Localized Debiased Machine Learning:
Efficient Inference on Quantile Treatment Effects and Beyond

Cornell University

Abstract

We consider the efficient estimation of a low-dimensional parameter in an estimating equation involving high-dimensional nuisances that depend on the parameter of interest. An important example is the (local) quantile treatment effect ((L)QTE) in causal inference, for which the efficient estimating equation involves as a nuisance the covariate-conditional cumulative distribution function evaluated at the quantile to be estimated. Debiased machine learning (DML) is a data-splitting approach to address the need to estimate nuisances using flexible machine learning methods that may not satisfy strong metric entropy conditions, but applying it to problems with parameter-dependent nuisances is impractical. For (L)QTE estimation, DML requires we learn the whole conditional cumulative distribution function, conditioned on potentially high-dimensional covariates, which is far more challenging than the standard supervised regression task in machine learning. We instead propose localized debiased machine learning (LDML), a new data-splitting approach that avoids this burdensome step and needs only estimate the nuisances at a single initial rough guess for the parameter. For (L)QTE estimation, this involves just learning two binary regression (i.e., classification) models, for which many standard, time-tested machine learning methods exist, and the initial rough guess may be given by inverse propensity weighting. We prove that under lax rate conditions on nuisances, our estimator has the same favorable asymptotic behavior as the infeasible oracle estimator that solves the estimating equation with the unknown true nuisance functions. Thus, our proposed approach uniquely enables practically-feasible and theoretically-grounded efficient estimation of important quantities in causal inference such as (L)QTEs and in other coarsened data settings.

1 Introduction

In this paper, we consider estimating the parameters \( \theta^* = (\theta_1^*, \theta_2^*) \in \Theta \subseteq \mathbb{R}^d \) defined by the following \( d \)-dimensional estimating equation based on observations of \( N \) independent and identically distributed (iid) draws of a random variable \( Z \sim \mathbb{P} \):

\[
\mathbb{P} \psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z)) = 0,
\]

where \( \eta_1^*(Z, \theta_1) \) and \( \eta_2^*(Z) \) are two unknown nuisance functions and \( 0 \) is the zero vector in \( \mathbb{R}^d \). In particular, we propose a localized debiased machine learning (LDML) approach that performs similarly to an oracle estimator with known nuisances while – and in an important departure from previous work – avoiding estimating \( \eta_1^*(Z; \theta_1) \) for all \( \theta_1 \) and instead only estimating it for one \( \theta_1 \). Our proposed method thus enables practical and efficient estimation using time-tested machine learning.

*Alphabetical order.
methods for solving classification and regression, i.e., methods for fitting conditional expectation functions. Examples of such methods include random forests, gradient boosting, neural networks, among many others. In particular, since our approach will be shown to be largely insensitive to how these conditional expectation functions are fit, we may treat these off-the-shelf machine learning methods as a black-box regression or classification algorithms.

Preliminaries and notation. We let $d_1, d_2$ be the dimensions of $\theta_1^*, \theta_2^*$ respectively ($d_1 + d_2 = d$). For $f : \mathbb{R}^d \to \mathbb{R}^m$, $\partial_{\theta^j} f(\theta)$ is the $m \times d$-matrix-valued function with entry $\frac{\partial f_i(\theta)}{\partial \theta^j}$ in position $(i, j)$ and $\partial_{\theta^j} f(\theta)|_{\theta = \theta_0}$ is its evaluation at $\theta_0$. We let $\mathbb{P} (Z \in A)$ and $\mathbb{E} [Z \mid Z \in A]$ for measurable sets $A$ denote probabilities and expectations with respect to $\mathbb{P}$. Our data are $N$ samples $\{Z_i\}_{i=1}^N$ drawn iid from $\mathbb{P}$. We let $\mathbb{P} f(Z) = \int f \, d\mathbb{P}$ for measurable functions $f$ denote expectations with respect to $\mathbb{P}$ alone, while we let $\mathbb{E} f(Z; Z_1, \ldots, Z_n)$ denote expectations with respect to $Z$ and the data. Thus, if $\hat{\varphi}$ depends on the data, $\mathbb{P} f(Z; \hat{\varphi})$ remains a function of the data while $\mathbb{E} f(Z; \hat{\varphi})$ is a number. We let $\mathbb{P}_N$ denote the empirical expectation: $\mathbb{P}_N f(Z) = \frac{1}{N}\sum_{i=1}^N f(Z_i)$ for any measurable function $f$. Moreover, for vector-valued function $f(Z) = (f_1(Z), \ldots, f_m(Z))$, we let $\mathbb{P} f(Z) := (\mathbb{P} f_1(Z), \ldots, \mathbb{P} f_m(Z))$. For any $x \in \mathbb{R}^d$, we denote the open ball centered at $x$ with radius $\delta$ as $B(x; \delta)$. For $p > 0$ and a probability measure $\mathbb{Q}$, we denote $\|f\|_{\mathbb{Q}, p} = \int |f|^p \, d\mathbb{Q}$. We also use $\sigma(a)$ and $\mathbb{O}(a)$ to denote the stochastic orders with respect to the probability measure $\mathbb{P}$: for positive deterministic sequence $a_n$ and random variable sequence $X_n$, $X_n = \sigma(a_n)$ if $\mathbb{P}(|X_n|/a_n > \epsilon) \to 0$ for any $\epsilon > 0$ and $X_n = \mathbb{O}(a_n)$ if for any $\epsilon > 0$, there exists $M$ such that $\mathbb{P}(|X_n|/a_n \geq M) \leq \epsilon$ for sufficiently large $n$.

1.1 Motivating Example: Quantile Treatment Effects

A primary motivation of considering the setting of Eq. [1] is the estimation of quantile treatment effects. In this case, we consider a population $\mathbb{P}$ of units, each associated with some baseline covariates $X \in \mathcal{X}$, two potential outcomes $Y(0), Y(1) \in \mathbb{R}$ for each of two possible treatments, and a treatment indicator $T \in \{0, 1\}$. Since both potential outcomes are included in this description, we refer to $\mathbb{P}$ as the complete-data distribution. We are interested in the $\gamma$-quantile of $Y(1):$ the $\theta_1^*$ such that $\mathbb{P}(Y(1) \leq \theta_1^*) = \gamma$ (assuming existence and uniqueness), where $\gamma \in (0, 1)$. And, similarly we are interested in the quantile of $Y(0)$ and in the difference of the quantiles, known as the quantile treatment effect (QTE), but these estimation questions are analogous so for brevity we focus just on $\theta_1^*$, the $\gamma$-quantile of $Y(1)$ (see also Remark [3]). Compared to the average outcome and the average treatment effect (ATE), the quantile of outcomes and the QTE provide a more robust assessment of the effects of treatment that accounts for the risk to the population to be treated and are very important quantities in program evaluation.

We do not observe the potential outcomes but instead only the realized factual outcome corresponding to the assigned treatment, $Y = Y(T)$. Therefore, our data consists of $Z = (X, T, Y)$, whose distribution $\mathbb{P}$ is given by coarsening $\mathbb{P}$ via $Y = Y(T)$. Ignorable treatment assignment with respect to $X$ assumes that $Y(1) \perp T \mid X$ (i.e., no unobserved confounders) and overlap assumes that $\mathbb{P}(T = 1 \mid X) > 0$, and these ensure that $\theta_1^*$ is identifiable from observations of $Z$. Specifically, a straightforward identification is given by the so-called inverse propensity weighting (IPW) equation:

\[
\mathbb{P}\psi_{\text{IPW}}(Z; \theta_1^*, \eta_2^*(Z)) = 0,
\]

where

\[
\psi_{\text{IPW}}(Z; \theta_1, \eta_2(Z)) = \mathbb{I}[T = 1] \mathbb{I}[Y \leq \theta_1] / \eta_2(Z) - \gamma,
\]

\[
\eta_2^*(Z) = \mathbb{P}(T = 1 \mid X).
\]

In particular, estimating $\eta_2^*$ by some $\hat{\eta}_2$ and letting $\hat{\theta}_1^* \psi_{\text{IPW}}(Z_i; \theta_1, \hat{\eta}_2(Z_i)) = 0$, we obtain the standard IPW estimator with estimated propensities. In particular, estimating $\eta_2^*$
and finally solve empirical estimating equation

\[
\begin{align*}
\psi(Z; \theta_1, \eta_1(Z; \theta_1), \eta_2(Z)) &= 0, \\
\text{where } \psi(Z; \theta_1, \eta_1(Z; \theta_1), \eta_2(Z)) &= \mathbb{I} [T = 1] (\mathbb{I} [Y \leq \theta_1] - \eta_1(Z; \theta_1)) / \eta_2(Z) + \eta_1(Z; \theta_1) - \gamma,
\end{align*}
\]

Instead, one can alternatively obtain the following estimating equation from the efficient influence function for \( \theta_1^* \):

\[
\mathbb{P} \psi(Z; \theta_1^*, \eta_1^*(Z; \theta_1^*), \eta_2^*(Z)) = 0,
\]

An important feature of the above is that it satisfies a property known as Neyman orthogonality: the moment \( \mathbb{P} \psi(Z; \theta, \eta_1(Z; \theta_1), \eta_2(Z)) \) has zero derivative with respect to the nuisances at \( \theta_1^*, \eta_1^*, \eta_2^* \). This means that the estimating equation is robust to small perturbations in the nuisances so that errors therein contribute only to higher-order error terms in the final estimate of \( \theta_1^* \). In particular, Chernozhukov et al. [2018a] recently proposed to leverage Neyman orthogonality to enable the use of plug-in machine learning estimates of the nuisances. Their proposal, called debiased machine learning (DML), is as follows: split the data randomly into \( K \) folds, \( D_1, \ldots, D_K \), and then for each \( k = 1, \ldots, K \), use all but the \( k \)-th fold to construct nuisance estimates \( \hat{\eta}_1^{(k)}, \hat{\eta}_2^{(k)} \), and finally solve empirical estimating equation

\[
\frac{1}{N} \sum_{k=1}^{K} \sum_{i \in D_k} \psi(Z_i; \theta, \hat{\eta}_1^{(k)}(Z_i; \theta_1), \hat{\eta}_2^{(k)}(Z_i)) = 0
\]

to obtain the final estimator \( \hat{\theta} \). They prove that as long as the estimates \( \hat{\eta}_1^{(k)}, \hat{\eta}_2^{(k)} \) converge to \( \eta_1^*, \eta_2^* \) faster than \( o(N^{-1/4}) \), the estimate \( \hat{\theta} \) will have similar behavior to the oracle estimate that solves

\[
\frac{1}{N} \sum_{i=1}^{N} \psi(Z_i; \theta, \eta_1^*(Z_i; \theta_1), \eta_2^*(Z_i)) = 0,
\]

which is asymptotically normal and semiparametrically efficient. Since, apart from the mild rate requirement on \( \hat{\eta}_1^{(k)}, \hat{\eta}_2^{(k)} \), we assume no metric entropy conditions, this allows one to successfully use machine learning methods to learn nuisances and achieve asymptotically normal and efficient estimation.

The problem with this approach for estimating quantiles of outcomes (similarly, QTEs), however, is that it requires the estimation of a very complex nuisance function: \( \eta_1^*(Z; \theta_1) \) is the whole conditional cumulative distribution function of a real-valued outcome, potentially conditioned on high-dimensional covariates. While certainly nonparametric methods for estimating conditional distributions exist such as kernel estimators, this learning problem is much harder to do in a flexible, blackbox, machine-learning manner, compared to just estimating a single regression function. Moreover, in practical terms, using such estimates in solving the estimating equation will inevitably be rather unstable. This indeed stands in stark contrast to the estimation of ATEs, where applying DML requires a far simpler nuisance function given by the regression of outcome on covariates and treatment, \( \mathbb{E} [Y \mid X, T] \), for which a long list of practice-proven machine learning methods can be directly and successfully applied in practice. The key difference is that the nuisance function in ATE estimation does not depend on the estimand and can therefore be estimated in an independent manner and plugged in the estimating equation whereas the nuisance function in QTE estimation does depend on the estimand. This issue makes DML, despite its theoretical benefits, untenable in practice for the important task of QTE estimation.

The primary goal of this paper can be understood as extending DML to effectively tackle the
case where nuisances depend on the estimand by alleviating this dependence via localization. In particular, this will enable efficient estimation of important quantities such as QTEs in the presence of high-dimensional nuisances by using and debiasing black-box machine learning methods for the standard regression task.

The basic idea as it applies to the estimation of the quantile of outcomes, which we will generalize and analyze thoroughly in the below, is as follows. While perhaps inefficient, \( \hat{\theta}_1^{IPW} \) relies only on estimating a binary regression (\( \eta_1^{IPW} \)). This is amenable to machine learning approaches but may have a slow convergence rate in general. Despite this slow rate, however, this rough initial guess can sufficiently localize our nuisance estimation and it may suffice to only estimate a slow convergence rate in general. Despite this slow rate, however, this rough initial guess can localize the nuisance evaluated at just a single point of \( \theta_1 \), and then use this estimated nuisance at this initial estimate of \( \theta_1^\ast \) in place of \( \eta_1^\ast(Z;\theta_1) \) when solving the empirical estimating equation for \( \theta \).

For the estimation of quantile of outcomes, this means we only have to estimate the regression of the binary response \( \mathbb{I}[Y \leq \hat{\theta}_1^{IPW}] \) on \( X \), treating \( \hat{\theta}_1^{IPW} \) as fixed. In particular, we propose a special three-way data splitting procedure that debiases such plug-in nuisance estimates in order to obtain an estimate for \( \theta^\ast \) with near-oracle performance.

### 1.2 Another Example: Local Quantile Treatment Effects

The same applies to the estimation of local quantiles and local QTEs (LQTEs) using an instrumental variable (IV). If, instead of assuming ignorable treatment assignment, we have an IV \( W \) that satisfies the identification conditions of \[ \text{Imbens and Angrist 1994} \] (namely, for potential treatments \( T(w) \) and potential outcomes \( Y(t,w) \), we have exclusion \( \bar{Y}(t) := Y(t,w) = Y(t,1-w) \), exogeneity \( \bar{Y}(t), T(w) \perp W \mid X \), overlap \( \mathbb{P}(W = 1 \mid X) \in (0,1) \), relevance \( \mathbb{P}(T(1) = 1) > \mathbb{P}(T(0) = 1) \), and monotonicity \( T(1) \geq T(0) \)), we may seek to use observations of \( Z = (X,W,T,Y) \) to estimate the local \( \gamma \)-quantile of \( Y(1) \): \( \theta_1^\ast \) such that \( \mathbb{P}(Y(1) \leq \theta_1^\ast \mid T(1) > T(0)) = \gamma \). Similarly, we can also estimate the local \( \gamma \)-quantile of \( Y(0) \) or the LQTE, being their difference. Following \[ \text{Belloni et al. 2017} \], a Neyman orthogonal estimating equation for \( \theta_1^\ast \) is given by

\[
\psi(Z; \theta_1, \eta_{11}(Z; \theta_1), \eta_{21}(Z)) = \left( \eta_{11}(Z; \theta_1) - \eta_{12}(Z; \theta_1) + \frac{W}{\eta_{21}(Z)} \left( \mathbb{I}[T = 1, Y \leq \theta_1] - \eta_{11}(Z; \theta_1) \right) \right) - \frac{1 - W}{1 - \eta_{21}(Z)} \left( \mathbb{I}[T = 1, Y \leq \theta_1] - \eta_{12}(Z; \theta_1) \right) \times \frac{1}{\eta_{22}} - \gamma, \tag{4}
\]

where

\[
\eta_{11}(Z; \theta_1) = \frac{\mathbb{P}(T = 1, Y \leq \theta_1 \mid X,W = 1)}{\mathbb{P}(T = 1, Y \leq \theta_1 \mid X,W = 0)},
\]

\[
\eta_{12}(Z; \theta_1) = \mathbb{E} \left[ \mathbb{P}(T = 1 \mid X,W = 1) - \mathbb{P}(T = 1 \mid X,W = 0) \right],
\]

\[
\eta_{21}(Z) = \mathbb{P}(W = 1 \mid X),
\]

\[
\eta_{22}(Z) = \mathbb{E} \left[ \mathbb{P}(T = 1 \mid X,W = 1) - \mathbb{P}(T = 1 \mid X,W = 0) \right].
\]

The issue again is that \( \eta_{11}(Z; \theta_1) \) depends on \( \theta_1 \). Estimating \( \eta_{11}(Z; \theta_1) \) involves estimating the whole conditional cumulative distribution function of a real-valued outcome. (Notice \( \eta_{21}^\ast \) involves one functional component and one scalar component.) If we set \( \eta_{11}(Z; \theta_1) = (0,0) \) and plug it into \( \psi \) we instead get an IV analogue of the IPW estimate \[ \text{Abadie 2003} \]. While such a pure weighting estimator involves no estimand-dependent nuisances and is consistent when \( \eta_{21}^\ast \) is consistently estimated, it can be unstable and converge very slowly when \( \eta_{21,1}^\ast \) is estimated nonparametrically with flexible machine learning methods. Instead, our approach will be to use this estimate only as a rough initial guess for \( \theta_1^\ast \), which we then use to localize the estimation of \( \eta_{11}^\ast \).
1.3 A General Class of Examples: Estimating Equations with Incomplete Data

More generally, we can consider parameters \((\theta_1^*, \theta_2^*)\) defined as the solution to the following estimating equation on the (unavailable) complete data:

$$\mathbb{P}[U(Y(1); \theta_1) + V(\theta_2)] = 0,$$

for some given functions \(U(y; \theta_1)\) and \(V(\theta_2)\). Or, a local version of these:

$$\mathbb{P}[U(Y(1); \theta_1) + V(\theta_2) \mid T(1) \geq T(0)] = 0.$$

Quantiles are one example of this. Another example is conditional value at risk (CVaR) of outcomes:

$$\theta_2^* = \mathbb{P}[Y(1) \mathbb{I}[F_1(Y(1)) \geq \gamma]] / (1 - \gamma),$$

where \(F_1\) is the cumulative distribution function of \(Y(1)\), that is, the expectation of \(Y(1)\) conditioned on being above the \(\gamma\)-quantile (again, assuming uniqueness). Again, we may consider the CVaR of \(Y(0)\) and the differences of CVaRs as well. Letting

$$U(y; \theta_1) = \left[ \max\{\theta_1, \frac{1}{1-\gamma}(y - \gamma \theta_1)\} \right], \quad V(\theta_2) = \left[ \frac{-\gamma}{-\theta_2} \right],$$

Eq. (5) defines \((\theta_1^*, \theta_2^*)\) as the quantile and CVaR of \(Y(1)\) (and, Eq. (8) their local versions). Yet another example is the \(\gamma\)-expectile of \(Y(1)\), defined by the asymmetric least squares problem:

$$\theta_1^* = \arg\min_{\theta_1 \in \mathbb{R}} \mathbb{P}\left[[\gamma - \mathbb{I}(Y(1) - \theta_1 \leq 0)](Y(1) - \theta_1)^2\right].$$

The first order condition of the program above gives an estimating equation for complete data:

$$\mathbb{P}\left[U(Y(1); \theta_1)\right] = \mathbb{P}\left[(1 - \gamma)(Y(1) - \theta_1) - (1 - 2\gamma)\max(Y(1) - \theta_1, 0)\right] = 0.$$

Again, we can similarly consider expectile effects and local expectiles.

Under ignorable treatment assignment and overlap, a general-purpose Neyman-orthogonal estimating equation (using the available data \(Z\)) for the estimand \((\theta_1^*, \theta_2^*)\) defined by Eq. (5) is given by

$$\psi(Z; \theta, \eta_1^*(Z; \theta_1), \eta_2^*(Z)) = \frac{\mathbb{I}[T = 1]}{\eta_2^*(Z)} \left( U(Y; \theta_1) - \eta_1^*(Z; \theta_1) \right) + \eta_2^*(Z; \theta_1) + V(\theta_2),$$

where

\[
\begin{align*}
\eta_1^*(Z; \theta_1) &= \mathbb{E}[U(Y; \theta_1) \mid X, T = 1], \\
\eta_2^*(Z) &= \mathbb{P}(T = 1 \mid X).
\end{align*}
\]

Similarly, replacing ignorable treatment assignment with a valid IV, an analogous generalization of Eq. (5) exists for estimating the generalized parameters defined by Eq. (8). We can also consider estimating the parameters defined in Eq. (5) when the complete data is coarsened in other ways such as right censoring (above the coarsening is \((X, T, Y(0), Y(1)) \mapsto (X, T, Y(T))\)). When the coarsening is ignorable, analogous Neyman-orthogonal estimating equations can be derived [Tsiatis, 2006].

In all of the above examples, the nuisance \(\eta_1^*(Z; \theta_1)\) depends on the estimand. This occurs whether estimating quantiles, CVaR, or expectiles (more generally, whenever \(U(y; \theta_1)\) is not linear in \(\theta_1\)) and whether the identification is via ignorable treatment assignment, ignorable coarsening, or valid IV. And, in such cases, learning \(\eta_1^*(Z; \theta_1)\) for all \(\theta_1\) is a practically difficult problem that may consist of learning a whole conditional distribution function or a whole continuum of conditional expectation functions with high-dimensional covariates. On the other hand, for a single, fixed \(\bar{\theta}_1\), \(\eta_1^*(Z; \bar{\theta}_1)\) is just a single conditional expectation function, easily learned using off-the-shelf regression methods, including many practice-proven machine learning methods.
1.4 Related Literature

Chernozhukov et al. [2018a] further advocate the use of cross-fitting in addition to orthogonal estimating equations, so that the traditional Donsker assumption on nuisance estimators can be relaxed, and a broad array of black-box machine learning algorithms can be used instead. They refer to this generic approach as DML, which provides a principled framework to estimate low-dimensional target parameters with strong asymptotic guarantees when leveraging modern machine learning methods in nuisance estimation. Other forms of sample splitting and cross-fitting have also appeared in Bickel [1982], Fan et al. [2012], Klaassen [1987], Robins et al. [2008, 2013, 2017], Schick [1986], van der Vaart [1998a, 1998b], Zheng and van der Laan [2011]. Since the DML framework was introduced, numerous works have applied it in many different problems, such as heterogeneous treatment effect estimation [Curth et al., 2020, Fan et al., 2020, Kennedy, 2020, Nie and Wager, 2017, Oprescu et al., 2019, Semenova and Chernozhukov, 2020], causal effects of continuous treatments [Colangelo and Lee, 2020, Oprescu et al., 2019], instrumental variable estimation [Singh and Sun, 2019, Syrgkanis et al., 2019], partial identification [Bonvini and Kennedy, 2019, Kallus et al., 2019, Semenova, 2017, Yadlovsky et al., 2018], difference-in-difference models [Chang, 2020, Lu et al., 2019, Zimmert, 2018], off-policy evaluation [Athey and Wager, 2017, Demirer et al., 2019, Kallus and Uehara, 2020, Zhou et al., 2018], generalized method of moments [Belloni et al., 2018, Chernozhukov et al., 2016], improved machine learning nuisance estimation [Cui and Tchetgen, 2019, Farrell et al., 2018], statistical learning with nuisances [Foster and Syrgkanis, 2019], causal inference with surrogate observations [Kallus and Mao, 2020], linear functional estimation [Bradic et al., 2019, Chernozhukov et al., 2018c], etc. Our work complements this line of research by proposing a simple but effective way to handle estimand-dependent nuisances. This type of nuisances frequently appears in efficient estimation of complex causal effects such as QTEs, and applying DML directly would require estimating a continuum of nuisances, which is challenging in practice.

Estimand-dependent nuisances. Besides (local) quantiles and CVaR, many efficient estimation problems involve nuisances that depends on the estimand [e.g., Chen et al., 2005, Robins et al., 1994a, Tsiatis, 2006]. Previous approaches estimate the whole continuum of the estimand-dependent nuisances either by positing simple parametric model for conditional distributions [Tsiatis, 2006, Chap 10], using sieve estimators [Chen et al., 2005], or discretizing a hypothetical continuum of
regression estimators [Belloni et al., 2017]. In contrast, our proposed method obviates the need to estimate infinitely many nuisances by fitting nuisances only at a preliminary estimate of the parameter of interest. [Robins et al., 1994b] briefly touched on this idea when using parametric models for nuisance estimation. Our paper rigorously develops this approach in the DML framework [Chernozhukov et al., 2018a] and admits flexible machine learning methods for estimating nuisances that depend on the estimand.

Efficient estimation of (L)QTE. Firpo [2007] first considered efficient estimation of QTE and proposed an IPW estimator based on propensity scores estimated by a logistic sieve estimator. Under strong smoothness conditions, this IPW estimator is $\sqrt{N}$-consistent and achieves the semiparametric efficiency bound, which is reminiscent of analogous results for the IPW estimator for ATE with nonparametrically estimated propensities [Hirano et al., 2003]. Frölich and Melly [2007] consider a weighted estimator for LQTE with weights estimated by local linear regressions using high-order kernels and show that their estimator is also semiparametrically efficient. Although these purely weighted methods bypass the estimation of nuisances that depend on the estimand, their favorable behavior is restricted to certain nonparametric weight estimators and strong smoothness requirements. Díaz [2017] proposed a Targeted Minimum Loss Estimator (TMLE) estimator for efficient QTE estimation. Built on the efficient influence function with nuisances that depend on the quantile itself, this estimator requires estimating a whole conditional cumulative distribution function, which as discussed may be very challenging in practice using flexible machine learning methods. Belloni et al. [2017] similarly consider efficient estimation of LQTE with high-dimensional controls using a Neyman orthogonal estimating equation and a continuum of LASSO estimators for the estimand-dependent nuisance. In contrast, our proposed estimator can leverage the wide variety of flexible machine learning methods for the standard regression task for nuisance estimation, since we require estimating conditional cumulative distribution function only at a single point, which amounts to a binary regression problem.

