\pi_1 f, \pi_1 g), \text{dis}(\pi_1 g)\} = \text{dis}(\pi_1 f).$$

Let $\gamma$ and $\gamma'$ be two continuous loops in $X$ based at $x_0$. Let $\delta > \mu_{\theta_{\pi_1(\ast)}}(\gamma, \gamma')$. Then there exists $\epsilon \geq \delta$ and $\epsilon$-loops $\alpha$ and $\alpha'$, which are strong $\epsilon$-loops along $\gamma$ and $\gamma'$ respectively, such that $\alpha \sim_\epsilon \alpha'$ via an $\epsilon$-homotopy $H$. By an argument similar to that of Proposition 5.3, $f(\alpha)$ and $f(\alpha')$ are $(\epsilon + \text{dis}(f))$-loops, and $f(H)$ is an $(\epsilon + \text{dis}(f))$-homotopy. Directly checking from the definition, we see that $f(\alpha)$ and $f(\alpha')$ are strong $(\epsilon + \text{dis}(f))$-loops along $\alpha_1 f(\gamma)$ and $\alpha_1 f(\gamma')$, respectively. Thus, $\mu_{\theta_{\pi_1(Y)}}(\pi_1 f(\gamma), \pi_1 f(\gamma')) \leq \epsilon + \text{dis}(f)$. Letting $\delta \setminus \mu_{\theta_{\pi_1(Y)}}(\gamma, \gamma')$, we obtain $\mu_{\theta_{\pi_1(Y)}}(\pi_1 f(\gamma), \pi_1 f(\gamma')) \leq \mu_{\theta_{\pi_1(Y)}}(\gamma, \gamma') + \text{dis}(f)$. Using the fact that $\pi_1 f$ and $\pi_1 g$ are inverses of each other, we can prove in a similar way that $\mu_{\theta_{\pi_1(X)}}(\gamma, \gamma') \leq \mu_{\theta_{\pi_1(Y)}}(\pi_1 f(\gamma), \pi_1 f(\gamma')) + \text{dis}(g)$. It follows that

$$\left\|\mu_{\theta_{\pi_1(X)}} - \mu_{\theta_{\pi_1(Y)}} \circ (\pi_1 f, \pi_1 f)\right\|_\infty = \text{dis}(\pi_1 f) \leq \max\{\text{dis}(f), \text{dis}(g)\}.$$
Remark 5.19. Despite Theorem 5.18, it is not clear whether
\[ d_{GH} \left( \left( \pi_1(X), \mu_{\theta_{\pi_1(X)}} \right), \left( \pi_1(Y), \mu_{\theta_{\pi_1(Y)}} \right) \right) \leq d_{GH}(X, Y). \] (4)
The difficulty to prove such a claim is that arbitrary set maps do not necessarily induce homomorphisms between fundamental groups. In §6, we will prove a weaker version of Equation (4): with a factor 2 on the right hand side (cf. Theorem 6.2).

5.2.1. An application on Riemannian manifolds. As an application of Theorem 5.18, let us consider a connected Riemannian manifold \((M, g)\), where \(M\) is a smooth manifold and \(g\) smoothly assigns an inner product \(g_p\) to each tangent space \(T_pM\) for each \(p \in M\). Let \(\lambda : M \to \mathbb{R}_+\) be a smooth positive function. Then \((M, \lambda \cdot g)\) is also a Riemannian manifold. A change of Riemannian metric \(g \rightarrow \tilde{g}\) is called a \textit{conformal change}, if angles between two vectors with respect to \(g\) and \(\tilde{g}\) are the same at every point of the manifold. It is clear that \(g \rightarrow \lambda \cdot g\) is a conformal change. Let \(\lambda\) and \(\tilde{\lambda}\) be two smooth positive functions from \(M\) to \(\mathbb{R}_+\). Given any two distinct points \(x, x'\) in \(M\), if \(\gamma\) is a smooth curve on \(M\) from \(x\) to \(x'\), then
\[ L_{\lambda g}(\gamma) - L_{\tilde{\lambda} g}(\gamma) = \left| \int_\gamma \lambda g - \tilde{\lambda} g \right| \leq \|\lambda - \tilde{\lambda}\|_\infty \cdot \int_\gamma g, \]
where \(L_g(\gamma)\) represents the length of \(\gamma\) in \((M, g)\). It follows that
\[ d_{\lambda g}(x, x') \leq \inf_\gamma L_{\lambda g}(\gamma) + \inf_\gamma |L_{\lambda g}(\gamma) - L_{\tilde{\lambda} g}(\gamma)| \]
\[ \leq \inf_\gamma L_{\tilde{\lambda} g}(\gamma) + \|\lambda - \tilde{\lambda}\|_\infty \cdot \int_\gamma g \]
\[ \leq d_{\tilde{\lambda} g}(x, x') + \|\lambda - \tilde{\lambda}\|_\infty \cdot \text{diam}(M, g). \]
Thus, we have
\[ \|d_{\lambda g} - d_{\tilde{\lambda} g}\|_\infty \leq \|\lambda - \tilde{\lambda}\|_\infty \cdot \text{diam}(M, g). \] (5)
Since \((M, \lambda \cdot g)\) and \((M, \tilde{\lambda} \cdot g)\) have the same homotopy type, we can apply Theorem 5.18 and Equation 5 to obtain

Corollary 5.20.
\[ \left\| \mu_{\theta_{\pi_1(M, \lambda g)}} - \mu_{\theta_{\pi_1(M, \tilde{\lambda} g)}} \right\|_\infty \leq \|\lambda - \tilde{\lambda}\|_\infty \cdot \text{diam}(M, g). \]

For example, let us take \(M\) to be the 2-dimensional torus \(T^2\) and \(g\) to be the flat metric on it. In other words, \((T^2, g)\) is the quotient space of the Euclidean square \([0, 2\pi] \times [0, 2\pi]\) by identifying the opposite sides (see Figure 2). Then we have
\[ \|\mu_{\theta_{\pi_1(T^2, \lambda g)}} - \mu_{\theta_{\pi_1(T^2, \tilde{\lambda} g)}}\|_\infty \leq \|\lambda - \tilde{\lambda}\|_\infty \cdot \sqrt{5}\pi, \]

5.3. Persistent Homotopy Groups under Products. Let the Cartesian product \(X \times Y\) of two metric spaces be equipped with the \(\ell^\infty\) product metric:
\[ d_{X \times Y}(x, y) := \max\{d_X(x, x'), d_Y(y, y')\}, \forall x, x' \in X; y, y' \in Y. \]
Note that when \(X\) and \(Y\) are chain-connected, \(X \times Y\) is also chain-connected.
that if a compact geodesic metric space is both u.l.p.c. and u.s.l.s.c., then there is a dendrogram.

Corollary 5.22. Let \((X, x_0)\) and \((Y, y_0)\) be pointed metric spaces. There is a natural isomorphism of persistent groups:

\[
\pi_1(X \times Y, (x_0, y_0)) \cong \pi_1(X, x_0) \times \pi_1(Y, y_0),
\]

the product of \(\pi_1(X, x_0)\) and \(\pi_1(Y, y_0)\) (see Page 8). It follows that

\[
\pi_1(X \times Y, (x_0, y_0)) \cong \pi_1(X, x_0) \times \pi_1(Y, y_0). \tag{6}
\]

Remark 5.23. Recall from Theorem 5.14 that if a compact geodesic metric space \(X\) is both u.l.p.c. and u.s.l.s.c., then there is a dendrogram \(\theta_{\pi_1(X)}\) over \(\pi_1(X)\). Suppose \(Y\) is also such a space with a dendrogram \(\theta_{\pi_1(Y)}\) over \(\pi_1(Y)\). Since \(X \times Y\) is also geodesic, u.l.p.c. and u.s.l.s.c., the left hand side of Equation (6) induces a dendrogram \(\theta_{\pi_1(X \times Y)}\) over \(\pi_1(X \times Y)\). Meanwhile, the product of dendrograms \(\theta_{\pi_1(X)} \times \theta_{\pi_1(Y)}\) gives a dendrogram over \(\pi_1(X) \times \pi_1(Y) \cong \pi_1(X \times Y)\), cf. Page 16. In particular, the isomorphism given in Equation (6) implies that for each \(\epsilon \geq 0\) one has

\[
\theta_{\pi_1(X \times Y)}(\epsilon) = (\theta_{\pi_1(X)} \times \theta_{\pi_1(Y)})(\epsilon) := \begin{cases} 
\pi_1(X) \times \pi_1(Y), & \text{if } \epsilon > 0 \\
\pi_1(X) \times \pi_1(Y), & \text{if } \epsilon = 0,
\end{cases}
\]
as partitions of \(\pi_1(X \times Y)\).

Example 5.24. Consider the torus \(T^2(r_1, r_2) := \mathbb{S}^1(r_1) \times \mathbb{S}^1(r_2)\), where \(0 < r_1 \leq r_2\) and \(\mathbb{S}^1(r_1)\) and \(\mathbb{S}^1(r_2)\) are both endowed with their corresponding geodesic metrics. Then

\[
\pi_1(\mathbb{S}^1(r_1) \times \mathbb{S}^1(r_2)) = \mathbb{Z} \left(0, \frac{2\pi}{3} r_1\right) \times \mathbb{Z} \left(0, \frac{2\pi}{3} r_2\right) = (\mathbb{Z} \times \mathbb{Z}) \left(0, \frac{2\pi}{3} r_1, \frac{2\pi}{3} r_2\right),
\]

and the dendrogram associated to \(\pi_1(T^2(r_1, r_2))\) over \(\pi_1(T^2(r_1, r_2)) \cong \mathbb{Z} \times \mathbb{Z}\) is described in Figure 3.
5.1. To compute: corresponding undecorated persistence diagrams of $d$ and $X$ Persistent Fundamental Groups under Wedge Sums.

5.4. VR calculate PH $34$ Persistent Homotopy Groups of Metric Spaces

When $r_1 = r_2 = 1$, we write $T^2 := T^2(1, 1)$ and apply Example 5.12 to compute:

$$\Pi^n_{VR}(T^2) \cong \begin{cases} (\mathbb{Z} \times \mathbb{Z}) \left(0, \frac{2\pi}{3}\right), & \text{if } n = 1, \\ (\mathbb{Z} \times \mathbb{Z}) \left[\frac{2\pi}{3}, \frac{2\pi}{3}\right], & \text{if } n = 2. \end{cases}$$

As for the persistent homology groups of $S^1 \times S^1$, because $PH^i(S^1)$ is torsion free for each $i \geq 0$ and $\epsilon > 0$, the Künneth Theorem (cf. [32, Theorem 3B.5]) can be applied to calculate $PH^i_{VR}(T^2) \cong \bigoplus_{i=0}^n PH^i(S^1) \times PH^i_{\pi-i}(S^1)$. On the other hand, if the homology groups $PH^i_{VR}(T^2; \mathbb{R})$ are computed with coefficients in $\mathbb{R}$, then for all integers $k \geq 0$, the corresponding undecorated persistence diagrams of $T^2$ are (cf. [38, Example 4.3]):

$$dgm_{2k+1}(T^2) = \left\{ \left(\frac{k}{2k+1}, 2\pi\right), \left(\frac{k+1}{2k+3}, 2\pi\right) \right\},$$
$$dgm_{4k+2}(T^2) = \left\{ \left(\frac{k}{2k+1}, 2\pi\right), \left(\frac{k+1}{2k+3}, 2\pi\right) \right\},$$
$$dgm_{4k+4}(T^2) = \emptyset.$$

5.4. Persistent Fundamental Groups under Wedge Sums. The wedge sum $X \vee Y$ of two pointed metric spaces $X$ and $Y$ is the quotient space of the disjoint union of $X$ and $Y$ by the identification of basepoints $x_0 \sim y_0$: $X \vee Y = (X \sqcup Y) / \sim$. Denote the resulting basepoint of $X \vee Y$ by $z_0$. Let the wedge product be equipped with the gluing metric (see [3]):

$$d_{X \vee Y}(x, y) := d_X(x, x_0) + d_Y(y, y_0), \forall x \in X, y \in Y$$

and $d_{X \vee Y}|_{X \times X} = d_X, d_{X \vee Y}|_{Y \times Y} = d_Y$. Notice that the above definition can be generalized to the case when we glue $n$ different pointed metric spaces $(X_1, x_1), \ldots, (X_n, x_n)$ by identifying
$x_i \sim x_j$ for all $1 \leq i, j \leq n$. We denote the resulting space by $\bigvee_{i=1}^n (X_i, x_i)$, or $\bigvee_{i=1}^n X_i$ for simplicity, with the gluing metric:

$$d_{\bigvee_{i=1}^n} x_i (y_i, y_j) := d_{X_i} (y_i, x_i) + d_{X_j} (y_j, x_j), \forall i \neq j, y_i \in X_i, y_j \in X_j$$

and $d_{X_i \times X_j} |_{X_i \times X_i} = d_{X_i}$ for $1 \leq i \leq n$.

**Proposition 5.25** (Proposition 3.7, [3]). Let $X$ and $Y$ be pointed metric spaces. For each $\epsilon > 0$, we have the basepoint preserving homotopy equivalence

$$| VR_\epsilon (X) \vee VR_\epsilon (Y) | \cong VR_\epsilon (X \vee Y).$$

Furthermore, for $0 < \epsilon \leq \epsilon'$, we have the following commutative diagram:

$$
\begin{array}{ccc}
| VR_\epsilon (X) \vee VR_\epsilon (Y) | & \cong & | VR_{\epsilon'} (X) \vee VR_{\epsilon'} (Y) | \\
\downarrow & & \downarrow \\
| VR_\epsilon (X \vee Y) | & \cong & | VR_{\epsilon'} (X \vee Y) | 
\end{array}
$$

By applying the fundamental group functor to the above commuting diagram, where all maps preserve basepoints, we obtain a corollary about the persistent fundamental group of the wedge sum of metric spaces.

