This work analyzes the adiabatic decoherence of a many-body system coupled with a boson field. The studied system is a partition of equivalent elements with strong interactions within each element and no direct interaction between different elements, coupled with a common boson bath. This model aims to feature the decoherence mechanism that arises when the only interplay between different elements comes from the coupling of each element with a common environment. We restrict the analysis to “local” observables compatible with the anisotropy of the observable system, that is, to operators whose expectation values can be put in terms of a density operator reduced both over the environment (as usual in the spin-boson model) and also reduced to a single, representative element of the partition. Such condensed density matrix undergoes irreversible decoherence, which depends on an exponential decay represented by a function $\Gamma(t)$ and on a phase factor $\Upsilon(t)$. The first function depends on the temperature and the second does not, while both depend on the on the eigenvalues of the system-environment Hamiltonian (eigenselectivity). As a novel result, we find that the phase factor involves a macroscopic sum over all possible configurations of states in all the partition elements (except the representative one). This reference to the entire system introduces a relevant decay in the absolute value of the matrix elements. The result is applied to a system of spin 1/2 pairs in the context of solid state NMR. We estimate the decoherence rates in terms of physical constants of the model and find that it is mainly governed by the phase factor and its numerical value is remarkably similar to the experiment.

I. INTRODUCTION

Observed systems can rarely be considered as strictly isolated in nature; virtually all systems are subject to the action of some environment. The physical processes that lead a system to final equilibrium with a reservoir or environment can be in some cases extremely slow due to the inefficiency of relaxation mechanisms, even so, quantum coherences can vanish in an early time scale, before thermalization processes have any effect. This phenomenon, known as adiabatic quantum decoherence, is of great importance in quantum information processing technology, since it involves a rapid and irreversible loss of available quantum information in many-body systems, induced by the environment, even when the energy can in practice be conserved [1, 2]. Also, from the basic point of view, understanding adiabatic decoherence is a stimulating challenge, as it is a purely quantum process, associated with other quantum manifestations such as system-environment entanglement or multi-partite quantum correlations, and therefore linked to the very foundations of the theory. Decoherence has even be posed as the mechanism that selects the “preferred basis” in the context of quantum measurement [3, 4]. These fundamental problems demand to study the characteristics that the system-environment coupling must have in order to stand as the universal vehicle of quantum decoherence during the measurement process [5]. In this sense, both fundamentals and applications of many-body systems call for a description of quantum decoherence agents which allows a quantitative calculation of the decoherence rates in terms of physical properties of the observed system and the environment.

A widely used model for studying adiabatic decoherence is that of a qubit or spin coupled with a boson bath (spin-boson model). Such model provides an exact closed master equation for the density matrix in the adiabatic case (“pure dephasing”) that can be studied in the Markovian and non-Markovian regimes [6]. A different theoretical strategy is needed when the many-body character of the observed system plays a relevant role. An important experimental example where a system of qubits evolves in contact with a reservoir is provided by nuclear spins in solid-state and liquid crystal Nuclear Magnetic Resonance (NMR), where the system-environment interaction as well as the many-body character of the interacting spins can not be overlooked.

The NMR experimental setup allows tracking the spin dynamics along the different timescales imposed by the system-environment Hamiltonian. The long term spin-lattice relaxation processes that bring the spin system to thermal equilibrium with the environment, starting from a non equilibrium initial state, are very well understood in terms of thermal fluctuations of the environment (or lattice) [7]. The fact that the energy transfer involved in spin-lattice relaxation is a slow mechanism in comparison with the characteristic time scale of the NMR signals in solid-state experiments, led many to assume that the early spin dynamics before relaxation can be considered as that of a truly closed system which undergoes a unitary evolution [8, 9].

However, decoherence processes can affect the spin dynamics in a timescale much shorter than that of spin-lattice relaxation, and NMR techniques also allow to
scrutinize the spin dynamics within this time scale. Particularly, there is a set of pulse sequences with the effect of reversing the evolution under the dipole-dipole interaction Hamiltonian (hence known as time reversal sequences) [10]. The reversed signal amplitude attenuates irreversibly for increasing refocusing times and it has been proved that the decay cannot be ascribed to experimental misadjustments, nor to the non-reversed terms of the evolution Hamiltonian [11-13]. This phenomenon has been called decoherence in the NMR literature, since it concerns the decay of coherences (off-diagonal elements of the density matrix), and takes place over a time range much shorter than $T_1$.

Likewise, it is feasible to prepare and observe states of quasi-equilibrium, which the system attains over an early time scale, depending on the initial condition (ref. [14, 15]). In these states the dynamics of the NMR observables is described through a density matrix diagonal-in-blocks in the eigenbasis of the system-environment interaction Hamiltonian [14-16]. On a longer timescale these states relax to thermal equilibrium. The times needed for establishing quasi-equilibrium are experimentally similar to those of decoherence, suggesting that both phenomena have the same origin and mechanisms. So far, a quantitative theoretical explanation of decoherence in terms of identifiable physical processes has not yet been established.

The work of ref. [17] presented a theoretical approach based on the spin-phonon model to describe the irreversible decoherence in a system of dipole interacting spin pairs, adiabatically coupled with a phonon bath. In that approach, the system-bath interaction is given by the variation of dipole intra-pair energy due to the coupling with a phonon environment, which in turn correlates different pairs through their collective dynamics. Treating the observed spins as an open quantum system imposes an irreversible decay of the off-diagonal elements of the density matrix (in the basis of the interaction Hamiltonian). Physically, it reflects the interplay of two opposite tendencies: the internal spin dynamics promotes the build-up of multiple correlations while adiabatic decoherence degrades them with an efficiency that increases with the coherence order. This subtle mechanism should affect, in turn, the expectation values of the observable quantities.

The decoherent density matrix obtained in [17] was used to study the spin system purity, which can be conceived as an upper bound for the macroscopic observable magnetization (NMR signal amplitude) in a time-reversal NMR experiment [12]. The purity decoherence rate yielded by this model has a clear dependence on the main dipolar coupling strength, while is practically independent of the sample temperature. Both attributes agree with experimental decoherence rates of refocused NMR signals. Even when this approach allows estimating an upper bound and not a quantitative calculation from first principles, the qualitative agreement with the experiment suggests that the spin-phonon coupling provides a relevant decoherence mechanism for the irreversible decay of coherences. The magnitude of this upper bound strongly depends on the number of correlated spins at a given time, and this number is definitely controlled by the “spin-flip” terms of the dipolar Hamiltonian. resorting to reasonable hypotheses on the growth velocity of the number of correlated $^1H$ spins, based on studies of multiple quantum coherence in crystals with uniformly distributed spins [15], the upper bound from this model falls in a range compatible with experimental decoherence rates.

However, irreversible attenuation of coherences is a prevalent phenomenon, also observed in materials where the symmetry and interactions among spins may not ensure the long-range connectivity (via spin-flip terms) needed for the former mechanism to be dominant. For this reason, we aim to widen the study to other possible decoherence mechanisms. In this work we focus on decoherence in the kind of system where a partition in equivalent elements can be clearly identified, and where the interactions within each element are much stronger than between different elements. In this way we explore conditions that can be thought as an opposite limit of that analyzed in ref. [17], where decoherence efficiency is linked to the dynamics governed by the dipolar spin-flip terms, which enable the growth of multi-spin correlations. On the contrary, we now focus to models where such capability is inhibited by a clusterized distribution of the observed system [19, 20].

The attributes described above are not uncommon in nature, for example partly deuterated crystals [19], and natural hydrated crystals present much of these characteristics: in gypsum (dihydrated calcium sulfate) or POMH (hydrated phosphate oxalate), the nuclear spins of hydrogens of hydration water constitute a network of tightly dipole-coupled spin pairs, with weak inter-pair magnetic interaction. This kind of spin system can be treated as an ensemble of weakly interacting spin pairs from the viewpoint of many NMR experiments [15, 21]. The spin magnetization and the intra-pair dipolar energy are examples of local observables that can be described through this model. In sect. [11, 12] we derive the density matrix needed for calculating the time evolution of the expectation values of local observables, namely, operators that act separately on each element of the partition. Such density matrix is obtained by tracing over the environment and over the states of all the partition elements but a representative one. This quest can be given a rigorous treatment, hence, models like this can be used as a testbed for studying quantum correlations in real many-body systems.

The example analyzed in Section [11] allows obtaining an estimate of the decoherence rate on a concrete model that closely approximates the case of weakly interacting spin pairs in hydrated crystals. The selected example allows us to visualize that decoherence in this type of many-body system is controlled by quantum properties of collective nature, corresponding to a partition whose
elements interact only through a common quantum environment. What we learn from this simple case allows us to improve our understanding of the nature of quasi-equilibrium states, since the essence of the phenomenon is already present in this case. Other situations of greater complexity than the case discussed here, such as an ensemble of weakly interacting partition elements, could be treated in a similar framework as generalizations of the present approach.

II. DYNAMICS OF AN OBSERVED SYSTEM COUPLED WITH A BOSON BATH

We consider an open quantum system $S$ which can in principle be addressed, prepared and measured in contact with an environment or bath $E$ that cannot be observed nor controlled. This work focuses on observable systems $S$ that can be viewed as a partition of equivalent elements, where the interactions within each element are much stronger than between different elements.