Risk measures: quantiles and beyond. Quantiles are often used to assess risk, sometimes referred to as shortfall or value at risk in financial contexts. CVaR, also known as expected shortfall, is also a popular risk measure widely used in risk management and optimization due to its convexity [Acerbi and Tasche, 2002, Rockafellar and Uryasev, 2002]. In this paper, we consider as a special case of our method the joint estimating equation of quantile and CVaR. Like quantiles, expectiles [Aigner et al., 1976, Newey and Powell, 1987] and M-quantiles [Breckling and Chambers, 1988] are other ways to assess asymmetric risk and these also fit into our framework.

2 Method

We next present our methodology. We start by motivating our construction and then we state explicitly our meta-algorithm.

2.1 Motivation

Ideally, if the nuisances $\eta_1^*$ and $\eta_2^*$ were both known, then Eq. (1) suggests that $\theta^*$ could be estimated by solving the following estimating equation:

$$P_N [\psi(Z; \theta, \eta_1^*(Z, \theta_1), \eta_2^*(Z))] = 0.$$  (10)
Under standard regularity conditions for \(Z\)-estimation \cite{van_der_Vaart1998}, the resulting oracle estimator \(\hat{\theta}\) that solves Eq. \((10)\) is asymptotically linear (and hence \(\sqrt{N}\)-consistent and asymptotically normal):

\[
\sqrt{N}(\hat{\theta} - \theta^*) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} J_i^{*-1} \psi(Z_i; \theta^*, \eta^*_1(Z_i, \theta^*_1), \eta^*_2(Z_i)) + o_P(1), \tag{11}
\]

where \(J^*\) is the following Jacobian matrix

\[
J^* = \partial_{\theta^*} \{P[\psi(Z; \theta, \eta_1^*(Z, \theta_1), \eta_2^*(Z))]|_{\theta=\theta^*}.
\]

Furthermore, if the estimating function \(\psi(Z; \theta, \eta_1^*(Z, \theta_1), \eta_2^*(Z))\) is the semiparametrically efficient influence function, then \(\hat{\theta}\) also achieves the efficiency lower bound, that is, has minimal asymptotic variance among regular estimators \cite{van_der_Vaart1998}.

Since \(\eta_1^*\) and \(\eta_2^*\) are actually unknown, the oracle estimator \(\hat{\theta}\) is of course infeasible. Instead, we must estimate the nuisance functions. A direct application of DML would require us to learn the whole functions \(\eta_1^*\) and \(\eta_2^*\). That is, in order to attempt to solve Eq. \((10)\) we would need to estimate infinitely many nuisance functions, \(H_1 = \{\eta_1^*(\cdot, \theta_1) : \theta \in \Theta\}\).

To avoid the daunting task of estimating infinitely many nuisances, we will instead attempt to target the following alternative oracle estimating equation

\[
P_N[\psi(Z; \theta, \eta_1^*(Z, \theta_1), \eta_2^*(Z))] = 0. \tag{12}
\]

Although Eq. \((12)\) appears very similar to Eq. \((10)\), it only involves \(\eta_1^*(Z, \theta_1)\) at the single value \(\theta_1 = \theta_1^*\), as opposed to the infinitely many possible values for \(\theta_1\). In other words, among the whole family of nuisances \(H_1\), only \(\eta_1^*(Z, \theta_1^*) \in H_1\) is relevant for Eq. \((12)\). This formulation considerably reduces the need of nuisance estimation: now we only need to estimate \(\eta_1^*(Z, \theta_1^*)\) and \(\eta_2^*(Z)\), both functions only of \(Z\).

The (infeasible) estimators that solve each of Eqs. \((10)\) and \((12)\) have the same leading asymptotic behavior as long as the respective associated Jacobian matrices coincide, as posited by the following assumption, which we will show often holds for many applications and in particular holds for the setting of estimating equations with incomplete data presented in Section 1.3.

**Assumption 1 (Invariant Jacobian).**

\[
\partial_{\theta^*} \{P[\psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))]|_{\theta=\theta^*} = J^*.
\] \tag{13}

In the following proposition, we show that the critical Assumption \ref{invJ} enabling this handy reformulation can be guaranteed by an orthogonality condition in terms of Fréchet derivatives.

**Proposition 1 (Sufficient Conditions for Invariant Jacobian).** Assume that the map \((\theta, \eta_1(\cdot, \theta_1^*)) \mapsto P[\psi(Z; \theta, \eta_1(Z, \theta_1), \eta_2^*(Z))]\) is Fréchet differentiable at \((\theta^*, \eta_1^*(\cdot, \theta_1^*))\). Namely, assume that there exists a bounded linear operator \(D_{\eta_1^*}\), such that for any \((\theta, \eta_1(\cdot, \theta_1^*))\) within a small open neighborhood \(\mathcal{N}\) around \((\theta^*, \eta_1^*(\cdot, \theta_1^*))\),

\[
\|P[\psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] - P[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] - \partial_{\theta^*} \{P[\psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))]|_{\theta=\theta^*} (\theta - \theta^*) - D_{\eta_1^*} [\eta_1^*(\cdot, \theta_1) - \eta_1^*(\cdot, \theta_1^*)]\| = o(||\theta - \theta^*||) + o(||P[\eta_1^*(Z, \theta_1^*) - \eta_1^*(Z, \theta_1^*)]^2\|^{1/2}).
\]
Assume further that there exists $C > 0$ such that for any $(\theta, \eta_1(\cdot, \cdot), \theta_1^*) \in \mathcal{N}$
\[
\mathcal{D}_{\eta_1} [\eta_1'(\cdot, \cdot) - \eta_1^*(\cdot, \cdot)] = 0,
\]
\[
\mathbb{P} \left[ \left\| \eta_1^*(Z, \theta_1^*) - \eta_1(Z, \theta_1^*) \right\|^2 \right]^{1/2} \leq C \| \theta_1' - \theta_1^* \|.
\]
Then Assumption 1 is satisfied.

Here the condition in Eq. (14) is an orthogonality condition using the Fréchet derivative, which is stronger than the Gâteaux differentiability required in Neyman orthogonality (see Eq. (20)). Nevertheless, this condition is satisfied in many applications. For example, for our most general example of solving an estimating equation under incomplete data given in Eq. (9), we have that
\[
\mathbb{P} [\psi(Z; \theta, \eta_1(Z; \theta_1'), \eta_2^*(Z))] = \mathbb{P} [U(Y(1); \theta_1)] + V(\theta_2),
\]
which does not depend on $\eta_1$ at all. Thus, its Fréchet derivative with respect to $\eta_1$ trivially exists and is always 0, and therefore our Assumption 1 will be satisfied per Proposition 1. This means solving Eq. (10) or Eq. (12) will have the same asymptotic behavior. Both, however, are infeasible oracle estimating equations as they involve unknown nuisances. Nonetheless, Eq. (12) motivates a new algorithm that eschews estimating $\eta_1^*(\cdot, \cdot)$ in full.

### 2.2 The LDML Meta-Algorithm

Motivated by the new (infeasible) estimating equation, Eq. (12), we propose to estimate $\theta^*$ by the following new (feasible) three-way sample splitting method, which we term localized debiased machine learning (LDML). The algorithm has two parts: three-way-cross-fold nuisance estimation and solving the estimating equation. The latter part can be done in two possible ways. We therefore present each part separately. A schematic overview of the LDML procedure is sketched in Fig. 1.

We start by discussing how we estimate the nuisances that we will then plug into Eq. (12).

**Definition 1** (Three-way-cross-fold nuisance estimation). Fix integers $K \geq 3$ and $1 \leq K' \leq K - 2$. Then:

1. Randomly permute the data indices and let $\mathcal{D}_k = \{(k-1)N/K + 1, \ldots, [kN/K]\}, k = 1, \ldots, K$ be a random even $K$-fold split of the data.
2. For \( k = 1, \ldots, K \):

(a) Set \( \mathcal{H}_{k,1} = \{1, \ldots, K' + 1 \mid k \leq K' \} \setminus \{k\} \), \( \mathcal{H}_{k,2} = \{K' + 1 \mid k \leq K' + 1, \ldots, K\} \setminus \{k\} \).

(b) Use only the data in \( \mathcal{D}_{k}^{C,1} = \{ Z_i : i \in \bigcup_{k' \in \mathcal{H}_{k,1}} \mathcal{D}_{k'} \} \) to construct an initial estimator \( \hat{\theta}_{1,\text{init}}^{(k)} \) of \( \theta_1 \).

(c) Use only the data in \( \mathcal{D}_{k}^{C,2} = \{ Z_i : i \in \bigcup_{k' \in \mathcal{H}_{k,2}} \mathcal{D}_{k'} \} \) to construct estimator \( \hat{\eta}_1^{(k)} (\cdot; \hat{\theta}_{1,\text{init}}^{(k)}) \) of the nuisance \( \eta_1 (\cdot; \hat{\theta}_{1,\text{init}}^{(k)}) \), and use \( \mathcal{D}_{k}^{C,1} \cup \mathcal{D}_{k}^{C,2} \) to construct estimator \( \hat{\eta}_2^{(k)} \) of the nuisance \( \eta_2 \).

For illustration the first iteration of step 2 above is sketched in Fig. 1a along with the plugging in of estimated nuisances into the estimating equation (see Definitions 2 and 3 below).

Notice that since \( \mathcal{D}_{k}^{C,1} \) and \( \mathcal{D}_{k}^{C,2} \) are disjoint, \( \eta^*_1 (\cdot; \hat{\theta}_{1,\text{init}}^{(k)}) \) is a fixed, nonrandom function with respect to the data \( \mathcal{D}_{k}^{C,2} \). That is, the nuisance estimation task in step 2c appears as the estimation of a single \( \eta^*_1 (\cdot; \hat{\theta}_{1,\text{init}}^{(k)}) \in H_1 \) rather than the estimation of all of \( H_1 \).

A natural question is, what might be a reasonable initial estimator. In the examples given in Sections 1.1 and 1.3 (quantiles, QTEs, and general estimating equations with incomplete data), we can use an IPW estimate for \( \hat{\theta}_{1,\text{init}}^{(k)} \) (see Fig. 1b and Definition 5). We discuss this in detail in Section 5.2 where we provide sufficient conditions for such an estimate to satisfy our assumptions.

Given these nuisance estimates, we now discuss two approaches to solving the estimating equation. The first involves averaging solutions to Eq. \((12)\) estimated in each fold separately.

**Definition 2 (LDML1).** For \( k = 1, \ldots, K \), construct \( \hat{\theta}^{(k)} \) by solving

\[
\frac{1}{|\mathcal{D}_k|} \sum_{i \in \mathcal{D}_k} \psi(Z_i; \theta, \hat{\eta}_1^{(k)} (Z_i, \hat{\theta}_{1,\text{init}}^{(k)}), \hat{\eta}_2^{(k)} (Z_i)) = 0.
\]  \tag{15}

In fact, we can allow for a least-squares solution within an \( \varepsilon_N = o(N^{-1/2}) \) approximation error, which is useful if the empirical estimating equation has no solution. Namely, we let \( \hat{\theta}^k \) be any satisfying

\[
\left| \frac{1}{|\mathcal{D}_k|} \sum_{i \in \mathcal{D}_k} \psi(Z_i; \hat{\theta}^{(k)}, \hat{\eta}_1^{(k)} (Z_i, \hat{\theta}_{1,\text{init}}^{(k)}), \hat{\eta}_2^{(k)} (Z_i)) \right| \leq \inf_{\theta \in \Theta} \left| \frac{1}{|\mathcal{D}_k|} \sum_{i \in \mathcal{D}_k} \psi(Z_i; \theta, \hat{\eta}_1^{(k)} (Z_i, \hat{\theta}_{1,\text{init}}^{(k)}), \hat{\eta}_2^{(k)} (Z_i)) \right| + \varepsilon_N.
\]  \tag{16}

Then, we let the final estimator be

\[
\hat{\theta} = \frac{1}{K} \sum_{k=1}^K \hat{\theta}^{(k)}
\]  \tag{17}

The second approach involves solving the average of the estimate of Eq. \((12)\) in each fold.
Definition 3 (LDML2). We let the estimator $\hat{\theta}$ be given by solving

$$
\frac{1}{N} \sum_{k=1}^{K} \sum_{i \in D_k} \psi(Z_i; \theta, \hat{\eta}_1^{(k)}(Z_i, \hat{\theta}_{1,\text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z_i)) = 0.
$$

(18)

Similarly, we can allow for a least-squares solution with $\varepsilon_N = o(N^{-1/2})$ approximation error. Namely, we let $\hat{\theta}$ be any satisfying

$$
\frac{1}{N} \sum_{k=1}^{K} \sum_{i \in D_k} \psi(Z_i; \hat{\theta}, \hat{\eta}_1^{(k)}(Z_i, \hat{\theta}_{1,\text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z_i))
\leq \inf_{\theta \in \Theta} \left\| \frac{1}{N} \sum_{k=1}^{K} \sum_{i \in D_k} \psi(Z_i; \theta, \hat{\eta}_1^{(k)}(Z_i, \hat{\theta}_{1,\text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z_i)) \right\| + \varepsilon_N.
$$

(19)

Remark 1 (Averaging over random splitting). It is possible to use many other different ways of splitting data. For example, in both Definitions 2 and 3 we may consider averaging more than just $K$ solutions or equations. For each $k$, we can permute over all $\binom{K-1}{K' - 1}$ splits of $\{1, \ldots, K\} \setminus \{k\}$ into $K'$ and $K - 1 - K'$ folds used for fitting $\hat{\theta}_{1,\text{init}}^{(k)}$ and $\hat{\eta}_1^{(k)}(\cdot, \hat{\theta}_{1,\text{init}}^{(k)}), \hat{\eta}_2^{(k)}(\cdot)$. Or, we could even permute over all $\sum_{K'=1}^{K-2} \binom{K'-1}{K'-1}$ ways to split $\{1, \ldots, K\} \setminus \{k\}$ into two. Or, we can even repeat the initial random splitting into $K$ folds many times over and average the resulting estimates from either Definition 2 or 3 or take their median to avoid outliers, or solve the grand-mean of estimating equations. All of these procedures can provide improved finite-sample performance in practice as they can only reduce variance without affecting bias, and we do recommend these (see also Remark 5), but they have no effect on the leading asymptotic behavior, which remains the same whether you use one or more splits of the data into folds and/or one or more splits of $\{1, \ldots, K\} \setminus \{k\}$ into two.

3 Theoretical Analysis

In this section, we provide the sufficient conditions that guarantee the proposed estimator $\hat{\theta}$ in Definitions 2 and 3 is consistent and asymptotically normal. In particular, although the proposed estimator relies on plug-in nuisance estimators, it is asymptotically equivalent to the infeasible estimator Eq. (12) that uses the true nuisances, that is, it satisfies Eq. (11). While some of our conditions are analogous to those in Chernozhukov et al. 2018a, some are not and our proof takes a different approach that enables weaker conditions for convergence rates of the nuisance estimators.

Our asymptotic normality results may be stated uniformly over a sequence of models $\mathcal{P}_N$ for the data generating distribution $\mathbb{P} \in \mathcal{P}_N$. Our first set of assumptions ensure that $\theta^*$ is reasonably identified by the given estimating equation for all $\mathbb{P} \in \mathcal{P}_N$. We also assume that our estimating equation satisfies the Neyman orthogonality condition with respect to a nuisance realization set $\mathcal{T}_N$ that contains the nuisance estimates $\hat{\eta}_1(\cdot, \hat{\theta}_{1,\text{init}})$ and $\hat{\eta}_2(\cdot)$ with high probability. Note that the set $\mathcal{T}_N$ consists of pairs of functions of the data $Z$ alone and not of $\theta_1$. Therefore, we denote members of the set as $(\eta_1(\cdot, \theta'_1), \eta_2(\cdot)) \in \mathcal{T}_N$, where $\eta_1(\cdot, \theta'_1)$ is simply understood as a symbol representing of some fixed function of $Z$ alone.

Assumption 2 (Regularity of Estimating Equations). Assume there exist positive constants $c_1$ to $c_7$ such that the following conditions hold for all $\mathbb{P} \in \mathcal{P}_N$: 

11
Assumption 3

Our second set of assumptions involve conditions on our nuisance estimators in the incomplete data setting in Section 5. We will show how these conditions are ensured by some continuity and compactness condition. Finally, Assumption 2 condition vii is the Neyman nuisance estimators. The assumption is very mild as a metric entropy condition on \( \psi \) estimation (with uniform guarantees; see also Remark 3 below). Assumption 2 condition vi requires Assumption 2 conditions i–v constitute standard identification and regularity conditions for \( P \in \mathcal{P}_N \).

i. \( \Theta \) is a compact set and it contains a ball of radius \( c_1 N^{-1/2} \log N \) centered at \( \theta^* \).

ii. The map \((\theta, \eta_1(\cdot), \eta_2(\cdot)) \mapsto \mathbb{P}[\psi(Z; \theta, \eta_1(Z, \theta_1'), \eta_2(Z))] \) is twice continuously Gâteaux-differentiable.

iii. There exists a positive constant \( c_2 \) such that \( 2 \| \mathbb{P}[\psi(Z; \theta, \eta_1^*(Z, \theta_1'), \eta_2^*(Z))] \| \geq \| J^*(\theta - \theta^*) \| \wedge c_2 \).

iv. \( J^* \) is non-singular and its singular values are bounded between positive constants \( c_3 \) and \( c_4 \).

v. The covariate matrix \( \Sigma = \mathbb{E} \left[ J^{*\top} \psi(Z; \theta^*, \eta_1^*(Z, \theta_1'), \eta_2^*(Z)) \psi(Z; \theta^*, \eta_1^*(Z, \theta_1'), \eta_2^*(Z)) \right] \) satisfies that \( c_5 \leq \| \Sigma \| \leq c_6 \).

vi. The nuisance realization set \( \mathcal{T}_N \) contains the true nuisance parameters \((\eta_1^*(\cdot), \theta_1^*, \eta_2^*(\cdot)) \). Moreover, the parameter space \( \Theta \) is bounded and for each \((\eta_1(\cdot), \theta_1'), \eta_2(\cdot)) \in \mathcal{T}_N \), the function class \( \mathcal{F}_{\eta, \theta_1'} = \{ \psi_j(Z; \theta, \eta_1(Z, \theta_1'), \eta_2(Z)) : j = 1, \ldots, d, \theta \in \Theta \} \) is suitably measurable and its uniform covering entropy satisfies the following condition: for positive constants \( a, \nu, q \geq 2 \),

\[
\sup_{\mathcal{Q}} \log N(e \| F_{\eta, \theta_1'} \|_{\mathcal{Q}; 2}, \mathcal{F}_{\eta, \theta_1'}; \| \cdot \|_{\mathcal{Q}; 2}) \leq \nu \log(\log N), \quad \forall \theta \leq 1
\]

where \( F_{\eta, \theta_1'} \) is a measurable envelope for \( \mathcal{F}_{\eta, \theta_1'} \) that satisfies \( \| F_{\eta, \theta_1'} \|_{p; q} \leq c_7 \).

vii. For all \((\eta_1(\cdot), \theta_1'), \eta_2(\cdot)) \in \mathcal{T}_N \),

\[
\partial_r \left\{ \mathbb{E}[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1') + r(\eta_1(Z, \theta_1') - \eta_1^*(Z, \theta_1'), \eta_2(Z) + r(\eta_2(Z) - \eta_2^*(Z))) \} \right\} \bigg|_{r=0} = 0. \quad (20)
\]

Assumption 2 conditions \( \square \) constitue standard identification and regularity conditions for \( Z \)-estimation (with uniform guarantees; see also Remark 3 below). Assumption 2 condition \( \square \) requires that \( \psi \) is a well-estimable function of \( \theta \) for any fixed set of nuisances. Importantly, while it imposes a metric entropy condition on \( \psi \), this condition does not impose metric entropy conditions on our nuisance estimators. The assumption is very mild as \( \Theta \) is finite-dimensional, so it can be ensured by some continuity and compactness condition. Finally, Assumption 2 condition \( \square \) is the Neyman orthogonality condition [Chernozhukov et al., 2018a]. We will show how these conditions are ensured in the incomplete data setting in Section 5.

Our second set of assumptions involve conditions on our nuisance estimators.

Assumption 3 (Nuisance Estimation Conditions). Assume the following conditions hold for any \( \mathbb{P} \in \mathcal{P}_N \):

i. For some sequence of constants \( \Delta_N \rightarrow 0 \), the nuisance estimates \((\hat{\eta}_1(k), \hat{j}_{\text{init}}^{(k)}), \hat{\eta}_2(k)(\cdot)) \) belong to the realization set \( \mathcal{T}_N \) for all \( k = 1, \ldots, K \) with probability at least \( 1 - \Delta_N \).

ii. For some sequence of constants \( \delta_N, \tau_N \rightarrow 0 \), the following conditions on the following statistical rates \( r_N, \tau_N, \lambda_N \) hold:

\[
r_N := \sup_{(\eta_1(\cdot), \theta_1') \in \mathcal{T}_N, \theta \in \Theta} \| \mathbb{P}[\psi(Z; \theta, \eta_1(Z, \theta_1'), \eta_2(Z))] - \mathbb{P}[\psi(Z; \theta, \eta_1^*(Z, \theta_1'), \eta_2^*(Z))] \| \leq \delta_N \tau_N,
\]

\[
r_N := \sup_{\theta \in \Theta(\theta^* \cdot \tau_N), (\eta_1(\cdot), \theta_1'), \eta_2) \in \mathcal{T}_N} \left\| \left( \mathbb{P}[\psi(Z; \theta, \eta_1(Z, \theta_1'), \eta_2(Z)) - \psi(Z; \theta, \eta_1^*(Z, \theta_1'), \eta_2^*(Z))] \right) \right\| \leq \frac{\delta_N}{\log N},
\]

\[
\lambda_N = \lambda_N(\theta) := \sup_{r \in (0, 1)} \| \partial_r^2 f(r; \theta, \eta_1(\cdot, \theta_1'), \eta_2) \| \leq \left( \| \theta - \theta^* \| + N^{-1/2} \right) \delta_N \forall \theta \in \Theta(\theta^* \cdot \tau_N),
\]
where
\[ f(r; \theta, \eta_1(\cdot, \theta_1'), \eta_2) = \mathbb{P} \left\{ \psi[Z; \theta^* + r(\theta - \theta^*), \eta_1^*(Z, \theta_1') + r(\eta_1(\cdot, \theta_1') - \eta_1^*(Z, \theta_1'), \eta_2^*(Z) + r(\eta_2(Z) - \eta_2^*(Z))] \right\}. \]

iii. The estimating equation solution approximation error in Eq. (16) or (19) satisfies \( \varepsilon_N \leq \delta_N N^{-1/2} \).

Here our condition on \( \lambda_N \) differs from the counterpart condition in Chernozhukov et al. [2018a], which also leads to a different proof strategy. Our condition and proof generally requires weaker conditions for convergence rates of nuisance estimators. See the discussion following Theorem 3 and in Appendix B for more details. Moreover, the constants \( \Delta_N, \delta_N, \tau_N \) are all prespecified and do not depend on any particular instance \( \mathbb{P} \).

Our key result in this paper is the following theorem, which shows that the asymptotic distribution of our estimator is similar to the (infeasible) oracle estimator solving estimating equation Eq. (10) with known nuisances.

**Theorem 1** (Asymptotic Behavior of LDML). If Assumptions 1 to 3 hold with \( \max \{ N^{-1/2} \log^2 N (1 + N^{-1/2+1/q}), \delta_N N^{-1/2} \log N \} \leq \tau_N \leq \delta_N \), and \( \max \{ r_N \log^2 (1/r_N), N^{-1/2+1/q} \log (1/r_N) \} \leq \delta_N \), then the estimator \( \hat{\theta} \) given in either Definition 2 or Definition 3 is asymptotically linear and converges to a Gaussian distribution:

\[ \sqrt{N} \Sigma^{-1/2}(\hat{\theta} - \theta^*) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \Sigma^{-1/2} J^{*-1} \psi(Z; \theta^*, \eta_1^*(Z, \theta_1'), \eta_2^*(Z)) + O_{\mathbb{P}}(\rho_N) \overset{N}{\rightarrow} \mathcal{N}(0, I_d), \]

uniformly over \( \mathbb{P} \in \mathcal{P}_N \), where the asymptotic variance is

\[ \Sigma = \mathbb{E} \left[ J^{*-1} \psi(Z; \theta^*, \eta_1^*(Z, \theta_1'), \eta_2^*(Z)) \psi(Z; \theta^*, \eta_1^*(Z, \theta_1'), \eta_2^*(Z))^\top J^{*-1} \right] \]

and the remainder term satisfies that

\[ \rho_N = (N^{-1/2+1/q} + r_N') \log N + r_N' \log^2 (1/r_N') + N^{-1/2+1/q} \log (1/r_N') + \delta_N \leq \delta_N. \]

with \( O_{\mathbb{P}} \) dependent on only constants pre-specified in Assumptions 1 to 3 but not instance-specific constant.