**Corollary 5.26.** Let $(X, x_0)$ and $(Y, y_0)$ be pointed metric spaces, and let $z_0$ be the basepoint in $X \vee Y$ obtained by identifying $x_0$ and $y_0$. There is a natural isomorphism of persistent groups:

$$\Pi_1 (X \vee Y, z_0) \cong \Pi_1 (X, x_0) \ast \Pi_1 (Y, y_0),$$

the coproduct of $\Pi_1 (X)$ and $\Pi_1 (Y)$ given by componentwise free product (see Page 8).

**Proof.** This follows immediately from Theorem 4.15, Proposition 5.25 and the van-Kampen theorem (see [32, Theorem 1.20]).

**Example 5.27** (Bouquets of circles). Let $0 =: r_0 < r_1 < r_2 < \cdots < r_n$ and let $k_1, k_2, \cdots, k_n$ be positive integers. Consider a bouquet of circles given as follows: let

$$C = \left( \bigvee_{i=1}^{k_1} S^1 (r_1) \right) \vee \left( \bigvee_{i=1}^{k_2} S^1 (r_2) \right) \vee \cdots \vee \left( \bigvee_{i=1}^{k_n} S^1 (r_n) \right)$$

by gluing one point from each circle together. Then,

$$\Pi_1^f (C) = \begin{cases} \mathbb{Z}^{\ast (k_i + \cdots + k_n)}, & \text{if } \frac{2\pi}{3} r_{i-1} \leq \epsilon < \frac{2\pi}{3} r_i, \text{ for } i = 1, \cdots, n. \\ 0, & \text{if } \epsilon \geq \frac{2\pi}{3} r_n. \end{cases}$$

where $\Pi_1^0 (C) := \pi_1 (C) = \mathbb{Z}^{\ast (k_1 + \cdots + k_n)}$. In addition,

$$\Pi_1 (C) = \prod_{i=1}^n \mathbb{Z}^{\ast k_i} \left[ 0, \frac{2\pi}{3} r_i \right) = \prod_{i=1}^n \mathbb{Z}^{\ast (k_i + \cdots + k_n)} \left[ \frac{2\pi}{3} r_{i-1}, \frac{2\pi}{3} r_i \right).$$

Notice that the number of free generators of $\Pi_1^f (C)$ can be represented by a stair-case function:

$$f_C (\epsilon) := \begin{cases} k_i + \cdots + k_n, & \text{if } \epsilon \in \left[ \frac{2\pi}{3} r_{i-1}, \frac{2\pi}{3} r_i \right), \text{ for } i = 1, \cdots, n. \\ 0, & \text{if } \epsilon \in \left[ \frac{2\pi}{3} r_n, +\infty \right). \end{cases}$$

Taking $r_1 = 1, r_2 = 2$ and $r_3 = 3$, we obtain the function $f_C$ shown in Figure 4.
5.5. Relation to Persistent Homology Groups: Persistent Hurewicz Theorem. In [4], Barcelo et al. established a slightly different definition of $\varepsilon$-homotopy, where an $\varepsilon$-homotopy between two $\varepsilon$-chains $\gamma_1$ and $\gamma_2$ (of the same size $n$) is an $\varepsilon$-Lipschitz map $H : ([n] \times [m], \ell^1) \to (X, d_X)$, instead of equipping $[n] \times [m]$ with the $\ell^\infty$ metric as we do in this paper. They proved a discrete version of the Hurewicz theorem under the $\ell^1$ metric in [4]. Via a similar argument, we obtain the following:

**Theorem 5.28** (Discrete Hurewicz Theorem). Let $\varepsilon > 0$. Let $(X, x_0)$ be a pointed $\varepsilon$-connected metric space. Then there is a surjective group homomorphism

$$\rho_\varepsilon : \pi_1^\varepsilon(X, x_0) \to \text{PH}_1^{\text{VR},\varepsilon}(X) := \text{PH}_1^{\text{VR},\varepsilon}(X; \mathbb{Z})$$

such that $\ker(\rho_\varepsilon) = [\pi_1^\varepsilon(X, x_0), \pi_1^\varepsilon(X, x_0)]$, the commutator group of $\pi_1^\varepsilon(X, x_0)$.

By checking that $\rho := \{\rho_\varepsilon\}_{\varepsilon > 0} \in \text{Hom}(\text{PII}_1(X), \text{PH}_1^{\text{VR}}(X))$ (see Page 38) and applying the isomorphism theorem of persistent fundamental groups, we obtain the persistent Hurewicz theorem:

**Theorem 5.29** (Persistent Hurewicz Theorem). Let $X$ be a chain-connected metric space. Then there is a natural transformation

$$\text{PII}_1^K(X) \xrightarrow{\rho} \text{PH}_1^K(X),$$

where for each $\varepsilon > 0$, $\rho_\varepsilon$ is surjective and $\ker(\rho_\varepsilon)$ is the commutator group of $\text{PII}_1^K(\varepsilon)(X)$.

**Proof of Theorem 5.28.** Here we adapt the proof of Theorem 4.1 from [4]. For simplicity, we fix $\varepsilon$ and write $\rho$ for $\rho_\varepsilon$. Also, we write $d$ for $d_X$ and omit $*$ for the concatenation of discrete loops.

Let $[\gamma] \in \pi_1^\varepsilon(X, x_0)$ and choose a representative $\gamma = x_0x_1\cdots x_{n+1}$ with $x_{n+1} = x_0$. For each $i \in [n]$, since $d(x_i, x_{i+1}) \leq \varepsilon$, $\sigma_i := \{x_i, x_{i+1}\}$ is an 1-simplex in $\text{VR}_\varepsilon(X)$, implying that $\sum_i \sigma_i \in C_1(\text{VR}_\varepsilon(X); \mathbb{Z})$. Note that $\sum_i \sigma_i \in \ker(\partial_1)$, because

$$\partial_1 \left( \sum_i \sigma_i \right) = (x_1 - x_0) + (x_2 - x_1) + \cdots + (x_{n+1} - x_n) = 0.$$

Define $\tilde{\rho}(\gamma) = \sum_i \sigma_i$. Let $p : \ker(\partial_1) \to \text{PH}_1^{\text{VR},\varepsilon}(X)$ be the canonical projection, and define $\rho([\gamma]) := p(\tilde{\rho}(\gamma))$.

**Claim 1:** $\rho$ is well defined.
It suffices to prove that \( \rho \) is well-defined under basic moves. Let \( \gamma = x_0x_1 \cdots x_nx_0 \). Suppose that by removing some point \( x_i \) (\( 1 \leq i \leq n \)), we obtain an \( \epsilon \)-chain \( \gamma_i = x_0x_1 \cdots x_{i-1}x_{i+1} \cdots x_nx_0 \). Then,

\[
\tilde{\rho}(\gamma) - \tilde{\rho}(\gamma_i) = \{x_{i-1}, x_i\} + \{x_i, x_{i+1}\} - \{x_{i-1}, x_{i+1}\} = \partial_2(\{x_{i-1}, x_i, x_{i+1}\}).
\]

Because \( \gamma_i \) is an \( \epsilon \)-chain, \( d(x_{i-1}, d_{i+1}) \leq \epsilon \), and thus \( \{x_{i-1}, x_i, x_{i+1}\} \in C_2(\text{VR}_\epsilon(X); \mathbb{Z}) \). It follows that \( \tilde{\rho}(\gamma) - \tilde{\rho}(\gamma_i) \in \text{Im}(\partial_2) \) and \( \rho(\gamma) = \rho(\gamma_i) \).

If adding \( y_i \) results a new \( \epsilon \)-chain \( \gamma'_i = x_0x_1 \cdots x_{i-1}y_i \cdots x_{i+n}x_0 \), we can apply similar arguments to obtain \( \tilde{\rho}(\gamma) - \tilde{\rho}(\gamma'_i) = \partial_2(\{x_{i-1}, y_i, x_i\}) \in \text{Im}(\partial_2) \) and thus \( \rho(\gamma) = \rho(\gamma'_i) \).

**Claim 2:** \( \rho \) is a group homomorphism.

Let \( \gamma_1 = x_0x_1 \cdots x_{n_1}x_{n_1+1} \) and \( \gamma_2 = y_0y_1 \cdots y_my_{m+1} \) where \( x_0 = x_{n_1+1} = y_0 = y_{m+1} \). Then

\[
\tilde{\rho}(\gamma_1\gamma_2) = \sum_{i=0}^{n_1} \{x_i, x_{i+1}\} + \sum_{j=0}^{m} \{y_j, y_{j+1}\} = \tilde{\rho}(\gamma_1) + \tilde{\rho}(\gamma_2) \implies \rho(\gamma_1\gamma_2) = \rho(\gamma_1) + \rho(\gamma_2).
\]

**Claim 3:** \( \rho \) is surjective.

Let \( \lambda \in \ker(\partial_1) \). As an element of \( C_1(\text{VR}_\epsilon(X); \mathbb{Z}) \), \( \lambda \) can be written as \( \sum_{i=1}^k n_i\sigma_i \) for some \( n_i \in \mathbb{Z} \) and \( \sigma_i = \{x_i, y_i\} \) such that \( d(x_i, y_i) \leq \epsilon \) for all \( i \). Since \( \partial_1(\lambda) = 0 \), we have

\[
\sum_{i=1}^k n_i(y_i - x_i) = 0. \tag{7}
\]

Let \( S = \{x_i, y_i : i = 1, \cdots, k\} \). Given \( q \in S \),

\begin{itemize}
  \item let \( m_q \) be the sum of coefficients of \( q \) in Equation (7). Note that \( m_q = 0 \).
  \item let \( \beta_q \) be an \( \epsilon \)-chain from \( x_0 \) to \( q \) in \( X \).
\end{itemize}

For each \( i \), define \( \eta_i := \beta_{x_i}\sigma_i\beta_{y_i}^{-1} \). Clearly, every \( \eta_i \) is an \( \epsilon \)-loop. Let \( \gamma = \eta_1^{n_1}\eta_2^{n_2} \cdots \eta_k^{n_k} \), which is again an \( \epsilon \)-loop. In addition, we have \( \rho([\gamma]) = \lambda \), because

\[
\tilde{\rho}(\gamma) = \sum_{i=1}^k n_i(\tilde{\rho}(\beta_{x_i}) + \sigma_i - \tilde{\rho}(\beta_{y_i}))
\]

\[
= \sum_{i=1}^k n_i\sigma_i + \sum_{i=1}^k n_i(\tilde{\rho}(\beta_{x_i}) - \tilde{\rho}(\beta_{y_i}))
\]

\[
= \sum_{i=1}^k n_i\sigma_i + \sum_{q \in S} m_q\tilde{\rho}(\beta_q)
\]

\[
= \sum_{i=1}^k n_i\sigma_i = \lambda.
\]

**Claim 4:** \( \ker(\rho) = [\pi_1^*(X, x_0), \pi_1^*(X, x_0)] \).

By the previous claims, \( \text{Im}(\rho) = \text{PH}_1^{\text{VR}_\epsilon}(X) \) is Abelian. Since \( \text{Im}(\rho) \cong \pi_1^*(X, x_0)/\ker(\rho) \), it must be true that \( [\pi_1^*(X, x_0), \pi_1^*(X, x_0)] \subset \ker(\rho) \). It remains to prove the reverse inclusion. Let \( \gamma = v_0v_1 \cdots v_tv_{t+1} \), with \( v_0 = v_{t+1} = x_0 \), be an \( \epsilon \)-loop such that \( \gamma \in \ker(\rho) \). It follows from \( \rho(\gamma) = 0 \) that there exists \( \sigma = \sum_{i=1}^k n_i\sigma_i \) with \( \sigma_i = \{x_i, y_i, z_i\} \in C_2(\text{VR}_\epsilon(X); \mathbb{Z}) \) such
that
\[
\gamma = \partial_2(\sigma) = \sum_{i=1}^{k} n_i \left( \{x_i, y_i\} + \{z_i, x_i\} + \{y_i, z_i\} \right).
\] (8)

Denote \( \sigma_1 = \{x_i, y_i\}, \sigma_2 = \{y_i, z_i\} \) and \( \sigma_3 = \{z_i, x_i\} \).

- Let \( L := \{\sigma_i : i = 1, \cdots, k; j = 1, 2, 3\} \). Given \( \zeta \in L \), let \( m_\zeta \) be the sum of coefficients of \( \zeta \) in Equation (8).
- Let \( S \) be the set of endpoints of all \( \sigma_i \). For each \( q \in S \), let \( \beta_q \) be an \( \epsilon \)-chain from \( x_0 \) to \( q \) in \( X \).

For each \( i \), define \( \eta_i := (\beta_{x_i} \sigma_i \beta_{y_i}^{-1})(\beta_{y_i} \sigma_i \beta_{z_i}^{-1})(\beta_{z_i} \sigma_i \beta_{x_i}^{-1}) = \beta_{x_i} \sigma_i \beta_{x_i}^{-1} \), which is an \( \epsilon \)-chain. Assume \( \beta_{x_i} = x_0 w_1 \cdots w_i x_i \). It follows from \( \{x_i, y_i, z_i\} \in C_2(VR_\epsilon(X); \mathbb{Z}) \) that
\[
\eta_i = \begin{cases} 
\sum_{j=1}^{i} w_j x_0 w_1 \cdots w_j w_i x_0, \\
\sum_{j=1}^{i} w_j x_0 w_1 \cdots w_j w_i x_0 \\
\sum_{j=1}^{i} w_j x_0 w_1 \cdots w_j w_i x_0 \\
\sum_{j=1}^{i} w_j x_0 w_1 \cdots w_j w_i x_0
\end{cases}
\]

Let \( \eta = \eta_1 \eta_2 \cdots \eta_k \), which is \( \epsilon \)-homotopic to the constant loop \( x_0 \).