Let us call $\mathcal{H}_S$ and $\mathcal{H}_E$ to the Hilbert spaces of the system and environment, respectively. A basis for the compound system can be written as

$$\{ |s,e\rangle \equiv |s\rangle \otimes |e\rangle \}.$$  \hspace{1cm} (1)

Since only $S$ is accessible to measurement, the relevant observables have the form $Q = Q^{(s)} \otimes 1^{(e)}$, where the superscripts indicate the space ($\mathcal{H}_S$ or $\mathcal{H}_E$) where each operator acts on. The expectation value of such operator on a state $\rho(t)$ of the compound system can also be written in terms of $\rho^{(s)}(t)$, the density operator reduced over the environment variables (see Appendix A)

$$\langle Q \rangle (t) = \text{Tr} \{ Q \rho(t) \} = \text{Tr}_S \left\{ Q^{(s)} \rho^{(s)}(t) \right\},$$  \hspace{1cm} (2)

where $\text{Tr}_S \{ . \}$ stands for the trace over the $S$ variables, and

$$\rho^{(s)}(t) \equiv \sum_e \langle e | \rho(t) | e \rangle = \text{Tr}_E \{ \rho(t) \}.$$  \hspace{1cm} (3)

We are interested in describing observed systems which admit a partition on $N$ equivalent elements. In consonance with this attribute, we now consider a kind of observables on $\mathcal{H}_S$, which may be called “local observables”, having the form

$$O^{(s)} = \sum_{A=1}^N O_A^{(s)} = \sum_A 1^{(1)} \otimes \cdots \otimes O_A^{(A)} \otimes \cdots \otimes 1^{(N)},$$  \hspace{1cm} (4)

where $A = 1, \cdots, N$ labels the partition elements, and the superscripts (.) indicate the subspace where each operator belongs.

Experimental techniques frequently deal with observables $O^{(s)}$ which measure the same magnitude on each partition element, that is $O^{(1)} = \cdots = O^{(A)} = \cdots = O^{(N)}$. An example of a local observable is the transverse magnetization in NMR experiments.

Let us write the observed Hilbert space in a condensed form as

$$\mathcal{H}_S = \mathcal{H}_A \otimes \mathcal{H}_A,$$  \hspace{1cm} (5)

where $\mathcal{H}_A$ is the Hilbert space of a particular partition element and $\mathcal{H}_A$ the Hilbert space of all the other elements $A_1, \cdots, A_{N-1}$ into which $\mathcal{H}_S$ is partitioned. Let

$$\{ |m\rangle \} \equiv \{ |a, \bar{a}\rangle \}$$  \hspace{1cm} (6)

be a corresponding basis, where $a$ labels the basis vectors $|a\rangle \equiv |m_A\rangle$ of $\mathcal{H}_A$, and $\bar{a}$ labels the different combinations of states $|\bar{a}\rangle \equiv |m_1 \cdots m_i \cdots m_N\rangle$ with $i \neq A$ which span $\mathcal{H}_A$. The expectation value of a local observable like $O_A^{(s)}$, is then the sum over the partition elements $A$ of the individual averages

$$\langle O_A^{(s)}(t) \rangle = \sum_m \langle m | O_A^{(A)} | n \rangle \langle n | \rho^{(s)}(t) | m \rangle$$  \hspace{1cm} (7)

where owing to the definition $[4]$ of a local observable

$$\langle m | O^{(A)} | n \rangle \equiv \langle a, \bar{a} | O_A^{(s)} | a', \bar{a}' \rangle = \langle a | O^{(A)} | \bar{a}' \rangle \delta_{a,a'},$$  \hspace{1cm} (9)

where $\delta_{a,a'} \equiv \delta_{a_1,a_1'} \cdots \delta_{a_i,a_i'} \cdots \delta_{a_{N-1},\bar{a}_{N-1}}$. This leads to

$$\langle O_A^{(s)}(t) \rangle = \sum_{a,a'} \langle a | O^{(A)} | a' \rangle \sum_{\bar{a},\bar{a}'} \langle a', \bar{a}' | \rho^{(s)}(t) | a, \bar{a} \rangle \delta_{\bar{a},\bar{a}'}$$  \hspace{1cm} (10)

where we defined the density matrix reduced over $\mathcal{H}_A$ as

$$\sigma^{(A)}(t) \equiv \text{Tr}_A \{ \rho^{(s)}(t) \},$$  \hspace{1cm} (11)

and $\rho^{(s)}$ is the density operator reduced over $\mathcal{H}_E$. That is, the local density matrix $\sigma^{(A)}$ is the result of tracing over both the bath variables and over the Hilbert space $\mathcal{H}_A$ of all the partition elements except $A$. It is worth to mention that the doubly reduced $\sigma^{(A)}$ contains all the relevant information needed for calculating expectation values of local operators of the form $[4]$. Section II C is concerned with the evolution of this doubly reduced density operator imposed by the coupling with an environment. Before that, let us define the general form of the Hamiltonians of our system of interest.
A. Model Hamiltonians

As mentioned in the introduction, we aim to describe the decoherence of a spin system, induced by the coupling to a common phonon bath. The system-environment Hamiltonian has the form

$$ \mathcal{H} = \mathcal{H}_S + \mathcal{H}_I + \mathcal{H}_E, $$

and the characteristic features of the system, environment, and system-environment coupling we are interested in are:

**system Hamiltonian** $\mathcal{H}_S$: The observed system admits a partition, as stated near Eq. (3). Particularly, let us consider the case in which the partition elements do not interact directly with each other, but through a common environment represented by the boson bath. Accordingly, we write the system Hamiltonian as the sum of the interaction terms of each partition element

$$ \mathcal{H}_S^{(s)} = \sum_A \mathcal{H}_A^{(s)}. $$

Since the partition elements are assumed equivalent, we can write

$$ \mathcal{H}_A^{(s)} = \mathbb{I}^{(1)} \otimes \cdots \otimes \mathcal{H}^{(A)} \otimes \cdots \otimes \mathbb{I}^{(N)}, $$

where $\mathcal{H}^{(A)}(\neq \mathcal{H}^{(A')}, \forall A, A')$. The complete system Hamiltonian appearing in Eq. (12) should have the form $\mathcal{H}_S = \mathcal{H}_S^{(s)} \otimes \mathbb{I}^{(c)}$.

**environment Hamiltonian** $\mathcal{H}_E$: We represent the environment as a sum of uncoupled harmonic oscillators with frequencies $\omega_k$, where $k$ stands for wave vectors $\vec{k}$ and polarization $l$

$$ \mathcal{H}_E \equiv \mathbb{I}^{(s)} \otimes \sum_k \left[ \omega \mathbf{b}^\dagger \mathbf{b} \right]_k^{(e)}, $$

with the symbol $[,]_k$ indicating that all the operators and constants inside the brackets have the label $k,l$, and the index $(e)$ emphasizes that the boson creation and annihilation operators $\mathbf{b}^\dagger, \mathbf{b}$ refer to the environment degrees of freedom. The commutators involving these operators satisfy

$$ \left[ \mathbf{b}_k, \mathbf{b}^\dagger_{k'} \right]^{(e)} = \delta_{k,k'}, \quad \left[ \mathbf{b}_k, \mathbf{b}_{k'} \right]^{(e)} = 0, $$

$$ \left[ \mathbf{b}^\dagger_k, \mathbf{b}^\dagger_{k'} \right]^{(e)} = 0. $$

It is convenient to write the environment Hamiltonian as

$$ \mathcal{H}_E = \mathbb{I}^{(s)} \otimes \sum_k \mathbf{M}_k^{(e)}, $$

where we defined $\mathbf{M} \equiv \omega \mathbf{b}^\dagger \mathbf{b}$.

**system-environment interaction** $\mathcal{H}_I$: We define the interaction Hamiltonian that accounts for the coupling of the spin system to the boson bath, where each partition element interacts individually with the common environment.

The proposed Hamiltonian has the form

$$ \mathcal{H}_I \equiv \sum_A \mathcal{S}_A^{(s)} \otimes \sum_k \left[ g_A^s \mathbf{b}^\dagger + g_A b \right]_k^{(e)}, $$

where the hermitic spin operators $\mathcal{S}_A^{(s)}$ act on $\mathcal{H}_S$, and the system-environment coupling strength is represented by the complex constants $g_A^s$. We assume that the spin operators $\mathcal{S}_A^{(s)}$ are “local” in the sense of Eq. (1), that is

$$ \mathcal{S}_A^{(s)} = \mathbb{I}^{(1)} \otimes \cdots \otimes \mathcal{S}^{(A)} \otimes \cdots \otimes \mathbb{I}^{(N)}, $$

which also implies that

$$ [\mathcal{S}_A, \mathcal{S}_{A'}^{(s)}]^{(s)} = 0, \forall A, A'. $$

We find convenient to define a global spin operator

$$ \Lambda_k^{(s)} \equiv \sum_A \mathcal{S}_A^{(s)} g_A^k, $$

which allows writing

$$ \mathcal{H}_I = \sum_k \left[ \Lambda_k^{(s)} \otimes \mathbf{b}^{(e)} + \Lambda_k^{(s)} \otimes \mathbf{b}^{\dagger(e)} \right]_k, $$

This form makes it evident that the interaction Hamiltonian of our model differs from separable expressions of the type

$$ \Lambda^{(s)} \otimes \sum_k \left( g^s \mathbf{b}^\dagger + g b \right)_k, $$

that are frequently studied in the literature [22]. The form (18) represents a system-environment interaction where although the non interacting partition elements couple independently with the environment, they become correlated through the common bath.

Considering only the coupling of each partition element with the common environment is a convenient assumption that allows simplifying the mathematics of the problem while preserving the possibility of applying the model to a specific, experimentally accessible example. Besides, it allows to study the effects of decoherence dynamics in the limiting case where the system is composed by strictly non-interacting equivalent elements. A more general case that also introduces weak interaction between the partition elements is also possible and will be presented elsewhere.