**Remark 2** (Uniform convergence in distribution). Theorem 1 provides a uniform convergence to asymptotic normality (like Theorem 3.1 of Chernozhukov et al. [2018a] does for DML). This means that for any given sample size \( N \), the asymptotic approximation in Theorem 1 is uniformly valid for any instance \( \mathbb{P} \in \mathcal{P}_N \). Without uniformity, for any given instance \( \mathbb{P} \) the approximation above works well for sufficient large \( N \), but for any given sample size \( N \) there may always exist some bad instances such that the approximation above is inaccurate [Kasy, 2019]. Since it is unknown whether the true data generating process could be such a bad instance for any given dataset, uniform convergence provides stronger guarantee for finite-sample performance of our estimator.
Remark 3 (Conditions for a non-uniform result). When \( \mathcal{P}_N = \{P\} \) is a constant singleton, the result in Theorem 1 yields a standard (non-uniform) convergence in distribution. When \( \mathcal{P}_N = \{P\} \), much of Assumption 2 simplifies: the existence of the constants \( c_4, c_6 \) is trivial, the non-singularity of \( J^* \) is enough for \( c_3 \) to exist, and \( \theta^* \) being in the interior of \( \Theta \) is enough for \( c_1 \) to exist. Further, we can actually relax condition iv of Assumption 2 by allowing \( c_5 \) to be zero (in which case we should rephrase the asymptotic normality result in Theorem 1 by putting \( \Sigma \) on the right-hand side of the limit rather than inverting it).

4 Variance Estimation and Inference

In the previous section we established the asymptotic normality of the LDML estimator under lax conditions. This suggests that we can construct confidence intervals on \( \theta \) if we can estimate the asymptotic variance. In this section we provide a variance estimator and prove its consistency, resulting in asymptotically calibrated confidence intervals. For DML, Chernozhukov et al. (2018a) provides variance estimates only for score functions \( \psi \) that are linear in \( \theta \), which already excludes estimand-dependent scores and for handling estimand-dependent nuisances. Our results are therefore notable both for handling nonlinear and non-differantiable scores and for handling estimand-dependent nuisances.

Definition 4 (LDML variance estimator). Given \( \hat{\theta} \) from Definition 2 or 3 and an estimator \( \hat{J} \) of \( J^* \), set

\[
\hat{\Sigma} = \frac{1}{N} \sum_{k=1}^{K} \sum_{i \in D_k} \hat{J}^{-1} \psi(Z_i; \hat{\theta}, \hat{\eta}_1^{(k)}(Z_i, \hat{\theta}_1^{(k)}), \hat{\eta}_2^{(k)}(Z_i)) \psi^\top(Z_i; \hat{\theta}, \hat{\eta}_1^{(k)}(Z_i, \hat{\theta}_1^{(k)}), \hat{\eta}_2^{(k)}(Z_i)) \hat{J}^{-\top}.
\]

We next establish the consistency of the \( \hat{\Sigma} \), which relies on the following assumption.

Assumption 4. For some universal positive constant \( C \), assume

\[
m_N := \sup_{(\eta_1(\cdot, \theta^*_1), \eta_2) \in \mathcal{T}_N} \mathbb{P}[\|\psi(Z; \theta^*, \eta_1(Z, \theta^*_1), \eta_2(Z))\|^4]^{1/4} \leq C.
\]

and \( \forall \theta \in \mathcal{B}(\theta^*; \tau_N) \) and for some \( \beta > 0 \)

\[
\mathbb{P}[\|\psi(Z; \theta, \eta_1(Z, \theta^*_1), \eta_2(Z)) - \psi(Z; \theta^*, \eta_1(Z, \theta^*_1), \eta_2(Z))\|^2] \leq C\|\theta - \theta^*\|^\beta. \tag{21}
\]

Assume further \( \|\hat{J} - J^*\| = o(\rho_{J,N}) \leq \delta_N \).

Here, Eq. (21) implies Lipschitz continuity \( \theta \mapsto \psi(Z; \theta, \eta_1^*(Z, \theta^*_1), \eta_2^*(Z)) \) in terms of \( L_2 \) norm in the range space. This condition is much weaker than the differentiability of \( \theta \mapsto \psi(Z; \theta, \eta_1^*(Z, \theta^*_1), \eta_2^*(Z)) \). In fact, this condition can be satisfied even if \( \theta \mapsto \psi(Z; \theta, \eta_1^*(Z, \theta^*_1), \eta_2^*(Z)) \) is non-differentiable as in the estimation of QTEs (see Remark 6).

We then have the following theoretical guarantee.

Theorem 2. Suppose the assumptions in Theorem 1 and Assumption 4. Then,

\[
\hat{\Sigma} = \Sigma + O_p(\rho_N^q), \quad \rho_N^q = N^{-1/4+1/q} \{ \log N \}^{1/2} \{ 1 + N^{-1/4+1/q} \} + \rho_{J,N} + \rho_{\mathcal{P}_N} + N^{-\beta/4}.
\]

Given some \( \zeta \in \mathbb{R}^d \), the confidence interval \( \text{CI} := [\zeta^\top \hat{\theta} \pm \Phi^{-1}(1 - \alpha/2) \sqrt{\zeta^\top \hat{\Sigma} \zeta / N}] \) obeys

\[
\sup_{\mathcal{P}_N} |\mathbb{P}(\zeta^\top \theta^* \in \text{CI}) - (1 - \alpha)| = o(1).
\]
In Definition 4, we assumed that we have a consistent estimator $\hat{J}$ for $J$. How to construct such an estimator depends on the problem. When $\theta \mapsto \psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))$ is differentiable, an estimator may easily be constructed using $\hat{J} = \frac{1}{N} \sum_{k=1}^K \sum_{i \in D_k} \theta_0 \psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))$.

However, the estimating equation for QTE is not differentiable. Thus we rely on deriving the form of $J^*$ and estimate it directly. We discuss the case of variance estimation for QTE in detail in Remark 7.

### Remark 4 (Estimating and Conducting Inference on Treatment Effects)

Suppose we have two sets of parameters, $\theta_0^{(1)}$, $\theta_0^{(2)}$, each identified by its own estimating equation, $\psi_0^{(1)}$, $\psi_0^{(2)}$, and we are interested in estimating the difference, $\tau^* = \theta_0^{(1)} - \theta_0^{(2)}$. For example, $\theta_0^{(1)}$, $\theta_0^{(2)}$ can be the quantile and/or CVaR of $Y(0)$, $Y(1)$, respectively, and we are interested in the QTE and/or CVaR treatment effect. To do this we can simply concatenate the two sets of estimating equations and augment them with the additional set of equations $\theta^{(1)} - \theta^{(2)} - \tau^* = 0$. Estimating this set of estimating equations with LDML is equivalent to applying LDML to each of $\psi_0^{(1)}$, $\psi_0^{(2)}$ and letting $\hat{\tau}$ be the difference of the estimates $\hat{\theta}_0^{(1)}$, $\hat{\theta}_0^{(2)}$, where we may use the same data and the same folds for the two LDML procedures. For QTE and for other estimating equations with incomplete data (see Section 5), we can even share the nuisance estimates of the propensity score (i.e., $\hat{\eta}_1^{(1), (k)} = \hat{\eta}_2^{(0), (k)}$ in the below equation). The variance estimate one would derive for $\hat{\tau}$ from the augmented estimating equations is equivalent to

$$
\hat{\Sigma}_\tau = \frac{1}{N} \sum_{k=1}^K \sum_{i \in D_k} \omega_{i,k} \omega_{i,k}^\top, \quad \text{where} \quad \omega_{i,k} = (\hat{J}^{(1)})^{-1} \psi_0^{(1)}(Z_i; \hat{\theta}_0^{(1)}, \hat{\eta}_1^{(1), (k)}(Z_i, \hat{\theta}_1^{(1), (k)}), \hat{\eta}_2^{(1), (k)}(Z_i))

- (\hat{J}^{(0)})^{-1} \psi_0^{(0)}(Z_i; \hat{\theta}_0^{(0)}, \hat{\eta}_1^{(0), (k)}(Z_i, \hat{\theta}_1^{(0), (k)}), \hat{\eta}_2^{(0), (k)}(Z_i)).
$$

### Remark 5 (Reducing and Estimating Variance due to Random Splitting)

Remark 1 suggested various ways to average out the variation due to random splitting, including averaging multiple runs of the LDML algorithm. This is asymptotically equivalent to just one run but we can use this both to improve variance estimation and to account for the variance due to random splitting. In particular, letting $\theta_s$, $\Sigma_s$ be the parameter and variance estimates for each run of LDML for $s = 1, \ldots, S$, we can let $\hat{\theta}_s = \frac{1}{N} \sum_{i \in D_s} \theta_s$ and $\hat{\Sigma}_s = \frac{1}{N} \sum_{i \in D_s} (\hat{\Sigma}_s + \frac{1}{N} (\hat{\Sigma}_s - \hat{\Sigma}_s))^\top$ be the final parameter and variance estimates. Like $\hat{\theta}_s$, the first term in $\hat{\Sigma}_s$ reduces the variance in the estimate $\hat{\Sigma}_s$ itself. The second term in $\hat{\Sigma}_s$ accounts for the variance of $\hat{\theta}_s$ due to random splitting. Notice that the second term vanishes as $S \to \infty$; indeed then $\hat{\theta}_s$ has no variance due to random splitting as it is fully averaged over. Because $\hat{\theta}_s$ are each consistent, the second term also vanishes as $N \to \infty$. Removing the $\frac{1}{N}$ factor in the second term we can instead get an estimate of the variance of each single $\hat{\theta}_s$, rather than of $\hat{\theta}_s$, accounting for random splitting. This procedure extends a similar proposal by Chernozhukov et al. (2018a) for inference in linear estimating equations.

### Remark 6 (Condition Eq. (21) for QTE)

Since the efficient estimating equation of QTE in Eq. (3) involves the indicator function $\mathbb{I}[Y \leq \theta_1]$, the map $\theta \mapsto \psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))$ is obviously not differentiable. However, the condition in Eq. (21) amounts to

$$
\mathbb{P} \left[ \left( \mathbb{P}(T = 1) - \mathbb{P}(T = 1 \mid X) \mathbb{P}(Y \leq \theta_1) \right)^2 \right] \leq C |\theta_1 - \theta_1^*|^{\beta}.
$$

In Assumption 5, we will assume that $\mathbb{P}(T = 1 \mid X) \geq \epsilon_\pi$. Then it is easy to verify that the condition above is satisfied if $\mathbb{P}(Y(1) \leq \theta_1) - \mathbb{P}(Y(1) \leq \theta_1^*) \leq C \epsilon \pi |\theta_1 - \theta_1^*|^{\beta}$ for any $\theta_1 \in B(\theta_1^*; \tau_N)$. 

15
5 Application to Estimating Equations with Incomplete Data

In this section, we apply our method and theory to the problem of general estimating equations with incomplete data presented in Section 1.3, which subsumes the estimation of QTEs, quantile of potential outcomes, CVaR treatment effect, CVaR of potential outcomes, expectile treatment effect, and expectile of potential outcomes. And, as motivated in Section 1.1, in this problem there is a very natural initial estimator: the IPW estimator. As we will show, the LDML estimate for this problem using the IPW initial estimator can be computed using just blackbox algorithms for regression (possibly, binary), which is the standard supervised learning task in machine learning. And, under lax conditions, the estimate is also efficient, asymptotically normal, and amenable to inference.

Recall \( \theta \) is defined by the complete-data estimating equations in Eq. (5), namely, \( P[U(Y(1); \theta_1) + V(\theta_2)] = 0 \). Assuming ignorability and overlap, \( \theta \) is identified from the incomplete-data observations \( Z = (X, T, Y) \) where \( Y = Y(T) \). In particular, Eq. (9) provides a Neyman-orthogonal estimating equation identifying \( \theta \). For better interpretability, we give our nuisances names: we denote \( \pi^*(t \mid x) = P(T = t \mid X = x) \), \( \mu^*_j(x, t; \theta_1) = E[U_j(Y; \theta_1) \mid X = x, T = t] \), and \( \mu^*(x, t; \theta_1) = [\mu^*_1(x, t; \theta_1), \ldots, \mu^*_d(x, t; \theta_1)]^\top \). For estimating the parameters corresponding to \( Y(1) \), our estimand-independent nuisances are \( \eta_2(Z) = \pi^*(1 \mid X) \) (known as the propensity score) and our estimand-dependent nuisances are \( \eta_1^*(Z; \theta_1) = \mu^*(X, 1; \theta_1) \). The case for \( Y(0) \) is symmetric; note we also need the symmetric ignorability and overlap assumptions for identifiability: \( Y(0) \perp T \mid X \), \( P(T = 1 \mid X) < 1 \). Effects (e.g., QTEs) can be estimated by differences of estimates, where we can use the same data, the same fold splits, and the same estimates of \( \pi^* \) for both treatments (see Remark 4).

This problem also admits a simpler but possibly unstable (i.e., non-orthogonal) estimating equation using IPW, which suggests a possible initial estimator for use in LDML, using \( K' \geq 2 \) in Definition 1.

Definition 5 (IPW Initial Estimator). For each \( k = 1, \ldots, K \) and \( l \in \mathcal{H}_{k,1} \) as in Definition 1, use only the data in \( D_k^{C,1,l} = \{ Z_i : i \in \bigcup_{k' \in \mathcal{H}_{k,1} \setminus \{l\}} D_{k'} \} \) to construct a propensity score estimator \( \hat{\pi}^{(k,l)}(1 \mid \cdot) \) for \( \pi^*(1 \mid \cdot) \). Then let \( \hat{\theta}_{k, \text{init}} \) be given by solving the following estimating equation (or, its least squares solution up to approximation error of \( \epsilon_X \)):

\[
\frac{1}{|D_k^{C,1,l}|} \sum_{i \in \mathcal{H}_{k,1}} \sum_{i \in D_l} \psi_{\text{IPW}}(Z_i; \theta, \hat{\pi}^{(k,l)}) = 0, \quad \text{where} \quad \psi_{\text{IPW}}(Z; \theta, \pi) = \frac{\mathbb{I}(T = 1)}{\pi(1 \mid X)} U(Y; \theta_1) + V(\theta_2).
\]

Then, to compute the LDML estimate for estimating equations with incomplete data using the IPW initial estimate, one need only specify estimators for \( \pi^*(1 \mid \cdot) \) (to be used both on \( D_k^{C,1,l} \) and on \( D_k^{C,2} \)) and for \( \mu^*(\cdot, 1; \theta'_1) \) (to be used on on \( D_k^{C,2} \)). Note that, for given a fixed \( \theta'_1 \), both \( \pi^*(1 \mid \cdot) \) and \( \mu^*(\cdot, 1; \theta'_1) \) are conditional expectations of observables given \( X \). This means that the LDML estimate for estimating equations with incomplete data using the IPW initial estimate can be computed given just blackbox algorithms for (possibly, binary) regression.

5.1 Theoretical Analysis

In this section, we characterize the LDML estimate for estimating equations with incomplete data. First, we apply Theorem 1 to study the estimate with generic initial estimator. Then, we show the IPW initial estimator can satisfy the conditions of the results.
We first assume a strong form of the overlap condition and specify the convergence rates of the initial estimator and nuisance estimators used. We consider a generic treatment level $t \in \{0, 1\}$ in these two assumptions.

**Assumption 5** (Strong Overlap). Assume that there exists a positive constant $\varepsilon_\pi > 0$ such that for any $\mathbb{P} \in \mathcal{P}_N$, $\pi(t \mid X) \geq \varepsilon_\pi$ almost surely.

**Assumption 6** (Nuisance Estimation Rates). Assume that for any $\mathbb{P} \in \mathcal{P}_N$: condition (b) of Assumption (a) holds for a sequence of constants $\Delta_N \to 0$; with probability at least $1 - \Delta_N$,

$$\left\| \left\{ \mathbb{P} \left[ \hat{\mu}^{(k)}(X, t; \hat{\theta}^{(k)}_{1, \text{init}}) - \mu^*(X, t; \hat{\theta}^{(k)}_{1, \text{init}}) \right] \right\} \right\|^{1/2} \leq \rho_{\mu,N},$$

$$\left\{ \mathbb{P} \left[ \hat{\pi}^{(k)}(t \mid X) - \pi^*(t \mid X) \right] \right\}^{1/2} \leq \rho_{\pi,N}, \quad \| \hat{\theta}^{(k)}_{1, \text{init}} - \theta^* \| \leq \rho_{\theta,N};$$

and $\hat{\pi}^{(k)}(t \mid X) \geq \varepsilon_\pi$ almost surely.

The following theorem establishes that the asymptotic distribution of our proposed estimator is similar to the (infeasible) one that solves the semiparametric efficient estimating equation Eq. (9) with known nuisances.

**Theorem 3** (LDML for Estimating Equations with Incomplete Data). Let the estimator $\hat{\theta}$ be given by applying either Definition (a) or Definition (b) to the estimating equation in Eq. (9). Suppose Assumptions (a) and (b) hold for $t = 1$. Moreover, suppose that there exist positive constants $c', C$, and $c_1$ to $c_7$ such that for any $\mathbb{P} \in \mathcal{P}_N$ the following conditions hold for $t = 1$:

i. Conditions (a) (with $c_1$), (b) (with $c_5,c_6$), and (c) (with $c_7$) of Assumption (a) for the estimating equation in Eq. (9).

ii. Condition (ii) of Assumption (a).

iii. For $j = 1, \ldots, d$, $\theta \mapsto \mathbb{P}[U_j(Y(t); \theta_1) + V(\theta_2)]$ is differentiable at any $\theta$ in a compact set $\Theta$, and each component of its gradient is Lipschitz continuous at $\theta^*$ with Lipschitz constant $c'$. Moreover, for any $\theta \in \Theta$ such that $\|\theta - \theta^*\| \geq \frac{\varepsilon_\pi}{2\sqrt{d}c}$, $2\|\mathbb{P}[U(Y(t); \theta_1) + V(\theta_2)]\| \geq c_2$.

iv. The singular values of $\partial_{\theta^*} \mathbb{P}[U(Y(t); \theta_1) + V(\theta_2)]|_{\theta=\theta^*}$ are bounded between $c_3$ and $c_4$.

v. For any $\theta \in \mathcal{B}(\theta^*; \frac{4C\sqrt{d}_{\rho_{\pi,N}}}{\delta N\epsilon_\pi}) \cap \Theta$, $r \in (0,1)$, and $j = 1, \ldots, d$, there exist functions $h_1(x,t,\theta_1)$ and $h_2(x,t,\theta_1)$ such that almost surely

$$|\partial_\tau \mu^*_j(X,t;\theta_1^* + r(\theta_1 - \theta_1^*)| \leq h_1(X,t,\theta_1), \quad |\partial_\tau^2 \mu^*_j(X,t;\theta_1^* + r(\theta_1 - \theta_1^*))| \leq h_2(X,t,\theta_1),$$

and $\mathbb{P}[h_1(X,t,\theta_1)] < \infty$, $\mathbb{P}[h_2(X,t,\theta_1)] < \infty$.

vi. For $j = 1, \ldots, d$:

$$\left\{ \mathbb{P} \left[ \mu^*_j(X,t;\theta_1) \right] \right\}^{1/2} \leq C, \quad \text{for any } \theta \in \Theta, \quad (22)$$

$$\left\| \left\{ \mathbb{P} \left[ \partial_\tau \mu^*_j(X,t;\theta_1) \right] \right\} \right\|^{1/2} \leq C, \sigma_{\max} \left( \mathbb{P} \partial_\tau \partial_\theta \mu^*_j(X,t;\theta_1) \right) \leq C, \sigma_{\max} \left( \partial_\theta \partial_\theta^\top V_j(\theta_2) \right) \leq C,$$

$$\left\{ \mathbb{P} \left[ \mu^*_j(X,t;\theta_1) - \mu^*_j(X,t;\theta_1^*) \right] \right\}^{1/2} \leq C\|\theta_1 - \theta_1^*\| \quad \text{for any } \theta \in \mathcal{B}(\theta^*; \max\left\{ \frac{4C\sqrt{d}_{\rho_{\pi,N}}}{\delta N\epsilon_\pi}, \rho_{\theta,N} \right\}) \cap \Theta,$$
Then constructed according to Definition 5. If the following conditions hold for \( \rho_{\pi,N} + C\rho_\theta,N \) in Theorem 1.

An analogous result for the estimating equations involving \( \theta \) in Proposition 2.

Next, we show that the IPW initial estimator given in Definition 5 can satisfy the conditions on \( \rho \) in Assumption 3. We note that if we directly reach the same conclusion (see Appendix B for comparison of proof techniques). In contrast, our proof technique circumvents the extra condition \( \rho_{\pi,N} \) in Assumption 6.

In Theorem 3, condition iii and condition iv guarantee the identification condition iii and iv in Assumption 3. We note that if we directly follow the proof of Theorem 3.3 in Chernozhukov et al. [2018a], we need to additionally assume that \( \rho_{\pi,N} = o(N^{-1/4}) \) to reach the same conclusion (see Appendix B for comparison of proof techniques).

5.2 IPW Initial Estimator

Next, we show that the IPW initial estimator given in Definition 5 can satisfy the conditions on \( \hat{\theta}_{1,\text{init}} \) in Assumption 6.

**Proposition 2** (IPW Initial Estimator Rate). For \( k = 1, \ldots, K \), let the initial estimator \( \hat{\theta}^{(k)}_{1,\text{init}} \) be constructed according to Definition 5. If the following conditions hold for \( t = 1 \):

i. For each \( k \in \{1, \ldots, K\} \) and \( l \in \mathcal{H}_{k,1} \), \( \hat{\pi}^{(k,l)} \) satisfies the same conditions as for \( \hat{\pi}^{(k)} \) in Assumption 6.

ii. Conditions iii iv and Eq. (22) in Theorem 3 hold.

iii. There exists a nuisance realization set \( \Pi_N \) that contains the true propensity score \( \pi^* \) and also the propensity score estimators \( \hat{\pi}^{(k,l)} \) with at least probability 1 - \( \Delta_N \). Moreover, any \( \pi \in \Pi_N \) satisfies that \( \pi(t \mid X) \geq \epsilon_\pi \).

iv. For each \( \pi \in \Pi_N \), the function class \( \mathcal{G}_\pi = \left\{ \frac{1}{\pi(t \mid X)} U_j(Y; \theta_1) + V_j(\theta_2) : j = 1, \ldots, d, \theta \in \Theta \right\} \) is suitably measurable and its uniform covering entropy satisfies the following condition: for positive constants \( a', v' \) and \( q' > 2 \),

\[
\sup_{Q} \log N(\epsilon \|G_\pi\|_{Q,2}, \mathcal{G}_\pi, \|G_\pi\|_{Q,2}) \leq v' \log(a' \epsilon), \quad \forall 0 \leq \epsilon \leq 1
\]

where \( G_\pi \) is a measurable envelope for \( \mathcal{G}_\pi \). There exist constants \( c_8, c_9 \) such that for any \( \mathbb{P} \in \mathcal{P}_N \),

\[
\|G_\pi\|_{P,q'} \leq c_8 \text{ and } \sup_\theta \sup_{\pi \in \Pi_N} \|\frac{1}{\pi(t \mid X)} U_j(Y; \theta_1) + V_j(\theta_2)\|_{P,2} \leq c_9.
\]
Then there exists a constant \( c \) that only depends on pre-specified constants in the conditions such that with probability \( 1 - c (\log N)^{-1} \),

\[
\rho_{\theta,N} \leq \frac{2}{c_3} \left( \frac{C \sqrt{d}}{e_\pi} + 1 \right) \rho_{\pi,N}.
\]

As discussed above, we need not require the condition \( \rho_{\pi,N} = o(N^{-1/4}) \) in the general setting. However, in the special case when we construct \( \hat{\theta}_{1,\text{init}} \) using the IPW initial estimator and we impose the same rates on the propensity nuisance estimators used for constructing the IPW initial estimator and those used for constructing the final LDML estimator (condition 1 of Proposition 2), we may essentially be imposing this condition. This is because condition vii of Theorem 3 requires \( \rho_{\pi,N} \rho_{\theta,N} = O(N^{-1/2} \delta_N) \) while Proposition 2 gives \( \rho_{\theta,N} = O_P(\rho_{\pi,N}) \). Thus, unless \( \rho_{\theta,N} \) is somehow even faster than \( \rho_{\pi,N} \), we must have \( \rho_{\theta,N} \asymp \rho_{\pi,N} = o_P(N^{-1/4}) \).

But indeed we do not require this condition in general. One way to avoid it may be to use another initial estimator, such as one based on estimates of the whole conditional distribution of \( Y \mid T = 1, X \) or using (non-localized) DML.

### 5.3 Quantile and CVaR

Now we consider estimating quantile based on the semiparametrically efficient estimating equation in Eq. (3), or estimating quantile and CVaR simultaneously. Instantiating Eq. (9) for the simultaneous estimation of quantile and CVaR and rearranging, we obtain the following estimating equation:

\[
\psi(Z; \theta, \eta_1^*(Z; \theta_1), \eta_2^*(Z)) = \frac{I[T = 1]}{\eta_2^*(Z)} \left[ \frac{I[Y \leq \theta_1]}{1 - \gamma} \left( \max(Y - \theta_1, 0) - \eta_{1,1}^*(Z; \theta_1) \right) \right] + \left[ \frac{\eta_{1,1}^*(Z; \theta_1) - \gamma}{\theta_1 + 1 - \eta_{1,2}^*(Z; \theta_1) - \theta_2} \right],
\]

where

\[
\eta_1^*(Z; \theta_1) = \left[ \frac{P(Y \leq \theta_1 \mid X, T = 1)}{E[\max(Y - \theta_1, 0) \mid X, T = 1]} \right],
\]

\[
\eta_2^*(Z) = P(T = 1 \mid X).
\]

We use \( F_t(\cdot \mid x) \) and \( F_t(\cdot) \) to denote the conditional and unconditional cumulative distribution function of \( Y(t) \), respectively: for any \( y \), \( F_t(y \mid x) = P(Y(t) \leq y \mid X = x) \) and \( F_t(y) = P(Y(t) \leq y) \). The following propositions give the asymptotic behavior of our proposed estimators for quantile only and for quantile and CVaR. This conclusion is proved by verifying all conditions in Theorem 3.