Recall that \( \gamma = v_0 v_1 \cdots v_r \). Let \( \tau_i = \{v_i, v_{i+1}\} \) for \( i \in [r] \) and let \( \tau = \prod_{i=0}^{r} \beta_{v_i(0)} \tau_i \beta_{v_i(1)}^{-1} \), which is \( \epsilon \)-homotopic to \( \gamma \). Therefore, \( \gamma \sim \tau \eta^{-1} \).

For each \( \zeta \in L \), the loop \( \beta_{\zeta(0)} \zeta \beta_{\zeta(1)}^{-1} \) appears \( m_\zeta \) times in \( \tau \), and \( -m_\zeta \) times in \( \eta^{-1} \). So each \( \beta_{\zeta(0)} \zeta \beta_{\zeta(1)}^{-1} \) appears in \( \tau \eta^{-1} \) with exponent adding up to zero, so \( \left[ \gamma \right]_\epsilon = \left[ \tau \eta^{-1} \right]_\epsilon \in [\pi_1^\epsilon(X, x_0), \pi_1^\epsilon(X, x_0)] \).

**Proof of Theorem 5.29.** We follow the notations from the proof of Theorem 5.28, but adapt them to indicate their dependence on the index \( \epsilon \). For \( \epsilon > 0 \), we let \( \psi_1 \) be the first boundary map of chain complex of \( VR_\epsilon(X) \), let \( p^\epsilon \) be the canonical projection \( \ker(\partial_1^\epsilon) \to \phi_1^{VR, \epsilon}(X) \) and let \( \tilde{p}^\epsilon : \mathcal{L}^\epsilon(X, x_0) \to \ker(\partial_1^\epsilon) \) be given by
\[
\begin{array}{c}
x_0 x_1 \cdots x_n x_0 \leftrightarrow (x_0, x_1) + (x_1, x_2) + \cdots + (x_n, x_0)
\end{array}
\]

To prove the theorem, it suffices to check that \( \{\rho_\epsilon\}_{\epsilon>0} \in \text{Hom}(\phi^n_1(X), \phi_1^{VR, \epsilon}(X)) \). For \( 0 < \epsilon \leq \epsilon' \), it can be directly checked that each of the three squares in the following diagram commutes:
\[
\begin{array}{ccc}
\phi^n_1(X) & \xrightarrow{\psi} & \phi_1^{VR, \epsilon'}(X) \\
\uparrow & & \uparrow \\
\phi^n_1(X) & \xrightarrow{\psi} & \phi_1^{VR, \epsilon'}(X)
\end{array}
\]

\[
\begin{array}{ccc}
\phi^n_1(X) & \xrightarrow{\psi} & \phi_1^{VR, \epsilon'}(X) \\
\uparrow & & \uparrow \\
\phi^n_1(X) & \xrightarrow{\psi} & \phi_1^{VR, \epsilon'}(X)
\end{array}
\]

**Remark 5.30.** By the isomorphism of persistent fundamental groups (cf. Theorem 5.11), Theorem 5.28 follows from the standard Hurewicz theorem. Furthermore, for any \( n \geq 1 \), there exists a group homomorphism
\[
\phi_n^{K, \epsilon}(X, x_0) \xrightarrow{h_n} \phi_1^{K, \epsilon}(X, x_0).
\]

When \( X^\epsilon \) is such that \( \pi_i(X^\epsilon, x_0) = 0 \) for \( 1 \leq i \leq n - 1 \), the homomorphism \( h_n \) is an isomorphism.
6. Stability of Persistent Homotopy Groups

Recall that the interleaving distance between persistent groups $\mathbb{G}$ and $\mathbb{H}$ is given in Definition 3.8 by letting $\mathcal{C} = \text{Grp}$:

$$d_1(\mathbb{G}, \mathbb{H}) := \inf \{ \delta \geq 0 : \mathbb{G} \text{ and } \mathbb{H} \text{ are } \delta\text{-interleaved} \}.$$ 

In this section, we prove the following stability theorem for the interleaving distance of persistent K-homotopy groups (equivalently, for persistent VR-homotopy groups):

**Theorem 6.1** (*$d_1$*-stability for $\Pi_n^K(\bullet)$ and $\Pi_n^{VR}(\bullet)$). Let $(X, x_0)$ and $(Y, y_0)$ be pointed compact metric spaces. Then, for each $n \in \mathbb{Z}_{\geq 1}$,

$$d_1(\Pi_n^K(X, x_0), \Pi_n^K(Y, y_0)) \leq d_{GH}^p((X, x_0), (Y, y_0)).$$

If $X$ and $Y$ are chain-connected, then

$$d_1(\Pi_n^K(X), \Pi_n^K(Y)) \leq d_{GH}(X, Y).$$

Via the isomorphism $\Pi_n^K(\bullet) \cong \Pi_n^{VR}(\bullet)$, the above two inequalities also hold for $\Pi_n^{VR}(\bullet)$, up to a factor $\frac{1}{2}$.

As a consequence of the above theorem, we can derive a stability theorem for fundamental groups:

**Theorem 6.2** (*$d_{GH}$*-stability for $\theta_{\pi_1(\bullet)}$). If compact geodesic metric spaces $X$ and $Y$ are u.l.p.c. and u.s.l.s.c., then

$$d_{GH}\left(\left(\pi_1(X), \mu_{\theta_{\pi_1}(X)}\right), \left(\pi_1(Y), \mu_{\theta_{\pi_1}(Y)}\right)\right) \leq 2 \cdot d_{GH}(X, Y).$$

Given the isomorphism between the persistent fundamental group and the persistent K-fundamental group (cf. Theorem 5.11), another immediate application of Theorem 6.1 is the stability for persistent fundamental groups:

**Theorem 6.3** (*$d_1$*-stability for $\Pi_1(\bullet)$). Let $(X, x_0)$ and $(Y, y_0)$ be pointed compact metric spaces. Then

$$d_1(\Pi_1(X, x_0), \Pi_1(Y, y_0)) \leq 2 \cdot d_{GH}^p((X, x_0), (Y, y_0)).$$

6.1. Stability for $\Pi_n^K(\bullet)$, $\Pi_n^{VR}(\bullet)$ and $\pi_1(\bullet)$. To prove Theorem 6.1, we use the stability of homotopy interleaving distance under the Gromove-Hausdorff distance (see Theorem 3.12). As homotopy groups depend on basepoints when spaces are not connected, all maps between topological spaces are required to be basepoint preserving in this section.

Given an $\mathbb{R}_+$-space $V : (\mathbb{R}_+, \leq) \to \text{Top}$, we denote by $\lim V$ the limit of $V$ together with morphisms $v_t : \lim V \to V(t)$ for each $t \in \mathbb{R}_+$. For any $x \in \lim V$, let $(V, x)$ be the functor from $(\mathbb{R}_+, \leq)$ to $\text{Top}^*$ such that $(V, x)(t) = (V_t, v_t(x))$ and $(V, x)(t \leq s) = v_t^s$. Given two $\mathbb{R}_+$-spaces $V$ and $W$, as well as $x \in \lim V$ and $y \in \lim W$, we say that $(V, x)$ and $(W, y)$ are weakly equivalent if $V \simeq W$ via basepoint preserving maps. And $(V, x)$ and $(W, y)$ are said to be $\delta$-homotopy-interleaved if there exist $V', W' : (\mathbb{R}_+, \leq) \to \text{Top}^*$ such that $(V', x') \simeq (V, x)$, $(W', y') \simeq (W, y)$ for some $x' \in \lim V'$ and $y' \in \lim W'$, and $(V', x')$ and $(W', y')$ are $\delta$-interleaved.

**Lemma 6.4.** Let $V$ and $W$ be two $\mathbb{R}_+$-spaces. If $V \simeq W$, then there exists $x \in \lim V$ and $y \in \lim W$ such that $(V, x) \simeq (W, y)$. Moreover, if $(V, x) \simeq (W, y)$, then for all $n \geq 1$,

$$\pi_n \circ (V, x) \simeq \pi_n \circ (W, y).$$
Proof. Since \( V \simeq W \), there exist an \( \mathbb{R}_+ \)-space \( U \) and natural transformations \( f : U \Rightarrow V \) and \( g : U \Rightarrow W \) that are (objectwise) weak equivalences. Because of the universal property of \( \lim V \), there exists a morphism \( \lim f \) such that the following diagram commutes for all \( 0 < t \leq s \):

\[
\begin{array}{ccc}
V_t & \xleftarrow{f_t} & U_t \\
\downarrow & & \downarrow \\
\lim V & \xleftarrow{\lim f} & \lim U \\
\downarrow & & \downarrow \\
V_s & \xleftarrow{f_s} & U_s.
\end{array}
\]

Similarly, there exists a morphism \( \lim g : \lim U \rightarrow \lim W \) satisfying a similar commutative diagram. Take any \( z \in \lim U \) and let \( x := (\lim f)(z) \) and \( y := (\lim g)(z) \). It is clear that \( (V, x) \simeq (W, y) \).

In addition, we have the following commuting diagrams (for each \( 0 < t \leq s \)):

\[
\begin{array}{ccc}
\pi_n(V_t, v_t(x)) & \xrightarrow{\pi_n(f_t) \circ (\pi_n(g_t))^{-1}} & \pi_n(W_t, w_t(y)) \\
\downarrow & & \downarrow \\
\pi_n(V_s, v_s(x)) & \xleftarrow{\pi_n(f_s) \circ (\pi_n(g_s))^{-1}} & \pi_n(W_s, w_s(y)).
\end{array}
\]

Thus, \( \pi_n \circ (V, x) \) and \( \pi_n \circ (W, y) \) are naturally isomorphic. \( \square \)

Lemma 6.5. Let \( V \) and \( W \) be two \( \mathbb{R}_+ \)-spaces. Then, for any \( x \in \lim V \) and \( y \in \lim W \),

\[
d_1(\pi_n \circ (V, x), \pi_n \circ (W, y)) \leq d_{\text{HI}}((V, x), (W, y)).
\]

Proof. Suppose \( (V, x) \) and \( (W, y) \) are \( \delta \)-homotopy-interleaved for some \( \delta \geq 0 \). Then there exist \( V', W' : (\mathbb{R}_+, \leq) \rightarrow \text{Top}^* \) such that \( (V', x') \simeq (V, x) \), \( (W', y') \simeq (W, y) \) for some \( x' \in \lim V' \) and \( y' \in \lim W' \), and \( (V', x') \) and \( (W', y') \) are \( \delta \)-interleaved. By Lemma 6.4, we know that \( \pi_n \circ (V, x) \) and \( \pi_n \circ (V', x') \) are 0-interleaved, and \( \pi_n \circ (W, y) \) and \( \pi_n \circ (W', y') \) are 0-interleaved. Thus,

\[
d_1(\pi_n \circ (V, x), \pi_n \circ (W, y)) \leq d_1(\pi_n \circ (V, x), \pi_n \circ (V', x')) + d_1(\pi_n \circ (V', x'), \pi_n \circ (W', y')) + d_1(\pi_n \circ (W', y'), \pi_n \circ (W, y)) \\
\leq 0 + d_1((V', x'), (W', y')) + 0 \\
\leq \delta.
\]

\( \square \)

Proof of Theorem 6.6.1. We first notice that the proof of Theorem 3.12 (see [8, Page 20]) can be modified to show that

\[
d_{\text{HI}}(|\text{VR}(X)|, x_0), (|\text{VR}(Y)|, y_0)) \leq 2 \cdot d_{\text{GH}}^{\text{pt}}((X, x_0), (Y, y_0)).
\]
Applying Lemma 6.5, for each \( n \in \mathbb{Z}_{\geq 1} \) we obtain
\[
d_1 \left( \Pi_n^\mathrm{VR}(X, x_0), \Pi_n^\mathrm{VR}(Y, y_0) \right) = d_1 \left( \pi_n \circ (|\mathrm{VR}(X)|, x_0), \pi_n \circ (|\mathrm{VR}(Y)|, y_0) \right)
\leq d_{\mathrm{HI}} \left( (|\mathrm{VR}(X)|, x_0), (|\mathrm{VR}(Y)|, y_0) \right)
\leq 2 \cdot d_{\mathrm{GH}}^\mathrm{pt} ((X, x_0), (Y, y_0)).
\]

It follows from Corollary 5.10 that
\[
d_1 \left( \Pi_n^\kappa(X, x_0), \Pi_n^\kappa(Y, y_0) \right) = \frac{1}{2} \cdot d_1 \left( \Pi_n^\mathrm{VR}(X, x_0), \Pi_n^\mathrm{VR}(Y, y_0) \right) \leq d_{\mathrm{GH}}^\mathrm{pt} ((X, x_0), (Y, y_0)).
\]

When \( X \) and \( Y \) are chain-connected, we can take the infimum over all pairs \((x_0, y_0) \in X \times Y\) of both sides of the above Equation to get
\[
d_1 \left( \Pi_n^\kappa(X), \Pi_n^\kappa(Y) \right) = \frac{1}{2} \cdot d_1 \left( \Pi_n^\mathrm{VR}(X), \Pi_n^\mathrm{VR}(Y) \right) \leq d_{\mathrm{GH}}(X, Y).
\]

\( \square \)

**Proof of Theorem 6.2.** By Theorem 5.17, we have the leftmost inequality below:
\[
d_{\mathrm{GH}} \left( \left( \pi_1(X), \mu_{\theta_{\pi_1(X)}} \right), \left( \pi_1(Y), \mu_{\theta_{\pi_1(Y)}} \right) \right) \leq d_1(\theta_{\pi_1(X)}, \theta_{\pi_1(Y)}) \leq d_1(\Pi_1(X), \Pi_1(Y)). \tag{9}
\]

The second inequality is true because any \( \delta \)-interleaving between \( \Pi_1(X) \) and \( \Pi_1(Y) \) clearly induces a \( \delta \)-interleaving between \( \theta_{\pi_1(X)} \) and \( \theta_{\pi_1(Y)} \). It follows from Theorem 5.11 that
\[
d_1(\Pi_1(X), \Pi_1(Y)) = 2 \cdot d_1 \left( \Pi_1^\kappa(X), \Pi_1^\kappa(Y) \right). \tag{10}
\]

Finally we combine Equation (9) and Equation (10) together, and then apply Lemma 6.5 for the case \( n = 1 \), to obtain
\[
d_{\mathrm{GH}} \left( \left( \pi_1(X), \mu_{\theta_{\pi_1(X)}} \right), \left( \pi_1(Y), \mu_{\theta_{\pi_1(Y)}} \right) \right) \leq 2 \cdot d_{\mathrm{GH}}(X, Y).
\]

\( \square \)

To see that persistent homotopy sometimes provides better approximation of the Gromov-Hausdorff distance than persistent homology, we examine the following example.