Up to this point we have not imposed any restriction on the form of $\mathcal{H}_S$ and $\mathcal{S}^{(A)}$. Let us now focus the analysis...
on the case of Hamiltonians which satisfy the adiabatic condition, in the sense that the system-environment coupling does not involve energy exchange.

\[ [\mathcal{H}_S, \mathcal{H}_E] = 0, \quad [\mathcal{H}_I, \mathcal{H}_S] = 0, \quad [\mathcal{H}_I, \mathcal{H}_E] \neq 0. \quad (23) \]

Consequently the observed system Hamiltonian commutes with the total Hamiltonian, \([\mathcal{H}, \mathcal{H}_S] = 0\), which means that \(\mathcal{H}_S\) is time independent.

Having defined an interaction Hamiltonian \(\mathcal{H}_I\) where the spin part is a local operator, the adiabatic condition (23) also implies \([S^{(A)}, \mathcal{H}_S] = 0, \forall A\), and thus \([S^{(A)}, \mathcal{H}^{(A)}] = 0\). Then, we can write their common basis \(\{|m\rangle\}\) as a product of eigenvectors of the single partition elements

\[ \{|m\rangle\} \equiv \{|a\rangle \otimes |\tilde{a}_1\rangle \otimes \cdots \otimes |\tilde{a}_N\rangle\} \quad (24) \]

where

\[ \mathcal{H}_S^{(s)} \ket{m} = E_m \ket{m}, \quad (25) \]

and \(\{|a\rangle\}\) is the common eigenbasis of \(\mathcal{H}^{(A)}\) and \(S^{(A)}\), therefore

\[ S^{(A)} \ket{a} = \lambda_a \ket{a}, \quad \lambda_a \text{ the corresponding eigenvalue, and} \]

\[ \mathcal{H}^{(A)} \ket{a} = E_a \ket{a}, \quad (27) \]

and the energy of the whole observed system is

\[ E_m = \sum A E_a. \quad (28) \]

The action of the global spin operator, defined in (21), on this basis is

\[ \Lambda^{(s)}_k \ket{m} = \lambda^{(s)}_m \ket{m}, \quad (29) \]

where we defined

\[ \lambda^{(s)}_m \equiv \sum_A \lambda_a g^{(s)}_{ak}. \quad (30) \]

Notice that the eigenvalues (30) may not be real (if for example the constants \(g^{(s)}_{ak} \in \mathbb{C}\) as happens in the example of Section [III]) and the spin operators \(\Lambda^{(s)}_k\) be non-hermitic.

Also, under the adiabatic condition the time evolution operator can be factorized as

\[ U(t) = e^{-i\mathcal{H}_S t} e^{-i(\mathcal{H}_I + \mathcal{H}_E) t}. \quad (31) \]

Its action on the spin eigenstates \(\ket{m}\) yields

\[ U(t) \ket{m} = e^{-iE_m t} \prod_k e^{-i(M+J^{(s)}_m) t} \ket{m}, \quad (32) \]

where we defined an operator

\[ J^{(s)}_{mk} = \lambda^{(s)}_m b^{(s)}_{mk} + \lambda^{(s)}_m b^{(s)*}_{mk}, \]

which acts on \(\mathcal{H}_S\) (notice that operators with different index \(k\) commute, and also that \(J^{(s)}_{mk}\) involves the eigenvalues \(\lambda^{(s)}_m\) defined in (30)).

### B. Dynamics of the density operator reduced over the environment

In this section we calculate the density operator reduced to the observed Hilbert space

\[ \rho^{(s)}(t) \equiv \text{Tr}_{E} \{\rho(t)\}, \quad (33) \]

and its time evolution under the propagator of Eq. (31), using the Hamiltonians defined in Sec [II A] which satisfy the adiabatic condition stated in Eq. (23). This derivation generalizes the one presented in [17] to show explicitly both the real and imaginary parts of the decoherence function.

Let us assume a separable initial state

\[ \rho(0) = \rho_0^{(s)} \otimes \rho_{eq}^{(c)}, \quad (34) \]

where \(\rho_0^{(s)}\) is an arbitrary initial state of the observed system, and the environment state corresponds to a boson bath at thermal equilibrium,

\[ \rho_{eq}^{(c)} \equiv \frac{e^{-\beta H^{(c)}_E}}{\text{Tr}_{E} \left\{ e^{-\beta H^{(c)}_E} \right\}}, \quad (35) \]

with \(\beta \equiv h/(k_B T)\), \(k_B\) the Boltzmann constant, and \(T\) the absolute bath temperature. In terms of the definition (17), we can write

\[ \rho(0) = \rho_0^{(s)} \otimes \prod_k \Theta^{(c)}_k, \quad (36) \]

where

\[ \Theta^{(c)}_k \equiv e^{-\beta M^{(c)}_k}/\text{Tr}_{E} \left\{ e^{-\beta M^{(c)}_k} \right\}. \quad (37) \]

The time evolved elements of the density matrix reduced over the environment, in the eigenbasis (24) are

\[ \rho^{(s)}_{m,n}(t) \equiv \langle m | \text{Tr}_{E} \{\rho(t)\} | n \rangle = \text{Tr}_{E} \{ m | U(t) \rho_0 U(t)^\dagger | n \} \]

the reduced matrix elements can be written as

\[ \rho^{(s)}_{m,n}(t) \equiv \rho^{(s)}_{0(m,n)} e^{-i(E_m - E_n)t} \prod_k S^{k}_{m,n}(t), \quad (38) \]

where we defined

\[ \rho^{(s)}_{0(m,n)} e^{-i(E_m - E_n)t} \equiv \langle m | e^{-i\mathcal{H}_S t} \rho_0^{(s)} e^{i\mathcal{H}_S t} | n \rangle, \quad (39) \]

and

\[ S^{k}_{m,n}(t) \equiv \prod_k \text{Tr}_{E} \left\{ e^{-i(M+J^{(s)}_m)t} \Theta^{(c)} e^{i(M+J^{(s)}_k)t} \right\}^{(c)}_k. \quad (40) \]

In this way the time evolution of each matrix element in (38) is composed by two contributions of essentially different quality: the factor of Eq. (39) is related to the evolution under \(\mathcal{H}_S\) only (disregarding the presence of
where the symbol $\{\cdot\}$ is similar to those obtained in Refs. [17, 22], except we have seen [1, 23] that $\Gamma_{m,n}^{k}(t)$ is always real and positive, it can also be the imaginary part of $\lambda_{m,n}^{k}$.

According to (28), the difference between eigenvalues $\lambda_{m}^{k}$ and $\lambda_{n}^{k}$ (or their moduli) therefore they do not contribute to the decay of diagonal elements of the reduced density matrix (in this case also $\{\lambda_{m,n}^{k}\}$ is always real and positive, it can also be the imaginary part of $\lambda_{m,n}^{k}$). This action that depends on the eigenvalues of the interaction Hamiltonian is a fingerprint of adiabatic decoherence in open quantum systems and has been referred in recent literature as eigenselection [17, 24, 25].

It is worth to notice from Eqs. (42) that both $\Gamma_{m,n}^{k}(t)$ and $\Upsilon_{m,n}^{k}(t)$ depend on the differences between the eigenvalues $\lambda_{m}^{k}$ and $\lambda_{n}^{k}$ (or their moduli) therefore they do not contribute to the decay of diagonal elements of the reduced density matrix (in this case also $\{\lambda_{m,n}^{k}\}$ is always real and positive, it can also be the imaginary part of $\lambda_{m,n}^{k}$).

Finally, by replacing Eqs. (42) in Eq. (38), we can write a condensed expression

$$\rho_{m,n}^{(s)}(t) = \rho_{0(m,n)}^{(s)} e^{-i(E_{m} - E_{n})t} S_{m,n}(t),$$

where we define

$$S_{m,n}(t) = \prod_{k} S_{m,n}^{k}(t) = e^{-\Gamma_{m,n}^{k}(t) - i \Upsilon_{m,n}^{k}(t)},$$

and

$$\Gamma_{m,n}(t) = \sum_{k} \Gamma_{m,n}^{k}(t), \quad \text{and} \quad \Upsilon_{m,n}(t) = \sum_{k} \Upsilon_{m,n}^{k}(t).$$

We call $S_{m,n}(t)$ the decoherence function of the observed system, produced by the coupling with a common boson bath. The reason for this name will become evident in the next sections.

The time dependence of the density matrix reduced over the bath variables, in Eq. (43), has an oscillating factor related with the energy difference $(E_{m} - E_{n})$. The function $S_{m,n}(t)$ also introduces variation with time. The reduced density matrix equations of dynamics (41) and (42) is similar to those obtained in Refs. [17, 22], except for the term with $\{\lambda_{m,n}^{k}\}$ which arises from the dependence on $k$ of the eigenvalues $\lambda_{m,n}^{k}$. As a consequence, these quantities may be complex. In this, in a consequence of considering that all the partition elements $A$ interact with a common boson bath, as represented by the interaction Hamiltonian defined in (18).

It is worth to remark that from Eq. (42a) the function $\Gamma_{m,n}^{k}(t)$ is always real and positive, it can also be seen [11, 23] that $\Gamma_{m,n}(t)$ is Eq. (45) diverges as $t \to \infty$. Consequently, the modulus of the reduced density matrix elements attenuate irreversibly in time as

$$|\rho_{m,n}^{(s)}(t)| = |\rho_{m,n}^{(s)}(0)| e^{-\Gamma_{m,n}(t)},$$

which means that $\rho_{m,n}^{(s)}(t)$ undergoes a non unitary dynamics. On the other hand, the factor $e^{-i \Upsilon_{m,n}^{k}(t)}$ in Eq. (44) acts as a phase factor which does not contribute to the attenuation of $|\rho_{m,n}^{(s)}(t)|$.