**Proposition 3** (LDML for Quantile). Suppose Assumptions 5 and 6 hold. Suppose moreover there exist positive constants \( c_1' \sim c_5' \) and \( C \geq 1 \), such that for any \( P \in \mathcal{P}_N \), the following conditions hold for \( t = 1 \):

i. Condition 1 and 2 of Assumption 2, condition viii of Assumption 3, and condition vii in Theorem 3 for the estimating equation in Eq. (3) and the corresponding nuisance estimators.
ii. \( F_1(\theta_1) \) is twice differentiable with derivatives \( f_1(\theta_1), \hat{f}_1(\theta_1) \) that satisfy \( f_1(\theta_1) \leq c'_2 \) and \( |\hat{f}_1(\theta_1)| \leq c'_3 \) at any \( \theta \in \Theta \) and \( f_2(\theta^*_1) \geq c'_4 > 0 \). Moreover, \( |F_1(\theta^*_1) - F_1(\theta_1)| \geq c'_4 \) for \( |\theta_1 - \theta^*_1| \geq \frac{c'_4}{N} \).

iii. At any \( \theta \in B(\theta^*; \max\{4C\sqrt{d\rho_N}, \rho_0, \rho_N\}) \cap \Theta \), \( F_1(\theta_1 | X) \) is twice differentiable almost surely with first two order derivatives \( f_1(\theta_1 | X) \) and \( \hat{f}_1(\theta_1 | X) \) that satisfy \( f_1(\theta_1 | X) \leq C \) and \( |\hat{f}_1(\theta_1 | X)| \leq C \) almost surely.

Then

\[
\sqrt{N} \Sigma^{-1/2}(\hat{\theta} - \theta^*) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \Sigma^{-1/2} J^{*^{-1}} \psi(Z_i; \theta^*, \eta_1(Z_i; \theta^*_1), \eta_2(Z_i)) + O_P(\rho_N) \sim N(0, I_d),
\]

uniformly over \( \mathbb{P} \in \mathcal{P}_N \), where \( \psi(Z; \theta^*, \eta_1(Z; \theta^*_1), \eta_2(Z)) \) is given in Eq. \( \text{(3)} \) and \( J^* = f_1(\theta^*_1) \).

**Remark 7** (Estimating \( f_1(\theta^*_1) \) for Variance Estimation). If we want to conduct inference on the quantile or QTE using our method from Section 4, we need to estimate \( f_1(\theta^*_1) \). We only need to do this consistently, regardless of rate, in order to get correct asymptotic coverage. One simple approach is to use cross-fitted IPW kernel density estimation at \( \hat{\theta}_1 \):

\[
\hat{J} = \frac{1}{Nh} \sum_{k=1}^{K} \sum_{i \in \mathcal{D}_k} \frac{I[T_i = 1]}{\hat{\pi}^{(k)}(1 | X_i)} \kappa((Y_i - \hat{\theta}_1)/h),
\]

where \( \kappa(u) \) is a kernel function such as \( \kappa(u) = (2\pi)^{-1/2} \exp(-u^2/2) \) and \( h \to 0 \) is a bandwidth. Under Assumption 3, \( h \asymp N^{-1/5} \) would be the optimal bandwidth. While this together with any consistent estimate \( \hat{\pi}^{(k)} \) suffices for asymptotic coverage, the estimate may be unstable. It is therefore recommended to use self-normalization by dividing the above by \( \frac{1}{n} \sum_{k=1}^{K} \sum_{i \in \mathcal{D}_k} \frac{I[T_i = 1]}{\hat{\pi}^{(k)}(1 | X_i)} \) and to potentially clip propensities.

We could hypothetically also apply LDML to estimate \( \xi = \mathbb{E}[\kappa((Y(1) - \theta^*_1)/h))/h \) by augmenting the quantile estimating equation in Eq. \( \text{(3)} \) with one more estimating equation involving one more estimand-dependent nuisance:

\[
P[I[T = 1 | \kappa((Y(1) - \theta^*_1)/h) - \nu^*(X, 1; \theta^*_1))/\pi^*(1 | X_i) + \nu^*(X, 1; \theta^*_1) - h\xi] = 0
\]

where \( \nu^*(X, t; \theta_1) = \mathbb{E}[\kappa((Y(1) - \theta_1)/h) | X, T = t] \).

Applying LDML to this system of two estimating equations is equivalent to: estimate \( \hat{\theta}_1 \) using LDML as before and let

\[
\hat{\xi} = \frac{1}{nh} \sum_{k=1}^{K} \sum_{i \in \mathcal{D}_k} \frac{I[T_i = 1]}{\pi^*(1 | X_i)} (\kappa((Y(1) - \hat{\theta}_1)/h) - \hat{\nu}^{(k)}(X_i, 1; \hat{\theta}^{(k)}_{1, \text{init}})) + \hat{\nu}^{(k)}(X_i, 1; \hat{\theta}^{(k)}_{1, \text{init}}).
\]

Notice that this still only involves regression tasks for nuisance estimation. Then we can use \( \hat{\xi} \) to estimate the component of the Jacobian relevant to the variance of just \( \hat{\theta}_1 \). However, unless very precise coverage is desired, this may be complicating matters more than needed just for variance estimation with asymptotically correct coverage.
Proposition 4 (LDML for Quantile and CVaR). Suppose that for \( t = 1 \), the conditions in Proposition 3 hold for the estimating equation in Eq. (24), \( 2\mathbb{P}[U(Y(t); \theta_1) + V(\theta_2)] \geq c'_5 \) for \( \|\theta - \theta^*\| \geq \frac{\min(\gamma_1, (1-\gamma)c'_1, \gamma_1)}{4\gamma \max\{c'_4, c'_4\}} \) and \( U(Y(t); \theta_1) + V(\theta_2) \) given in Eq. (7), and that

\[
\left\{ \mathbb{P} [\mathbb{E}[\max\{Y(t) - \theta_1, 0\} | X]]^{1/2} \right\}^{1/2} \leq C \ \forall \theta \in \Theta.
\]

Then

\[
\sqrt{N} \Sigma^{-1/2}(\hat{\theta} - \theta^*) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \Sigma^{-1/2} J^* \psi(Z_i; \theta^*, \eta^*_1(Z_i, \theta^*), \eta^*_2(Z_i)) + O_P(\rho) \sim N(0, I_d),
\]

uniformly over \( \mathbb{P} \in \mathcal{P}_N \), where \( \psi(Z; \theta^*, \eta^*_1(Z; \theta^*_1), \eta^*_2(Z)) \) is given in Eq. (24), and

\[
J^* = \begin{bmatrix} f_t(\theta^*_1) & 0 \\ 0 & -1 \end{bmatrix}.
\]

Analogous conclusions for both Propositions 3 and 4 hold for \( Y(0) \) when all assumptions hold for \( t = 0 \) instead of \( t = 1 \).

5.4 Expectiles

Next, we apply our method and analysis to estimating the \( \gamma \)-expectile \( \theta_1 \) of \( Y(1) \), as defined in Eq. (8). Instantiating Eq. (9) for expectiles and rearranging, we get the following efficient estimating equation from incomplete data:

\[
\psi(Z; \theta_1, \eta^*_1(Z; \theta_1), \eta^*_2(Z)) = \frac{I(T = 1)}{\eta^*_2(Z)} \left[ (1 - \gamma)(Y - \eta^*_2(Z)) - (1 - 2\gamma)(\max(Y - \theta_1, 0) - \eta^*_1(Z; \theta_1)) \right] + \left[ (1 - \gamma)\eta^*_2(Z) - (1 - 2\gamma)\eta^*_1(Z; \theta_1) \right],
\]

where

\[
\eta^*_1(Z; \theta_1) = \mathbb{E}[\max(Y - \theta_1, 0) | X, T = 1],
\]

\[
\eta^*_2(Z; \theta_1) = \left[ \mathbb{E}[Y | X, T = 1] \right] \left[ \mathbb{P}(T = 1 | X) \right].
\]

The next result gives the asymptotic behavior of LDML applied to these equations.

Proposition 5. Suppose that there exist positive constants \( C, c'_4 \), such that for any \( \mathbb{P} \in \mathcal{P}_N \), the following conditions hold for \( t = 1 \) and \( \theta \in \Theta \):

i. Condition i and condition iv in Theorem 3 for the estimating equation in Eq. (25) and the corresponding nuisance estimators.

ii. \( f_t(\theta_1) \) is continuous at \( \theta^*_1 \), and \(| - (1 - 2\gamma)f_t(\theta^*_1) - \gamma| \geq c'_4 \). Moreover, for any \( \theta \in \Theta \) such that \( \|\theta - \theta^*\| \geq \frac{c'_4}{2} \), \( 2\mathbb{P}[U(Y(t); \theta_1)] \geq c'_5 \) for \( U(Y(t); \theta_1) \) given in Eq. (8).

iii. At any \( \theta \in \mathcal{B}(\theta^*; \max\{4C\sqrt{\rho}, \rho_\theta, N\}) \cap \Theta \), \( f_t(\theta_1 | X) \) is almost surely differentiable with first-order derivative \( f_t(\theta_1 | X) \), and second-order derivative \( \dot{f}_t(\theta_1 | X) \leq C \) almost surely;

iv. \( \left\{ \mathbb{P} [\mathbb{E}[Y(t) | X]^2]^{1/2} \right\}^{1/2} \leq C \), and \( \left\{ \mathbb{P} [\mathbb{E}[\max\{Y(t) - \theta_1, 0\} | X]^2]^{1/2} \right\}^{1/2} \leq C \) for any \( \theta \in \Theta \).
Then
\[
\sqrt{N} \Sigma^{-1/2}(\hat{\theta}_1 - \theta^*_1) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \Sigma^{-1/2} J^*^{-1} \psi(Z_i; \theta^*_1, \eta^*_1(Z_i), \eta^*_2(Z_i)) + O_P(\rho_N) \sim N(0, I_d),
\]
uniformly over \( \mathbb{P} \in \mathcal{P}_N \), where \( \psi(Z; \theta^*_1, \eta^*_1(Z), \eta^*_2(Z)) \) is given in Eq. \((25)\) and \( J^* = -\gamma - (1 - 2\gamma)F_t(\theta^*_1) \). Analogous conclusion for percentile of \( Y(0) \) holds when all assumptions above hold for \( t = 0 \).

When constructing confidence intervals, we only need to estimate \( F_t(\theta^*_1) \) to estimate \( J^* \). This can be easily estimated by the inverse propensity reweighted estimator \( \frac{1}{N} \sum_k \sum_{i \in D_k} \frac{\mathbb{I}[t_i = t]}{\hat{\pi}_i(X_i)} \mathbb{I}[Y_i \leq \hat{\theta}_1] \), or an imputation estimator based on \( \hat{\mu}(k) \) or a doubly robust estimator that uses both \( \hat{\pi}(k) \) and \( \hat{\mu}(k) \).

6 Local Quantile Treatment Effect

In this section, we consider estimating the local quantile treatment effect using an IV by applying LDML to the efficient estimating equation \( \psi(Z; \theta_1, \eta_1(Z; \theta_1), \eta_2(Z)) \) given in Eq. \((4)\). For better readability, we denote the event of being a complier as \( C = \mathbb{I}[T(1) > T(0)] \), the scaler nuisance as \( \nu^* = \nu_{2,2}^* = \mathbb{E}[\mathbb{P}(T = 1 \mid X, W = 1) - \mathbb{P}(T = 1 \mid X, W = 0)] \), and the functional nuisances as \( \hat{\pi}^*(X) = \hat{\pi}(W = 1 \mid X), \tilde{\mu}_w^*(X; \theta_1) = \mathbb{P}(T = 1, Y \leq \theta_1 \mid X, W = w) \) for \( w = 0, 1 \). We fit nuisance estimators for the function nuisance parameters based on the sample-splitting scheme given in Definition \(1\), which we denote as \( \hat{\pi}(k)(X) \) and \( \hat{\mu}(k)(X; \theta_1, \theta_1, \hat{\mu}(k)(X; \theta_1, \hat{\theta}_{1, \text{init}})) \) respectively for \( k = 1, \ldots, K \). For \( \nu^* \), any consistent estimator \( \hat{\nu} \) would do – it can but does not have to be estimated by cross-fitting.

We next assume a strong form of the overlap and relevance assumptions and specify the convergence rates of the initial estimator and nuisance estimators used. We again consider a generic treatment level \( t \in \{0, 1\} \) in these two assumptions.

Assumption 7 (IV Assumptions). Assume that there exists a positive constant \( \epsilon > 0 \) such that for any \( \mathbb{P} \in \mathcal{P}_N, \hat{\pi}(X) \geq \epsilon \) and \( \nu^* = \mathbb{E}[\mathbb{P}(T = 1 \mid X, W = 1) - \mathbb{P}(T = 1 \mid X, W = 0)] \geq \epsilon \) almost surely.

Assumption 8 (Nuisance Estimation Rates). Assume that for any \( \mathbb{P} \in \mathcal{P}_N \): with probability at least \( 1 - \Delta_N \),
\[
\left\| \mathbb{P} \left[ \hat{\pi}^*(X) - \hat{\pi}^*_w(X; \theta_{1, \text{init}}) \right] \right\|^{1/2} \leq \hat{\rho}_{\pi, N}, \quad \nu^* = \mathbb{E}[\mathbb{P}(T = 1 \mid X, W = 1) - \mathbb{P}(T = 1 \mid X, W = 0)] \geq \epsilon \text{ almost surely.}
\]

and \( \hat{\pi}(k)(X) \geq \epsilon \) and \( \hat{\nu} \geq \epsilon \) almost surely.

Proposition 6. Fix \( t = 1 \) and let \( \Theta \) be a compact set. Suppose that there exist constants \( c', C \) such that the following conditions hold for any instance \( \mathbb{P} \in \mathcal{P}_N \):

1. For any \( \theta_1 \in \Theta \), the distribution function of \( Y(t) \) for compliers, denoted as \( F_t(\theta_1 \mid C) \), is twice continuously differentiable, and its derivative \( f_t(\theta_1 \mid C) \) satisfies that \( f_t(\theta_1 \mid C) \leq c_4 \) and \( \hat{f}_t(\theta_1 \mid C) \leq c' \), and \( f_t(\theta_1 \mid C) \geq c_3 > 0 \). Moreover, \( 2|F_t(\theta_1 \mid C) - \hat{F}_t(\theta_1 \mid C)| \geq c_2 \) for \( |\theta_1 - \theta^*_1| \geq \frac{c_4}{2c_2} \).
2. At any $\theta_1 \in B(\theta_1^*; \max\{8C_{\rho_6,N}, \rho_{\theta,N}\}) \cap \Theta$, the conditional distribution function of $Y(t)$ for compliers given $X$, denoted as $F_t(\theta_1 \mid X, C)$, is twice differentiable almost surely with first two order derivatives $f_t(\theta_1 \mid X, C)$ and $f_{\tilde{t}}(\theta_1 \mid X, C)$ that satisfy $f_t(\theta_1 \mid X, C) \leq C$ and $\left| f_{\tilde{t}}(\theta_1 \mid X, C) \right| \leq C$ almost surely.

3. The nuisance estimator convergence rates satisfy that $\hat{\rho}_{\pi,N} \leq \frac{\delta_\pi^2}{\log N}$, $\hat{\rho}_{\mu,N} + C\hat{\rho}_{\theta,N} \leq \frac{\delta_\mu^2}{\log N}$, $\hat{\rho}_{\nu,N} \leq \frac{\delta_\nu^2}{\log N}$, $\delta_\pi^2 \leq \frac{\delta_\mu^2}{4C^2}$, $\delta_\mu^2 \leq \frac{\delta_\nu^2}{\log N}$, $\delta_\nu^2 \leq \frac{\delta_\mu^2}{16C^2}$.

Then

$$\sqrt{N} \Sigma^{-1/2}(\hat{\theta} - \theta^*) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \Sigma^{-1/2} J^{-1} \psi(Z_i; \theta^*, \eta_1^*(Z_i, \theta_1^*), \eta_2^*(Z_i)) + O_P(\rho_N) \sim N(0, I_d),$$

uniformly over $\mathbb{P} \in \mathcal{P}_N$, where $\psi(Z; \theta^*, \eta_1^*(Z; \theta_1^*), \eta_2^*(Z))$ is given in Eq. [4] and $J^* = f_t(\theta_1^* \mid C)$.

**Remark 8 (Constructing $\hat{\nu}$ and $\hat{\theta}_{1,\text{init}}$).** The scalar nuisance $\nu^*$ constitutes the ATE of the IV on treatment assignment. Proposition [6] requires an extremely weak rate condition on its estimate $\hat{\nu}$, essentially just requiring a consistent estimator. Therefore, any consistent ATE estimator may be used, such as IPW. For concreteness, we suggest to use DML to estimate $\hat{\nu}$. Namely, we also cross-fit estimates $\hat{\nu}^{(k)}$ for $\nu^*(X, W) = \mathbb{P}(T = 1 \mid X, W)$ and we let

$$\hat{\nu} = \frac{1}{N} \sum_{k=1}^{K} \sum_{i \in D_k} \left( \frac{W_i - \hat{\nu}^{(k)}(X_i)}{\hat{\nu}^{(k)}(X_i)} \right) \left( T_i - \hat{\nu}^{(k)}(X_i, W_i) \right) + \hat{\nu}^{(k)}(X_i, 1) - \hat{\nu}^{(k)}(X_i, 0).$$

As mentioned in Section 1.2, for $\hat{\theta}_{1,\text{init}}$ we can use a weighting estimator analogous to the cross-fitted IPW estimator (Definition 5): plug $\eta_1(Z; \theta_1) = (0, 0)$ into Eq. [4], cross-fit $\eta_2$, take the empirical average, and solve the equation to obtain $\hat{\theta}_{1,\text{init}}$.

**Remark 9 (Estimating $f_t(\theta_1^* \mid C)$ for Variance Estimation).** If we want to use our variance estimator from Section 4 we need to estimate $J^* = f_t(\theta_1^* \mid C)$. We can follow a similar approach as in Remark 7 and use a kernel estimator. Namely, we can let

$$J = \frac{1}{\hat{\nu} N h} \sum_{k=1}^{K} \sum_{i \in D_k} \frac{W_i - \hat{\nu}^{(k)}(X_i)}{\hat{\nu}^{(k)}(X_i)} \left( T_i - \hat{\nu}^{(k)}(X_i, W_i) \right) \mathbb{I}[T_i = t] \kappa((Y_i - \hat{\theta}_1)/h).$$

7 Empirical Results

In this section, we demonstrate the use of LDML in both a simulation study and an empirical study of the effects of 401(k) eligibility and participation. Replication code is available at https://github.com/CausalML/LocalizedDebiasedMachineLearning.

7.1 Simulation Study

First, we consider a simulation study to compare the performance of LDML estimates to benchmarks. We consider estimating $\theta_1^*$ as the second tertile of $Y(1)$ from incomplete data. The distribution $\mathbb{P}$ is as follows. First, we draw 20-dimensional covariates $X$ from the uniform distribution

---

**RAW TEXT END**
on $[0,1]^{20}$. Then, we draw $T$ from Bernoulli($\Phi(3(1 - X_1 - X_3))$), where $\Phi$ is the standard normal cumulative distribution function, and we draw $Y(1)$ from $\mathcal{N}(\mathbb{I}[X_1 + X_2 \leq 1], 2X_3)$. We only observe $Y(1)$ when $T = 1$.

We consider estimating $\theta^*_1$ using four different methods. First, we consider LDML applied to the efficient estimating equation (Eq. (3)) with $K = 5$, $K' = 2$, $\hat{\theta}^{(k)}_{1,\text{init}}$ estimated using 2-fold cross-fitted IPW with random-forest-estimated propensities, $\hat{\pi}^{(k)}(1 \mid X)$, $\hat{\mu}^{(k)}(X, 1; \hat{\theta}^{(k)}_{1,\text{init}})$) and similarly estimated by random forests. Second, we consider $K = 5$-fold cross-fitted IPW with random-forest-estimated propensities. Third, we consider DML with $K = 5$ and the estimand-dependent nuisance estimated using a discretization approach similar to the suggestion of Belloni et al. [2018]: for $j = 1, \ldots, 99$ fix $\theta_{1,j}$ to be the $j/100$ marginal quantile of $Y$ and fit $\hat{\mu}^{(k)}(X, 1; \hat{\theta}^{(k)}_{1,\text{init}})$ using random forests; then apply DML with the restricted discretized estimand range $\{\theta_{1,j} : j = 1, \ldots, 99\}$. We refer to this method as DML-D for discretized. Fourth, we consider DML with $K = 5$ and where the estimand-dependent nuisance is estimated using an approach similar to Bertsimas and Kallus [2014], Meinshausen [2006]: namely, fit a random forest regression to the out-of-fold data $\{(X_i, Y_i) : i \notin D_k, T_i = 1\}$ to obtain $B$ regression trees $\tau_j : \text{support}(X) \rightarrow \{1, \ldots, \ell_j\}$, then set $\hat{\mu}^{(k)}(X, 1; y) = \sum_{i \notin D_k : T_i = 1} \frac{\mathbb{I}[Y_i \leq y]}{B} \sum_{j=1}^B \sum_{i' \notin D_k, \tau_j(i') = \tau_j(X_i)} \frac{\mathbb{I}[\tau_j(X_i) = \tau_j(X_i')]}{\sum_{i' \notin D_k, \tau_j(i') = \tau_j(X_i')} \mathbb{I}[\tau_j(X_i) = \tau_j(X_i')]}. We refer to this method as DML-F for forest. For each method, we run it three times with new random fold splits (with the same data) and take the median of the three results to be the estimate.

For each of $n = 100, 200, \ldots, 25600$, we consider 75 replications of drawing a dataset of size $n$ and constructing each of the above four estimates. We plot the mean-squared error of each method and $n$ over the 75 replications in Fig. 2a. The shaded regions show plus/minus one standard error of this as the sample mean of 75 squared errors. We clearly see that LDML offers significant improvements over the other methods when we use flexible machine learning methods to tackle estimand-dependent nuisances.

In Fig. 2b we additional report the coverage of the true parameter using the standard error estimate.

proposed in Remarks 5 and 7. Namely, for each of the three random runs of each method, we take the sample standard deviation of the estimated influence function evaluated at the final estimand and with the cross-fitted nuisances and divide it by $\sqrt{n}$ times an estimate of $f_t(\theta^*)$ given by cross-fitted IPW kernel density estimation at the estimand. (We do the same for the IPW estimate for the sake of comparison but note IPW’s asymptotic variance may also depend on the propensity-estimation variance, unlike LDML and DML.) We take the median of these standard errors over the three runs and add to it the standard deviation of estimands over the three runs divided by $\sqrt{3}$. Then we consider the 95% confidence interval given by the estimand plus/minus 1.96 of this estimated standard error. Figure 2b shows the sample mean coverage of $\theta^*_1$ over the 75 replications, and the shaded region shows plus/minus one standard error of this sample mean. As Fig. 2b shows, LDML offers good coverage while the other methods have too much bias to get correct coverage based only on standard errors.

7.2 Effect of 401(k) Eligibility on Net Financial Assets

Next we consider an empirical case study to demonstrate the estimation of QTE using LDML in practice and with a variety of machine learning nuisance estimators. We use data from Chernozhukov and Hansen [2004] to estimate the QTEs of 401(k) retirement plan eligibility on net financial assets.
Eligibility for 401(k) (here considered the treatment, $T$) is not randomly assigned, but is argued in Chernozhukov and Hansen [2004] to be ignorable conditioned on certain covariates: age, income, family size, years of education, marital status, two-earner household status, availability of defined benefit pension plan to household, IRA participation, and home ownership status. Net financial assets (the outcome, $Y$) are defined as the sum of IRA and 401(k) balances, bank accounts, and other interest-earning accounts and assets minus non-mortgage debt. While Chernozhukov and Hansen [2004] considered controlling for these in a low-dimensional linear specification, it is not clear whether such is sufficient to account for all confounding. Consequently, Belloni et al. [2017] considered including higher-order terms and interactions, but needed to theoretically construct a continuum of LASSO estimates and may not be able to use generic black-box regression methods. Finally, Chernozhukov et al. [2018a] considered using generic machine learning methods, but only tackled ATE estimation.