**Example 6.6** (\( S^1 \times S^1 \) vs. \( S^1 \vee S^1 \)). Let \( T^2 = S^1 \times S^1 \) denote the torus constructed as the \( \ell^\infty \) product of two unit circles, and let \( C = S^1 \vee S^1 \) be the wedge sum of two unit circles. By Example 5.12 and Example 5.27, the persistent homology groups of \( C \) are: for all \( k \geq 1 \),
\[
\mathrm{PH}_n^\mathrm{VR}(C) \cong \begin{cases} 
\left( \mathbb{Z} \times \mathbb{Z} \right) \left( \frac{k-1}{2k-2}, \frac{k}{2k-1} \right) 2\pi, & \text{if } n = 2k-1, \\
\left( \mathbb{Z}^\times \times \mathbb{Z}^\times \right) \left[ \frac{k}{2k+1}, \frac{k}{2k+2} \right] 2\pi, & \text{if } n = 2k.
\end{cases}
\]

Following from the above, we can compute the persistent homology with coefficients in \( \mathbb{R} \) and obtain the undecorated persistence diagrams of \( C \) as follows: for all \( k \geq 0 \),
\[
d_{\mathrm{dgm}}_{2k+1}(C) = \left\{ \left( \frac{k}{2k+1} 2\pi, \frac{k+1}{2k+3} 2\pi \right), \left( \frac{k}{2k+1} 2\pi, \frac{k+2}{2k+3} 2\pi \right) \right\},
\]
\[
d_{\mathrm{dgm}}_{2k+2}(C) = \varnothing.
\]

It is clear that \( \mathrm{dgm}_0(C) = \mathrm{dgm}_0(T^2) = \{(0, \infty)\} \). Together with Example 5.24, for all \( k \geq 0 \), we have \( \mathrm{dgm}_{2k+1}(T^2) = \mathrm{dgm}_{2k+1}(C) \), \( \mathrm{dgm}_{4k+4}(T^2) = \mathrm{dgm}_{4k+4}(C) \),
\[
\mathrm{dgm}_{4k+2}(T^2) = \left\{ \left( \frac{k}{2k+1} 2\pi, \frac{k+1}{2k+3} 2\pi \right) \right\} \text{ and } \mathrm{dgm}_{4k+2}(C) = \varnothing.
\]
Thus,
\[
\sup_{n \geq 0} d_B \left( \operatorname{dgm}_n(T^2), \operatorname{dgm}_n(C) \right) = \sup_{n=4k+2, k \geq 0} d_B \left( \operatorname{dgm}_n(T^2), \operatorname{dgm}_n(C) \right)
\]
\[
\sup_{k \geq 0} d_B \left( \left\{ \left( \frac{k}{2k+1}, \frac{k+1}{2k+3} \cdot 2\pi \right) \right\}, \emptyset \right)
\]
\[
= \sup_{k \geq 0} d_B \left( \left( \frac{\pi}{2k+3} \right) \right) = \frac{\pi}{3}.
\]

Thus, the best approximation of \( d_{GH}(T^2, C) \) given by persistence diagrams is obtained at homological dimension 2. Now let us see that the same lower bound for \( d_{GH}(T^2, C) \) can already be realized by the interleaving distance between persistent fundamental groups. Recall that
\[
\Pi_1(T^2) = \langle \mathbb{Z} \times \mathbb{Z} \rangle \left( 0, \frac{2\pi}{3} \right) \text{ and } \Pi_1(C) = \langle \mathbb{Z} \ast \mathbb{Z} \rangle \left( 0, \frac{2\pi}{3} \right).
\]

We claim that
\[
d_1(\Pi_1(T^2), \Pi_1(C)) = \frac{\pi}{3}.
\]
Indeed, because the composition of group homomorphisms \( \mathbb{Z} \ast \mathbb{Z} \rightarrow \mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{Z} \ast \mathbb{Z} \) can never be \( \text{Id}_{\mathbb{Z} \ast \mathbb{Z}} \), it must be true that \( d_1(\Pi_1(T^2), \Pi_1(C)) \geq \frac{\pi}{3} \). By directly checking that \( \Pi_1(T^2) \) and \( \Pi_1(C) \) are \( \frac{\pi}{3} \)-interleaved, we can conclude that \( d_1(\Pi_1(T^2), \Pi_1(C)) = \frac{\pi}{3} \).

**Example 6.7** (\( S^1 \times S^m \) vs. \( S^1 \lor S^m \)). For \( m \geq 1 \), let \( S^m \) denote the \( m \)-sphere of radius 1, equipped with the geodesic distance. We denote \( a_m := \frac{1}{2} \arccos \left( -\frac{1}{m+1} \right) \). By the remarks on Page 508 of [36], \( \left( S^m \right)^\epsilon \) is homotopy equivalent to \( S^m \) for any \( \epsilon \in (0, a_m) \) and the inclusion \( \left( S^m \right)^\epsilon \hookrightarrow \left( S^m \right)^{\epsilon'} \) is a homotopy equivalence for \( 0 < \epsilon \leq \epsilon' \leq a_m \). Thus,
\[
\left( \left| VR_{2*} \left( S^m \right) \right| \right)_{(0,a_m)} \cong \left( S^m \right)^* \left|_{(0,a_m)} \right. \cong S^m(0, a_m),
\]
where \( \left|_{(0,a_m)} \right. \) means restriction of functors to the interval \( (0, a_m) \) and \( S^m(0, a_m) \) is an interval persistence module (see Page 12). Since \( a_m \leq a_1 \), we have \( \left( \left| VR_{2*} \left( S^1 \right) \right| \right)_{(0,a_m)} \cong S^1(0, a_m) \), and thus, for each \( n \geq 1 \),

| \( \Pi^n_{VR} \left|_{(0,2a_m)} \right. \) | \( \Pi^n_{VR} \left|_{(0,2a_m)} \right. \) |
|---|---|
| \( S^1 \times S^m \) | \( \left( \pi_n \left( S^1 \times S^m \right) \right) \left( 0, 2a_m \right) \) | \( \left( H_n \left( S^1 \times S^m \right) \right) \left( 0, 2a_m \right) \) |
| \( S^1 \lor S^m \) | \( \left( \pi_n \left( S^1 \lor S^m \right) \right) \left( 0, 2a_m \right) \) | \( \left( H_n \left( S^1 \lor S^m \right) \right) \left( 0, 2a_m \right) \) |

When \( n = m \geq 2 \), we apply Proposition 3.1 to the above table to obtain

| \( \Pi^m_{VR} \left|_{(0,2a_m)} \right. \) | \( \Pi^m_{VR} \left|_{(0,2a_m)} \right. \) |
|---|---|
| \( S^1 \times S^m \) | \( Z(0, 2a_m) \) | \( Z(0, 2a_m) \) |
| \( S^1 \lor S^m \) | \( \left( Z[t, t^{-1}] \right) \left( 0, 2a_m \right) \) | \( Z(0, 2a_m) \) |

Because the composition \( Z[t, t^{-1}] \rightarrow Z \rightarrow Z[t, t^{-1}] \) can never be \( \text{Id}_{Z[t, t^{-1}]} \), the leftmost inequality below is true:
\[
\frac{1}{2} \cdot a_m \leq \frac{1}{2} \cdot d_1 \left( \left( \Pi^m_{VR} \left( S^1 \lor S^m \right), \Pi^m_{VR} \left( S^1 \times S^m \right) \right) \right) \leq d_{GH} \left( S^1 \lor S^m, S^1 \times S^m \right).
\]
The rightmost inequality follows from Theorem 6.1. On the contrary, the restriction of persistent homology \( \Pi^m_{VR} \left|_{(0,2a_m)} \right. \) is not enough to distinguish \( S^1 \lor S^m \) and \( S^1 \times S^m \). The reason to work on the restriction instead of the whole persistent group is that homotopy
groups $\pi_n (|VR_\epsilon (S^m)|)$ (or homology groups $H_n (|VR_\epsilon (S^m)|)$) are not totally known when $\epsilon \geq a_m$.

When $n = 1$, we have seen in Example 6.6 that

\[
\begin{array}{c|c|c}
S^1 \times S^1 & \Pi_1^{VR} & \Phi_1^{VR} \\
\hline
(S \times Z)(0, \frac{2\pi}{3}) & (Z \times Z)(0, \frac{2\pi}{3}) & (Z \times Z)(0, \frac{2\pi}{3}) \\
S^1 \vee S^1 & (Z \ast Z)(0, \frac{2\pi}{3}) & (Z \times Z)(0, \frac{2\pi}{3}) \\
\end{array}
\]

Example 6.8 ($S^1 \times S^1$ vs. $S^1 \vee S^1 \vee S^2$). By an argument similar to that of Example 6.7, we obtain the following table for $a_2 = \frac{1}{2} \arccos (-\frac{1}{3})$ and each $n \geq 1$:

\[
\begin{array}{c|c|c}
S^1 \times S^1 & \Pi_n^{VR} |_{(0,2a_2)} & \Phi_n^{VR} |_{(0,2a_2)} \\
\hline
(S \times Z)(0, 2a_2) & (H_n(S^1 \times S^1))(0, 2a_2) & (H_n(S^1 \times S^1))(0, 2a_2) \\
S^1 \vee S^1 \vee S^2 & (\pi_n(S^1 \vee S^1 \vee S^2))(0, 2a_2) & (H_n(S^1 \vee S^1 \vee S^2))(0, 2a_2) \\
\end{array}
\]

Because $S^1 \times S^1$ and $S^1 \vee S^1 \vee S^2$ have isomorphic homology groups in all dimensions, their persistent homology restricted on the interval $(0, 2a_2)$ are also isomorphic. However,

\[
\Pi_1^{VR} |_{(0,2a_2)}(S^1 \times S^1) = (Z \times Z)(0, 2a_2) \text{ and } \Pi_1^{VR} |_{(0,2a_2)}(S^1 \vee S^1 \vee S^2) = (Z \ast Z)(0, 2a_2)
\]

are not isomorphic. Moreover, because the composition of group homomorphisms $Z \ast Z \to Z \times Z \to Z \ast Z$ can never be $\text{Id}_{Z \ast Z}$, the leftmost inequality below is true:

\[
\frac{1}{2} \cdot a_2 \leq \frac{1}{2} \cdot d_1(\Pi_1^{VR}(S^1 \vee S^1 \vee S^2), \Pi_1^{VR}(S^1 \times S^2)) \leq d_{GH}(S^1 \vee S^1 \vee S^2, S^1 \times S^2).
\]

The rightmost inequality follows from Theorem 6.1 with $n = 1$.

6.2. Second Proof of Stability for $\Pi_1(\bullet)$. In this section, inspired by Wilkins’ work [49] we provide an alternative proof of Theorem 6.3. This alternative proof is more constructive and independent of the notion of persistent K-fundamental groups. Let us recall the theorem here:

**Theorem 6.3** ($d_1$-stability for $\Pi_1(\bullet)$). Let $(X, x_0)$ and $(Y, y_0)$ be pointed compact metric spaces. Then

\[
d_1(\Pi_1(X, x_0), \Pi_1(Y, y_0)) \leq 2 \cdot d_{GH}^{pt}((X, x_0), (Y, y_0)).
\]

Based on [49, Lemma 6.3.3], we first introduce a way to construct maps between discrete fundamental groups and prove Lemma 6.10.