C. Dynamics of the density operator reduced to one element of the partition

As seen in Eqs. (7) and (10), the expectation value of a local observable like (4) is related to that of a single partition element. The reduced density operator $\sigma^{(A)}(t)$ entering in such expectation value involves the whole observed system through the trace over the complement Hilbert space, as in Eq. (11) $(\sigma^{(A)}(t) = Tr_{\bar{A}} \{\rho^{(s)}(t)\})$.

In this section we calculate the matrix elements of $\sigma^{(A)}(t)$ using the $\rho_{m,n}^{(s)}(t)$ calculated in Eq. (43), as follows

$$\sigma_{a,a'}^{(A)}(t) = \sum_{\bar{a},\bar{a}'} \rho_{a,a'\bar{a}'\bar{a}}^{(s)}(t) \delta_{\bar{a},\bar{a}'} = \sum_{\bar{a}} \rho_{m,n}^{(s)}(0) e^{-i(E_{m} - E_{n})t} S_{m,n}(t)|_{a=\bar{a}'},$$

where the symbol $|a=\bar{a}'\rangle$ indicates that the matrix elements entering into the sum are only those having the same index in the subspace $H_{A}$ while $a$ and $a'$ can be different. Notice that this prescription applies also to $(E_{m} - E_{n})|a=\bar{a}'\rangle$, and to $S_{m,n}(t)|a=\bar{a}'\rangle$ which entails evaluating the functions (42a) and (42b) under the same conditions.

According to (28), the difference between eigenvalues of the system Hamiltonian becomes

$$(E_{m} - E_{n})|a=\bar{a}'\rangle = (E_{a} - E_{a'}) \quad (48)$$

therefore this factor is out of the partial trace. In order to evaluate $\Gamma_{m,n}^{k}(t)|a=\bar{a}'\rangle$ and $\Upsilon_{m,n}^{k}(t)|a=\bar{a}'\rangle$ we rewrite the eigenvalues $\lambda_{m}$ defined in Eq. (39) as

$$\lambda_{m}^{k} = \lambda_{m} g_{k}^{A} + \sum_{A_{i} \neq A} \Lambda_{i} g_{k}^{A_{i}},$$

with $g_{k}^{A}$.
and get
\[
\begin{align*}
(\lambda_m^k - \lambda_n^k)|_{\bar{a} = \bar{a}'} &= (\lambda_a - \lambda_a')g^A_k \\
(\lambda_m^k + \lambda_n^k)^{*}|_{\bar{a} = \bar{a}'} &= (\lambda_a + \lambda_a')g^A_k + 2 \sum_{\bar{a} \neq \bar{a}'} \lambda_{\bar{a}} g^{A*}_k
\end{align*}
\] (50a)
(50b)
\[\Im \{\lambda_m^k \lambda_n^k\}|_{\bar{a} = \bar{a}'} = \sum_{\bar{a} \neq \bar{a}'} \lambda_{\bar{a}} (\lambda_a - \lambda_a') \Im \{g^A_k g^{A*}_k\}. \] (50c)

After using (50) in Eqs. (42a) and (42b), the functions included in the decoherence function can be written as
\[\Gamma_{m,n}(t)|_{\bar{a} = \bar{a}'} = (\lambda_a - \lambda_a')^2 \gamma(\beta, t), \] (51)
and
\[\Upsilon_{m,n}(t)|_{\bar{a} = \bar{a}'} = (\lambda_a^2 - \lambda_a^2)\varepsilon(t) + (\lambda_a - \lambda_a')\chi^{(a)}_A(t), \] (52)
where we defined
\[\gamma(\beta, t) \equiv \sum_k 2 \frac{|g^A_k|^2}{\omega_k^2} \sin^2(\omega_k t/2) \coth(\beta \omega_k/2), \]
\[\varepsilon(t) \equiv \sum_k \frac{|g^A_k|^2}{\omega_k^2} (\sin(\omega_k t) - \omega_k t), \]
\[\chi^{(a)}_A(t) \equiv \sum_{\bar{a} \neq \bar{a}} \lambda_{\bar{a}} \zeta_{A, \bar{a}}, \]
and
\[\zeta_{A, \bar{a}}(t) \equiv \sum_k \left[ 2g^A_k |g^A_k| \sin(\omega_k t) - \omega_k t \right] + \frac{4\gamma |g^A_k|^2}{\omega_k^2} \sin^2(\omega_k t/2). \]

Here we can see that the exponential factors in the density operator reduced over $\mathcal{H}_A$ are then
\[\sigma^{(A)}_{\bar{a}, \bar{a}'}(t) = e^{-i(E_a - E_{a'})t} e^{-i(\lambda_a - \lambda_{a'})^2 \gamma(\beta, t)} \times e^{-i(\lambda_a^2 - \lambda_a^2)\varepsilon(t)} \times \sum_{\bar{a}} \rho^{(a)}_{\bar{a}, \bar{a}'}(0) e^{-i((\lambda_a - \lambda_{a'})\chi^{(a)}_A(t))}. \] (54)

**III. APPLICATION: ENSEMBLE OF NON-INTERACTING SPIN PAIRS COUPLED TO A COMMON PHONON BATH**

This section aims to provide a test on the accuracy of the model derived so far to treat a case where the observed system is composed of nuclear spin-pairs coupled to a phonon bath. That is, the partition elements are dipole interacting pairs of spins 1/2.

We focus on a problem where the observed system is a collection of non-interacting pairs of dipole coupled spins 1/2 arranged at the sites of a cubic lattice. As depicted in FIG. 1. Dipole interacting spin pairs (circles) at the sites of a cubic lattice (x).
Fig. 1 and represent the environment by a phonon bath, as in Eq. (19). We write the system Hamiltonian as a sum of the secular dipolar interaction of the spin pairs \[ \mathcal{H}_S^{(s)} = \sum_{A} \mathcal{H}_A^{(s)} \otimes I^{(c)} \] (55)

where \( A \) labels pairs and \[ \mathcal{H}_A^{(s)} \equiv \sqrt{6} \Omega_0 (r_{12}^A) I_1^{(1)} \otimes \cdots \otimes T_{2,0}^{(A)} \otimes \cdots \otimes I^{(N)} \] (56)

with \[ \Omega_0 (r_{12}^A) \equiv \frac{\mu_0 \gamma^2 \hbar}{8 \pi} \left[ 1 - 3 \cos^2 (\theta_{r, z}) \right] \] (57)

is the dipolar coupling (in frequency units), \( \theta_{r, z} \) is the angle between the laboratory \( z \)-axis and the direction of vector \( r_{12}^A \) (see Fig. 1), \( \gamma_p \) is the proton gyromagnetic constant, and \[ T_{2,0}^{(A)} \equiv \frac{1}{\sqrt{6}} \left[ 3 I_z^{(A_1)} I_z^{(A_2)} - I_z^{(A_1)} \cdot I_z^{(A_2)} \right] \] (58)

is the secular component of the second order spherical tensor which involves the spin operators of spins at pair \( A \).

We assume that the interaction energy between the spin pairs and the phonons resides in the small variations of the intra-pair coupling caused by the phonons throughout the lattice. In order to write the interaction Hamiltonian we follow references [17, 28] and consider the position vector of spin \( i \) within the lattice as the sum of a mean value (or equilibrium value), \( r_{0i} \), plus a small displacement \( u_i \). We write \( r_{0i} = r_A \pm \frac{d}{2} \), where \( r_A \) is the mean position of the \( A \)-th pair and \( d \) is a unit vector parallel to the line connecting the spins 1 and 2 at the \( A \)-th pair, and \( d \) is the equilibrium intra-pair distance. We expand \( (r_{12}^A)^{-3} \) in terms of the displacement, considered as a quantum variable as \[ u_i \equiv \sum_k \bar{c}_k \bar{c}_k^\dagger q_{0i} \ \left( b_k + b_k^\dagger \right) \] (59)

where \( k \) refers to the phonon wave vectors with frequency \( \omega_k \), \( \bar{c}_k \) is a unit polarization vector, and \( \bar{c}_k \equiv \frac{\hbar}{2 \omega_k N m_p} \), with \( m_p \) the mass of the described particles (protons). This procedure allows writing the interaction Hamiltonian \[ \mathcal{H}_I \equiv -\frac{3}{d} \sum_{A} \mathcal{H}_A^{(s)} \otimes \sum_k (g^{A_1}_k \ b + g^{A_2}_k \ b^\dagger) \] (60)

In this model, the system-environment coupling coefficients have the following expression in terms of the lattice parameters \[ g^{A}_k \equiv \left( \bar{c}_k \cdot \frac{d}{2} \right) e^{-i \bar{r}_A \cdot \bar{c}_k} (-2i) \sin \left( \bar{k} \cdot \frac{d}{2} \right), \] (61)

By comparing the interaction Hamiltonian (60) of this model example with the general expression of Eq. (18), we can identify \[ S_A^{(s)} \leftrightarrow -3 \sqrt{6} \frac{\Omega_0 (d)}{d} T_{2,0}^{(A)} \] (62)

We may now identify the basis \( \{|a_a\} \) for the spin pair with the triplet-singlet basis, which is an eigenbasis of the secular dipolar tensor \[ T_{2,0}^{A} \equiv \frac{1}{2 \sqrt{6}} \kappa_a \ |a\rangle \langle a| \] where the corresponding eigenvalues are \[ \kappa_a \equiv -\frac{3}{2} \frac{\Omega_0 (d)}{d} \kappa_a^2, \] (63)