In contrast, we will use LDML to estimate and conduct inference on the QTEs of 401(k) eligibility on net assets using a variety of flexible black-box regression methods. First, to understand the effect of different choices in the application of LDML to the problem, we consider estimating the 25%, 50%, and 75% QTE while varying $K$ in $\{5, 15, 25\}$ and varying the nuisance estimators. We consider estimating both propensities ($\eta^*_2$) and conditional probabilities ($\eta^*_1$) with each of: boosting (using $R$ package gbm), LASSO (using $R$ package hdm), and a one-hidden-layer neural network (using $R$ package nnet). For LASSO, we use a 275-dimensional expansion of the covariates by considering higher-order terms and interactions. In each instantiation of LDML, we construct folds so to ensure a balanced distribution of treated and untreated units, we let $K' = (K - 1)/2$, we use the IPW initial estimator for $\hat{\theta}_1, \text{init}$, we normalize propensity weights to have mean 1 within each treatment group, we use estimates given by solving the grand-average estimating equation as in Definition 3, and for variance estimation we estimate $J^*$ using IPW kernel density estimation as in Remark 7. The solution to the LDML-estimated empirical estimating equation must occur at an observed outcome $Y_i$ and that we can find the solution using binary search after sorting the data along outcomes. We re-randomize the fold construction and repeat each instantiation 100 times. We then remove the outlying 2.5% from each end and report $\hat{\theta}^\text{mean}, \Sigma^\text{mean}$ as in Remark 5. The resulting estimates and standard errors are shown in Table 1. As can be seen, the estimates are overall roughly stable across methods and across $K$.

Next, we consider estimating a range of QTEs. We focus on nuisance estimation using LASSO and fix $K = 15$. We then estimate the 10%, 11%, ..., 89%, and 90% quantiles and QTEs. We plot the resulting LDML estimates with 90% confidence intervals in Fig. 3a and compare these to the raw unadjusted marginal quantiles within each treatment group.

### 7.3 Effect of 401(k) Participation on Net Financial Assets

Next, we estimate the effect of 401(k) participation on net assets. Participation in a 401(k) plan (here considered the treatment, $T$) is not randomly assigned: individuals with a preference for saving may save more in non-retirement accounts than others whether they were to participate in retirement savings or not. There may be many other confounding factors, such as the possibility of higher financial acumen of savers leading to higher net worth otherwise. It is unlikely that we can control for all these factors using observable covariates. Instead, we rely on instrumenting on eligibility since, as argued in Section 7.2, eligibility is ignorable given covariates. Additionally, one cannot participate if one is ineligible, ensuring monotonicity, and some eligible individuals do participate, ensuring relevance. Assuming that eligibility cannot affect net assets except through its effect on participation, we have that eligibility for a 401(k) (here considered as $W$) is valid IV.
(a) The quantiles by and QTEs of 401(k) eligibility estimated by LDML.

(b) The local quantiles by and LQTEs of 401(k) participation estimated by LDML.

Figure 3: LDML estimates of a range of (local) quantiles and (L)QTEs with confidence 90% intervals and comparison to raw unadjusted marginal quantiles by treatment group.

We can therefore use it to estimate local quantiles by and LQTEs of 401(k) Participation on the population of individuals that would participate if eligible.

We use LDML applied to the Neyman orthogonal estimating equation Eq. (4). Again, we consider the impact of different choices in the application of LDML. We repeat the same specification as above, using each possible nuisance estimator to fit instrument propensities ($\eta_2^*$) and conditional probabilities ($\eta_1^*$). We use the same nuisance estimator to also fit treatment propensities given instrument and use together with estimates of instrument propensities to estimate $\nu^*$ using DML. We display the results for the 25%, 50%, and 75% quantiles while varying $K$ and the nuisance estimators in Table 2. The qualitative results regarding the stability of LDML across methods and $K$ remain the same. Then, focusing as before on nuisance estimation using LASSO and on $K = 15$, we also estimate a range of local quantiles and QTEs, which we plot along with 90% confidence intervals in Fig. 3b. Again, we compare to the raw unadjusted marginal quantiles within each treatment group.

8 Conclusion

In many causal inference and missing data settings, the efficient influence function involves nuisances that depend on the estimand of interest. A key example provided was that of QTE under ignorable treatment assignment and LQTE estimation using an IV, where in both cases the efficient influence function depends on the conditional cumulative distribution function evaluated at the quantile of interest. This structure, common to many other important problems, makes the application of existing debiased machine learning methods difficult in practice. In quantile estimation, it requires we learn the whole conditional cumulative distribution function. To avoid this difficulty, we proposed the LDML approach, which localized the nuisance estimation step to an initial rough guess of the
estimand. This was motivated by the fact that under a Fréchet-derivative orthogonality condition the oracle estimating equation is asymptotically equivalent to one where the nuisance is evaluated at the true parameter value, which our localization approach targets. Assuming only standard identification conditions, Neyman orthogonality, and lax rate conditions on our nuisance estimates, we proved the LDML enjoys the same favorable asymptotics as the oracle estimator that solves the estimating equation with the true nuisance functions. This newly enables the practical efficient estimation of important quantities such as QTEs using machine learning.

Appendices

A Proofs

A.1 Proof for Section 2

Proof for Proposition 1 For any \( \theta = (\theta_1, \theta_2) \) such that \( (\theta, \eta_1^*(\cdot, \theta)) \in \mathcal{N} \), the asserted Fréchet differentiability and orthogonality condition imply that

\[
\|P[\psi(Z; \theta, \eta_1^*(Z, \theta_1), \eta_2^*(Z))] - P[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))]\| \\
- \partial_\theta \{P[\psi(Z; \theta, \eta_1^*(Z, \theta_1), \eta_2^*(Z))]\}_{\theta=\theta^*} = o(\|\theta - \theta^*\|).
\]

This means that \( J^* = \partial_\theta \{P[\psi(Z; \theta, \eta_1^*(Z, \theta_1), \eta_2^*(Z))]\} \|_{\theta=\theta^*} \).

A.2 Proof for Section 3

Proof for Theorem 1 Fix any sequence \( \{P_N\}_{N \geq 1} \) that generates the observed data \((Z_1, \ldots, Z_N)\) and satisfies that \( P_N \in \mathcal{P}_N \) for all \( N \geq 1 \). Because this sequence is chosen arbitrarily, to prove that the asserted conclusion holds uniformly over \( P \in \mathcal{P}_N \), we only need to prove

\[
\sqrt{N} \Sigma^{-1/2}(\hat{\theta} - \theta^*) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \Sigma^{-1/2} \left[J^*^{-1}\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z)) \right] + O_{P_N}(\rho_N) \xrightarrow{d} \mathcal{N}(0, I_d).
\]

For \( k = 1, \ldots, K \), we use \( P_{N,k} \) to represent the empirical average operator based on \( D_k \). For example, \( P_{N,k}[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] = \frac{1}{|D_k|} \sum_{i \in D_k} \psi(Z_i; \theta^*, \eta_1^*(Z_i, \theta_1^*), \eta_2^*(Z_i)) \). Analogously, \( P_N \) is the empirical process operator for the whole dataset, i.e., \( P_N f(Z) = \frac{1}{N} \sum_{i=1}^{N} f(Z_i) \). \( G_{N,k} \) is the empirical process operator \( \sqrt{N}(P_{N,k} - P) \). Moreover, for a given \( N, P_{N,k}, P_N \) and the population average operator \( P \) are all derived from the underlying true distribution \( P_N \), but we supress such dependence for ease of notations. Throughout the proof, we condition on the event \( (\bar{\eta}_i(\cdot, \bar{\theta}_{1,\text{init}}), \bar{\eta}_2(\cdot)) \in \mathcal{T}_N \), which happens with at least \( P_N \)-probability \( 1 - \Delta_N \) according to Assumption 3 condition 4. All statements involving \( o(\cdot) \), \( O_{P_N}(\cdot) \) or \( \lesssim \) notations in this proof depend on only constants pre-specified in Assumptions 2 and 3 and do not depend on constants specific to the instance \( P_N \). This should be clear from the proof, and the fact that the maximal inequality in Lemma 6.2 of Chernozhukov et al. 2018 only depend on pre-specified parameters. Here we prove the asymptotic distribution of \( \hat{\theta} \) given in Definition 3 first.

**Step I: Prove a preliminary convergence rate for \( \hat{\theta} \):** \( \|\hat{\theta} - \theta^*\| \leq \tau_N \) with \( P_N \)-probability \( 1 - o(1) \). Here we prove this by showing that with \( P_N \)-probability \( 1 - o(1) \),

\[
\left\|P[\psi(Z; \hat{\theta}, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))]\right\| = o(\tau_N)
\]

so that Assumption 2 implies that

\[
\|J^*(\hat{\theta} - \theta^*)\| \wedge c_2 = o(\tau_N).
\]

Since the singular values of \( J^* \) are lower bounded by \( c_3 > 0 \), we can conclude that with \( P_N \)-probability \( 1 - o(1) \), \( \|\hat{\theta} - \theta^*\| \leq \tau_N \) for \( N \) exceeding an instance-independent threshold.
In order to prove Eq. (26), we use the following decomposition:

\[
\begin{align*}
\Pr\left[\psi(Z; \hat{\theta}, \hat{\eta}_1^*(Z, \theta_1^*), \eta_2^*(Z))\right] &= \frac{1}{K} \sum_{k=1}^{K} \Pr\left[\psi(Z; \hat{\theta}, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))\right] \\
& \quad - \Pr\left[\psi(Z; \hat{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))\right] \\
& \quad + \frac{1}{K} \sum_{k=1}^{K} \left\{ \Pr\left[\psi(Z; \hat{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))\right] - \Pr\left[\psi(Z; \hat{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))\right]\right\} \\
& \quad + \frac{1}{K} \sum_{k=1}^{K} \left\{ \Pr\left[\psi(Z; \theta^*, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))\right] - \Pr\left[\psi(Z; \theta^*, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))\right]\right\} \\
& \quad + \frac{1}{K} \sum_{k=1}^{K} \left\{ \Pr\left[\psi(Z; \theta^*, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))\right] - \Pr\left[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))\right]\right\}.
\end{align*}
\]

Denote

\[
\mathcal{I}_{1,k} = \sup_{\theta \in \Theta} \|\Pr[\psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] - \Pr[\psi(Z; \theta, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))]\|,
\]

\[
\mathcal{I}_{2,k} = \sup_{\theta \in \Theta} \|\Pr[\psi(Z; \theta, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))] - \Pr[\psi(Z; \theta, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))]\|.
\]

Then obviously,

\[
(a) + (c) \leq \frac{2}{K} \sum_{k=1}^{K} \mathcal{I}_{1,k}, (b) + (d) \leq \frac{2}{K} \sum_{k=1}^{K} \mathcal{I}_{2,k}.
\]

To bound (c), note that Eq. (19) implies

\[
\begin{align*}
\| \frac{1}{K} \sum_{k=1}^{K} \Pr[\psi(Z; \theta, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))] \| & \leq \inf_{\theta \in \Theta} \left\| \frac{1}{K} \sum_{k=1}^{K} \Pr[\psi(Z; \theta, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))] \right\| + \varepsilon_N \\
& \leq \inf_{\theta \in \Theta} \left\| \frac{1}{K} \sum_{k=1}^{K} \Pr[\psi(Z; \theta, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1, \text{init}}^{(k)}), \hat{\eta}_2^{(k)}(Z))] \right\| + \varepsilon_N.
\end{align*}
\]
Thus
\[(c) \leq \frac{1}{K} \sum_{k=1}^{K} \|P_{N,k} \left[ \psi(Z; \hat{\theta}, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z)) \right] \| + \frac{1}{K} \sum_{k=1}^{K} \|P_{N,k} \left[ \psi(Z; \theta^*, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z)) \right] \|
\]
\[
\leq \frac{2}{K} \sum_{k=1}^{K} \left\| P_{N,k} \left[ \psi(Z; \theta^*, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z)) \right] \right\| + \varepsilon_N
\]
\[
\leq \frac{2}{K} \sum_{k=1}^{K} \left\| P_{N,k} \left[ \psi(Z; \theta^*, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z)) \right] - P[\psi(Z; \theta^*, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z))] \right\|
\]
\[
+ \frac{2}{K} \sum_{k=1}^{K} \left\| P[\psi(Z; \theta^*, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z))] - P[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] \right\| + \varepsilon_N
\]
\[
\leq \frac{2}{K} \sum_{k=1}^{K} I_{1,k} + \frac{2}{K} \sum_{k=1}^{K} I_{2,k} + \varepsilon_N.
\]

Therefore,
\[
P[\psi(Z; \hat{\theta}, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] \leq \frac{4}{K} \sum_{k=1}^{K} I_{1,k} + \frac{4}{K} \sum_{k=1}^{K} I_{2,k} + \varepsilon_N.
\]

Note that Assumption 3 condition ii implies that \( I_{1,k} \leq \delta_N \tau_N \) and the Assumption 3 condition iii implies that \( \varepsilon_N \leq \delta_N N^{-1/2} = o(\tau_N) \).

To bound \( I_{2,k} \), note that conditionally on \( \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z) \), the function class \( F_{1,\hat{\eta}(k),\hat{\theta}_{1,\text{init}}} = \{ \psi_j(\cdot; \theta, \hat{\eta}_1(k)(\cdot, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(\cdot)) : j = 1, \ldots, d, \theta \in \Theta \} \) satisfies the asserted entropy condition in Assumption 2 and has envelope \( F_{1,\hat{\eta}(k),\hat{\theta}_{1,\text{init}}} \) that satisfies
\[
\sup_{\theta \in \Theta} P[\psi(Z; \theta, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z))] \leq P[F_{1,\hat{\eta}(k),\hat{\theta}_{1,\text{init}}}^2] \leq C_{q,c_7}
\]
for a positive constant \( C_{q,c_7} \) that only depends on \( q \) and \( c_7 \) specified in Assumption 2.

Then conditionally on \( \hat{\theta}_{1,\text{init}}, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z) \), we can use Lemma 6.2 eq. (A.1) in Chernozhukov et al. [2018a] to prove that with \( P_N \)-probability \( 1 - o(1) \),
\[
\sup_{\theta \in \Theta} P[\psi(Z; \theta, \hat{\eta}_1(k)(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(k)(Z))] \lesssim \log N(1 + N^{-1/2+1/q}),
\]
which also holds unconditionally according to Lemma 6.1 of in Chernozhukov et al. [2018a]. This further implies that \( I_{2,k} \lesssim N^{-1/2} \log N(1 + N^{-1/2+1/q}) = o(N^{-1/2} \log^2 N(1 + N^{-1/2+1/q})) = o(\tau_N) \). Thus
\[
P[\psi(Z; \hat{\theta}, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] \leq 4\delta_N \tau_N + 4N^{-1/2} \log N(1 + N^{-1/2+1/q}) + \delta_N N^{-1/2} = o(\tau_N).
\]

**Step II: Linearization and \( \sqrt{N} \)-Consistency.** In Step I, we proved that \( \| \hat{\theta} - \theta^* \| \leq \tau_N \) with \( P_N \)-probability \( 1 - o(1) \). Conditioned on this event, we will show that
\[
\| \sqrt{N} P_N[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] + \sqrt{N} J^*(\hat{\theta} - \theta^*) \|
\leq \varepsilon_N N^{1/2} + I_3 + I_4 + \frac{1}{K} \sum_{k=1}^{K} I_{5,k},
\]
(28)
where

\[ \mathcal{I}_3 := \inf_{\theta \in \Theta} \sqrt{N} \left\| \frac{1}{K} \sum_{k=1}^{K} \mathbb{P}_N[\psi(Z; \theta, \hat{\theta}_1^{(k)}(Z, \hat{\theta}_{1,\text{init}}), \hat{\theta}_2^{(k)}(Z))] \right\|, \]

\[ \mathcal{I}_4 := \sqrt{N} \sup_{r \in (0,1), (\eta_1(\cdot, \theta'), \eta_2) \in T_N} \| \partial^2_r f(r; \hat{\theta}, \eta_1(\cdot, \theta'), \eta_2) \|, \]

\[ \mathcal{I}_{5,k} := \sup_{\|\theta - \theta^*\| \leq r_N} \| \mathbb{G}_{N,k} \left[ \psi(Z; \theta, \hat{\theta}_1^{(k)}(Z, \hat{\theta}_{1,\text{init}}), \hat{\theta}_2^{(k)}(Z)) - \psi(Z; \theta^*, \eta_1^*(Z, \theta^*_1), \eta_2^*(Z)) \right] \|. \]

Here Assumption 3 guarantees that \( \mathcal{I}_4 \leq 3 \left( 1 + \sqrt{N} \|\hat{\theta} - \theta^*\| \right) \), and the assumption that \( \varepsilon_N = \delta_N N^{-1/2} \) guarantees that \( \varepsilon_N N^{1/2} \leq \delta_N \). In step III and IV, we will further bound \( \mathcal{I}_{5,k} \leq 3 N^{-1/2} (1 + \sqrt{N} \|\hat{\theta} - \theta^*\|) \), respectively. Consequently, with \( P_N \) probability \( 1 - o(1) \),

\[ \| \sqrt{N} \mathbb{P}_N[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] + \sqrt{N} J^*(\hat{\theta} - \theta^*) \| \leq \left( 1 + \sqrt{N} \|\hat{\theta} - \theta^*\| \right) + \rho'_N + \delta_N. \]  

(29)

This implies that

\[ \sqrt{N} \|\hat{\theta} - \theta^*\| - \| \sqrt{N} J^{*,-1} \mathbb{P}_N[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] \| \leq \left( 1 + \sqrt{N} \|\hat{\theta} - \theta^*\| \right) \]

\[ \leq \| \sqrt{N} \|\hat{\theta} - \theta^*\| = \left( \delta_N \left( 2 + \sqrt{N} \|\hat{\theta} - \theta^*\| \right) \right) + \rho_N \]

\[ \leq \| \sqrt{N} \|\hat{\theta} - \theta^*\| \leq \frac{1}{c_3} \left( \delta_N \left( 2 + \sqrt{N} \|\hat{\theta} - \theta^*\| \right) \right) + \rho_N \]

By Assumption 2 and Markov inequality,

\[ \| \sqrt{N} J^{*,-1} \mathbb{P}_N[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] \| = O_{P_N}(\sqrt{c_6}). \]

Thus, with \( P_N \) probability \( 1 - o(1) \),

\[ \sqrt{N} \|\hat{\theta} - \theta^*\| \leq \delta_N + \rho'_N. \]

Plugging this back into Eq. (29) gives

\[ \| \sqrt{N} \mathbb{P}_N[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] + \sqrt{N} J^*(\hat{\theta} - \theta^*) \| = O_{P_N}(\delta_N + \rho_N). \]

Thus,

\[ \| \Sigma^{-1/2} J^{*,-1} \sqrt{N} \mathbb{P}_N[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] + \Sigma^{-1/2} \sqrt{N} (\hat{\theta} - \theta^*) \|

\leq \| \Sigma^{-1/2} \| J^{*,-1} \| \| \sqrt{N} \mathbb{P}_N[\psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))] + \sqrt{N} J^*(\hat{\theta} - \theta^*) \|

\leq \delta_N + \rho'_N = \rho_N, \]

because \( \| J^{*,-1} \| \leq 1/c_3 \) and \( \| \Sigma^{-1/2} \| \leq 1/\sqrt{c_5} \).
Now we prove the decomposition Eq. (28). Note that for any $\theta \in \Theta$ and $(\eta_1(\cdot, \theta_1), \eta_2) \in \mathcal{T}_N$

\[
\sqrt{N} \left\{ \frac{1}{K} \sum_{k=1}^{K} \mathbb{P}_{N,k} [\psi(Z; \theta, \eta_1(Z, \theta_1), \eta_2(Z))] \right\} \\
= \sqrt{N} \left\{ \frac{1}{K} \sum_{k=1}^{K} \mathbb{P}_{N,k} [\psi(Z; \theta, \eta_1(Z, \theta_1), \eta_2(Z))] - \mathbb{P} [\psi(Z; \theta, \eta_1(Z, \theta_1), \eta_2(Z))] \right\} \\
+ \frac{1}{K} \sum_{k=1}^{K} \mathbb{P} [\psi(Z; \theta, \eta_1(Z, \theta_1), \eta_2(Z))] - \mathbb{P} [\psi(Z; \theta^*, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z))] \\
+ \frac{1}{K} \sum_{k=1}^{K} \sqrt{N} \left\{ \mathbb{P} [\psi(Z; \theta, \eta_1(Z, \theta_1), \eta_2(Z))] - \mathbb{P} [\psi(Z; \theta^*, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z))] \right\} \\
+ \mathbb{P}_N [\psi(Z; \theta^*, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z))].
\]

(30)

If we apply Eq. (30) with $\theta = \hat{\theta}$ and $(\eta_1(\cdot, \theta_1), \eta_2)$ equal $(\hat{\eta}_1^{(k)}(\cdot, \hat{\theta}_1^{(k)}), \hat{\eta}_2^{(k)})$ for the $k$th fold, and apply Eq. (19), then

\[
\left\| \frac{1}{K} \sum_{k=1}^{K} \mathbb{G}_{N,k} \left[ \psi(Z; \hat{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_1^{(k)}), \hat{\eta}_2^{(k)}(Z)) - \psi(Z; \theta^*, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z)) \right] \right\| \\
+ \sqrt{N} \left\{ \frac{1}{K} \sum_{k=1}^{K} \mathbb{P} \left[ \psi(Z; \hat{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_1^{(k)}), \hat{\eta}_2^{(k)}(Z)) \right] - \mathbb{P} [\psi(Z; \theta^*, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z))] \right\} \\
+ \sqrt{N} \mathbb{P}_N [\psi(Z; \theta^*, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z))] \\
= \sqrt{N} \left\| \frac{1}{K} \sum_{k=1}^{K} \mathbb{P}_{N,k} [\psi(Z; \hat{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_1^{(k)}), \hat{\eta}_2^{(k)}(Z))] \right\| \\
\leq \sqrt{N} \inf_{\theta \in \Theta} \left\| \frac{1}{K} \sum_{k=1}^{K} \mathbb{P}_{N,k} [\psi(Z; \theta, \eta_1^{(k)}(Z, \theta_1^{(k)}), \eta_2^{(k)}(Z))] \right\| + \varepsilon_N \sqrt{N}.
\]

(31)

Here

\[
\left\| \mathbb{G}_{N,k} \left[ \psi(Z; \hat{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_1^{(k)}), \hat{\eta}_2^{(k)}(Z)) - \psi(Z; \theta, \eta_1(Z, \theta_1), \eta_2(Z)) \right] \right\| \leq \mathcal{I}_{5,k}
\]

(32)
and the second order Taylor expansion at \( r = 0 \) gives that for some data-dependent \( \tilde{r} \in (0, 1) \),

\[
\sqrt{N}\left\{ \mathbb{P}\left[ \psi(Z; \hat{\theta}, \hat{\eta}_1(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(Z)) \right] - \mathbb{P}\left[ \psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z)) \right] \right\}
= \sqrt{N}\left\{ f(1; \hat{\theta}, \hat{\eta}_1(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(Z)) - f(0; \hat{\theta}, \hat{\eta}_1(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(Z)) \right\}
= \sqrt{N}\left\{ J^* (\hat{\theta} - \theta^*) + \partial_r \mathbb{P}\left[ \psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), r(\hat{\eta}_1(Z, \hat{\theta}_{1,\text{init}}) - \eta_1^*(Z, \theta_1^*), \eta_2^*(Z))) \right] \right\}_{|r=0}
+ \partial_r \mathbb{P}\left[ \psi(Z; \theta^*, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z)) \right] \right\}_{|r=\tilde{r}}
= \sqrt{N}\left\{ J^* (\hat{\theta} - \theta^*) + \partial_r^2 f(\tilde{r}; \hat{\theta}, \hat{\eta}_1(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2(Z)) \right\}_{|r=\tilde{r}}
\]

(33)

where the third equality uses the Neyman orthogonality in Assumption \( \Box \) condition \( \Box \).

Combining Eq. (31), Eq. (32) and Eq. (33) gives decomposition Eq. (28).

**Step III: bounding** \( \mathcal{I}_{5,k} \). To bound \( \mathcal{I}_{5,k} \), we still condition on \( \hat{\eta}_1^{(k)}(\cdot, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2^{(k)} \), and then apply Lemma 6.2 in [Chernozhukov et al. 2018a] with function class

\[
\mathcal{F}_{\tilde{h}(k), \tilde{h}_{1,\text{init}}^{(k)}} = \left\{ \psi_j(\cdot; \theta, \hat{\eta}_1^{(k)}(\cdot, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2^{(k)}) - \psi_j(\cdot; \theta^*, \eta_1^{*(\cdot, \theta^*)}, \eta_2^*) : j = 1, \ldots, d, \theta \in \Theta, \|\theta - \theta^*\| \leq \tau_N \right\}.
\]

We can verify that \( \mathcal{F}_{\tilde{h}(k), \tilde{h}_{1,\text{init}}^{(k)}} \) satisfies similar entropy condition with envelope \( F_{1,\tilde{h}(k), \tilde{h}_{1,\text{init}}^{(k)}} + F_{1,\eta^*, \theta^*} \).

Moreover, Assumption \( \Box \) implies that

\[
\sup_{\|\theta - \theta^*\| \leq \tau_N} \|\psi(Z; \theta, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2^{(k)}(Z)) - \psi(Z; \theta^*, \eta_1^{*(Z, \theta_1^*)}, \eta_2^*(Z))\|_{\mathbb{P}, 2} \leq r_N'.
\]

Thus conditionally on \( \hat{\theta}_{1,\text{init}}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2^{(k)}(Z), \) we can use Lemma 6.2 eq. (A.1) in [Chernozhukov et al. 2018a] to show that with \( P_N \)-probability \( 1 - o(1) \),

\[
\mathcal{I}_{5,k} \leq (N^{-1/2 + 1/q} + r_N') \log N + r_N' \log^{1/2}(1/r_N') + N^{-1/2 + 1/q} \log(1/r_N')
\]

which also holds unconditionally according to Lemma 6.1 in [Chernozhukov et al. 2018a].