**Definition 6.9** ($\epsilon, \delta$-homomorphisms). Let $X$ and $Y$ be compact metric spaces with basepoints $x_0$ and $y_0$, respectively. Let

\[
R : X \leftrightarrow Z \xrightarrow{\phi_Y} Y
\]

be a pointed tripod (i.e., there exits $z_0 \in Z$ such that $\phi_X(z_0) = x_0$ and $\phi_Y(z_0) = y_0$) with $\text{dis}(R) \leq \epsilon$. Since $\phi_Y$ is surjective, for each $\delta > 0$ and each $\delta$-loop $\beta : [n] \to Y$, there is a discrete loop $\gamma_\beta$ in $Z$ such that $\phi_Y \circ \gamma_\beta = \beta$ and $\gamma_\beta(0) = \gamma_\beta(n) = z_0$, as expressed by the following diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{\phi_X} & Z \\
\downarrow{\phi_Y} & & \downarrow{\phi_Y} \\
Y & \end{array}
\]
Lemma 6.10. Using the above, we define a map

$$\psi_{\delta}^{\epsilon + \epsilon} : \pi_1^\delta(Y, y_0) \to \pi_1^{\epsilon + \epsilon}(X, x_0)$$

such that $[\beta]_\delta \mapsto [\phi_Y \circ \gamma_\beta]_{\epsilon + \delta}$, and similarly a map

$$\phi_{\delta}^{\epsilon + \epsilon} : \pi_1^\delta(Y, y_0) \to \pi_1^{\epsilon + \epsilon}(X, x_0)$$

such that $[\alpha]_\delta \mapsto [\phi_X \circ \gamma_\alpha]_{\epsilon + \delta}$.

We call the maps $\psi_{\delta}^{\epsilon + \epsilon}$ and $\phi_{\delta}^{\epsilon + \epsilon}$ the $(\epsilon, \delta)$-homomorphisms induced by the tripod $R$.

In [49], Wilkins’ construction of group homomorphisms between discrete fundamental groups is induced by some isometric embeddings of $X$ and $Y$ into a common metric space $Z$, and is applicable to any $\epsilon > 2d^Z_H(X, Y)$. Notice that given a tripod $R$ between metric spaces $X$ and $Y$, $R$ induces a metric space $Z_R$ which $X$ and $Y$ are isometrically embedded into, with $d^Z_H(X, Y) = 2 \text{dis}(R)$. We will prove in the next lemma that Definition 6.9 defines group homomorphisms for all $\epsilon > 2 \text{dis}(R) = d^Z_R(X, Y)$, which is an improvement over Wilkins’ construction.

**Lemma 6.10.** With the notation from Definition 6.9, the $(\epsilon, \delta)$-homomorphisms induced by a tripod $R$:

$$\psi_{\delta}^{\epsilon + \epsilon} : \pi_1^\delta(Y, y_0) \to \pi_1^{\epsilon + \epsilon}(X, x_0)$$

and

$$\phi_{\delta}^{\epsilon + \epsilon} : \pi_1^\delta(Y, y_0) \to \pi_1^{\epsilon + \epsilon}(Y, y_0)$$

are well-defined group homomorphisms. Furthermore,

$$\psi_\epsilon := \{\psi_{\delta}^{\epsilon + \epsilon}\}_{\delta > 0} \in \text{Hom}^\epsilon(\Pi_1(Y), \Pi_1(X)), \phi_\epsilon := \{\phi_{\delta}^{\epsilon + \epsilon}\}_{\delta > 0} \in \text{Hom}^\epsilon(\Pi_1(X), \Pi_1(Y)),$$

and

$$\psi_\epsilon \circ \phi_\epsilon = 1_{\Pi_1^\epsilon(X)}, \phi_\epsilon \circ \psi_\epsilon = 1_{\Pi_1^\epsilon(Y)}.$$ 

In other words, $\Pi_1(X)$ and $\Pi_1(Y)$ are $\epsilon$-interleaved via $\psi_\epsilon$ and $\phi_\epsilon$.

**Proof.** Fix $\delta > 0$. For a $\delta$-loop $\beta$ in $Y$, since $\phi_Y$ is surjective, let $\gamma_\beta$ be a discrete loop in $Z$ such that $\phi_Y(\gamma_\beta) = \beta$ and $\gamma_\beta(0) = \gamma_\beta(n) = z_0$. Because of the fact that $(\phi_X(\gamma_\beta), \beta) \in R_L$ and by Lemma 4.22, $\phi_X(\gamma_\beta)$ is an $(\epsilon + \delta)$-loop in $X$. So $\psi_{\delta}^{\epsilon + \epsilon}$ maps to $\pi_1^{\epsilon + \delta}(X, x_0)$.

**Claim 1:** $\psi_{\delta}^{\epsilon + \epsilon}$ is independent of the choice of $\gamma_\beta$.

Suppose $\beta = y_0 y_1 \cdots y_n$ with $y_n = y_0$ is a $\delta$-loop in $Y$. Suppose that $\gamma_\beta = z_0 \cdots z_n$ and $\gamma'_\beta = z'_0 \cdots z'_n$, where $z_n = z'_n = z_0$ is the basepoint of $Z$. For each $i \in [n]$, as $y_i = \phi_Y(z_i) = \phi_Y(z'_i)$, we have

$$d_X(\phi_X(z_i), \phi_X(z'_i)) \leq d_Y(y_i, y_i) + \text{dis}(R) \leq \epsilon,$$

and for each $i = 0, \cdots, n - 1$, we have

$$d_X(\phi_X(z_i), \phi_X(z'_{i+1})) \leq d_Y(y_i, y_{i+1}) + \text{dis}(R) \leq \delta + \epsilon.$$

Thus, inserting $\phi_X(z'_i)$ between $\phi_X(z_{i-1})$ and $\phi_X(z_i)$ is a basic move up to $(\delta + \epsilon)$-homotopy, for all $i = 1, \cdots, n$. This results into the following $(\delta + \epsilon)$-chain in $X$:

$$\phi_X(z_0) \phi_X(z'_1) \phi_X(z_1) \cdots \phi_X(z'_n) \phi_X(z_n).$$
By sequentially removing $\phi_X(z_i)$ for each $i = 1, \ldots, n$, we obtain a $(\delta + \epsilon)$-homotopy from $\phi_X(\gamma_\beta)$ to $\phi_X(\gamma'_\beta)$. Hence, $[\phi_X(\gamma_\beta)]_{\delta+\epsilon} = [\phi_X(\gamma'_\beta)]_{\delta+\epsilon}$.

Claim 2: $\psi_{\delta}^{\delta+\epsilon}$ is independent of the choice of $\beta$.

Suppose $\beta \sim_1 \beta'$ in $Y$, where $\beta = y_0y_1 \cdots y_n$ and $\beta' = y'_0y'_1 \cdots y'_m$ with $y_n = y'_m = y_0$. Then there is a $\delta$-homotopy in $Y$:

$$H_Y = \{ \beta = \beta_0, \beta_1, \ldots, \beta_{k-1}, \beta_k = \beta' \}$$

such that each $\beta_j$ differs from $\beta_{j-1}$ by a basic move. For each $\beta_j$, let $\gamma_{\beta_j}$ be a discrete loop in $Z$ such that $\phi_Y(\gamma_{\beta_j}) = \beta_j$ and $\gamma(0) = \gamma(1)$, where $z_0 = 0$. Then

$$H_X = \{ \phi_X(\gamma_{\beta_0}), \phi_X(\gamma_{\beta_1}), \ldots, \phi_X(\gamma_{\beta_{k-1}}), \phi X(\gamma_{\beta_k}) \}$$

is an $(\epsilon + \delta)$-homotopy between $\phi_X(\gamma_\beta)$ and $\phi_X(\gamma_{\beta'})$. Therefore,

$$\psi_{\delta}^{\delta+\epsilon}([\beta]_\delta) = [\phi_X(\gamma_\beta)]_{\epsilon+\delta} = [\phi_X(\gamma_{\beta'})]_{\epsilon+\delta} = \psi_{\delta}^{\delta+\epsilon}([\beta']_\delta).$$

Claim 3: $\psi_{\delta}^{\delta+\epsilon}$ is a group homomorphism.

Take two $\delta$-loops $\beta$ and $\beta'$ in $Y$, and choose $\gamma_\beta$ and $\gamma_{\beta'}$ so that $\psi_{\delta}^{\delta+\epsilon}([\beta]_\delta) = [\phi_X(\gamma_\beta)]_{\epsilon+\delta}$ and $\psi_{\delta}^{\delta+\epsilon}([\beta']_\delta) = [\phi_X(\gamma_{\beta'})]_{\epsilon+\delta}$ as before. It follows from $\phi_X(\gamma_\beta * \gamma_{\beta'}) = \phi_X(\gamma_{\beta'}) * \phi_X(\gamma_\beta)$ that $(\phi_X(\gamma_\beta) * \phi_X(\gamma_{\beta'}), \beta * \beta') \in R_\delta$. Thus,

$$\psi_{\delta}^{\delta+\epsilon}([\beta * \beta']_\delta) = [\phi_X(\gamma_\beta) * \phi_X(\gamma_{\beta'})]_{\epsilon+\delta} = \psi_{\delta}^{\delta+\epsilon}([\beta]_\delta) \psi_{\delta}^{\delta+\epsilon}([\beta']_\delta).$$

Claim 4: $\Pi_1(Y)$ and $\Pi_1(Y)$ are $\epsilon$-interleaved via $\psi_\epsilon$ and $\phi_\epsilon$.

Note that the following diagram commutes for all $\delta \leq \delta'$:

$$\begin{array}{c}
\Pi_1^0(Y) \\ \Phi_{\delta,\delta'}^Y \downarrow \\
\Pi_1^\delta(Y) \\ \psi_\epsilon \downarrow \\
\Pi_1^{\delta+\epsilon}(X)
\end{array}$$

Indeed, given a $\delta$-loop $\beta$ in $Y$, let $\gamma_\beta$ be a discrete loop in $Z$ chosen as before. Then,

$$\psi_\epsilon \circ \Phi_{\delta,\delta'}^Y([\beta]_\delta) = \psi_\epsilon([\beta]_\delta) = [\phi_X(\gamma_\beta)]_{\delta'+\epsilon},$$

$$\Phi_{\delta,\delta'+\epsilon}^X \circ \psi_\epsilon([\beta]_\delta) = \Phi_{\delta,\delta'+\epsilon}^X([\phi_X(\gamma_\beta)]_{\delta+\epsilon}) = [\phi_X(\gamma_\beta)]_{\delta'+\epsilon}. $$

Therefore, $\psi_\epsilon \in \text{Hom}'(\Pi_1(Y), \Pi_1(X))$ and a similar argument can be applied to prove that $\phi_\epsilon \in \text{Hom}'(\Pi_1(X), \Pi_1(Y))$. Also, by directly checking the relevant definitions, it is not hard to see that $\psi_\epsilon \circ \phi_\epsilon = 1_{\Pi_1(X)}^\delta$ and $\phi_\epsilon \circ \psi_\epsilon = 1_{\Pi_1(Y)}^\delta$. \hfill $\square$

It is clear that Lemma 6.10 immediately implies Theorem 6.3.

The next lemma refines Lemma 6.3.3 from [49] by improving the factors in equations (11) and (12) from $\frac{1}{2}$ to $\frac{1}{2}$.

**Lemma 6.11.** Let $X$ and $Y$ be chain-connected compact metric spaces.

1. Assume that there exist $\delta > \lambda > 0$ and $\epsilon > 0$ such that $\Phi_{X,\epsilon+\delta}^X$ is surjective. If

$$d_{GH}(X,Y) < \frac{1}{2} \min\{\epsilon, \delta - \lambda\},$$

then there exists a pointed tripod $R$ such that for any $(x_0, y_0) \in R$, the $(\epsilon, \delta)$-homomorphism $\psi_{\delta}^{\delta+\epsilon} : \pi_1^0(\delta, y_0) \rightarrow \pi_1^{\delta+\epsilon}(X,x_0)$ induced by $R$ is surjective.
(2) Suppose that there exist $\lambda < \epsilon$ such that $\Phi^X_{t_1, t_2}$ and $\Phi^Y_{t_1, t_2}$ are surjective for every $\lambda \leq t_1 < t_2 \leq \epsilon$. Given $\lambda < \delta < \delta' < \epsilon$, if

$$d_{GH}(X, Y) < \frac{1}{2} \min\{\delta - \lambda, \delta' - \delta, \epsilon - \delta'\},$$

then we have the following commutative diagram:

$$\begin{array}{ccc}
\pi^\epsilon_1(Y) & \xrightarrow{\psi^\delta} & \pi^\epsilon_1(X) \\
\Phi^Y_{\delta', \epsilon} & & \Phi^X_{\delta, \epsilon} \\
\pi^\delta_1(Y) & \xleftarrow{\phi^\delta} & \pi^\delta_1(X)
\end{array}$$

Proof. For Part (1), let $\tau := \frac{1}{2} \min\{\epsilon, \delta - \lambda\}$. Since $d_{GH}(X, Y) < \tau$, there exists a tripod

$$R : X \leftarrow \phi^X X \rightarrow Z \rightarrow Y$$

with $\text{dis}(R) < 2\tau \leq \epsilon$. Take a pair $(x_0, y_0) \in R$, and then let $X$ and $Y$ are based at $x_0$ and $y_0$, respectively. Let $\psi^\delta_{\phi^X} : \pi^\delta_1(Y, y_0) \rightarrow \pi^\delta_1(X, x_0)$ be the $(\epsilon, \delta)$-homomorphism induced by $R$ given in Definition 6.9. It has been proved in Lemma 6.10 that $\psi^\delta_{\phi^X}$ is a group homomorphism. It remains to show $\psi^\delta_{\phi^X}$ is surjective. Let $\alpha$ be an $(\epsilon + \delta)$-loop in $X$. Because $\Phi^X_{\lambda, \epsilon + \lambda}$ is surjective, there exists a $\lambda$-loop $\alpha'$ in $X$ that refines $\alpha$. Let $\gamma_{\alpha'}$ be a discrete loop in $(Z, z_0)$ such that $\phi_X(\gamma_{\alpha'}) = \alpha'$. By Lemma 4.22, $\phi_Y(\gamma_{\alpha'})$ is a $(\lambda + \text{dis}(R))$-loop, and thus a $(\delta + \epsilon)$-loop because $\lambda < \delta$ and $\text{dis}(R) < \epsilon$. It follows that

$$\psi^\delta_{\phi^X}([\phi_Y(\gamma_{\alpha'})]_\delta) = [\phi_X(\gamma_{\alpha'})]_{\epsilon + \delta} = [\alpha]_{\epsilon + \delta}.$$

Hence, $\psi^\delta_{\phi^X}$ is surjective. As $X$ and $Y$ are chain-connected, the same result holds for any other choice of basepoints.