Notice also that \[ \mathcal{H}_S |m\rangle = E_m |m\rangle = \frac{\Omega_0 (d)}{2} \sum_A \kappa_a |m\rangle, \] and consequently the system energy difference involved in Eq. (47) is \[ (E_m - E_n) |a = \bar{a} = \bar{a}' \rangle = \frac{\Omega_0 (d)}{2} (\kappa_a - \kappa_{a'}) \] (65)

Substituting Eqs. (61) and (64) in Eq. (49), the decoherence functions are \[ \Gamma_{m,n}(t) |a = \bar{a} = \bar{a}' \rangle = \frac{9}{4} \left( \frac{\Omega_0 (d)}{d} \right)^2 |\kappa_a - \kappa_{a'}|^2 \gamma(\beta, t) \] (66a)

\[ \Upsilon_{m,n}(t) |a = \bar{a} = \bar{a}' \rangle = \frac{9}{4} \left( \frac{\Omega_0 (d)}{d} \right)^2 \times \left[ (\kappa_a^2 - \kappa_{a'}^2) \epsilon(t) + (\kappa_a - \kappa_{a'}) \tilde{\chi}_A^{(a)}(t) \right], \] (66b)

where we defined the following functions that are similar to those in Eq. (53) with the coupling coefficients as in Eq. (61)

\[ \tilde{\chi}_A^{(a)}(t) \equiv \sum_{A_1} \kappa_{a_1} \tilde{\zeta}_{A,A_1}(t), \] (67a)

\[ \gamma(\beta, t) \equiv \sum_k \frac{|g_k|^2}{\omega_k^2} \left[ 1 - \cos(\omega_k t) \coth \left( \frac{\beta \hbar \omega_k}{2} \right) \right], \] (67b)
\[ \varepsilon(t) = \sum_{k} \frac{|g_k|^2}{\omega_k^2} \left[ \sin(\omega_k t) - \omega_k t \right], \quad (67c) \]

where \( \zeta_{A,A_i}(t) \) in Eq. (67a) is

\[ \zeta_{A,A_i}(t) = 2 \sum_{k} \frac{|g_k|^2}{\omega_k^2} \left\{ \cos \left[ k \cdot r_{A,A_i} \cos(\theta_{A,A_i}) \right] \left[ \sin(\omega_k t) - \omega_k t \right] \right. \\
\left. + \sin \left[ k \cdot r_{A,A_i} \cos(\theta_{A,A_i}) \right] \left[ 1 - \cos(\omega_k t) \right] \right\}, \quad (68) \]

In Eq. (67b) \( \beta \equiv \hbar / (K_B T) \), \( K_B \) the Boltzmann constant, and \( T \) the absolute temperature of the bath. In Eq. (68) \( r_{A,A_i} \equiv |\vec{r}_A - \vec{r}_{A_i}| \), \( \theta_{A,A_i} \) is the angle between vector \( \vec{r}_{A,A_i} \) and the intra-pair versor \( \hat{d} \), therefore \( \hat{d} \cdot \vec{r}_{A,A_i} = r_{A,A_i} \cos(\theta_{A,A_i}) \).

By comparing equations (66a) and (66b) one can notice that the real and imaginary parts of the decoherence function are radically different in nature. In fact, the real part depends only on the state of the target pair \( A \) and practically coincides with the result of the usual spin-boson theory. By other hand, the imaginary part contributes a noteworthy characteristic since it depends on the state of all the neighbors of pair \( A \) through the sum over \( A_i \neq A \) in Eq. (67a). Also, it is strictly temperature independent, namely, it does not reflect any statistical thermal property of the environment. This contribution instead has a purely Hamiltonian origin.

In order to evaluate the decay time related with decoherence functions obtained in Eqs. (66), we introduce the following assumptions:

1. The spin pairs are arranged in a cubic lattice and the pair axis \( \hat{d} \) coincides with one of the axis of the unit cell.
2. The lattice parameter \( a \) is larger than the pair size \( d \), that is \( d/a \ll 1 \).
3. The elastic constant of a pair is much smaller along the intra-pair direction than in perpendicular directions.
4. The elastic constant of a pair is much larger than between different pairs.

Under these reasonable conditions we can assume that the mechanical waves propagate mainly along \( \hat{d} \), therefore one can only involve vectors \( \vec{k} \) along such direction and the polarization \( l \) assumes a single value. In other words, the dynamics will be mainly driven by the components of \( \vec{k} \) along the intra-pair direction, which in turn establishes a one-dimensional description of the wave vector

\[ k = \frac{2\pi}{N_1 a} n \quad \text{with} \quad n = 0, \pm 1, \cdots, \pm \frac{N_1}{2}, \]

where \( N_1 \sim \sqrt{N} \) is the number of pairs along \( \hat{d} \).

5. \( N_1 \) is large, so we can replace

\[ \sum_k \to \frac{N_1 a}{2\pi} \int_{-k_M}^{k_M} dk, \quad (69) \]

with \( k_M = \pi/a \).

6. We select the following realistic values for the constants involved in Eqs. (66), (67a), and (67):

\( d = 0.158[\text{nm}] \) and \( a = 1.58[\text{nm}] \) correspond to the intra and inter pair distances in gypsum, \( c = 8000[\text{m/s}] \), is the speed of sound in the sample along \( d \), \( m_p = 1.67 \times 10^{-27}[\text{kg}] \) is the proton mass, and \( T = 300[\text{K}] \).

7. In Eq. (67), the dispersion relation \( \omega_k \) for acoustic phonons and under assumption (4) can be well approximated by

\[ \omega_k = \omega_{k(max)} \left| \sin \left( k a/2 \right) \right|, \quad (70) \]

We further simplify this by assuming a linear relation

\[ \omega_k = c |k|, \quad (71) \]

throughout the \( k \) range, that is \( \omega_k \leq \omega_{k(max)} = \pi c/a \). This assumption introduces an error when evaluating the sum (or integral) (67), when \( d \) is large, however, the frequency dependence in Eq. (67) goes as \( \omega_k^{-2} \), and thus the greater values of \( k \) are less significant than the lower \( k \) region.

8. The optical modes will be neglected because their frequencies are greater than the maximum frequency of the acoustic mode and therefore contribute negligibly to Eqs. (67).

With these assumptions and using that \( |k|d \ll 1 \) and \( \frac{\beta \hbar \omega_k}{2} \ll 1 \), we may approximate

\[ |g_k|^2 \simeq \frac{\hbar d^2}{2cN_1 m_p} |k| \quad \Rightarrow \quad \frac{|g_k|^2}{\omega_k^2} \simeq \frac{\hbar d^2}{2c^3 N_1 m_p} \frac{1}{|k|^4}, \quad (72a) \]

\[ \coth \left( \frac{\beta \hbar \omega_k}{2} \right) \simeq \frac{2K_B T}{\hbar c} \frac{1}{|k|^4}, \quad (72b) \]

where we used the dispersion relation \( \omega_k = c |k| \), in Eq. (72a), we can finally get the approximate functions

\[ \gamma(\beta, t) \simeq \frac{d^2}{2c^3 m_p} \frac{K_B T a}{t}, \quad (73a) \]

\[ \varepsilon(t) \simeq -d^2 \frac{\hbar}{2c^2 m_p} t, \quad (73b) \]
\[ \zeta_{A,\bar{A}}(t) \simeq \frac{d^2}{e^2 m_p} t S_{A,\bar{A}}, \]  

(73c)

with

\[ S_{A,\bar{A}} \equiv \frac{\sin \left[ \pi r_{A,\bar{A}} \cos (\theta_{A,\bar{A}}) / a \right]}{\pi r_{A,\bar{A}} \cos (\theta_{A,\bar{A}}) / a} . \]  

(74)

The expression for the pair-reduced matrix elements in the case of non-interacting spin pairs comes after replacing the decoherence function (with the approximate functions \( 73) \)) in Eq. \( 54) \)

\[ \sigma_{a,a}(t) = e^{i2\pi \nu_0 (\kappa_a - \kappa_{a'}) t} e^{-|\kappa_a - \kappa_{a'}|^2 t / \tau_\gamma} \times e^{i2\pi \nu_0 (\kappa_a - \kappa_{a'}) t} \times \sum_a \rho^{(s)}_{\bar{a},a,a}(0) e^{-i4\pi \nu_0 (\kappa_a - \kappa_{a'}) \hat{\chi}_A^{(s)}(t)}, \]  

(75)

where we defined the constants

\[ \nu_0 \simeq 152[kHz], \quad \tau_\gamma \simeq 3173[s], \quad \nu_\epsilon \simeq 6.5 \times 10^{-9}[kHz]. \]  

(77)

The fact that \( \nu_\epsilon \ll \nu_0 \) allows us to neglect the exponential that involves \( \nu_\epsilon \) in the second row of Eq. \( 75) \). Besides this, since \( |\kappa_{m,a} - \kappa_{n,a}|_{\max} = 3 \), the minimum decay constant of the exponent containing \( \tau_\gamma \) is very long

\[ \tau_{\gamma(\min)} = \tau_\gamma / |\kappa_{m,a} - \kappa_{n,a}|_{\max} \simeq 352.6[s]. \]  

(78)

Let us now focus on the sum in the third row of Eq. \( 75) \). We are interested in comparing the time evolution of a local observable calculated with the reduced density matrix, with one measured in a NMR experiment, therefore we choose an experimentally accessible initial state. Notice that NMR techniques are frequently designed to prepare states having the form

\[ \rho^{(s)}(0) = \frac{\mathbb{I}^{(s)}}{N} + \Delta \rho^{(s)}(0) \]  