**Step IV: bounding** \( \mathcal{I}_3 \). Let \( \overline{\theta} = \theta^* - J^*_{-1} P_N [\psi(Z; \theta^*, \eta_1^*(Z, \theta^*), \eta_2^*(Z))] \). Since \( \mathbb{P}[\psi(Z; \theta^*, \eta_1^*(Z, \theta^*), \eta_2^*(Z))] = 0, J^* \) is nonsingular with singular values bounded away from 0 by \( c_3 \), and \( \|\mathbb{P}[\psi(Z; \theta^*, \eta_1^*(Z, \theta^*), \eta_2^*(Z))]\| = O_{P_N}(N^{-1/2}), \|\overline{\theta} - \theta^*\| = O_{P_N}(N^{-1/2}) = o_{P_N}(\tau_N) \). According to Assumption \( \Box \) condition \( \Box \) \( \overline{\theta} \in \Theta \) with \( P_N \) probability \( 1 - o(1) \). Therefore,

\[
\mathcal{I}_3 \leq \sqrt{N} \left\| \frac{1}{K} \sum_{k=1}^{K} P_N[\psi(Z; \overline{\theta}, \hat{\eta}_1^{(k)}(Z, \hat{\theta}_{1,\text{init}}), \hat{\eta}_2^{(k)}(Z))] \right\|
\]

Then apply the linearization Eq. (30) and Taylor expansion similar to Eq. (33) with \( \theta = \overline{\theta} \) and
(η₁(·, θ₁), η₂) equal (η̂₁(k)(·, θ̂₁(k)), η̂₂(k)) for the kth fold, we can get that
\[
\sqrt{N} \left| \frac{1}{K} \sum_{k=1}^{K} \mathbb{P}_{N,k}[\psi(Z; \bar{\theta}, \hat{\eta}_{1}^{(k)}(Z), \hat{\eta}_{2}^{(k)}(Z))] \right|
\]
\[
\leq \sqrt{N} \left| \mathbb{P}_{N}[\psi(Z; \bar{\theta}, \eta_{1}^{*}(Z), \eta_{2}^{*}(Z))] + J^{*}(\bar{\theta} - \theta^{*}) + I_{4} + \frac{1}{K} \sum_{k=1}^{K} I_{5,k} \right|
\]
= I_{4} + \frac{1}{K} \sum_{k=1}^{K} I_{5,k}.
where the last equality here holds because \( \mathbb{P}_{N}[\psi(Z; \bar{\theta}, \eta_{1}^{*}(Z), \eta_{2}^{*}(Z))] + J^{*}(\bar{\theta} - \theta^{*}) = 0 \) as a consequence of the special construction of \( \bar{\theta} \).

**Extension: \( \hat{\theta} \) defined in Definition 2** By applying step I to IV to sample estimating equation Eq. (16), we can get that for \( k = 1, \ldots, K \),
\[
\sqrt{N/K} \Sigma^{-1/2}(\hat{\theta}^{(k)} - \theta^{*}) = \frac{1}{\sqrt{N/K}} \sum_{i \in \mathcal{D}_{k}} \Sigma^{-1/2} J^{* - 1} \psi(Z_{i}; \theta^{*}, \eta_{1}^{*}(Z_{i}), \eta_{2}^{*}(Z_{i})) + O_{p}(\rho_{N}/K).
\]
Since \( K \) is a fixed integer that does not grow with \( N \), the equation above implies that the asserted conclusion in Theorem 1 also holds for \( \hat{\theta} = \frac{1}{K} \sum_{k=1}^{K} \hat{\theta}^{(k)}. \)

**A.3 Proof for Section 4**

**Proof of Theorem 1** We introduce a notation \( \otimes a = a a^{\top} \), we prove that
\[
||\mathbb{P}_{N,k}[\otimes \psi(Z; \hat{\theta}, \hat{\eta}_{1}^{(k)}(Z), \hat{\eta}_{2}^{(k)}(Z))] - \mathbb{P}[\otimes \psi(Z; \theta^{*}, \eta_{1}^{*}(Z), \eta_{2}^{*}(Z))]|| = O_{p}(\rho_{N}). \quad (34)
\]
for any \( k \in [1, \ldots, K] \). Then, the statement is immediately concluded. For all \( j, l \in [1, \ldots, d_{1}] \) (\( d = d_{1} + d_{2} \)), it follows if we have \( I_{jl} = O_{p}(\rho_{N}) \), where
\[
I_{jl} := ||\mathbb{P}_{N,k}[\psi_{j}(Z; \hat{\theta}, \hat{\eta}_{1}^{(k)}(Z), \hat{\eta}_{2}^{(k)}(Z))] - \mathbb{P} \psi_{j}(Z; \theta^{*}, \eta_{1}^{*}(Z), \eta_{2}^{*}(Z))||.
\]
Here, to simplify the notation, we use \( \hat{\eta}_{1}^{(k)} = \hat{\eta}_{1}^{(k)}(Z), \hat{\eta}_{2}^{(k)} = \hat{\eta}_{2}^{(k)}(Z), \theta_{\text{init}}^{*} = \theta_{\text{init}}^{*}(Z), \eta_{1}^{*} = \eta_{1}^{*}(Z), \eta_{2}^{*} = \eta_{2}^{*}(Z) \). This is decomposed as \( I_{jl} \leq I_{jl,1} + I_{jl,2} \), where
\[
I_{jl,1} := ||\mathbb{P}_{N,k}[\psi_{j}(Z; \hat{\theta}, \hat{\eta}_{1}^{(k)}(Z), \hat{\eta}_{2}^{(k)}(Z))] - \mathbb{P}_{N,k}[\psi_{j}(Z; \theta^{*}, \eta_{1}^{*}, \eta_{2}^{*})]|\|
\]
\[
I_{jl,2} := ||\mathbb{P}_{N,k}[\psi_{j}(Z; \theta^{*}, \eta_{1}^{*}, \eta_{2}^{*})]|\| - \mathbb{P}[\psi_{j}(Z; \theta^{*}, \eta_{1}^{*}, \eta_{2}^{*})]|\|.
\]
We show each term is \( O_{p}(\rho_{N}). \)

We bound \( I_{jl,2} \). This is upper bounded as
\[
\mathbb{P}[I_{jl,2}] \leq N^{-1} \mathbb{P}[\psi_{j}^{2}(Z; \theta^{*}, \eta_{1}^{*}, \eta_{2}^{*})]|\| \leq N^{-1} \mathbb{P}[\psi_{j}^{4}(Z; \theta^{*}, \eta_{1}^{*}, \eta_{2}^{*})]|\|^{1/2} \leq N^{-1} \mathbb{P}[|\|\psi(Z; \theta^{*}, \eta_{1}^{*}, \eta_{2}^{*})|\|^{4} \]
Here, we use the fourth moment assumption. From conditional Markov inequality, therefore, \( \mathcal{I}_{j,1} = O_p(1/N^{-1/2}) \). Next, we bound \( \mathcal{I}_{j,1} \). Then, from the same argument in the proof of Theorem 3.2 \cite{Chernozhukov2018}, we have
\[
\mathcal{I}_{j,1}^2 \leq R_N \times \left\{ \mathbb{P}_{N,k}[\|\psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] + R_N \right\},
\]
\[
R_N = \mathbb{P}_{N,k}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2].
\]
In addition, from the bounded moment assumption,
\[
\mathbb{P}[\mathbb{P}_{N,k}[\|\psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]] = \mathbb{P}[\mathbb{P}_{N,k}[\|\psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]] = \mathbb{P}[\|\psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] \leq C^2.
\]
From Markov inequality, we have
\[
\mathbb{P}_{N,k}[\|\psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] = O_p(1).
\]
It remains to bound \( R_N \). We have
\[
R_N = \mathbb{P}_{N,k}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]
\]
\[
\leq \mathbb{P}_{N,k}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1^*, \hat{\eta}_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] + \mathbb{P}_{N,k}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2].
\]
Then, the first term of Eq. \((35)\) is upper bounded with probability \( 1 - o(1) \) as
\[
\mathbb{P}_{N,k}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1^*, \hat{\eta}_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]
\]
\[
= \frac{1}{\sqrt{N}} \mathbb{G}_{N,k}[\|\psi(Z; \hat{\theta}, \eta_1^*, \eta_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] + \mathbb{P}[\|\psi(Z; \hat{\theta}, \eta_1^*, \eta_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]
\]
\[
\leq \sup_{\theta \in \Theta} \frac{1}{\sqrt{N}} \mathbb{G}_{N,k}[\|\psi(Z; \theta, \eta_1^*, \eta_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] + \mathbb{P}[\|\psi(Z; \hat{\theta}, \eta_1^*, \eta_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]
\]
\[
\lesssim N^{-1/2+2/q} \log N\{1 + N^{-1/2+2/q}\} + \|\hat{\theta} - \theta^*\|^2 = N^{-1/2+2/q} \log N\{1 + N^{-1/2+2/q}\} + N^{-\beta/2}.
\]
In the last inequality, we use Lemma 6.2 \cite{Chernozhukov2018}. Here, the envelops exists since
\[
\|\psi(Z; \theta, \eta_1^*, \eta_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2 \leq C F_{\eta^*, \theta^*}^2.
\]
for some constant \( C \) depending on \( d_1, d_2 \) and it satisfies the moment condition \( \|F_{\eta^*, \theta^*}\|_{\mathbb{P}, q} \leq c_1 \) for \( q > 4 \). In addition, the metric entropy assumption is satisfied since
\[
\sup_{\theta \in \Theta} \log N(\epsilon \|C F_{\eta^*, \theta^*}\|_{\mathbb{Q}, 2}, \left\{ \|\psi(Z; \theta, \eta_1^*, \eta_2^*) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2 \right\}, \| \cdot \|_{\mathbb{Q}, 2}) \lesssim \log N(\epsilon \|C F_{\eta^*, \theta^*}\|_{\mathbb{Q}, 2}, \| \cdot \|_{\mathbb{Q}, 2})^2 \lesssim \nu \log(n/\epsilon).
\]
Similarly, the second term of Eq. \((35)\) is upper bounded with probability \( 1 - o(1) \) as
\[
\mathbb{P}_{N,k}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]
\]
\[
= \frac{1}{\sqrt{N}} \mathbb{G}_{N,k}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] + \mathbb{P}[\|\psi(Z; \hat{\theta}, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2]
\]
\[
\leq \sup_{\theta \in \Theta} \frac{1}{\sqrt{N}} \mathbb{G}_{N,k}[\|\psi(Z; \theta, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta^*, \eta_1^*, \eta_2^*) \|^2] + \sup_{\theta \in \mathcal{B}(\theta^*, r_N)} \mathbb{P}[\|\psi(Z; \theta, \hat{\eta}_1, \hat{\eta}_2) - \psi(Z; \theta, \eta_1^*, \eta_2^*) \|^2]
\]
\[
\lesssim N^{-1/2+1/q} \log N\{1 + N^{-1/2+2/q}\} + \{r_N^2\}^2.
\]
In the last inequality, we use Lemma 6.2 \cite{Chernozhukov2018} and Assumption 3. In the end, we have
\[
R_N = O_p(N^{-1/4+1/q}\{\log N\}^{1/2}\{1 + N^{-1/4+1/q}\} + r_N) + N^{-\beta/4}.
\]
This concludes the proof.
A.4 Proof for Section 5

Proof for Theorem 3. In this part, we prove the asymptotic distribution of our estimators corresponding to the general estimating equation Eq. [9]. We prove this by verifying all conditions in the assumptions for Theorem 3.

Verifying Assumption 1. 

\[ J^* = \partial_\theta \left\{ \mathbb{P} \left[ \psi(Z; \theta, \eta_1^*(Z, \theta_2), \eta_2^*(Z)) \right] \right\}_{\theta = \theta^*} \]

\[ = \partial_\theta \left\{ \frac{I(T = t)}{\pi^*(t \mid X)} U(Y; \theta_1) - \frac{I(T = t) - \pi^*(t \mid X)}{\pi^*(t \mid X)} \mu^*(X, t; \theta_1) + V(\theta_2) \right\}_{\theta = \theta^*} \]

\[ = \partial_\theta \left\{ \frac{I(T = t)}{\pi^*(t \mid X)} U(Y; \theta_1) + V(\theta_2) \right\}_{\theta = \theta^*} \]

\[ = \partial_\theta \left\{ \frac{I(T = t)}{\pi^*(t \mid X)} U(Y; \theta_1) - \frac{I(T = t) - \pi^*(t \mid X)}{\pi^*(t \mid X)} \mu^*(X, t; \theta_1^*) + V(\theta_2) \right\}_{\theta = \theta^*} \]

\[ = \partial_\theta \left\{ \mathbb{P} \left[ \psi(Z; \theta, \eta_1^*(Z, \theta_1^*), \eta_2^*(Z)) \right] \right\}_{\theta = \theta^*}, \]

where the second and third equality follow because \( \mathbb{P} \left[ \frac{I(T = t) - \pi^*(t \mid X)}{\pi^*(t \mid X)} \mu^*(X, t; \theta_1) \right]_{\theta = \theta^*} = 0. \)

Verifying Assumption 2. We first verify conditions [iii] and [iv] in Assumption 2. We denote that \( J_{jk}(\theta) = \partial_{\theta_{(k)}} \mathbb{P} \left[ U_j(Y(t); \theta_1) + V_j(\theta_2) \right] \) where \( \theta_{(k)} \) is the \( k \)-th component of \( \theta = (\theta_1, \theta_2) \). By condition [iii], \( J_{jk}(\theta) \) is Lipschitz continuous at \( \theta^* \) with Lipschitz constant \( c' \). So for any \( \varepsilon > 0 \), if \( \theta \) belongs to the open ball \( B(\theta^*; \varepsilon/c') \), then

\[ |J_{jk}(\theta) - J_{jk}(\theta^*)| = |\partial_{\theta_{(k)}} \mathbb{P} \left[ U_j(Y(t); \theta_1) + V_j(\theta_2) \right] - \partial_{\theta_{(k)}} \mathbb{P} \left[ U_j(Y(t); \theta_1^*) + V_j(\theta_2^*) \right]| \leq \varepsilon. \]

By first order Taylor expansion, for any \( \theta \in B(\theta^*; \delta) \), there exists \( \tilde{\theta} \in B(\theta^*; ||\theta - \theta^*||) \) such that

\[ \mathbb{P} \left[ U(Y(t); \theta_1) + V(\theta_2) \right] = \mathbb{E} \left[ U(Y(t); \hat{\theta}) \right] \]

\[ \geq \mathbb{E} \left[ U(Y(t); \theta^*) \right] - \varepsilon \sqrt{\delta} \cdot ||\theta^* - \theta|| \]

\[ \geq \mathbb{E} \left[ J^*(\theta) \right] - \varepsilon \sqrt{\delta} \cdot ||\theta^* - \theta|| \]

\[ \geq \frac{1}{2} \mathbb{E} \left[ J^*(\theta) \right] - \frac{1}{2} \mathbb{E} \left[ J^*(\theta) \right] \]

\[ = \frac{1}{2} \mathbb{E} \left[ J^*(\theta) \right], \]

where the second last inequality holds if we choose \( \varepsilon \leq \frac{c_1}{2\sqrt{\delta}} \leq \frac{1}{2\sqrt{\delta}} \sigma_{\min}(J^*(\theta^*)) \), where \( \sigma_{\min}(J^*(\theta^*)) \) is the smallest singular value of \( J^*(\theta^*) \). Thus

\[ \inf_{\theta \in B(\theta^*; \varepsilon/c')} 2 \mathbb{P} \left[ U(Y(t); \theta_1^*) + V(\theta_2) \right] \geq \mathbb{E} \left[ J^*(\theta) \right] - \varepsilon \sqrt{\delta} \cdot ||\theta^* - \theta||. \]

Moreover, for any \( \theta \in \Theta \setminus B(\theta^*; \frac{c_1}{2\sqrt{\delta}}) \), \( 2 \mathbb{P} \left[ U(Y(t); \theta_1^*) + V(\theta_2) \right] \geq c_2 \) according to condition [iii].

Therefore, \( 2 \mathbb{P} \left[ U(Y(t); \theta_1^*) + V(\theta_2) \right] \geq J^*(\theta) - \varepsilon \sqrt{\delta} \cdot ||\theta^* - \theta||. \)

Moreover, the singular values \( J^* \) are bounded between \( c_3, c_4 \) according to condition [iv].
We then verify condition vii in Assumption 2 for any \((\eta_1(\cdot, \theta_1^*), \eta_2) \in \mathcal{T}_N\),

\[
\partial_r \left\{ \mathbb{P} \left[ \psi(Z; \theta^*, \eta_1(Z; \theta_1^*) + r(\eta_1(\cdot, \theta_1^*) - \eta_1^*(Z; \theta_1^*)), \eta_2^*(Z) \right] \right\} \Big|_{r=0} = \partial_r \left\{ \mathbb{P} \left[ \psi(Z; \theta^*, \eta_1^*(Z; \theta_1^*)), \eta_2^*(Z) + r(\eta_2(Z) - \eta_2^*(Z)) \right] \right\} \Big|_{r=0} = 0.
\]

Verifying Assumption 3: We take \(\mathcal{T}_N\) to be the set that contains all \((\mu(\cdot, \theta_1^*), \pi(\cdot))\) that satisfies the following conditions:

\[
\left\| \left\{ \mathbb{P} \left[ \mu(X, T; \theta_1^*) - \mu^*(X, T; \theta_1^*) \right] \right\} \right\|^{1/2} \leq \rho_{\mu, N},
\]

\[
\left\{ \mathbb{P} \left[ \pi(T \mid X) - \pi^*(T \mid X) \right] \right\}^{1/2} \leq \rho_{\pi, N}, \quad \|\theta_1^* - \theta_1^\star\| \leq \rho_{\theta, N},
\]

with \(\rho_{\pi, N}(\rho_{\mu, N} + C\rho_{\theta, n}) \leq \frac{\varepsilon_3}{2} \delta_N N^{-1/2}, \rho_{\pi, N} \leq \frac{\delta_3^3}{\log N}, \text{ and } \rho_{\mu, N} + C\rho_{\theta, N} \leq \frac{\delta_3^2}{\log N}.
\]

Then Assumption 6 and condition vii in Theorem 3 guarantee that the nuisance estimates \((\hat{\mu}(\cdot, \hat{\theta}_{1,\text{init}}), \hat{\pi}) \in \mathcal{T}_N\) with probability, namely, condition vii in Assumption 3 is satisfied.

Before verifying other conditions, first note that the condition vi states that

\[
\left\{ \mathbb{P} \left[ \mu^*(X, T; \theta_1^*) - \mu^*(X, T; \theta_1^* \right] \right\}^{1/2} \leq C\|\theta_1 - \theta_1^\star\|, \quad \forall \|\theta_1 - \theta_1^\star\| \leq \rho_{\theta, N},
\]

which implies that for any \((\mu(\cdot, \theta_1^*), \pi(\cdot)) \in \mathcal{T}_N\),

\[
\left\| \left\{ \mathbb{P} \left[ \mu(X, T; \theta_1^*) - \mu^*(X, T; \theta_1^*) \right] \right\} \right\| \leq \left\{ \mathbb{P} \left[ \mu(X, T; \theta_1^*) - \mu^*(X, T; \theta_1^*) \right] \right\}^{1/2} + \left\{ \mathbb{P} \left[ \mu^*(X, T; \theta_1^*) - \mu^*(X, T; \theta_1^*) \right] \right\}^{1/2} = \rho_{\mu, N} + C\rho_{\theta, N}. 
\]
Thus the condition on \( r_N \): for any \((\eta_1(\cdot; \theta'_1), \eta_2(\cdot)) = (\mu(\cdot, \theta'_1), \pi(\cdot)) \in \mathcal{T}_N\), and \( \theta \in \Theta \),

\[
\| \mathbb{P} \left[ \psi(Z; \theta, \eta_1(Z; \theta'_1), \eta_2(Z)) \right] - \mathbb{P} \left[ \psi(Z; \theta, \eta_1^*(Z; \theta'_1), \eta_2^*(Z)) \right] \| \\
\leq \| \mathbb{P} \left[ \frac{(T = t)}{\pi(t \mid X)} - \frac{(T = t)}{\pi^*(t \mid X)} \right] \left( U(Y; \theta_1) - \mu^*(X, T; \theta'_1) \right) \| \\
+ \| \mathbb{P} \left[ \frac{(T = t)}{\pi(t \mid X)} - \frac{(T = t)}{\pi^*(t \mid X)} \right] \left( \mu^*(X, T; \theta'_1) - \mu(X, T; \theta'_1) \right) \| \\
+ \| \mathbb{P} \left[ \frac{(T = t)}{\pi^*(t \mid X)} \right] [\mu^*(X, T; \theta'_1) - \mu(X, T; \theta'_1)] \| \\
\leq \frac{1}{\varepsilon_\pi} \left\{ \mathbb{P} \left[ \pi(t \mid X) - \pi^*(t \mid X) \right]^2 \right\}^{1/2} \left\{ \mathbb{P} \left[ \mu^*(X, T; \theta_1) - \mu^*(X, T; \theta'_1) \right]^2 \right\}^{1/2} \\
+ \frac{1}{\varepsilon_\pi} \left\{ \mathbb{P} \left[ \pi(t \mid X) - \pi^*(t \mid X) \right]^2 \right\}^{1/2} \left\{ \mathbb{P} \left[ \mu(X, T; \theta'_1) - \mu^*(X, T; \theta'_1) \right]^2 \right\}^{1/2} \\
\leq \frac{1}{\varepsilon_\pi} \rho_{\pi,N} \times (2C\sqrt{d} + \rho_{\mu,N} + C\rho_{\theta,N}) \leq \frac{4C}{\varepsilon_\pi} \sqrt{d} \rho_{\pi,N}.
\]

Thus the condition on \( r_N \) is satisfied with \( \tau_N \) such that \( \tau_N = \frac{4C\sqrt{d} \rho_{\pi,N}}{\delta_N \varepsilon_\pi} \).