For Part (2), let $\tau$ be equal to the right side of Equation (12). As in Part (1), we choose a tripod $R$ with $\text{dis}(R) < 2\tau$. Take a pair $(x_0, y_0) \in R$, and then let $X$ and $Y$ are based at $x_0$ and $y_0$, respectively. Let $\alpha$ be a $\delta$-loop in $X$, and let $\gamma_{\alpha}$ be a discrete loop in $(Z, z_0)$ such that $\phi_X(\gamma_{\alpha}) = \alpha$. Since $\delta + 2\tau \leq \delta'$, we have $\phi^\delta_{\phi^X}([\alpha]_\delta) = [\phi_Y(\gamma_{\alpha})]_{\delta'}$. Thus,

$$\psi^\delta_{\phi^X} \circ \Phi^Y_{\delta', \epsilon} \circ \phi^\delta_{\phi^X}([\alpha]_\delta) = \psi^\delta_{\phi^X} \circ \Phi^Y_{\delta', \epsilon}([\phi_Y(\gamma_{\alpha})]_{\delta'}) = \psi^\delta_{\phi^X}([\phi_Y(\gamma_{\alpha})]_{\epsilon'}) = [\alpha]_{\epsilon'} = \Phi^X_{\delta, \epsilon}([\alpha]_\delta).$$

□

7. Application to Finite Metric Spaces

In this section, we analyze several examples of finite metric spaces to further understand the generalized subdendrograms obtained in Lemma 4.27. In general, given a pointed metric space $(X, x_0)$, the set of discrete loops $L(X, x_0)$ is in bijection with the set $X^N = \{x_i \in X : x_i \in X\}$. Even when $X$ is a finite metric space, $L(X, x_0)$ can have large cardinality, making the illustration of its subdendrogram rather difficult. To simplify the graphical representation of the resulting subdendrograms, we introduce the equivalence relation $\sim$ on $L(X, x_0)$ given by:

$$\gamma \sim \gamma' \text{ iff } \gamma \text{ and } \gamma' \text{ have the same birth time } \delta \geq 0 \text{ and } \gamma \sim^\epsilon_{\delta} \gamma',$$

which implies that $\gamma \sim^\epsilon_{\delta} \gamma'$ for all $\epsilon \geq \delta$. Clearly, $\sim$ is an equivalence relation and we denote

$$L(X, x_0) := L(X, x_0) / \sim,$$
and write $[\gamma]$ for the equivalence class of a discrete loop $\gamma$ under the relation $\sim$. Let $p_X : \mathcal{L}(X, x_0) \to L(X, x_0)$ be the resulting quotient map, i.e., $p_X(\gamma) = [\gamma]$. It is not hard to see that $L(X, x_0)$ is a monoid under the operation $p_X(\gamma) \cdot p_X(\gamma') := p_X(\gamma \ast \gamma')$. The existence of inverse elements is not guaranteed because $\gamma \ast \gamma^{-1}$, where birth($\gamma$) = $\delta > 0$, is a $\delta$-loop and cannot be equivalent to the 0-loop $x_0$. Let $L^\epsilon(X, x_0)$ be the set of equivalence classes of discrete loops in $X$ with birth time $\epsilon$, i.e.,

$$L^\epsilon(X, x_0) := \left( \mathcal{L}^\epsilon(X, x_0) - \bigcup_{\delta < \epsilon} \mathcal{L}^\delta(X, x_0) \right) / \sim.$$ 

It is clear that $L^\epsilon(X, x_0)$ is a semigroup, i.e., it is closed under the operation $\ast$ which satisfies the associative property. Furthermore, $L^\epsilon(X, x_0)$ is a sub-semigroup of $L(X, x_0)$.

It can be directly checked that the constructions and results in §3.4 all apply here:

- The pseudo-ultrametric $\mu^{(1)}_X$ on $\mathcal{L}(X, x_0)$ induces a pseudo-ultrametric on $L(X, x_0)$, still denoted by $\mu^{(1)}_X$. In particular, for any two discrete loops $\gamma$ and $\gamma'$,

  $$\mu^{(1)}_X ([\gamma], [\gamma']) := \mu^{(1)}_X (\gamma, \gamma').$$

- Let $(X, x_0)$ and $(Y, y_0)$ be in $\mathcal{M}^{pt}$. Then each pointed tripod

  $$R : X \leftarrow Z \rightarrow Y$$

  induces the following tripod between $L(X, x_0)$ and $L(Y, y_0)$:

  $$R_L := L(X, x_0) \leftarrow L(Z, z_0) \rightarrow L(Y, y_0),$$

  with $\text{dis}(R) \leq \text{dis}(R_L)$.

- Given $(X, x_0)$ and $(Y, y_0)$ in $\mathcal{M}^{pt}$,

  $$d_{GH}(L(X, x_0), L(Y, y_0)) \leq d_{GH}^{pt}((X, x_0), (Y, y_0)).$$

- Let $X$ be a compact geodesic space or a finite metric space. The map $\epsilon \mapsto \pi^\epsilon_1(X, x_0)$ induces a generalized subdendrogram over $L(X, x_0)$, denoted by $\theta^\epsilon_{L(X, x_0)}$.

**Proposition 7.1.** Given $(X, x_0) \in \mathcal{M}^{pt}$ and $\epsilon > 0$, if $L^\epsilon(X, x_0)$ is non-empty, then $L^\epsilon(X, x_0)$ is isomorphic to a sub-semigroup of $\pi^\epsilon_1(X, x_0)$.

**Proof.** It suffices to show the map $f : L^\epsilon(X, x_0) \to \pi^\epsilon_1(X, x_0)$, with $[\gamma] \mapsto [\gamma]$, is an injective semigroup homomorphism. Given discrete loops $\gamma$ and $\gamma'$ with birth time $\epsilon$ such that $\gamma \sim \gamma'$, we have $\gamma \sim^1 \gamma'$. Thus, $f$ is well-defined. Clearly, $f$ preserve the semigroup operation. It remains to check that $f$ is injective. Indeed, if $f([\gamma]) = f([\gamma'])$ for some $\gamma$ and $\gamma'$ with birth time $\epsilon$, then $\gamma \sim^\epsilon \gamma'$. Thus, we have $\gamma \sim \gamma'$.

The following corollary follows immediately:

**Corollary 7.2.** Let $(X, x_0) \in \mathcal{M}^{pt}$ and $\epsilon > 0$. If $\pi^\epsilon_1(X, x_0) = 0$ and $L^\epsilon(X, x_0) \neq \emptyset$, i.e., there exists a discrete loop $\gamma_\epsilon$ in $X$ with birth time $\epsilon$, then

$$L^\epsilon(X, x_0) = \{[\gamma_\epsilon]\}.$$
Finite Tree Metric Spaces. Recall from Page 9 that a finite tree metric space \((T, d_T)\) is a finite metric space where \(d_T\) satisfies the four-point condition. It is proved in Theorem 2.1 of [15, Supplementary material] that the \(k\)-th homology group of \(\text{VR}_k(T)\) is 0 for all \(k \geq 1\). By adapting the proof, we obtain the following theorem applicable to persistent fundamental groups:

**Theorem 7.3.** Let \(T\) be a finite tree metric space and fix \(\epsilon > 0\). For each \(x_0 \in T\), we have

\[
\Pi_1(T, x_0) = 0.
\]

**Proof.** Recall from Theorem 4.15 that \(\pi_1(T, x_0) \approx \pi_1(|\text{VR}_\epsilon(T)|, x_0)\). When \(\epsilon \geq \text{diam}(T)\), \(|\text{VR}_\epsilon(T)|\) is contractible and thus has trivial fundamental group. Let us assume \(\epsilon < \text{diam}(T)\) and show that \(\pi_1(|\text{VR}_\epsilon(T)|, x_0) = 0\) for all \(x_0 \in T\) by induction on the cardinality of \(T\).

It is clear that the statement is true when \(T\) contains only one point. Now we suppose that \(\pi_1(|\text{VR}_\epsilon(T')|, x'_0) = 0\) for all \(x'_0 \in T'\), whenever \(T'\) is a tree metric space with cardinality < \(n\). Let \(T\) be a tree metric space with \(n\) points, based at point \(x_0\). Recall the equivalence relation \(\sim_\epsilon\) given on Page 17, under which \(T\) breaks up into equivalence classes \(T = \bigcup_\alpha T_\alpha\). When \(T\) is not \(\epsilon\)-connected, each \(T_\alpha\) has cardinality < \(n\). By the induction hypothesis, if \(x_0 \in T_\beta\) for some \(\beta\), then \(\pi_1(|\text{VR}_\epsilon(T)|, x_0) = \pi_1(|\text{VR}_\epsilon(T_\beta)|, x_0) = 0\).

We suppose next that \(T\) is \(\epsilon\)-connected. Let \(x_1\) and \(x_2\) be two points in \(T\) such that \(d_T(x_1, x_2) = \text{diam}(T)\). We denote \(T_1 := T - \{x_1\}\) and \(T_2 := T - \{x_2\}\). It has been shown in Proposition 2.2 and Theorem 2.1 of [15, Supplementary material] that the following are true:

- \(|\text{VR}_\epsilon(T)| = |\text{VR}_\epsilon(T_1)| \cup |\text{VR}_\epsilon(T_2)|\), where \(|\text{VR}_\epsilon(T_i)|\) is path connected for \(i = 1, 2\);
- \(|\text{VR}_\epsilon(T_1)| \cap |\text{VR}_\epsilon(T_2)| = |\text{VR}_\epsilon(T - \{x_1, x_2\})|\) is path connected.
- \(|\text{VR}_\epsilon(T_1)|\), \(|\text{VR}_\epsilon(T_2)|\) and \(|\text{VR}_\epsilon(T - \{x_1, x_2\})|\) all have trivial fundamental groups based at \(x_0\), by the induction hypothesis.

Let \(x_0\) be distinct from \(x_1\) and \(x_2\). Then we can apply the van-Kampen theorem (see [32, Theorem 1.20]) to conclude:

\[
\pi_1(|\text{VR}_\epsilon(T)|, x_0) = \pi_1(|\text{VR}_\epsilon(T_1)|, x_0) * \pi_1(|\text{VR}_\epsilon(T_2)|, x_0) = 0
\]

As \(|\text{VR}_\epsilon(T)|\) is connected, we finally obtain \(\pi_1(|\text{VR}_\epsilon(T)|, \tilde{x}_0) = \pi_1(|\text{VR}_\epsilon(T)|, x_0)\) for any \(\tilde{x}_0 \in T\). \(\Box\)

7.1. Finite Metric Spaces Arising from Graphs. Next we study the discrete loop set and the persistent fundamental group of graphs. All our graphs are finite, undirected and simple (i.e., with no self-loops or multiple edges) graphs, with weight 1 on each edge. Given a graph \(G\), we can obtain a metric space by equipping the vertex set with the shortest path distance \(d_G\). For simplicity, the resulting metric space is written as \((G, d_G)\), where the base space shall be understood as the vertex set of \(G\). The *girth* of a graph is the length of its shortest cycle or \(\infty\) for a forest (see [1]).

**Proposition 7.4** (Fact 2.1 & Proposition 2.2, [1]). For any connected graph \(G\) and \(r \geq 1\), the map of fundamental groups

\[
\pi_1(|\text{VR}_1(G)|) \mapsto \pi_1(|\text{VR}_r(G)|)
\]

induced by the inclusion \(\text{VR}_1(G) \hookrightarrow \text{VR}_r(G)\) is surjective. Furthermore, if \(r \geq 1\) is such that \(G\) is a graph of girth at least \(3r + 1\), then

\[
\pi_1(|\text{VR}_{k-1}(G)|) \cong \pi_1(|\text{VR}_k(G)|)
\]
for each $2 \leq k \leq r$.

Let $n \in \mathbb{Z}_{\geq 3}$. A cycle graph $C_n$ is a graph on $n$ vertices containing a single cycle through all its vertices. A star graph $S_n$ is a tree on $n$ vertices where one vertex (called the center) has degree $n - 1$ and the others have degree 1. Because of the symmetry, the set of discrete loops $\mathcal{L}(C_n, v_0)$ and the persistent fundamental group $\Pi_1(C_n, v_0)$ do not depend on choices of the basepoint $v_0$. As for $S_n$, we always choose its center to be the basepoint. For convenience, we denote the vertex set $V(C_n) = \{0, 1, \cdots, n-1\}$ such that $d_{C_n}(i, i + 1) = 1$, and denote the vertex set $V(S_n) = \{0, 1, \cdots, n-1\}$, with 0 the basepoint in both cases.

![Graphs $C_3$ (left) and $S_4$ (right).](image)

For later purpose, we introduce another metric space on the set of $n$ points, $E_n := (\{0, 1, \cdots, n-1\}, d_{E_n})$, where

$$d_{E_n}(i, j) = \begin{cases} 1, & \text{if } i \neq j, \\ 0, & \text{if } i = j. \end{cases}$$

**Theorem 7.5** (Corollary 6.6, [1]). For any $n \geq 3$ and $0 \leq r < \frac{n}{2}$, there are homotopy equivalences

$$|\text{VR}_r(C_n)| \cong \begin{cases} S^{2l+1}, & \text{if } \frac{l}{2l+1} < \frac{r}{n} < \frac{l}{2l+3} \text{ for some } l = 0, 1, \cdots, \\ S^{2l}, & \text{if } \frac{r}{n} = \frac{l}{2l+1} \text{ for some } l = 0, 1, \cdots. \end{cases}$$

For any integer $k \geq \frac{1}{2}n$, $|\text{VR}_k(C_n)|$ is contractible.