(79)

where \( N \equiv Tr_\mathcal{A}\mathbb{I} = N_A^N \), and \( N_A \equiv Tr_\mathcal{A}\mathbb{I}^{(A)} \), and the second term, sometimes called deviation density operator, can be written in terms of traceless operators only. Moreover, we will use initial states where \( \Delta \rho^{(s)}(0) \) can be written in terms of local traceless operators, that is

\[ \Delta \rho^{(s)}(0) = \frac{1}{N_A^{N-1}} \sum_A \mathbb{I}^{(1)} \otimes \cdots \otimes \Delta \sigma^{(A)}(0) \otimes \cdots \otimes \mathbb{I}^{(N)} \]  

(80)

A common example of an initial state like this is the simple case of the state obtained after applying a saturating \( \pi/2 \) pulse to a spin system in thermal equilibrium with an external magnetic field \( \vec{B} = B_0 \hat{z} \). In the high temperature limit and for the case where the system is partitioned into spin pairs, we can write

\[ \Delta \sigma^{(A)}(0) = -\frac{h \nu_0 B_0}{K_B T} I_x^{(A)}, \]  

(81)

where the \( x \) component of the spin operator of the spin pair is \( I_x^{(A)} \equiv I_x^{(A1)} \otimes I_x^{(A2)} + I_x^{(A1)} \otimes I_x^{(A2)} \),

As commented in Sect \( \Pi \) decoherence affects only the non-diagonal elements of the density matrix in the basis of the interaction Hamiltonian \( H_I \) (in this case is the same basis of \( \mathcal{H}_S \)). Therefore, the time dependent terms of the reduced density matrix \( \sigma^{(A)} \) of Eq. \( 75 \) involve only the diagonal elements of \( \Delta \rho^{(s)}(0) \), having the general form

\[ \Delta \rho^{(s)}_{\bar{a},a,a}(0) = \frac{1}{N_A} \left[ \Delta \sigma^{(A)}_{a,a}(0) + \delta_{a,a'} \sum_{\bar{A},\bar{A}' \neq A} \Delta \sigma^{(\bar{A},\bar{A}')}_{\bar{a},\bar{a}}(0) \right]. \]  

(82)

After these considerations on the initial state, we can write the off diagonal elements of the reduced density matrix \( 75 \) as

\[ \Delta \sigma^{(A)}_{a,a}(t) = e^{i2\pi \nu_0 (\kappa_a - \kappa_{a'}) t} e^{-|\kappa_a - \kappa_{a'}|^2 t / \tau_\gamma} \times e^{i2\pi \nu_0 (\kappa_a - \kappa_{a'}) t} \Delta \sigma^{(A)}_{a,a}(0) G_A(t), \]  

(83)

where we defined the function \( G_A(t) \) that deserves a separate comment

\[ G_A(t) \equiv \frac{1}{N_A^{N-1}} \sum_{\bar{a}} e^{i4\pi \nu_0 (\kappa_a - \kappa_{\bar{a}}) \hat{\chi}_A^{(s)}(t)}. \]  

(84)

with

\[ \hat{\chi}_A^{(s)} = \sum_{\bar{A} \neq A} \kappa_{\bar{a}} S_{A,\bar{A}} \bar{a}. \]  

(85)

Notice that \( G_A(t) \) involves the sum over the states \( \bar{a} \) (from the partial trace) and also contains a sum over the sites \( \bar{A} \neq A \) within the auxiliary function \( \hat{\chi}_A^{(s)}(t) \). In this way, \( G_A(t) \) involves the eigenvalues of all the pairs or partition elements. In other words, this function links the decoherence dynamics of pair \( A \) with all the other pairs, and even though the pairs were assumed non-interacting in \( \mathcal{H}_S \) and \( \mathcal{H}_I \). Besides this, and owing to the fact that the sum over \( \{\bar{a}\} \), has a macroscopic number of terms, the function \( \hat{\chi}_A^{(a)} \) practically attains continuous values with probability \( p(\chi_A) \). Then we can approximate the sum in Eq. \( 84 \) by an integral as

\[ G_A(t) \simeq \int d\chi_A e^{i4\pi \nu_0 (\kappa_a - \kappa_{\bar{a}}) \hat{\chi}_A^{(s)}(t)} p(\chi_A). \]  

(86)
With the aim of estimating the contribution of \( G_A \) to the decoherence rate, we propose that \( p(\chi_A) \) is a Gaussian distribution with standard deviation \( \sigma_{\chi_A} \) centered at \( \chi_A = 0 \), and extend the integration limits to infinity, then

\[
G_A(t) \simeq e^{-\frac{1}{2} \left[ 4\pi \nu_e (\kappa_a - \kappa_a') \sigma_{\chi_A} \right]^2 t^2} = e^{-[(\kappa_a - \kappa_a') t/\tau_\chi]^2},
\]

where we introduced a characteristic time

\[
\tau_\chi \equiv \left[ \sqrt{2} \nu_e \sigma_{\chi_A} \right]^{-1}.
\]

Then, with these considerations on the function \( G(t) \) and on the magnitudes of the constants calculated in Eq. (27), we may write the reduced density matrix elements in terms of the initial state, the dipolar frequency \( \nu_0 \), and the decay time \( \tau_\chi \) as

\[
\Delta \sigma_{a,a'}^{(A)}(t) \simeq \Delta \sigma_{a,a'}^{(A)}(0) e^{i \nu_0 (\kappa_a - \kappa_a') t} e^{-[(\kappa_a - \kappa_a') t/\tau_\chi]^2},
\]

In this way the matrix elements of the pair-reduced density matrix decrease in time with different decay constants given by \( (\kappa_a - \kappa_a')/\tau_\chi \). If this matrix is used to calculate the expectation values of operators of the kind \( \langle O_A \rangle \), their time dependence will also reflect the attenuation effect introduced by the spin-environment contact and the existence of other elements of the partition (or many-body character of the interaction Hamiltonian).

Let us now estimate the values of the decay time \( \tau_\chi \), associated to \( e^{\hat{\mathbf{Y}}(t)} \) in a particular case, associated to the term \( \hat{\mathbf{Y}} \) of the decoherence function. (88) we need to fix some criteria

- For simplicity, we consider that the pairs are arranged at the sites of a cubic lattice of parameter \( \mathbf{a} \), then we write \( r_{A,A'} = \sqrt{n_x^2 + n_y^2 + n_z^2} \mathbf{a} \).
- Let \( \mathbf{d} \parallel \mathbf{z} \), then \( r_{A,A'} \cos(\theta_{A,A'})/a = n_z \), which implies that the function turns into a Sinc function \( S_{A,A'} = \sin(\pi n_z)/(\pi n_z) \). Then this function is zero for every integer \( n_z \) except for \( n_z = 0 \), that is, for the sites lying on a plane perpendicular to \( \mathbf{d} \). In other words, only a two-dimensional set of sites \( A' \) contributes to the three-dimensional sum in Eq. (88), then if the complete sample has, say \( N \approx 1 \times 10^{23} \) sites, only \( N_{\chi} \approx N^{2/3} \approx 2.15 \times 10^{15} \) of them contribute to \( \chi_A \).
- Let us assume that the width of \( p(\chi_A) \) is \( \sigma_{\chi_A} \approx \sqrt{N_{\chi}} \), as usual in a binomial distribution, therefore \( \sigma_{\chi_A} \approx 46.4 \times 10^6 \).

Using these assumptions, we get an estimation for the decay constant

\[
\tau_\chi \simeq 373 \mu s.
\]
case of some actual systems, and when applied to a particular case – dipole coupled pairs of $^1H$ spins from the hydration water molecules in gypsum coupled with the lattice phonons – yields decoherence rates that share the same qualitative and quantitative characteristics than experimental ones.

In this work we restrict the analysis to local observables (defined in Eq. (1)) compatible with the anisotropy of the observable system, that is, to operators whose expectation values can be put in terms of a density operator which is also reduced to a single, representative element of the partition. This extra reduction does not mean introducing additional simplifying hypotheses, but rather it is a natural consequence of the partitionable form of the studied model. It implies the passage from a description in terms of the “grand” density operator $\rho^{(s)}(t)$ to a “condensed” density operator $\sigma^{(A)}(t)$ whose dynamics reflects the quantum correlation with the whole system through the interaction with a common bath. That is, although $\sigma^{(A)}$ acts on the Hilbert space of a single-element it retains, in fact, track of the existence and dynamics of the rest of the solid, which was originally contained in each element of the grand matrix. Consequently, the expectation values of local observables reflect the many-body correlations, despite being a sum of contributions from individual partition elements.

An additional feature of the condensed density operator is that it depends on local variables only, in a closed way. The reduction involves a sum over all the possible configurations of quantum states of the rest of the open system. In this sense, we can say that the decoherent dynamics of the partitionable system arises from the interference between all possible quantum states that the many-body system can attain. This is a purely quantum effect as it is Hamiltonian in nature.

The usual procedure of reducing over the environment variables \cite{17, 22} introduces a decoherence function with two exponential factors, a real one $\Gamma(t)$ and an imaginary one $\Upsilon(t)$, defined in Eq. (42). The second reduction considered in this work also yields a decoherent density operator $\sigma^{(A)}(t)$ that keeps a clear dependence on the eigenvalues of the system-environment Hamiltonian (eigenselectivity), which is a fingerprint of adiabatic decoherence. However, some novel properties of the decoherence function arise, particularly related with the function $\chi^{(a)}(t)$ defined in Eqs. (52) and (53):

- $\chi^{(a)}(t)$ contains a sum over sites $\bar{A}_i$ (see Eq. (53)) and thus depends on the eigenvalues of all the partition elements, even when direct interactions between elements is ruled out in the Hamiltonians that drive the dynamics.