Next, we verify the condition on \( r'_N \): for any \( \theta \) such that \( \| \theta - \theta^* \| \leq \frac{4C\sqrt{d} \rho_{\pi,N}}{\delta_N \varepsilon_\pi} \), and any \((\eta_1(\cdot; \theta'_1), \eta_2(\cdot)) = (\mu(\cdot, \theta'_1), \pi(\cdot)) \in \mathcal{T}_N\),

\[
\| \mathbb{P} \left[ \psi(Z; \theta, \eta_1(Z; \theta'_1), \eta_2(Z)) - \psi(Z; \theta, \eta_1^*(Z; \theta'_1), \eta_2^*(Z)) \right] \| \\
\leq \left\{ \mathbb{P} \left[ \left( \frac{(T = t)}{\pi(t \mid X)} - \right. \right. \left. \left. \frac{(T = t)}{\pi^*(t \mid X)} \right) \right] \left( \mu_1^*(X, T; \theta_1) - \mu_1^*(X, T; \theta'_1) \right) \right\}^{1/2} \\
+ \left\{ \mathbb{P} \left[ \left( \frac{(T = t)}{\pi(t \mid X)} - \right. \right. \left. \left. \frac{(T = t)}{\pi^*(t \mid X)} \right) \right] \left( \mu_2^*(X, T; \theta_1) - \mu_2^*(X, T; \theta'_1) \right) \right\}^{1/2} \\
+ \left\{ \mathbb{P} \left[ \left( \pi(t \mid X) - \pi^*(t \mid X) \right) \right] \left( \mu_1^*(X, T; \theta'_1) - \mu_1(X, T; \theta'_1) \right) \right\}^{1/2} \\
+ \left\{ \mathbb{P} \left[ \left( \pi(t \mid X) - \pi^*(t \mid X) \right) \right] \left( \mu_2^*(X, T; \theta'_1) - \mu_2(X, T; \theta'_1) \right) \right\}^{1/2} \\
\leq \frac{4C^2 \sqrt{d} \rho_{\pi,N}}{\delta_N \varepsilon_\pi^2} + \frac{1}{\varepsilon_\pi} (\rho_{\mu,N} + C\rho_{\theta,N}) + \frac{1}{\varepsilon_\pi} (\rho_{\mu,N} + C\rho_{\theta,N})
\]

So when \( \rho_{\pi,N} \leq \frac{\delta_N^3}{\log N} \), and \( \rho_{\mu,N} + C\rho_{\theta,N} \leq \frac{\delta_N^3}{\log N} \), \( r'_N = \frac{\delta_N^3}{\varepsilon_\pi^2 \log N} \left( 4C^2 \sqrt{d} + 2\varepsilon_\pi \right) \leq \frac{\delta_N}{\log N} \) if \( \delta_N \leq \frac{\varepsilon_\pi^2}{4C^2 \sqrt{d} + 2\varepsilon_\pi} \).
Finally, to verify the condition on $\chi_N$, we note that for any $\theta$ such that $\|\theta - \theta^*\| \leq \frac{4C\sqrt{2\rho_{x,N}}}{\delta_{N}\varepsilon}$, and any $(\eta_1(\cdot; \theta_1^*), \eta_2(\cdot)) = (\mu(\cdot, \theta_1^*), \pi(\cdot)) \in T_N$

$$f(r; \theta, \eta_1(Z; \theta_1^*), \eta_2)$$

$$= \mathbb{P}\left\{ \frac{\mathbb{I}(T = t)}{\pi^r(T | X) + r(\pi(T | X) - \pi^r(T | X))} \left[ \mu^r(X, T; \theta_1^* + r(\theta_1 - \theta_1^*)) - \mu^r(X, T; \theta_1^*) \right] - r(\mu(X, T; \theta_1^*) - \mu^r(X, T; \theta_1^*)) + \left[ \mu^r(X, t; \theta_1^* + r(\theta_1 - \theta_1^*)) - \mu^r(X, t; \theta_1^*) \right] + V(\theta_2^r + r(\theta_2 - \theta_2^*)) \right\}$$

Thus the first order derivative is

$$\partial_r f(r; \theta, \eta_1(Z; \theta_1^*), \eta_2)$$

$$= -\mathbb{P}\left\{ \frac{\mathbb{I}(T = t)}{\pi^r(T | X) + r(\pi(T | X) - \pi^r(T | X))} \left[ \mu^r(X, T; \theta_1^* + r(\theta_1 - \theta_1^*)) - \mu^r(X, T; \theta_1^*) \right] \right\} + \mathbb{P}\left\{ \frac{\mathbb{I}(T = t)}{\pi^r(T | X) + r(\pi(T | X) - \pi^r(T | X))} \times \partial_{\theta_1^*} \mu^r(X, T; \theta_1^*) \big|_{\theta_1 = \theta_1^* + r(\theta_1 - \theta_1^*)} \right\}$$

$$\times \mathbb{P}\left\{ [\mu(X, t; \theta_1^*) - \mu^r(X, t; \theta_1^*)] \right\} + \partial_{\theta_2^r} V(\theta_2) \big|_{\theta_2 = \theta_2^r + r(\theta_2 - \theta_2^*)}$$

The second order derivative is

$$\partial_r^2 f(r; \theta, \eta_1(Z; \theta_1^*), \eta_2)$$

$$= \mathbb{P}\left\{ \frac{2\mathbb{I}(T = t)}{(\pi^r(T | X) + r(\pi(T | X) - \pi^r(T | X)))^2} \left( \mu^r(X, T; \theta_1^* + r(\theta_1 - \theta_1^*)) \right) - \left[ \mu^r(X, T; \theta_1^*) \right] \right\}$$

$$\times [\mu(X, t; \theta_1^*) - \mu^r(X, t; \theta_1^*)] \right\} + \partial_{\theta_2^r} V(\theta_2) \big|_{\theta_2 = \theta_2^r + r(\theta_2 - \theta_2^*)}$$

All exchange of integration and differentiation above is guaranteed by condition in Theorem 3
Note that

\[
\begin{align*}
\mathbb{E} \left[ \left( \pi(T \mid X) - \pi^e(T \mid X) \right) \partial_{\theta_1}^* \mu^e(X, T; \theta_1) \mid \theta_1 = \theta_1^* + \epsilon(\theta_1 - \theta_1^*) \right] \\
&= \mathbb{E} \left[ \left( \pi(T \mid X) - \pi^e(T \mid X) \right) \partial_{\theta_1}^* \mathbb{E} [U(Z; \theta_1) \mid X, T] \mid \theta_1 = \theta_1^* + \epsilon(\theta_1 - \theta_1^*) \right] \\
&\leq \mathbb{E} \left[ \left( \pi(T \mid X) - \pi^e(T \mid X) \right)^2 \right]^{1/2} \cdot \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2} \\
&\leq C \sqrt{d} \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2} + \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2} \leq C \sqrt{d} \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2}.
\end{align*}
\]

and

\[
\sup_{r \in (0, 1)} \left( \mathbb{E} \left[ \left( \pi(T \mid X) - \pi^e(T \mid X) \right)^2 \right]^{1/2} \cdot \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2} \right) \leq C \sqrt{d} \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2}.
\]

Thus for any \( \theta \) such that \( ||\theta - \theta^*|| \leq \frac{4C \sqrt{d} \rho_{\pi, N}}{\delta_0 N \epsilon_{\pi}} \),

\[
\| \partial^2_f(r; \theta, \mu(X, T; \theta^*_1), \pi) \| \leq \rho_{\pi, N} \left( \frac{C \sqrt{d}}{\delta_0 N} \right) \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2} + C \rho_{\pi, N} \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2} + C \rho_{\pi, N} \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2} + C \rho_{\pi, N} \mathbb{E} \left[ \left( \theta_1 - \theta_1^* \right)^2 \right]^{1/2}
\]

(36)
Given $\rho_{\pi,N} \leq \frac{\delta_N}{\log N}$, when $\frac{\delta_N}{\log N} \leq \frac{\varepsilon^2}{2c^2d}$ and $\frac{\delta_N}{\log N} \leq \frac{\varepsilon^2}{2c^2d}$, $\frac{\varepsilon^2}{2c^2d} \rho_{\pi,N} \|\theta - \theta^*\| + \frac{C\sqrt{N}}{\varepsilon} \rho_{\pi,N}\|\theta_1 - \theta^*_1\| \leq \delta_N\|\theta - \theta^*\|$. Moreover, when $\rho_{\pi,N}(\rho_{\mu,N} + C\rho_{\theta,N}) \leq \frac{\frac{\varepsilon}{2c^2d}N^{-1/2}}{3\frac{\varepsilon}{2c^2d}} \rho_{\pi,N}(\rho_{\mu,N} + C\rho_{\theta,N}) \leq \delta_NN^{-1/2}$. Consequently, $\|\partial^2 f(r; \theta, \mu(X, T; \theta_1', \pi))\| \leq \delta_N(\|\theta - \theta^*\| + N^{-1/2})$.

**Proof for Propositions 3 and 4** We prove Proposition 4 by verifying the assumptions in Theorem 3. Proposition 3 is proved by omitting the arguments about the second component.

**Verifying condition i in Theorem 3** Note that

$$\mathbb{P}[U(Y(t); \theta_1) + V(\theta_2)] = \left[\theta_1 + \frac{F_t(\theta_1) - \gamma}{1 - \gamma} \mathbb{E}[Y(t) - \theta_1] + \theta_2\right].$$

When $F_t(\theta_1)$ is differentiable, $\mathbb{P}[U(Y(t); \theta_1) + V(\theta_2)]$ is also differentiable by Leibnitz integral rule, with derivative

$$J(\theta) = \begin{bmatrix} f_t(\theta_1) & 0 \\ -\frac{F_t(\theta_1) - \gamma}{1 - \gamma} & -1 \end{bmatrix}.$$

Thus

$$J^* = \begin{bmatrix} f_t(\theta_1^*) & 0 \\ -\frac{F_t(\theta_1^*) - \gamma}{1 - \gamma} & 1 \end{bmatrix}.$$

Under the condition that $f_t(\theta_1^*) > c_1'$, we have that $\|J^{*-1}\| \leq 1/c_1'$. Thus the condition iv of Assumption 2 is satisfied. Since $\Theta$ is compact, $\{y \mapsto I[y \leq \theta_1], \theta \in \Theta\}$, $\{y \mapsto \max\{\theta_1, \frac{1}{1 - \gamma}(y - \theta_1)\} - \theta_2, \theta \in \Theta\}$ are obviously Donsker classes, so condition vi of Assumption 2 is satisfied.

**Verifying conditions iii and iv in Theorem 3** It is straightforward to show that $J(\theta)$ is invertible with the following matrix as its inverse:

$$J^{-1}(\theta) = \begin{bmatrix} \frac{f_t(\theta_1)}{F_t(\theta_1) - \gamma} & 0 \\ -\frac{F_t(\theta_1) - \gamma}{f_t(\theta_1)(1 - \gamma)} & -1 \end{bmatrix}.$$

Note that $\sigma_{\max}(J(\theta^*)) \leq 2\max\{f_t(\theta_1^*), 1\} \leq 2\max\{c_2', 1\}$ and $\sigma_{\min}(J(\theta^*)) = 1/\sigma_{\max}(J^{-1}(\theta^*)) \geq \min\{\frac{1}{2}, \frac{1}{1 - \gamma}, \frac{1}{\gamma}c_1'\} \geq \frac{1}{2}\min\{1, \frac{1 - \gamma}{\gamma}c_1, c_1'\}$. Thus condition iv in Theorem 3 is satisfied with $c_3 = \frac{1}{2}\min\{1, \frac{1 - \gamma}{\gamma}c_1, c_1'\}$ and $c_4 = \max\{1, c_3\}$.

Since $f_t(\theta_1) \leq c_2'$ and $\hat{f}_t(\theta_1) \leq c_3'$, it follows that each element in $J(\theta)$ is Lipschitz continuous at $\theta^{*}$ with Lipschitz constant $c' = \max\{c_2', c_3'\}$. Moreover, for $\theta \in \Theta$ such that $\|\theta - \theta^*\| \geq \frac{\sqrt{2}}{2\sqrt{2}c'}$, there exists $\theta$ between $\theta$ and $\theta^*$ such that $\|\mathbb{P}[U(Y(t); \theta_1) + V(\theta_2)]\| \geq c_5'$. This means that condition iii in Theorem 3 is satisfied with $c' = \max\{c_2', c_3'\}$ and $c_2 = 2c_5'$. Note that when we estimate quantile only, we only require $|F(\theta_1^*) - F(\theta_1)| \geq c_4'$ for $|\theta_1 - \theta_1^*| \geq \frac{c_4'}{2c'}$. Then condition iii in Theorem 3 is satisfied with $c' = c_3'$ and $c_2 = 2c_3'$, and condition iii in Theorem 3 is satisfied with $c_3 = c_1'$ and $c_4 = 2c_2'$.

**Verifying condition v in Theorem 3** This condition can be verified by the following facts: for any $\theta_1$ such that $|\theta_1 - \theta_1^*| \leq \max\{\frac{4C\sqrt{\rho_{\theta,N}}}{\delta_N}, \rho_{\theta,N}\}$,

$$|\partial_{\mu^*(X, t; \theta^*_1 + r(\theta_1 - \theta^*_1))}| = |\partial_{\mu^*(X, t; \theta^*_1 + r(\theta_1 - \theta^*_1))}| = \left|\partial_{\mu^*(X, t; \theta^*_1 + r(\theta_1 - \theta^*_1))}\right| |X| = \left|\partial_{\mu^*(X, t; \theta^*_1 + r(\theta_1 - \theta^*_1))}\right| \leq C |\theta_1 - \theta_1^*|.$$

$$|\partial^2_{\mu^*(X, t; \theta^*_1 + r(\theta_1 - \theta^*_1))}| = \left|\partial^2_{\mu^*(X, t; \theta^*_1 + r(\theta_1 - \theta^*_1))}\right| |X| = \left|\partial^2_{\mu^*(X, t; \theta^*_1 + r(\theta_1 - \theta^*_1))}\right| \leq C |\theta_1 - \theta_1^*|^2.$$
and

\[
|\partial_r \mu_2^*(X, t; \theta_1^* + r(\theta_1 - \theta_1^*))| = |\partial_r \left\{ \theta_1^* + r(\theta_1 - \theta_1^*) + \frac{1}{1 - \gamma} \mathbb{E} \left[ \max(Y - \theta_1^* - r(\theta_1 - \theta_1^*), 0) \mid X, T = t \right] \right\} | \\
= |\theta_1 - \theta_1^*| \left| 1 - \frac{1}{1 - \gamma} (1 - F_t(\theta_1^* + r(\theta_1 - \theta_1^*) \mid X) \right| \leq |\theta_1 - \theta_1^*|
\]

\[
|\partial^2_r \mu_2^*(X, t; \theta_1^* + r(\theta_1 - \theta_1^*))| = |\theta_1 - \theta_1^*|^2 |f_t(\theta_1^* + r(\theta_1 - \theta_1^*) \mid X) \leq C |\theta_1 - \theta_1^*|^2.
\]

**Verifying condition vi in Theorem 3**. For any \((\theta_1, \theta_2) \in \Theta,\)

\[
\left\{ \mathbb{P} \left[ \mu_1^*(X, t; \theta_1) \right] \right\}^{1/2} = |F_t(\theta_1 \mid X) - \gamma| \leq 1 \\
\left\{ \mathbb{P} \left[ \mu_2^*(X, t; \theta_1) \right] \right\}^{1/2} = \mathbb{P} \left\{ \left[ \mathbb{E}[\max(Y(t) - \theta_1, 0) \mid X] \right] \right\}^{1/2} \leq C.
\]

By first order Taylor expansion, for any \(\theta_1\) such that \(|\theta_1 - \theta_1^*| \leq \max\left\{ \frac{4C\sqrt{\delta_{\rho, N}}}{\delta_N \varepsilon_n}, \rho_{\theta, N} \right\},\) there exists \(\hat{\theta}_1\) between \(\theta_1\) and \(\theta_1^*\) such that

\[
\left\{ \mathbb{P} \left[ \mu_1^*(X, t; \theta_1) - \mu_1^*(X, t; \theta_1^*) \right] \right\}^{1/2} \leq C |\theta_1 - \theta_1^*| \\
\left\{ \mathbb{P} \left[ \mu_2^*(X, t; \theta_1) - \mu_2^*(X, t; \theta_1^*) \right] \right\}^{1/2} \leq C |\theta_1 - \theta_1^*|.
\]

Moreover, for any \(\theta_1\) such that \(|\theta_1 - \theta_1^*| \leq \max\left\{ \frac{4C\sqrt{\delta_{\rho, N}}}{\delta_N \varepsilon_n}, \rho_{\theta, N} \right\},\)

\[
\mathbb{P} \left\{ \left[ \partial_{\theta_1} \mu_1^*(X, t; \theta_1) \right] \right\}^{1/2} = \mathbb{P} \left\{ \left[ f_t(\theta_1 \mid X) \right] \right\}^{1/2} \leq C, \\
\mathbb{P} \left\{ \left[ \partial_{\theta_1} \mu_2^*(X, t; \theta_1) \right] \right\}^{1/2} = \mathbb{P} \left\{ \left[ F_t(\theta_1 \mid X) - 1 \right] \right\}^{1/2} \leq 1,
\]

\[
\mathbb{P} \left[ \left| \frac{\partial^2}{\partial^2 \theta_1} \mu_1^*(X, t; \theta_1) \right| \right] = \mathbb{P} \left[ \left| f_t(\theta_1 \mid X) \right| \right] \leq C, \\
\mathbb{P} \left[ \left| \frac{\partial^2}{\partial^2 \theta_1} \mu_2^*(X, t; \theta_1) \right| \right] = \mathbb{P} \left[ \left| f_t(\theta_1 \mid X) \right| \right] \leq C,
\]

\[
\left( \partial_{\theta_1} \partial_{\theta_2} V_j(\theta_2) \right) = 0 \leq C.
\]

**Proof for Proposition 5**. We only need to verify the conditions in Theorem 3.

**Verifying condition iii and iv in Theorem 3**. According to Eq. (8), the estimating equation for complete data is given by

\[
U(Y(1); \theta_1) = (1 - \gamma) (Y(1) - \theta_1) - (1 - 2\gamma) \max(Y(1) - \theta_1, 0).
\]
It follows that
\[
\frac{\partial}{\partial \theta_1} \mathbb{P} [U(Y(t); \theta_1)] = -(1 - \gamma) - (1 - 2\gamma) \frac{\partial}{\partial \theta_1} \mathbb{P} [\max (Y(t) - \theta_1, 0)] \\
= -(1 - \gamma) - (1 - 2\gamma) \int_{\theta_1}^{\infty} (y - \theta_1) f_1(y) dy \\
= -(1 - \gamma) + (1 - 2\gamma) \int_{\theta_1}^{\infty} f_1(y) dy \\
= -\gamma - (1 - 2\gamma) F_1(\theta_1).
\]

Here the differentiability of \( \frac{\partial}{\partial \theta_1} \mathbb{P} [U(Y(t); \theta_1)] \) is guaranteed by Leibniz integral rule, the continuity of its derivative at \( \theta_1^* \) is guaranteed by the continuity of \( F_1(\theta_1) \) at \( \theta_1^* \), and \( J(\theta_1^*) = \frac{\partial}{\partial \theta_1} \mathbb{P} [U(Y(t); \theta_1)] \big|_{\theta_1 = \theta_1^*} = -\gamma - (1 - 2\gamma) F_1(\theta_1^*) \), whose singular value \(|-\gamma - (1 - 2\gamma) F_1(\theta_1^*)|\) is bounded between \( c_4^* \) and \( \max \{ \gamma, 1 - \gamma \} \). Moreover, \( \frac{\partial}{\partial \theta_1} \mathbb{P} [U(Y(t); \theta_1)] \leq \max \{ \gamma, 1 - \gamma \} \), which implies that \( \mathbb{P} [U(Y(t); \theta_1)] \) is Lipschitz continuous with Lipschitz constant \( \max \{ \gamma, 1 - \gamma \} \leq 1 \). Therefore, the constants \( c' \) in condition iv of Theorem 3 and constant \( c_3 \) in condition iv of Theorem 3 can be set as \( c_3 = c_4^* \), \( c' = 1 \). The assumption that \( \| \theta - \theta^* \| \geq \frac{c_1}{2\sqrt{d}} \) implies that \( 2\mathbb{P} [U(Y(t); \theta_1)] \geq c_5^* \) for any \( \theta \in \Theta \) ensures the condition iv of Theorem 3 with constant \( c_2 = c_5^* \).

**Verifying condition iv in Theorem 3.** Note that for any \( \theta \in \mathcal{B}(\theta^*; \frac{4C\sqrt{\rho_{\delta, \pi}}}{\delta_N + \varepsilon}) \cap \Theta \),
\[
\mu^*(X, 1; \theta_1^* + r(\theta - \theta_1^*)) = \mathbb{E} [U(Y; \theta_1^* + r(\theta - \theta_1^*)) \mid X, T = 1] \\
= (1 - \gamma) \eta_{\delta, 1}^*(Z) - (1 - 2\gamma) \eta_{\gamma}^*(Z; \theta_1^* + r(\theta - \theta_1^*)).
\]

Thus
\[
|\partial_\theta \mu^*(X, 1; \theta_1^* + r(\theta - \theta_1^*))| = |-\gamma(\theta_1 - \theta_1^*) - (1 - 2\gamma)(\theta_1 - \theta_1^*) F_1(\theta_1^* + r(\theta - \theta_1^*) \mid X)| \\
\leq 2|\theta_1 - \theta_1^*|,
\]
\[
|\partial_\theta^2 \mu^*(X, 1; \theta_1^* + r(\theta - \theta_1^*))| = |1 - 2\gamma| |\theta_1 - \theta_1^*| f_1(\theta_1^* + r(\theta - \theta_1^*) \mid X) \leq C|1 - 2\gamma| |\theta_1 - \theta_1^*|,
\]
which trivially imply condition iv in Theorem 3.

**Verifying condition iv in Theorem 3.** Again
\[
\mu^*(X, 1; \theta_1) = (1 - \gamma) \eta_{\delta, 1}^*(Z) - (1 - 2\gamma) \eta_{\gamma}^*(Z; \theta_1).
\]

The the asserted assumption iv means that \( \left\{ \mathbb{P}[\eta_{\delta, 1}^*(Z)] \right\}^{1/2} \leq C \) and \( \left\{ \mathbb{P}[\eta_{\gamma}^*(Z; \theta_1)] \right\}^{1/2} \leq C \) for any \( \theta \in \text{Theta} \), thus \( \left\{ \mathbb{P}[\mu^*(X, 1; \theta_1)] \right\}^{1/2} \) is upper bounded by \( |1 - \gamma| + |1 - 2\gamma| C \leq 2C \) for any \( \theta \in \text{Theta} \).

Plus, for any \( \theta_1 \in \mathcal{B}(\theta_1^*; \max \{ \frac{4C\sqrt{\rho_{\delta, \pi}}}{\delta_N + \varepsilon}, \rho_{\delta, \pi} \}) \cap \Theta \)
\[
\left\{ \mathbb{P} \left[ \frac{\partial}{\partial \theta_1} \mu^*(X, 1; \theta_1) \right]^2 \right\}^{1/2} \leq \sup_x | -\gamma - (1 - 2\gamma) F_1(\theta_1 \mid X = x) | \leq 2, \\
\mathbb{P} \left[ \frac{\partial^2}{\partial \theta_1^2} \mu^*(X, 1; \theta_1) \right] \leq |1 - 2\gamma| \mathbb{P} [f_1(\theta_1 \mid X)] \leq C|1 - 2\gamma|,
\]

49
and there exists $\tilde{\theta}_1$ between $\theta_1$ and $\theta^*_1$ such that

$$\left\{ P\left[ \mu^*(X, 1; \theta_1) - \mu^*(X, 1; \theta^*_1) \right] = 2|\theta_1 - \theta^*_1| \leq 2|\theta_1 - \theta^*_1| \right\}^{1/2}$$

\[ \begin{align*}
\left\{ P\left[ \mu^*(X, 1; \theta_1) - \mu^*(X, 1; \theta^*_1) \right] \right\}^{1/2} = |\theta_1 - \theta^*_1| \leq 2|\theta_1 - \theta^*_1|.
\end{align*} \]

Proof for Proposition 2. We follow the proof of Theorem 1 to consider any sequence of data generating process $P_N \in \mathcal{P}_N$ but we suppress it for ease of notations. We prove the conclusion for a generic $k \in \{1, \ldots, K\}$. For $l \in \mathcal{H}_{k,1}$, we denote $P_{N,l}$ and $G_{N,l}$ as the empirical average operator and empirical process operator for data in the $D_l$. Throughout the proof, we condition on the event that the convergence rate of propensity score estimator $\hat{\pi}^{(k,l)}$ in mean squared error is $\rho_{\pi,N}$ and it is lower bounded by $\epsilon_\pi$, which holds with at least probability $1 - \Delta_N$ according to Assumption 6. In this proof, all notations $\lesssim$ only involve pre-specified constants and not any instance-dependent constants.

We use the following decomposition analogous to that in Step I of proof for Theorem 1

$$\mathbb{P}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \pi^*) \right] = \frac{1}{K^l} \sum_{l \in \mathcal{H}_{k,1}} \left\{ \mathbb{P}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \pi^*) \right] - \mathbb{P}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \hat{\pi}^{(k,l)}) \right] \right\}$$

$$+ \frac{1}{K^l} \sum_{l \in \mathcal{H}_{k,1}} \left\{ \mathbb{P}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \hat{\pi}^{(k,l)}) \right] - \mathbb{P}_{N,l}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \hat{\pi}^{(k,l)}) \right] \right\}$$

$$+ \frac{1}{K^l} \sum_{l \in \mathcal{H}_{k,1}} \left\{ \mathbb{P}_{N,l}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \hat{\pi}^{(k,l)}) \right] - \mathbb{P}_{N,l}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \hat{\pi}^{(k,l)}) \right] \right\}$$

$$+ \frac{1}{K^l} \sum_{l \in \mathcal{H}_{k,1}} \left\{ \mathbb{P}_{N,l}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \hat{\pi}^{(k,l)}) \right] - \mathbb{P}_{N,l}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \hat{\pi}^{(k,l)}) \right] \right\}$$

By following the Step I of proof for Theorem 1, we can also analogously show that

$$\left\| \mathbb{P}\left[ \psi_{\text{IPW}}(Z; \hat{\theta}^{(k), \text{init}}, \pi^*) \right] \right\| \leq \frac{4}{K^l} \sum_{l \in \mathcal{H}_{k,1}} T_{1,l} + \frac{4}{K^l} \sum_{l \in \mathcal{H}_{k,1}} T_{2,l} + \epsilon_N$$

where

$$T_{1,l} = \sup_{\theta \in \Theta} \left\| \mathbb{P}\left[ \psi_{\text{IPW}}(Z; \theta, \pi^*) \right] - \mathbb{P}\left[ \psi_{\text{IPW}}(Z; \theta, \hat{\pi}^{(k,l)}) \right] \right\|$$

$$T_{2,l} = \sup_{\theta \in \Theta} \left\| \mathbb{P}\left[ \psi_{\text{IPW}}(Z; \theta, \hat{\pi}^{(k,l)}) \right] - \mathbb{P}_{N,l}\left[ \psi_{\text{IPW}}(Z; \theta, \hat{\pi}^{(k,l)}) \right] \right\|. $$
Bounding $I_{1,t}$. Note that by Eq. (22),
\[
I_{1,t} = \| P \left[ \psi_{IPW}(Z; \theta, \hat{\pi}^{(k,l)}) \right] \| \\
= \sup_{\theta \in \Theta} \left\{ \| P \left[ \mu^*(X, t; \theta_1) \left( \hat{\pi}^{(k,l)}(X) - \pi^*(X) \right) \right] \| \right\} \\
= \sqrt{d \rho_{\pi,N}} \max_{l} \left\{ \| P \left[ \mu_j^*(X, t; \theta) \right] \| \right\}^{1/2} \\
\leq C \sqrt{d \rho_{\pi,N}}.
\]

Bounding $I_{2,t}$. Note that
\[
\sqrt{\frac{N}{K'}} I_{2,t} = \sqrt{\frac{N}{K'}} \sup_{\theta \in \Theta} \left\{ \| G_{N,l} \left[ \psi_{IPW}(Z; \theta, \hat{\pi}^{(k,l)}) \right] \| \right\} \\
= \sup_{\theta \in \Theta} \left\{ \| G_{N,l} \left[ \psi_{IPW}(Z; \theta, \hat{\pi}^{(k,l)}) \right] \| \right\} \\
\]
Given that condition vi in Assumption 2 is satisfied for the estimating equation $\psi_{IPW}$, we can follow the end of step I in the proof for Theorem 1 to prove that with $P_N$ probability $1 - c (\log N)^{-1}$ for a constant $c$ that depends only on constants in the assumptions,
\[
\sup_{\theta \in \Theta} \left\{ \| G_{N,l} \left[ \psi_{IPW}(Z; \theta, \hat{\pi}^{(k,l)}) \right] \| \right\} \lesssim \log \left( \frac{N}{K'} \right) + \left( \frac{N}{K'} \right)^{-1/2 + 1/q'} \log \left( \frac{N}{K'} \right),
\]
so that $I_{2,t} \lesssim \left( \frac{K'}{N} \right)^{1/2} \log \left( \frac{K'}{N} \right) + \left( \frac{K'}{N} \right)^{1 - \frac{1}{q'}} \log \left( \frac{K'}{N} \right) < \rho_{\pi,N}$.