For $n \in \mathbb{Z}_{\geq 3}$ and $r = 0, \cdots, \left\lfloor \frac{n}{2} \right\rfloor$, we denote the following $r$-loop in $C_n$ as

$$\gamma_r := 0r(r+1)\cdots(n-1)0.$$ 

Although $\gamma_r$ depends on $n$, for simplicity of notation we do not specify $n$ unless necessary.

**Proposition 7.6.** Fix $n \in \mathbb{Z}_{\geq 3}$.

1. Let $\lfloor x \rfloor$ denote the largest integer less than or equal to $x$. Then

$$\Pi_1(C_n) = \text{PH}^{\text{VR}}_1(C_n) = \mathbb{Z} \left[ 1, \left\lfloor \frac{n+2}{3} \right\rfloor \right].$$

Furthermore, for $r = 1, \cdots, \left\lfloor \frac{n-1}{3} \right\rfloor$, a generator of $\Pi_1(C_n)$ is $[\gamma_r]_r$.

2. We have pseudo-ultrametric space

$$L(C_n) = \left\{ [\gamma_0], [\gamma_r^k], [\gamma_s] : r = 1, \cdots, \left\lfloor \frac{n-1}{3} \right\rfloor; s = \left\lfloor \frac{n+2}{3} \right\rfloor, \cdots, \left\lfloor \frac{n}{2} \right\rfloor; k \in \mathbb{Z} - \{0\} \right\},$$

with the pseudo-metric $\mu^{(1)}_{C_n}$ given by: for $k, k' \in \mathbb{Z} - \{0\}$,

$$\mu^{(1)}_{C_n}([\gamma_r^k], [\gamma_{r'}^{k'}]) = \begin{cases} 0, & \text{if } r = r' = 0 \\ \max \left\{ \left\lfloor \frac{n-1}{3} \right\rfloor, r \right\}, & \text{if } r' = 0, \ r \geq 1 \\ \max \{r, r'\}, & \text{otherwise.} \end{cases}$$
Proof. For Part (1), we first apply Theorem 7.5 to obtain that \(|\text{VR}_r(C_n)| \cong S^1\) iff \(1 \leq r < \left\lfloor \frac{n+2}{3} \right\rfloor\) and \(\Pi^r_1(C_n) = \text{PH}^r_1(C_n) = 0\) otherwise. Clearly, a generator of \(\Pi^1_1(C_n)\) is \([\gamma_1]_1\). Since the girth of \(C_n\) is \(n\), Proposition 7.4 implies that the inclusion \(\text{VR}_1(C_n) \hookrightarrow \text{VR}_r(C_n)\) induces an isomorphism
\[
\Pi^1_1(C_n) \to \Pi^r_1(C_n) \text{ with } [\gamma_1]_1 \mapsto [\gamma_1]_r = [\gamma_r],
\]
for \(r = 1, \ldots, \left\lfloor \frac{n-1}{3} \right\rfloor\). Thus, \([\gamma_r]_r\) is a generator of \(\Pi^r_1(C_n)\) for \(r = 1, \ldots, \left\lfloor \frac{n-1}{3} \right\rfloor\).

For (2), we first notice that the possible birth times of discrete loops in \(C_n\) are \(0, \ldots, \left\lfloor \frac{n-2}{3} \right\rfloor\) and each \(\gamma_r\) has birth time \(r\). For \(r = 0\) or \(\left\lfloor \frac{n-2}{3} \right\rfloor, \ldots, \left\lfloor \frac{n}{2} \right\rfloor\), because Part (1) implies that \(\Pi^r_1(C_n) = 0\), by Proposition 7.2 we then have
\[
L^r(C_n) = \{[\gamma_r]\}.
\]
When \(r = 1, \ldots, \left\lfloor \frac{n-2}{3} \right\rfloor\), we claim
\[
L^r(C_n) = \{[\gamma_r^k] : k \in \mathbb{Z} - \{0\}\}.
\]
It is clear that \(\{[\gamma_r^k] : k \in \mathbb{Z} - \{0\}\} \subset L^r(C_n)\), so it remains to show that any discrete loop with birth time \(r\) is \(r\)-homotopic to \(\gamma_r^k\) for some \(k \in \mathbb{Z} - \{0\}\), which is true because \(\Pi^r_1(C_n)\) is generated by \([\gamma_r]_r\). The calculation of \(\mu^{(1)}_{C_n}\) is straightforward, given Proposition 7.4. \(\square\)

Remark 7.7. Note that \((L(C_n), \mu^{(1)}_{C_n})\) can be represented by the generalized subdendrogram depicted in Figure 6, where the pseudo-ultrametric induced by the generalized subdendrogram (see Page 17) agrees with \(\mu^{(1)}_{C_n}\).

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{generalized_subdendrogram.png}
\caption{Generalized subdendrogram over \(L(C_n)\), where \(k\) runs over non-zero integers for each \([\gamma_r^k]\) when \(r = 1, \ldots, \left\lfloor \frac{n-1}{3} \right\rfloor\).}
\end{figure}
Now let us apply Proposition 7.6 to the cases $n = 3$ and $4$. It follows that $\Pi_1(C_3) = 0$, and $\left( L(C_3), \mu^{(1)}_{C_3} \right)$ is a two-point pseudo-metric space given by the distance matrix

$$
\mu^{(1)}_{C_3} = \begin{bmatrix} [\gamma_0] & [\gamma_1] \\ 0 & 1 & [\gamma_0] \end{bmatrix}.
$$

Similarly, we have $\Pi_1(C_4) = \mathbb{Z}[1, 2]$. The corresponding generalized subdendrograms over $L(C_3)$ and $L(C_4)$ are depicted in Figure 7.

![Figure 7. Generalized subdendrogram over $L(C_3)$ (left) and $L(C_4)$ (right).](image)

**Proposition 7.8.** Fix $n \in \mathbb{Z}_{\geq 3}$. Then,

1. $\Pi_1(S_n) = 0$;
2. $L(S_n) = \{[\lambda_0], [\lambda_1], [\lambda_2]\}$, where $\lambda_0 = 0$, $\lambda_1 = 010$ and $\lambda_2 = 0120$. And the pseudo-metric $\mu^{(1)}_{S_n}$ is given by the distance matrix

$$
\mu^{(1)}_{S_n} = \begin{bmatrix} [\lambda_0] & [\lambda_1] & [\lambda_2] \\ 0 & 1 & 2 & [\lambda_0] \\ 1 & 2 & [\lambda_1] \\ 2 & [\lambda_2] \end{bmatrix}.
$$

**Proof.** The possible birth times of discrete loops in $S_n$ are 0, 1 and 2. Since $S_n$ is a finite tree, by Proposition 7.3 we have $\Pi_1(S_n) = 0$ for all $r$. It then follows from Proposition 7.2 that there is only one equivalence class for each possible birth time, which are $\lambda_0$, $\lambda_1$ and $\lambda_2$. \qed

The corresponding generalized subdendrogram over $L(S_n)$ is depicted in Figure 8.

Next we compute the Gromov-Hausdorff distance between cycle graphs and star graphs, and then compare it with several distances given in Proposition 7.11.

**Proposition 7.9.** For $m, n \in \mathbb{Z}_{\geq 3}$, we have

$$
d_{GH}(C_m, S_n) = \begin{cases} \frac{1}{2} \left( \left\lfloor \frac{m}{2} \right\rfloor - 1 \right), & \text{if } m \geq 6, \\ 1, & \text{if } 3 \leq m \leq 5 \text{ and } m < n - 1, \\ \frac{1}{2}, & \text{if } 3 \leq m \leq 5 \text{ and } m \geq n - 1. \end{cases}
$$
Remark 7.10. Exactly same statement in Proposition 7.9 is true for $d_{GH}^{pt}((C_m, 0), (S_n, 0))$ as well, because the proof still holds if we require all tripods to be pointed, i.e., containing $(0, 0)$.

Proposition 7.11. For $m, n \in \mathbb{Z}_{\geq 3}$, we have the following:

1. $d_{GH}\left(\left(C_m, \mu^{(0)}_{C_m}\right), \left(S_n, \mu^{(0)}_{S_n}\right)\right) = \frac{1}{2}$ when $m \neq n$, and 0 otherwise.

2. $\frac{1}{2} \cdot d_{t}(\Pi_1(C_m), \Pi_1(S_n)) = \frac{1}{2} \cdot d_{B}(dgm_1(C_m), dgm_1(S_n)) = \frac{1}{4} \cdot \left(\left\lfloor \frac{m+2}{3} \right\rfloor - 1\right)$.

Remark 7.12. Since Proposition 7.9 implies that $d_{GH}(C_m, S_n) \to \infty$ as $m \to \infty$, we can see that the value given by Proposition 7.11 (1) is not ideal as a lower bound for $d_{GH}(C_m, S_n)$.

Although strictly less than $d_{GH}(C_m, S_n)$, Proposition 7.11 (2) increases to infinity as $m \to \infty$.

Proof of Proposition 7.9. The proof is divided into four cases:

(a) $m \geq 6$.
(b) $m \geq 4$ and $m \geq n - 1$.
(c) $m = 4$ or 5, and $m < n - 1$.
(d) $m = 3$.

To distinguish points in $C_m$ and $S_n$, we will write the vertex set of $C_m$ as $\{0, 1, \ldots, m - 1\}$ and the vertex set of $S_n$ as $\{0, 1, \ldots, n - 1\}$. For any two positive integers $l$ and $k$, by $l \mod k$ we will mean the remainder of the Euclidean division of $l$ divided by $k$.

When $m \geq 4$, diam$(C_m) = \left\lfloor \frac{m}{2} \right\rfloor + 1 = \text{rad}(S_n)$ and each point in $C_m$ has an antipode. Thus, we can apply Proposition 3.6 to obtain

$$\frac{1}{2} \cdot \left(\left\lfloor \frac{m}{2} \right\rfloor - 1\right) \leq d_{GH}(C_m, S_n) \leq \frac{1}{2} \cdot \left\lfloor \frac{m}{2} \right\rfloor. \tag{13}$$

For case (a): $m = 6$, we claim that $d_{GH}(C_m, S_n) = \frac{1}{2} \cdot \left(\left\lfloor \frac{m}{2} \right\rfloor - 1\right)$. Because of Equation (13), it remains to construct a tripod $R$ such that $\text{dis}(R) \leq \left\lfloor \frac{m}{2} \right\rfloor - 1$. In other words, we want the tripod $R$ to satisfy the following condition: $\forall (i_1, j_1), (i_2, j_2) \in R$,

$$|d_{C_m}(i_1, i_2) - d_{S_n}(j_1, j_2)| < \left\lfloor \frac{m}{2} \right\rfloor.$$

Given $m \geq 6$, it is always true that $\forall (i_1, j_1), (i_2, j_2) \in R$,

$$\left\lfloor \frac{m}{2} \right\rfloor < -2 \leq d_{C_m}(i_1, i_2) - d_{S_n}(j_1, j_2) \leq \left\lfloor \frac{m}{2} \right\rfloor. \tag{14}$$
Since the leftmost inequality of Equation (14) is strict, we have that
\[
|d_{C_m}(i_1, i_2) - d_{S_n}(j_1, j_2)| = \left\lfloor \frac{m}{2} \right\rfloor,
\]
iff \(d_{C_m}(i_1, i_2) - d_{S_n}(j_1, j_2) = \left\lfloor \frac{m}{2} \right\rfloor\),
iff \(d_{C_m}(i_1, i_2) = \left\lfloor \frac{m}{2} \right\rfloor\) and \(d_{S_n}(j_1, j_2) = 0\).