- The phase factor $\Upsilon(t)$ does not enter in the magnitude of the grand matrix elements $\left| \rho^{(s)}_{m,n}(t) \right|$, in contrast, the magnitude of the condensed matrix elements $\left| \sigma^{(A)}_{a,a'}(t) \right|$ do have an explicit dependence on $\Upsilon(t)$, and through it on the whole observed system.

- The function $\Upsilon(t)$ does not reflect the thermal properties of the environment, hence its absolute independence from bath temperature.

It is worth to remark that when the general result is applied to a particular example (non-interacting spin-pairs coupled with a phonon bath), we could also perform a quantitative estimation of the decoherence rates. These parameters, calculated in terms of physical constants of the model system (gypsum crystal in this case), are also mainly governed by the imaginary part of the decoherence function and its approximate value is remarkably similar to the experimental one.

On the other hand, the real part of the decoherence function in $\sigma^{(A)}(t)$ does not differ from that in the grand density operator $\rho^{(s)}(t)$ and reflects the dependence on the bath temperature. It is interesting to realize that this function has negligible contribution to the decoherence rate in the non-interacting cases treated in this work. However, this contribution may instead become dominating in cases of non-partitionable systems where the system dynamics allows a fast growth of multi-spin correlations (as the case treated in ref. \cite{12}). In other words, the relative importance of $\Gamma(t)$ and $\Upsilon(t)$ in a general case will be determined by the internal dynamics of the spin system, given by both the system, and system-environment Hamiltonians $H_S$ and $H_I$.

In summary, we see that the decoherence function in this model of non-interacting partition elements in contact with a common boson bath captures essential features of the decoherence phenomenon and also enables a quantitative calculation which opens the possibility of accounting for actual experimental results. Comparison with experiment will allow to refine model Hamiltonians in order to scrutinize in the microscopic origin of the interactions involved in irreversible phenomena like the build-up of quasi-equilibrium states or the attenuation of refocused signals in solid state NMR. By the same token, in our view, these transient processes are a consequence of adiabatic decoherence, which brings the non-equilibrium density operator to a diagonal form in the preferred basis.

From a fundamental point of view, progress in the characterization of adiabatic decoherence in real many-body open quantum systems can contribute to the field of irreversibility in quantum systems where the measurement problem is one the most conspicuous examples. In this context, simple cases like the one treated here can also be of use to learn about the role of decoherence in the dynamics of quantum correlations in bipartite systems.

Appendix A: Reduced density operator

The density operator reduced over the environment variables derives from

\[ \langle \mathcal{Q} \rangle (t) = \text{Tr}\{Q \rho(t)\} \]

\[ = \sum_{s,s',e,e'} \langle s', e' | Q^{(s)} | s, e \rangle \langle s, e | \rho(t) | s', e' \rangle \]

\[ = \sum_{s,s'} \langle s' | Q^{(s)} | s \rangle \langle s | \sum_{e} (e | \rho(t) | e) \rangle | s' \rangle \]

\[ = \text{Tr}_S \left\{ Q^{(s)} \rho^{(s)}(t) \right\} , \]

where we use that

\[ \langle s', e' | Q^{(s)} | s, e \rangle = \langle s' | Q^{(s)} | s \rangle \delta_{e', e}. \]
Appendix B: Partial trace over the environment

In this appendix we calculate the trace over the environment variables used in Eq. (33). We follow the strategy described in Ref. [22], and apply it to a more general Hamiltonian, like the one of Eq. (22). In Sec B 1 we summarize the coherent states formalism [29, 30] and the calculation of the trace is shown in Sec B 2.

1. Coherent states

The coherent states \( \{|z_k\} \) are the eigenstates of the annihilation operator

\[
b_k^{(c)}|z_k\rangle = z_k|z_k\rangle,
\]

where \( z_k \in \mathbb{C} \). Their expression in terms of the number states \( \{|n_k\} \) is [29, 30]

\[
|z_k\rangle \equiv e^{-\frac{1}{2}|z_k|^2} \sum_{n_k=0}^{\infty} \frac{(z_k)^n}{\sqrt{n!}} |n_k\rangle,
\]

where the quantum number \( n_k \) corresponds to the number of bosons with wave number \( k \) and polarization \( \ell \).

Coherent states are normal \( \langle z_k | z_k \rangle = 1 \), but not orthogonal

\[
\langle z_k | z_k' \rangle = e^{\bar{z}_k \cdot z_k - \frac{1}{2} |z_k|^2 - \frac{1}{2} |z_k'|^2},
\]

and form an over-complete set that satisfies

\[
\int d^2 z_k |z_k\rangle \langle z_k| = 1^{(c)},
\]

where the differential is

\[
d^2 z_k \equiv \frac{1}{\pi} dx_k dy_k,
\]

with \( x_k \equiv \Re\{z_k\} \) and \( y_k \equiv \Im\{z_k\} \) the real and imaginary parts of \( z_k \), respectively.

Using these definitions, the trace of an operator over the environment space can be written as

\[
\text{Tr}_E \{ \mathcal{E}^{(c)} \} = \int d^2 z_k \langle z_k | \mathcal{E}^{(c)} | z_k \rangle.
\]

We use this property to calculate the desired partial trace in Eq. (38)

\[
S_{m,n}^k(t) = \int d^2 z \langle z | e^{-i(M+J_m)t} \Theta e^{i(M+J_m)t} | z \rangle
\]

\[
= \frac{1}{Z} \int \int d^2 z_0 d^2 z_1 d^2 z_2 \langle z_0 | e^{-i(M+J_m)t} | z_1 \rangle \times \langle z_1 | e^{-\beta \omega b_1^\dagger b_1} | z_2 \rangle \langle z_2 | e^{i(M+J_m)t} | z_0 \rangle,
\]

where all the operators belong to \( \mathcal{H}_E \), and we omit index \( k \). The partition function \( Z \) in (B7) is

\[
Z \equiv \int d^2 z \langle z | e^{-\beta \omega b_1^\dagger b_1} | z \rangle.
\]

Let us now write the matrix elements involved in (B7) and (B8):

\[
\langle z_1 | e^{-\beta \omega b_1^\dagger b_1} | z_2 \rangle \equiv \sum_{n=0}^{\infty} \langle z_1 | e^{-\beta \omega b_1^\dagger b_1} | n \rangle \langle n | z_2 \rangle
\]

\[
= \sum_{n=0}^{\infty} e^{-n \beta \omega} \langle z_1 | n \rangle \langle n | z_2 \rangle
\]

\[
= e^{-\frac{1}{2} (|z_1|^2 + |z_2|^2)} \sum_{n=0}^{\infty} \langle z_1^* e^{\beta \omega} z_2 \rangle_n^2
\]

\[
= e^{-\frac{1}{2} |z_1|^2 - \frac{1}{2} |z_2|^2 + z_1^* e^{-\beta \omega} z_2}
\]

\[
= \langle z_1 | z_2 \rangle e^{z_1^* (e^{-\beta \omega} - 1) z_2},
\]

where we used the properties [B1, B3].

In order to write the factors involving \( \lambda_m \), we first define a displaced operator

\[
a_m \equiv b + \frac{\lambda_m}{\omega},
\]

such that the coherent states are also eigenstates of \( a \) with eigenvalues \( \lambda_m \). If \( \lambda_m \) is real, we can use Coherent states to write the factors involving \( e^{i(M+J_m)t} \), and apply the results to a more general Hamiltonian.

and we define a modified number operator \( \hat{N}_m \equiv a_m^\dagger a_m \) with a set of orthogonal eigenstates \( \{|\eta_m\} \), where \( \langle \eta_m | \eta_m' \rangle = \delta_{\eta_m, \eta_m'} \), so that

\[
\hat{N}_m |\eta_m\rangle = a_m^\dagger a_m |\eta_m\rangle = |\eta_m\rangle |\eta_m\rangle,
\]

which satisfy

\[
a_m |\eta_m\rangle = \sqrt{\eta_m} |\eta_m - 1\rangle, a_m^\dagger |\eta_m\rangle = \sqrt{\eta_m + 1} |\eta_m + 1\rangle,
\]

with \( a_m |0\rangle = 0 \), and the closure relation

\[
\sum_{\eta_m=0}^{\infty} |\eta_m\rangle \langle \eta_m | = 1.
\]

With these definitions the eigenstates of \( a_m \) can be written in terms of the basis \( \{|\eta_m\}\) [30], as

\[
|\eta_m\rangle \equiv e^{-\frac{1}{2} |\eta_m|^2} \sum_{\eta_m=0}^{\infty} \frac{(\eta_m)^{\eta_m}}{\sqrt{\eta_m!}} |\eta_m\rangle,
\]

and also the exponent \( M+J_m \) may be expressed in terms of the displaced creation and annihilation operators as

\[
M+J_m = \omega b_1^\dagger b_1 + \lambda_m^* b + \lambda_m b^\dagger = \omega \hat{N}_m - |\lambda_m|^2 \omega.
\]
Then, we can use Eq. (B9) to calculate the matrix elements
\[
\langle \hat{J}_1, m | e^{-i(M+J)t} | \hat{J}_2, m \rangle = e^{i \omega t \frac{\Lambda_m^2}{\omega}} \\
\times \sum_{\eta_m = 0}^{\infty} \langle \hat{J}_1, m | e^{-i \omega t \hat{a}_m^\dagger \hat{a}_m} | \eta_m \rangle \langle \eta_m | \hat{J}_2, m \rangle
\]
\[
= e^{i \omega t \frac{\Lambda_m^2}{\omega}} \langle \hat{J}_1, m | \hat{J}_2, m \rangle e^{i \hat{J}_1, m (e^{-i \omega t - 1}) \hat{J}_2, m},
\]
Using the definition of \(J_m\) and \(\hat{J}_m\) in the scalar product of Eq. (B3), one gets
\[
\langle \hat{J}_1, m | \hat{J}_2, m \rangle = \langle z_1 | z_2 \rangle e^{\frac{\Lambda_m^2}{\omega^2}} (z_1 - z_2)^* - \frac{\Lambda_m}{\omega} (z_1 - z_2),
\]
and inserting this expression in (B17), the desired matrix elements become
\[
\langle z_1 | e^{-i(M+J)t} | z_2 \rangle = e^{i \omega t \frac{\Lambda_m^2}{\omega}} \langle z_1 | z_2 \rangle \\
\times e^{\frac{\Lambda_m^2}{\omega}} (z_1 + \frac{\Lambda_m}{\omega})(e^{-i \omega t - 1})(z_2 + \frac{\Lambda_m}{\omega}).
\]
As commented above, the eigenstates \(|z\rangle\) and \(|\hat{J}_m\rangle\) of the displaced operator \(a_m\) may differ at most in a phase factor, that is
\[
| \hat{J}_m \rangle = e^{i \phi_m} | z \rangle,
\]
where it can be shown that the phase is
\[
\phi_m = \frac{1}{\omega} \Im \{ \lambda_m^2 z \}.
\]