Therefore, with $P_N$-probability $1 - c (\log N)^{-1},$
\[
P \left[ \psi_{IPW}(Z; \hat{\theta}_{init}^{(k)}, \pi^*) \right] \leq \left( \frac{C \sqrt{d}}{\epsilon_{\pi}} + 1 \right) \rho_{\pi,N}.
\]

In the proof of Theorem 3 we have showed that conditions iii and iv in Theorem 3 imply that
\[
\| J^* (\hat{\theta}_{init}^{(k)} - \theta^*) \| \wedge c_0 \leq 2 \left\{ \| \psi_{IPW}(Z; \hat{\theta}_{init}^{(k)}, \pi^*) \| \right\} \leq 2 \left( \frac{C \sqrt{d}}{\epsilon_{\pi}} + 1 \right) \rho_{\pi,N}.
\]

Therefore, with probability $1 - c (\log N)^{-1},$
\[
\rho_{\theta,N} = \left\| \hat{\theta}_{1,init}^{(k)} - \theta^* \right\| \leq \left\| \hat{\theta}_{init}^{(k)} - \theta^* \right\| \leq \frac{2}{c_3} \left( \frac{C \sqrt{d}}{\epsilon_{\pi}} + 1 \right) \rho_{\pi,N}.
\]

\[\square\]

A.5 Proof for Section 6

Proof for Proposition 6. We note that the structure of the estimating equation in Eq. (4) is very similar to the estimating equation in Eq. (6) except that we have one extra scalar nuisance $\nu^* = \nu_{2,2}^{*}$.
in the denominator. So our proof for Proposition 6 is largely analogous to the proof for Theorem 3.

Verifying Assumption 1. Then adapt these results to LQTE by further relying on the fact that we may estimate it without sample splitting, we need to replace \( \mathcal{I}_{2,k} \) and \( \mathcal{I}_{5,k} \) in the step I and II of the proof for Theorem 4 by the following terms:

\[
\mathcal{I}_{2,k} = \sup_{\theta \in \Theta, \nu \in [e,1]} |\mathbb{P}_{N,k} \left[ \psi(Z; \theta, \hat{\mu}^{(k)}(Z, \hat{\theta}^{(k)}_{1,\text{init}}), \hat{\pi}^{(k)}(Z), \nu) - \mathbb{P}[\psi(Z; \theta, \hat{\mu}^{(k)}(Z, \hat{\theta}^{(k)}_{1,\text{init}}), \hat{\pi}^{(k)}(Z), \nu) \right] |
\]

\[
\mathcal{I}_{5,k} = \sup_{\|\theta - \theta^*\| \leq \tau_N, \nu \in [e,1]} |\mathbb{G}_{N,k} \left[ \psi(Z; \theta, \hat{\mu}^{(k)}(Z, \theta^*_1), \hat{\pi}^{(k)}(Z), \nu) - \psi(Z; \theta, \hat{\mu}^{(k)}(Z, \hat{\theta}^{(k)}_{1,\text{init}}), \hat{\pi}^{(k)}(Z), \nu) \right] |
\]

These can be ensured by limiting the metric entropy of the function class \( \{\psi(Z; \theta_1, \hat{\mu}(X; \theta_1), \hat{\pi}(X), \nu) : \theta_1 \in \Theta, \nu \in (e,1]\} \)

for any possible realization \( \hat{\mu}(X; \theta_1), \hat{\pi}(X) \) of the nuisance estimators \( \hat{\mu}^{(k)}(Z, \theta^*_1), \hat{\pi}^{(k)}(Z) \). We will prove that this is satisfied for estimating LQTE. Moreover, when verifying other conditions in Assumptions 1 to 3, we mainly use the fact that \( \nu \psi(Z; \theta, \hat{\mu}(Z, \theta^*_1), \hat{\pi}(Z), \nu) \) is similar to the estimating equation in Eq. (9) so that we can apply the proof for Theorem 3 to \( \nu \psi(Z; \theta, \hat{\mu}(Z, \theta^*_1), \hat{\pi}(Z), \nu) \) and then adapt these results to LQTE by further relying on the fact that \( \nu^*, \nu \in [e,1] \).

Verifying Assumption 1. Note that

\[
J^* = \partial_{\theta_1} \left\{ \mathbb{P} \left[ \psi(Z; \theta_1, \eta^*_1(Z, \theta_1), \eta^*_2(Z)) \right] \right\} |_{\theta = \theta^*} = 0
\]

\[
J^*(\theta_1) = \partial_{\theta_1} \left\{ \mathbb{P} \left[ \psi(Z; \theta_1, \eta^*_1(Z, \theta_1), \eta^*_2(Z)) \right] \right\} |_{\theta = \theta^*}
\]

where the second and third equality follow because \( \mathbb{P} \left[ \frac{W - \hat{\pi}^{(k)}(X)}{\hat{\pi}^{(k)}(X)} \hat{\mu}^{(k)}(X; \theta_1) \right] = 0 \) for \( w = 0, 1 \).

Verifying Assumption 2. Given that \( \mathbb{P} \left[ \psi(Z; \theta_1, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z)) \right] = F_t(\theta_1 \mid C) \) and that \( F_t(\theta_1 \mid C) \) is twice continuously differentiable, condition 3 in Assumption 2 holds.

Note that

\[
J(\theta_1) = \partial_{\theta_1} \mathbb{P} \left[ \psi(Z; \theta_1, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z)) \right] = \partial_{\theta_1} F_t(\theta^*_1 \mid C) = f_t(\theta^*_1 \mid C) \in [c_3, c_4].
\]

Thus condition 3 in Assumption 2 is satisfied.

Since \( f_t(\theta_1 \mid C) \leq c' \), we have that \( J(\theta_1) \) is Lipschitz continuous with a Lipschitz constant \( c' \). Moreover, for any \( \theta_1 \) satisfying \( |\theta_1 - \theta^*_1| \geq \frac{c_2}{c_0} \), our condition ensures that \( 2 \mathbb{P} \left[ \psi(Z; \theta_1, \eta^*_1(Z, \theta^*_1), \eta^*_2(Z)) \right] -
\( P [ \psi (Z; \theta_1^*, \eta_1^*(Z; \theta_1^*), \eta_2^*(Z)) | = 2 | F_1 (\theta_1 | C) - F_1 (\theta_1^* | C) | \geq c_2 \). Thus \( J (\theta_1) \) satisfies condition \( \text{iii} \) in Theorem 3. It follows from the proof of Theorem 3 that condition \( \text{iii} \) in Assumption 2 is satisfied.

We now show a stronger version of \( \text{vi} \) in Assumption 2. We rewrite the estimating equation on \( \psi(Z; \theta_1, \tilde{\mu}(X; \theta_1), \tilde{\pi}(X), \nu) \). For any \( \tilde{\mu}, \tilde{\pi} \), consider the following function class

\[
\tilde{\mathcal{F}}_{\tilde{\mu}, \tilde{\pi}} = \{ \psi(Z; \theta_1, \tilde{\mu}(X; \theta_1), \tilde{\pi}(X), \nu) : \theta_1 \in \Theta, \nu \in (\epsilon, 1) \}. 
\]

Since \( I [T = 1, Y \leq \theta_1] \) is bounded and \( \nu^* \) is bounded and not equal to 0, we know that \( \tilde{\mathcal{F}}_{\tilde{\mu}, \tilde{\pi}} \) satisfies the metric entropy condition in \( \text{vi} \) of Assumption 2 as well.

Finally we prove condition \( \text{vii} \) in Assumption 2. By following the proof of Theorem 3, we can analogously prove that

\[
\partial_r \left\{ P \psi(Z; \theta_1^*, \tilde{\mu}^*(X; \theta_1^*) + r(\tilde{\mu}^*(X; \theta_1^*) - \tilde{\mu}^*(X; \theta_1^*)), \tilde{\pi}^*(X) + r(\tilde{\pi}^*(X) - \tilde{\pi}^*(X)), \nu^* \right\} \bigg|_{r = 0} = 0.
\]

Moreover, we can verify that

\[
\partial_r \left\{ P \psi(Z; \theta_1^*, \tilde{\mu}^*(X; \theta_1^*) \tilde{\pi}^*(X), \nu^* + r(\nu - \nu^*) \right\} \bigg|_{r = 0} = -\frac{1}{\nu^*} P \psi(Z; \theta_1^*, \tilde{\mu}^*(X; \theta_1^*) \tilde{\pi}^*(X), \nu^*)(\nu - \nu^*) = 0.
\]

Verifying Assumption 3. Consider the nuisance realization set \( \mathcal{T}_N \) that contains all elements \((\hat{\mu}_1(X; \theta_1^*), \hat{\mu}_0(X; \theta_1^*), \tilde{\pi}, \theta_1^*, \nu) \) that satisfy the following condition:

\[
\left\{ \left( P \left[ \tilde{\mu} \left( X; \hat{\theta}_{1, \text{init}} \right) \right] - \tilde{\mu}^* \left( X; \hat{\theta}_{1, \text{init}} \right) \right) \right\}^{1/2} \leq \tilde{\rho}_{\mu, N}, \quad w = 0, 1
\]

\[
\left\{ P \left[ \tilde{\pi} (X) - \tilde{\pi}^*(X) \right]^{2} \right\}^{1/2} \leq \tilde{\rho}_{\pi, N}, \quad \| \theta_1^* - \theta_1^* \| \leq \tilde{\rho}_{\theta, N}, \quad | \nu - \nu^* | \leq \rho_{\nu, N}, \quad \tilde{\pi} (X) \geq \epsilon, \quad \nu \geq \epsilon.
\]

Then \((\hat{\mu}_1(X; \theta_1^*), \hat{\mu}_0(X; \theta_1^*), \tilde{\pi}, \hat{\theta}_{1, \text{init}}, \tilde{\nu}) \in \mathcal{T}_N \) with probability at least \( 1 - \Delta_N \) according to Assumption 8 i.e., condition \( \text{ii} \) in Assumption 3 is satisfied.

We next verify the condition on \( r_N \). First, note that the form of \( \nu \psi(Z; \theta_1, \tilde{\mu}(X; \theta_1), \tilde{\pi}(X), \nu) \) is very close to the form of the estimating equation in Eq. (9). Thus we can follow the proof of Theorem 3 to show that

\[
\sup_{(\hat{\mu}_1(X; \theta_1^*), \hat{\mu}_0(X; \theta_1^*), \tilde{\pi}, \theta_1^*, \nu) \in \mathcal{T}_N, \theta_1 \in \Theta} \left| \nu^* P \left[ \psi(Z; \theta_1, \tilde{\mu}(X; \theta_1), \tilde{\pi}(X), \nu) \right] - \nu^* P \left[ \psi(Z; \theta_1^*, \tilde{\mu}^*(X; \theta_1), \tilde{\pi}^*(X), \nu^*) \right] \right| \leq 8 C \rho_{\pi, N} \frac{\delta_N \epsilon}{\epsilon}
\]

It follows that

\[
\sup_{(\hat{\mu}_1(X; \theta_1^*), \hat{\mu}_0(X; \theta_1^*), \tilde{\pi}, \theta_1^*, \nu) \in \mathcal{T}_N, \theta_1 \in \Theta} \left| P \left[ \psi(Z; \theta_1, \tilde{\mu}(X; \theta_1), \tilde{\pi}(X), \nu) \right] - P \left[ \psi(Z; \theta_1^*, \tilde{\mu}^*(X; \theta_1), \tilde{\pi}^*(X), \nu^*) \right] \right| \leq \sup_{(\hat{\mu}_1(X; \theta_1^*), \hat{\mu}_0(X; \theta_1^*), \tilde{\pi}, \theta_1^*, \nu) \in \mathcal{T}_N, \theta_1 \in \Theta} \frac{8 C \rho_{\pi, N}}{\delta_N \epsilon^2} + \frac{|\nu - \nu^*|}{\nu} \left| P \left[ \psi(Z; \theta_1^*, \tilde{\mu}^*(X; \theta_1), \tilde{\pi}^*(X), \nu^*) \right] \right| \leq \frac{8 C \rho_{\pi, N}}{\delta_N \epsilon^2}
\]

where the last inequality holds because \( \nu \geq \epsilon \) and \( P \left[ \psi(Z; \theta_1^*, \tilde{\mu}^*(X; \theta_1), \tilde{\pi}^*(X), \nu^*) \right] = 0 \). Therefore, the condition on \( r_N \) is satisfied with \( \tau_N = \frac{8 C \rho_{\pi, N}}{\delta_N \epsilon^2} \).
Next, we verify the condition on $r_N'$. By following the proof of Theorem 3 and Proposition 3, we can again prove that under condition 2

$$\sup_{(\tilde{\mu}_1(X;\theta'_1),\tilde{\rho}_0(X;\theta'_1),\tilde{\pi},\nu')\in T_N,\theta_1\in\Theta} \left( \mathbb{P} \left[ \nu \psi(Z;\theta_1,\tilde{\mu}(X;\theta_1),\tilde{\pi}(X),\nu) - \psi(Z;\theta_1^*,\tilde{\mu}^*(X;\theta_1),\tilde{\pi}^*(X),\nu^*) \right] \right) \leq \frac{8C^2\rho_{\pi,N}}{\delta_N\epsilon^2} + \frac{4}{\epsilon} (\rho_{\mu,N} + C\rho_{\theta,N}) + \frac{4}{\epsilon^2} (\rho_{\mu,N} + C\rho_{\theta,N})$$

Thus

$$\sup_{(\tilde{\mu}_1(X;\theta'_1),\tilde{\rho}_0(X;\theta'_1),\tilde{\pi},\nu')\in T_N,\theta_1\in\Theta} \left( \mathbb{P} \left[ \psi(Z;\theta_1,\tilde{\mu}(X;\theta_1),\tilde{\pi}(X),\nu) - \psi(Z;\theta_1^*,\tilde{\mu}^*(X;\theta_1),\tilde{\pi}^*(X),\nu^*) \right] \right) \leq \frac{8C^2\rho_{\pi,N}}{\delta_N\epsilon^2} + \frac{4}{\epsilon^2} (\rho_{\mu,N} + C\rho_{\theta,N}) + \frac{4}{\epsilon^2} (\rho_{\mu,N} + C\rho_{\theta,N})$$

By the fact that $\nu,\nu^* \in [\varepsilon,1]$, $\tilde{\mu}_w(X;\theta_1) \in [0,1]$, $\tilde{\pi}(X) \in [\varepsilon,1]$, we can easily verify that

$$\sup_{(\tilde{\mu}_1(X;\theta'_1),\tilde{\rho}_0(X;\theta'_1),\tilde{\pi},\nu')\in T_N,\theta_1\in\Theta} (\nu - \nu^*) \mathbb{P} \left[ \psi(Z;\theta_1^*,\tilde{\mu}^*(X;\theta_1),\tilde{\pi}^*(X),\nu^*) \right] \leq \frac{1}{\epsilon} + \frac{2}{\epsilon^2} \rho_{\nu,N}$$

Therefore,

$$\sup_{(\tilde{\mu}_1(X;\theta'_1),\tilde{\rho}_0(X;\theta'_1),\tilde{\pi},\nu')\in T_N,\theta_1\in\Theta} \left( \mathbb{P} \left[ \psi(Z;\theta_1,\tilde{\mu}(X;\theta_1),\tilde{\pi}(X),\nu) - \psi(Z;\theta_1^*,\tilde{\mu}^*(X;\theta_1),\tilde{\pi}^*(X),\nu^*) \right] \right) \leq \frac{8C^2\rho_{\pi,N}}{\delta_N\epsilon^3} + \frac{4}{\epsilon^2} (\rho_{\mu,N} + C\rho_{\theta,N}) + \frac{4}{\epsilon^2} (\rho_{\mu,N} + C\rho_{\theta,N}) + \frac{3}{\epsilon^2} \rho_{\nu,N}$$

So when $\rho_{\pi,N} \leq \frac{\delta_N^2}{\log N}$, and $\rho_{\mu,N} + C\rho_{\theta,N} \leq \frac{\delta_N^2}{\log N}$, and $\rho_{\nu,N} \leq \frac{\delta_N^2}{\log N}$, $r_N' = \frac{\delta_N^2}{\epsilon^3 \log N} (8C^2 + 11) \leq \frac{\delta_N^2}{\log N}$ if $\delta_N \leq \frac{\delta_N^2}{8C^2 + 11}$.

Finally, we verify the condition on $\lambda_N'$. Note that we can follow the proof of Theorem 3 to show that for any $\theta_1$ such that $|\theta_1 - \theta_1^*| \leq \frac{8C^2\rho_{\pi,N}}{\delta_N\epsilon^2}$,

$$\partial^2 \left\{ \mathbb{P} \left[ \psi(Z;\theta_1^*,\tilde{\mu}^*(X;\theta_1^*) + r(\tilde{\mu}^*(X;\theta_1) - \tilde{\mu}^*(X;\theta_1^*)),\tilde{\pi}^*(X) + r(\tilde{\pi}(X) - \tilde{\pi}^*(X)),\nu^* \right] \right\} \leq \frac{6}{\epsilon^3} \rho_{\pi,N} (\rho_{\mu,N} + C\rho_{\theta,N}) + \frac{8C^2}{\epsilon^3 \rho_{\pi,N}} |\theta_1 - \theta_1^*| + \frac{2C}{\epsilon^2} \rho_{\pi,N} |\theta_1 - \theta_1^*|,$$

and

$$\partial^2 \left\{ \mathbb{P} \left[ \psi(Z;\theta_1^*,\tilde{\mu}^*(X;\theta_1^*),\tilde{\pi}^*(X),\nu^* + r(\nu - \nu^*)) \right] \right\} = \frac{\mathbb{P} \left[ \psi(Z;\theta_1^*,\tilde{\mu}^*(X;\theta_1^*),\tilde{\pi}^*(X),\nu^*) \right]}{2\nu^3} (\nu - \nu^*)^2 = 0,$$
and
\[ \partial_{\nu} \partial_{\nu} \{ \mathbb{P}(\psi(Z; \theta_1^*, \mu^*(X; \theta_1^*) + r(\hat{\mu}(X; \theta_1^*) - \mu^*(X; \theta_1^*)), \pi^*(X), \nu^* + r'(\nu - \nu^*)) \} = - \frac{(\nu - \nu^*)}{\nu^* + r'(\nu - \nu^*)} \partial_{\nu} \{ \mathbb{P}(\psi(Z; \theta_1^*, \mu^*(X; \theta_1^*) + r(\hat{\mu}(X; \theta_1^*) - \mu^*(X; \theta_1^*)), \pi^*(X), \nu^*) \} = 0, \]
and
\[ \partial_{\nu} \partial_{\nu} \{ \mathbb{P}(\psi(Z; \theta_1^*, \mu^*(X; \theta_1^*), \pi^*(X) + r(\hat{\pi}(X) - \pi^*(X)), \nu^* + r'(\nu - \nu^*)) \} = - \frac{(\nu - \nu^*)}{\nu^* + r'(\nu - \nu^*)} \partial_{\nu} \{ \mathbb{P}(\psi(Z; \theta_1^*, \mu^*(X; \theta_1^*, \pi^*(X) + r(\hat{\pi}(X) - \pi^*(X)), \nu^*) \} = 0. \]

Given \( \rho_{\pi,N} \leq \frac{\delta^3}{\log N} \), when \( \frac{\delta_{\pi,N}}{\log N} \leq \frac{c^3}{16C^2} \) and \( \frac{\delta_{\pi,N}}{\log N} \leq \frac{c^4}{4C^2} \), \( \frac{8C^2}{c^3} \rho_{\pi,N}(\theta_1 - \theta_1^*) + \frac{2C}{c^3} \rho_{\pi,N}(\theta_1 - \theta_1^*) \leq \delta_{N}(\theta_1 - \theta_1^*). \) Moreover, when \( \rho_{\pi,N}(\rho_{\mu,N} + C \rho_{\theta_2,N}) \leq \frac{c^3}{4C^2} \delta_{N}N^{-1/2} \), \( \frac{4}{c^3} \rho_{\pi,N}(\rho_{\mu,N} + C \rho_{\theta_2,N}) \leq \delta_{N}N^{-1/2} \). Consequently,
\[ \partial_{\nu}^{2} \{ \mathbb{P}(\psi(Z; \theta_1^*, \mu^*(X; \theta_1^*) + r(\hat{\mu}(X; \theta_1^*) - \mu^*(X; \theta_1^*)), \pi^*(X) + r(\hat{\pi}(X) - \pi^*(X)), \nu^* + r(\nu - \nu^*)) \} \leq \delta_{N}(\|\theta - \theta^*\| + N^{-1/2}). \]

\[ \square \]

B Comparison with \cite{chernozhukov2018double}.

Our proof of Theorem 1 and the proof of Theorem 3.3 in \cite{chernozhukov2018double} are overall similar, but critically differ in Step II. In Step II, both proofs are based on the following decomposition:
\[ \|J^{-1}\sqrt{N}\mathbb{P}_{N}[\psi(Z; \theta^*, \eta^*_1(Z, \theta_1^*), \eta^*_2(Z))] + \sqrt{N}(\hat{\theta} - \theta^*)\| \leq \varepsilon_{N}N^{1/2} + 2\mathcal{I}_4 + 2\mathcal{I}_5, \] (37)
where
\[ \mathcal{I}_4 := \sqrt{N} \sup_{r \in (0,1), (\eta_1(\cdot, \cdot), \eta_2) \in \mathcal{T}_N} \|\partial^2 f(r; \hat{\theta}, \eta_1(\cdot, \cdot), \eta_2)\|, \]
\[ \mathcal{I}_5 := \mathcal{G}_N \left[ \psi(Z; \hat{\theta}, \hat{\eta}_1(Z, \hat{\theta}_{1, \text{init}}), \hat{\eta}_2(Z)) - \psi(Z; \theta^*, \eta^*_1(Z, \theta_1^*), \eta^*_2(Z)) \right], \]
and \( \mathcal{I}_5 = O_{p}(\delta_{N}) \) is proved analogously in both proofs.

However, our proof and the proof in \cite{chernozhukov2018double} assume different rate on \( \lambda_{N} \) and thus \( \mathcal{I}_4 \):
\[ \text{Our condition} \quad \lambda_{N} \leq \left( \|\hat{\theta} - \theta^*\| + N^{-1/2} \right) \delta_{N} \] (38)
\[ \text{Condition in} \quad \lambda_{N} \leq N^{-1/2} \delta_{N} \] (39)

Under our condition, \( \mathcal{I}_4 \leq \left( \sqrt{N}\|\hat{\theta} - \theta^*\| + 1 \right) \delta_{N} \), then jointly considering the left hand side and right hand side in Eq. (37) gives \( \|\hat{\theta} - \theta^*\| = O_{p}(N^{-1/2}) \), which in turn implies that \( \mathcal{I}_4 = O(\delta_{N}) \), and thus the asserted conclusion in Theorem 1. In contrast, the counterpart condition in \cite{chernozhukov2018double} guarantees that \( \mathcal{I}_4 = O(\delta_{N}) \) directly without needing to consider both sides of Eq. (37) jointly.
Now we use the example of estimating equation for incomplete data to show that the condition Eq. (39) in Chernozhukov et al. [2018a] generally requires stronger conditions for the convergence rates of nuisance estimators than our condition Eq. (38).

According to Eq. (36), under suitable regularity conditions,

$$
\| \partial^2 f(r; \hat{\theta}, \mu(X, T; \theta_1'), \pi) \| = O(\rho_{\pi,N}\rho_{\mu,N}) + O(\| \hat{\theta} - \theta^* \|^2) + O(\rho_{\pi,N}\| \hat{\theta}_1 - \theta_1^* \|)
$$

Since Step I in the proof of Theorem 1 already proves that $\| \hat{\theta} - \theta^* \| \leq \frac{\rho_{\pi,N}}{\delta_N}$, we need $\rho_{\pi,N}\rho_{\mu,N} \leq \delta_N N^{-1/2}$, $\rho_{\pi,N}\rho_{\theta,N} \leq \delta_N N^{-1/2}$, and $\rho_{\pi,N} \leq \delta_N$ to guarantee our condition. Thus our condition in Eq. (38) only requires that the product error rates to vanish faster than $O(N^{-1/2})$, which is common in debiased machine learning for linear estimating equation Chernozhukov et al. [2018a].

In contrast, to guarantee the condition in Chernozhukov et al. [2018a] given in Eq. (39), we need to assume that $\rho_{\pi,N} \leq \delta_N^{3/2} N^{-1/4}$, besides the conditions on product error rates. Therefore, following the proof in Chernozhukov et al. [2018a] directly will require the propensity score to converge faster than $O(N^{-1/4})$, no matter how fast the initial estimator $\hat{\theta}_{1,\text{init}}$ and the regression estimator $\hat{\mu}(\cdot, \hat{\theta}_{1,\text{init}})$ converge.