Therefore, to construct a tripod \(R\) with \(\text{dis}(R) \leq \left\lfloor \frac{m}{2} \right\rfloor - 1\), it suffices to construct a tripod where any pair of antipodes in \(C_m\) do not correspond to the same point in \(S_n\). More precisely, \(R\) shall satisfy the condition:

\[
\forall(i_1, j_1), (i_2, j_2) \in R, \text{ if } d_{C_m}(i_1, i_2) = \left\lfloor \frac{m}{2} \right\rfloor, \text{ then } j_1 \neq j_2. (*)
\]

Suppose \(m = 2k\) for some \(k \geq 3\). When \(m \geq n\), we define a tripod \(R_1\) between \(C_m\) and \(S_n\) by

\[
R_1 := \{(i, 2i \text{ mod } n), (k + i, (2i + 1) \text{ mod } n) : i = 0, \ldots, k - 1\}.
\]

When \(m < n\), we define a tripod \(R_2\) between \(C_m\) and \(S_n\) by

\[
R_2 := \{(i \text{ mod } m, 2i), ((k + i) \text{ mod } m, 2i + 1) : i = 0, \ldots, \left\lfloor \frac{n-1}{2} \right\rfloor\}.
\]

Next we assume \(m = 2k + 1\) for some integer \(k \geq 3\). When \(m \geq n\), we define a tripod \(R_3\) between \(C_m\) and \(S_n\) by

\[
R_3 := \{(0, 0), (k - i, (2i + 1) \text{ mod } n), (m - i, 2i \text{ mod } n) : i = 0, \ldots, k - 1\}.
\]

When \(m < n\), we define a tripod \(R_4\) between \(C_m\) and \(S_n\) by

\[
R_4 := \{((k - i) \text{ mod } m, 2i + 1), ((m - i) \text{ mod } m, 2i) : i = 0, \ldots, \left\lfloor \frac{n-1}{2} \right\rfloor\}.
\]

It can be directly checked that \(R_1, R_2, R_3\) and \(R_4\) are tripods satisfying Condition (*)

For case (b): \(m \geq 4\) and \(m \geq n - 1\), we claim that \(d_{GH}(C_m, S_n) = \frac{1}{2} \cdot \left\lfloor \frac{m}{2} \right\rfloor - 1\). Let \(k := \left\lfloor \frac{m}{2} \right\rfloor\). Because of Equation (13), it remains to construct a tripod \(R\) such that \(\text{dis}(R) \leq \left\lfloor \frac{m}{2} \right\rfloor - 1\). We will use the same constructions \(R_1, R_2, R_3\) and \(R_4\) as case (a) in corresponding cases. Indeed, when \(m\) is even, we use \(R_1\) if \(m \geq n\) and \(R_2\) if \(m = n - 1\); when \(m\) is odd, we use \(R_3\) if \(m \geq n\) and \(R_4\) if \(m = n - 1\). Assume \(l = 1, 2, 3, 4\). Let \(i_1\) and \(i_2\) be any two points from \(C_m\), and suppose \((i_1, j_1)\) are \((i_2, j_2)\) in \(R_l\). If \(i_2 = i_1 + k\), then it can be checked that

\[
0 \leq k - 2 \leq d_{C_m}(i_1, i_2) - d_{S_n}(j_1, j_2) \leq k - 1. \quad (15)
\]

If \(d_{C_m}(i_1, i_2) \leq k - 1\), then

\[-(k - 1) \leq -1 \leq d_{C_m}(i_1, i_2) - d_{S_n}(j_1, j_2) \leq k - 1. \quad (16)
\]

The second inequality of Equation (16) is true because when \(i_1 = i_2 \neq 0\), we always have \(j_1 = j_2\) due to the construction of \(R_1\), and when \(i_1 = i_2 = 0\), we have \(d_{S_n}(j_1, j_2) \leq 1\) (for \(R_2\) and \(R_4\), this argument relies on the condition \(m = n - 1\)). By Equation (15) and Equation (16), we have \(\text{dis}(R_l) \leq k - 1\).

For case (c): \(m = 4\) or 5, and \(m < n - 1\), we claim that \(d_{GH}(C_m, S_n) = \frac{1}{2} \cdot \left\lfloor \frac{m}{2} \right\rfloor = 1\). By the upper bound from Equation (13), it suffices to show that for each tripod \(R\) between \(C_m\) and \(S_n\), \(\text{dis}(R) \geq \left\lfloor \frac{m}{2} \right\rfloor = 2\). By the pigeonhole principle, since \(m < n - 1\), there must be two elements \(i, j \in \{1, \ldots, n - 1\}\) such that \((l, i), (l, j) \in R\) for some \(l \in C_m\). Therefore, \(\text{dis}(R) \geq d_{S_n}(i, j) = 2\).

For case (d): \(m = 3\), since \(\text{diam}(C_3) = 1\) and \(\text{diam}(S_n) = 2\), Proposition 3.5 implies that

\[
\frac{1}{2} = \frac{1}{2} \cdot |1 - 2| \leq d_{GH}(C_m, S_n) \leq \frac{1}{2} \cdot \max\{1, 2\} = 1.
\]
If \( m < n - 1 \), we can apply the pigeonhole principle as in case (c), to show each tripod between \( C_m \) and \( S_n \) has distortion 2. Thus, \( d_{\text{GH}}(C_m, S_n) \) reaches the upper bound value 1. If \( m \geq n - 1 \), i.e., \( n = 3 \) or \( 4 \), we claim that \( d_{\text{GH}}(C_m, S_n) = \frac{1}{2} \) by constructing tripod with distortion 1. Indeed, we can again utilize the construction \( R_3 \) for \( n = 3 \) and \( R_4 \) for \( n = 4 \). It is not hard to verify that their distortions are both 1.

\[ \Box \]

Proof of Proposition 7.11. For (1), we first notice that \( \left( C_m, \mu_{C_m}^{(0)} \right) \cong (E_m, d_{E_m}) \) and \( \left( S_n, \mu_{S_n}^{(0)} \right) \cong (E_n, d_{E_n}) \), where the metric space \( (E_n, d_{E_n}) \) is given in Page 49. When \( m = n \), it is clear that \( d_{\text{GH}}((E_n, d_{E_n}),(E_n, d_{E_n})) = 0 \). When \( m \neq n \), suppose without loss of generality that \( m > n \). We claim that

\[ d_{\text{GH}}((E_m, d_{E_m}),(E_n, d_{E_n})) = \frac{1}{2}. \]

By Proposition 3.5, \( d_{\text{GH}}((E_m, d_{E_m}),(E_n, d_{E_n})) \leq \frac{1}{2} \). It remains to show that \( \frac{1}{2} \) is also a lower bound for \( d_{\text{GH}}((E_m, d_{E_m}),(E_n, d_{E_n})) \). Given any pointed tripod \( R \), as \( E_m \) has more points than \( E_n \), some distinct points in \( E_m \) must correspond to the same point in \( E_n \). Thus, \( \text{dis}(R) \geq 1 - 0 = 1 \).

For Part (2), note that

\[ d_1(\text{PII}_1(C_m), \text{PII}_1(S_n)) = d_1(\text{PH}_1^{\text{VR}}(C_m), \text{PH}_1^{\text{VR}}(S_n)) = d_\text{B}(\text{dg}_1(C_m), \text{dg}_1(S_n)). \]

It follows from Proposition 7.6 (1) that \( \text{dg}_1(C_m) = \left\{ \left(1, \left[ \frac{m+2}{3} \right] \right) \right\} \) for \( m > 3 \) and \( \emptyset \) for \( m = 3 \), and from Proposition 7.8 (1) it follows that \( \text{dg}_1(S_n) = \emptyset \). Thus,

\[ d_\text{B}(\text{dg}_1(C_m), \text{dg}_1(S_n)) = \frac{1}{2} \cdot \left[ \left[ \frac{m+2}{3} \right] - 1 \right]. \]

\[ \Box \]

7.2. Discretization of \( S^1 \). Let the unit circle \( S^1 \) be embedded into the complex plane with the center at 0, i.e., \( S^1 = \{ z \in \mathbb{C} : |z| = 1 \} \). Again, we equip \( S^1 \) with its geodesic metric \( d \). For \( n \in \mathbb{Z}_{\geq 0} \), we consider the metric subspace of \( (S^1, d) \):

\[ \Delta_n := \left\{ \frac{2\pi ik}{n} : k \in [n-1] \right\}, \]

where \( i = \sqrt{-1} \). For simplicity, we write \( \Delta_n = \{0, 1, \cdots, n-1\} \) and assume 0 is the basepoint. Also, we denote \( d |_{\Delta_n \times \Delta_n} \) by \( d_n \) and note that \( (\Delta_n, d_n) \cong (C_n, \frac{2\pi}{n} d_{C_n}) \). For example, Figure 9 shows the graphs corresponding to \( \Delta_3 \) and \( \Delta_4 \).

\[ \text{Figure 9. Graphs of } \Delta_3 \text{ (left) and } \Delta_4 \text{ (right).} \]

Proposition 7.13. We have the following:

1. \( d_{\text{GH}}((\Delta_3, d_3), (\Delta_4, d_4)) = \frac{\pi}{4} \).
2. \( d_{\text{GH}}((\Delta_3, \mu_{\Delta_3}^{(0)}), (\Delta_4, \mu_{\Delta_4}^{(0)})) = \frac{\pi}{4} \).
\( (3) \) \( d_{\text{GH}} \left( \left( L(\Delta_3), \mu_{\Delta_3}^{(1)} \right), \left( L(\Delta_4), \mu_{\Delta_4}^{(1)} \right) \right) = \frac{\pi}{6}. \)

\( (4) \) \( \frac{1}{2} \cdot d_t(\text{PP}_1(\Delta_3), \text{PP}_1(\Delta_4)) = \frac{1}{2} \cdot d_B(\text{dgm}_1(\Delta_3), \text{dgm}_1(\Delta_4)) = \frac{\pi}{8}. \)

**Proof.** For (1), we first note that \( \text{Im}(d_3) = \{0, \frac{2\pi}{3}\} \) and \( \text{Im}(d_4) = \{0, \frac{\pi}{2}, \pi\} \). For any pointed tripod \( R : (\Delta_3, 0) \leftrightarrow \left< Z \xrightarrow{\psi} (\Delta_4, 0) \right> \), we have

\[
\frac{\pi}{2} = \min \left\{ \pi - 0, \frac{\pi}{2} - 0 \right\} \leq \max_{z, z' \in Z} \left| d_3(\phi(z), \phi(z')) - d_4(\psi(z), \psi(z')) \right| \leq \text{dis}(R),
\]

since \( \Delta_4 \) has more elements than \( \Delta_3 \). It follows that \( d_{\text{GH}}(\Delta_3, \Delta_4) \geq \frac{\pi}{4} \). Next we construct a tripod \( R \) whose distortion is \( \frac{\pi}{2} \), by first defining two set maps \( f \) and \( g \) as in Figure 10. We set \( Z = \Delta_3 \sqcup \Delta_4 \), and define set maps \( \phi = (\text{Id}_{\Delta_3}, f) : \Delta_3 \sqcup \Delta_4 \to \Delta_3 \) and \( \psi = (g, \text{Id}_{\Delta_4}) : \Delta_3 \sqcup \Delta_4 \to \Delta_4 \). This forms a pointed tripod \( R \). By direct calculation, we obtain \( \text{dis}(R) = \frac{\pi}{2} \).

![Figure 10](image)

For (2), apply a similar argument as in Part (1): since \( \Delta_4 \) has more elements than \( \Delta_3 \), any pointed tripod \( R \) satisfies

\[
\frac{\pi}{2} = \frac{\pi}{2} - 0 \leq \text{dis}(R).
\]

It follows that \( d_{\text{GH}} \left( \left( \Delta_3, \mu_{\Delta_3}^{(0)} \right), \left( \Delta_4, \mu_{\Delta_4}^{(0)} \right) \right) \geq \frac{\pi}{4} \). To see that \( d_{\text{GH}} \left( \left( \Delta_3, \mu_{\Delta_3}^{(0)} \right), \left( \Delta_4, \mu_{\Delta_4}^{(0)} \right) \right) = \frac{\pi}{4} \), we utilize the same set maps \( f \) and \( g \) given in Figure 10 and construct the same tripod \( R \) as in (1). With the metrics \( \mu_{\Delta_3}^{(0)} \) and \( \mu_{\Delta_4}^{(0)} \), a direct calculation shows that \( \text{dis}(R) = \frac{\pi}{4} \).

For (3), we first apply Proposition 3.5 to see that

\[
d_{\text{GH}} \left( \left( L(\Delta_3), \mu_{\Delta_3}^{(1)} \right), \left( L(\Delta_4), \mu_{\Delta_4}^{(1)} \right) \right) \geq \frac{1}{2} \cdot \left( \pi - \frac{2\pi}{3} \right) = \frac{\pi}{6}.
\]

Next we construct a tripod \( R \) whose distortion is \( \frac{\pi}{3} \), by first defining two set maps \( f \) and \( g \) as in Figure 11. We set \( Z = L(\Delta_3) \sqcup L(\Delta_4) \), and define set maps \( \phi = (\text{Id}_{L(\Delta_3)}, f) \) and \( \psi = (g, \text{Id}_{L(\Delta_4)}) \). These define a pointed tripod \( R \), with \( \text{dis}(R) = \frac{\pi}{6} \).

For (4), because \( (\Delta_n, d_n) \cong (C_n, \frac{2\pi}{n} d_{C_n}) \), we have

\[
\text{PP}_1(\Delta_3) = \emptyset \quad \text{and} \quad \text{PP}_1(\Delta_4) = \mathbb{Z} \left[ \frac{\pi}{2}, \pi \right].
\]

Therefore, \( \text{dgm}_1(\Delta_3) = \emptyset \) and \( \text{dgm}_1(\Delta_4) = \{\left( \frac{\pi}{2}, \pi \right)\} \). It follows immediately that

\[
d_t(\text{PP}_1(\Delta_3), \text{PP}_1(\Delta_4)) = d_t(\text{PH}_1^{VR}(\Delta_3), \text{PH}_1^{VR}(\Delta_4)) = \frac{\pi}{B(\text{dgm}_1(\Delta_3), \text{dgm}_1(\Delta_4))} = \frac{\pi}{2}.
\]

\( \square \)
Recall from Page 49 that in the cycle graph $C_n$, we defined the discrete loop $\gamma_r$ for $r = 1, \cdots, \lceil \frac{n-1}{3} \rceil$. As $\Delta_n$ and $C_n$ have the same underlying space $\{0, \cdots, n-1\}$, the notation $\gamma_r$ can be inherited. Although $\gamma_r$ depends on $n$, we will not specify $n$ in the notation when the concept is clear. The dots in $L(\Delta_4)$ represent $[\gamma_1^k]$ for integer $k \neq 0, 1$.

**Remark 7.14.** The symmetry property of $(\Delta_n, d_n)$ guarantees that $d_{GH}(\Delta_3, d_3, \Delta_4, d_4) = d_{GH}^{pt}(\Delta_3, 0, d_3, \Delta_4, 0, d_4)$. In Theorem 4.3, Theorem 4.23 and Theorem 6.3, we have proved that (2), (3) and (4) are lower bounds of (1), the Gromov-Hausdorff distance, under certain restrictions.
Bibliography