2. Calculation of the trace

This section aims to calculating the integral proposed in Eq. (B7). By inserting the results (B9) and (B19) in Eq. (B7), we get
\[
S^k_{m,n}(t) = e^{\frac{\Lambda_m^2}{\omega^2} (e^{-i \omega t - 1} + |z_1|^2)} e^{\frac{\Lambda_n^2}{\omega^2} (e^{i \omega t} - 1)} \omega \frac{a_m n \omega}{Z},
\]
with the following definitions
\[
S_0(t) \equiv \int d^2 z_1 d^2 z_2 \langle z_1 | z_2 \rangle e^{-\rho \omega \langle z_1 |^2 \langle z_2 |^2 \rangle \omega \frac{a_m n \omega}{Z},}
\]
\[
S(t) \equiv \int d^2 z_1 e^{-|z|^2} e^{i \omega t} \frac{a_m n \omega}{Z},
\]
where
\[
a_0 = z_1^* e^{i \omega t} + \lambda_m^* (e^{i \omega t} - 1) / \omega.
\]
\[
b_0 = z_1 e^{-i \omega t} + \lambda_m (e^{-i \omega t} - 1) / \omega.
\]
The general form of the integrals in (B23) and (B24) is
\[
S \equiv \int d^2 z e^{-r |z|^2 + \alpha z + \beta z^*} \\
= \frac{1}{\pi} \int d^2 x e^{-rx^2 + (a+b)x} \int d^2 y e^{-ry^2 + i(a-b)y},
\]
where the coefficients \(\{a, b\} \in \mathbb{C} \land r \in \mathbb{R}\). In the second line of Eq. (B26), we used \(z \equiv x + iy\), with \(x, y \in \mathbb{R}\), and the differential defined in (B5). The two factors in (B26) have the general form
\[
\hat{S} = \int_{-\infty}^{\infty} dv e^{-r \hat{v}^2 + \alpha \hat{v}},
\]
\[
\text{con} \{v, r\} \in \mathbb{R} \land c \in \mathbb{C}\). Setting \(c = \alpha + i \beta\), with \(\{a, \beta\} \in \mathbb{R}\), Eq. (B27) can be written as
\[
\hat{S} = \int_{-\infty}^{\infty} dv e^{-r \hat{v}^2 + \alpha \hat{v}} e^{-i \beta \hat{v}} \\
= \frac{1}{\sqrt{\pi}} e^{\frac{1}{2} (\beta^2 - \frac{\alpha^2}{\beta^2})} \int_{-\infty}^{\infty} dv e^{-r \hat{v}^2 - i \beta \hat{v}},
\]
where
\[
-r v^2 + \alpha v = -r \left( v - \frac{\alpha}{2r} \right)^2 + \frac{\alpha^2}{2r},
\]
and \(\delta = v - \alpha/(2r)\). The last row in Eq. (B28) is the Fourier transform of a gaussian function, then
\[
\int_{-\infty}^{\infty} dv e^{-r \hat{v}^2 - i \beta \hat{v}} = \sqrt{\frac{\pi}{r}} e^{-\beta^2/(4r)}.
\]
Then (B27) becomes
\[
\hat{S} = \sqrt{\frac{\pi}{r}} e^{\frac{1}{2} (\beta^2 - \frac{\alpha^2}{\beta^2})} = \sqrt{\frac{\pi}{r}} e^{(\alpha \hat{v})^2/(4r)}.
\]
This result is useful in all the integrals involved in (B22).

We now use (B30) in (B27), so that \(S\) in (B26) becomes
\[
S = \frac{1}{r} \int z_1 e^{(a+b) - (a-b)/r} = \frac{1}{r} e^{ab/r}.
\]
Setting \(r = 1\), in Eq. (B31) we use the same result to solve (B24), which results
\[
S_0(t) = e^{a_0 b_0},
\]
with \(a_0 b_0\) as in (B25). We now may use (B32) in Eq. (B23), to get
\[
S_0(t) = e^{\lambda_m \lambda_n^* (e^{i \omega t - 1}) (e^{-i \omega t - 1}) / \omega^2 S_2(t),}
\]
where we defined
\[
S_2(t) \equiv \int d^2z_2 e^{-|z_2|^2 - (\lambda_m - \lambda_n)(e^{i\omega t} - 1)} z_2^* S_1(t),
\]  
(B34)
\[
S_1(t) \equiv \int d^2z_1 e^{-|z_1|^2 + a_1 z_1 + b_1 z_1^*} = e^{a_1 b_1},
\]  
(B35)

with
\[
a_1 \equiv z_2^* + (\lambda_m - \lambda_n)^* (e^{-i\omega t} - 1)/\omega,
\]  
(B36a)
\[
b_1 \equiv z_2 e^{-\beta \omega}.
\]  
(B36b)

Then, \( S_2(t) \) becomes
\[
S_2(t) = \int d^2z_2 e^{-r_2|z_2|^2 + a_2 z_2 + b_2 z_2^*} = \frac{1}{r_2} e^{a_2 b_2/r_2},
\]  
(B37)

where we defined the coefficients
\[
r_2 \equiv 1 - e^{-\beta \omega},
\]  
(B38a)
\[
a_2 \equiv (\lambda_m - \lambda_n)^* (e^{-i\omega t} - 1) e^{-\beta \omega}/\omega,
\]  
(B38b)
\[
b_2 \equiv -(\lambda_m - \lambda_n) (e^{i\omega t} - 1)/\omega.
\]  
(B38c)

Replacing (B37) in Eq. (B33), and after some algebra, the integral in (B23) adopts the expression
\[
S_3(t) = \frac{1}{1 - e^{-\beta \omega}} \times e^{\frac{4}{\omega} \sin^2(\omega/2) [-|\lambda_m - \lambda_n|^2 e^{-\beta \omega}/(1 - e^{-\beta \omega}) + \lambda_m \lambda_n]},
\]  
(B39)

where we used
\[
(e^{i\omega t} - 1)(e^{-i\omega t} - 1) = 2 [1 - \cos(\omega t)] = 4 \sin^2(\omega t/2).
\]

Now, the partition function \( Z \) is
\[
Z = \int d^2z e^{-(1 - e^{-\beta \omega}) |z|^2} = \frac{1}{1 - e^{-\beta \omega}},
\]  
(B40)

where we used (B31), with the coefficients \( r = 1 - e^{-\beta \omega} \) and \( a = b = 0 \).

Finally, replacing \( S_3(t) \) from (B39) and the partition function (B40) in the decoherence function \( S_{m,n}^k(t) \) of Eq. (B22), one obtains the following expression
\[
S_{m,n}^k(t) = e^{-\frac{2}{\omega} |\lambda_m - \lambda_n|^2 \sin^2(\omega/2) \coth(\beta \omega/2)}
\times e^{-\frac{\omega}{2} \{ (|\lambda_m|^2 - |\lambda_n|^2) \sin(\omega t) - \omega| - 4 \lambda_m \lambda_n^* \sin^2(\omega t/2) \}},
\]  
(B41)

which has the desired form shown in Eq. (41). In order to write the exponent in Eq. (B41), we used the common relations
\[
-2i |\lambda_m|^2 e^{-i\omega t/2} \sin(\omega t/2) + 2i |\lambda_n|^2 e^{i\omega t/2} \sin(\omega t/2)
\]
\[
+ 4\lambda_m \lambda_n^* \sin^2(\omega t/2) = -2 \left( |\lambda_m|^2 + |\lambda_n|^2 \right) \sin^2(\omega t/2),
\]
\[
-2i \left( |\lambda_m|^2 - |\lambda_n|^2 \right) \sin(\omega t/2) \cos(\omega t/2)
\]
\[
+ 4\lambda_m \lambda_n^* \sin^2(\omega t/2) = -2 |\lambda_m - \lambda_n|^2 \sin^2(\omega t/2),
\]
\[
- i \left( |\lambda_m|^2 - |\lambda_n|^2 \right) \sin(\omega t) - 4i \lambda_m \lambda_n^* \sin^2(\omega t/2),
\]  
(B42)

- also
\[
e^{\pm i\omega t} - 1 = \pm 2i e^{\pm i\omega t/2} \sin(\omega t/2),
\]
- and finally
\[
(1 + e^{-\beta \omega})/(1 - e^{-\beta \omega}) = \coth(\beta \omega/2).
\]
