# AN EIGENVALUE ESTIMATE FOR A ROBIN $p$-LAPLACIAN IN $C^{1}$ DOMAINS 

KONSTANTIN PANKRASHKIN

#### Abstract

Let $\Omega \subset \mathbb{R}^{n}$ be a bounded $C^{1}$ domain and $p>1$. For $\alpha>0$, define the quantity $$
\Lambda(\alpha)=\inf _{u \in W^{1, p}(\Omega), u \neq 0}\left(\int_{\Omega}|\nabla u|^{p} \mathrm{~d} x-\alpha \int_{\partial \Omega}|u|^{p} \mathrm{~d} s\right) / \int_{\Omega}|u|^{p} \mathrm{~d} x
$$ with $\mathrm{d} s$ being the hypersurface measure, which is the lowest eigenvalue of the $p$-laplacian in $\Omega$ with a non-linear $\alpha$-dependent Robin boundary condition. We show the asymptotics $\Lambda(\alpha)=(1-p) \alpha^{p /(p-1)}+o\left(\alpha^{p /(p-1)}\right)$ as $\alpha$ tends to $+\infty$. The result was only known for the linear case $p=2$ or under stronger smoothness assumptions. Our proof is much shorter and is based on completely different and elementary arguments, and it allows for an improved remainder estimate for $C^{1, \lambda}$ domains.

## 1. Introduction

Let $\Omega \subset \mathbb{R}^{n}$ be a bounded $C^{1}$ domain and $p>1$. For $\alpha>0$ define

$$
\Lambda(\alpha):=\inf _{u \in W^{1, p}(\Omega), u \neq 0}\left(\int_{\Omega}|\nabla u|^{p} \mathrm{~d} x-\alpha \int_{\partial \Omega}|u|^{p} \mathrm{~d} s\right) / \int_{\Omega}|u|^{p} \mathrm{~d} x
$$

where $\mathrm{d} s$ is the hypersurface measure. Denote $q:=\frac{p}{p-1}$ the Hölder conjugate of $p$. In this note we prove the following result:

Theorem 1. As $\alpha$ tends to $+\infty$ there holds

$$
\begin{equation*}
\Lambda(\alpha)=(1-p) \alpha^{q}+o\left(\alpha^{q}\right) \tag{1}
\end{equation*}
$$

In addition, if $\Omega$ is of class $C^{1, \lambda}$ with some $\lambda \in(0,1)$, then the remainder estimate can be improved to $O\left(\alpha^{k}\right)$ with $k:=\frac{q+\lambda}{1+\lambda} \in\left(\frac{q+1}{2}, q\right)$.

A standard argument shows that $\Lambda(\alpha)$ can be viewed as the lowest eigenvalue of a non-linear problem involving the $p$-laplacian $\Delta_{p}: u \mapsto \nabla \cdot\left(|\nabla u|^{p-2} \nabla u\right)$,

$$
-\Delta_{p} u=\Lambda|u|^{p-2} u \text { in } \Omega, \quad|\nabla u|^{p-2} \frac{\partial u}{\partial \nu}=\alpha|u|^{p-2} u \text { on } \partial \Omega,
$$

with $\nu$ being the outer unit normal, see e.g. [7. It seems that the asymptotic behavior for large $\alpha$ was first addressed by Lacey, Ockedon and Sabina 8] for the linear situation $(p=2)$, and $C^{1}$ domains represent a borderline case. On one hand, the asymptotic behavior (1) is not valid for non-smooth domains [1, 6, 9. On the other hand, for $C^{1,1}$ domains one has $\Lambda(\alpha)=(1-p) \alpha^{q}-H \alpha+o(\alpha)$ with $H$ being the maximum mean curvature of the boundary [7], which is much more detailed, but the proof depends heavily on the existence of a tubular neighborhood of the boundary and on the regularity of boundary curvatures. We refer to the

[^0]review [2, Sec. 4.4.2] for a detailed discussion of the linear case. Lou and Zhu in [10] established the asymptotics (11) for $C^{1}$ domains and $p=2$ using an involved combination of a blow up argument with the non-existence of positive solutions for some linear boundary value problems. We provide a very short elementary proof based on an integration by parts combined with a simple regularization, which is by introducing additional ingredients in the proof of the Sobolev trace theorem in Grisvard's book [5, Sec. 1.5]. This allows one to include all values of $p$ and to obtain an improved remainder estimate for $C^{1, \lambda}$ domains with minimal additional effort. Remark that our proof works for $\lambda=1$ as well, but the final result is weaker than the one of [7] mentioned above. By analogy, we do not expect our remainder estimate for $C^{1, \lambda}$ case to be optimal: we collect some observations in Section 3. In particular, Corollary 4 states that the remainder estimate for $C^{1}$ domains cannot be improved to $O\left(\alpha^{r}\right)$ with $r<q$.

## 2. Proof of Theorem 1

2.1. Lower bound. We will need a very simple extension result given by the following Lemma 2, While it is just a version of Tietze extension theorem, see e.g. [11, §8.4], we prefer to give a complete direct proof at the end of this subsection.

Lemma 2. The outer unit normal $\nu$ on $\partial \Omega$ can be extended to a continuous map $\mu: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ satisfying $|\mu(x)| \leq 1$ for all $x \in \bar{\Omega}$. If $\Omega$ is of class $C^{1, \lambda}$, then the above map $\mu$ may be chosen of class $C^{0, \lambda}$.

Let $\mu$ as in Lemma2 2 and pick $\varepsilon \in(0,1)$, then there exists a $C^{1} \operatorname{map} \mu_{\varepsilon}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ with $\left|\mu_{\varepsilon}(x)-\mu(x)\right| \leq \varepsilon$ for all $x \in \bar{\Omega}$. For any $u \in C^{1}(\bar{\Omega})$ the divergence theorem gives
(2) $\int_{\partial \Omega}|u|^{p} \mu_{\varepsilon} \cdot \nu \mathrm{d} s=\int_{\Omega} \nabla \cdot\left(|u|^{p} \mu_{\varepsilon}\right) \mathrm{d} x=\int_{\Omega}\left(p|u|^{p-2} u \nabla u \cdot \mu_{\varepsilon}+|u|^{p}\left(\nabla \cdot \mu_{\varepsilon}\right)\right) \mathrm{d} x$.

In $\Omega$ we estimate pointwise $\left|\mu_{\varepsilon}\right| \leq|\mu|+\varepsilon \leq 1+\varepsilon$ and $\left|\nabla \cdot \mu_{\varepsilon}\right| \leq c_{\varepsilon}$ with a suitable constant $c_{\varepsilon}>0$. On $\partial \Omega$ we have $\mu=\nu$ and $\mu_{\varepsilon} \cdot \nu=\nu \cdot \nu+\left(\mu_{\varepsilon}-\mu\right) \cdot \nu \geq 1-\varepsilon$. Therefore, Eq. (2) yields

$$
(1-\varepsilon) \int_{\partial \Omega}|u|^{p} \mathrm{~d} s \leq(1+\varepsilon) p \int_{\Omega}|u|^{p-1}|\nabla u| \mathrm{d} x+c_{\varepsilon} \int_{\Omega}|u|^{p} \mathrm{~d} x .
$$

Using Young's inequality, for any $\delta>0$ we estimate

$$
|u|^{p-1}|\nabla u|=\left(\delta^{-1}|u|^{p-1}\right)(\delta|\nabla u|) \leq \frac{1}{q} \delta^{-q}|u|^{p}+\frac{1}{p} \delta^{p}|\nabla u|^{p},
$$

then

$$
(1-\varepsilon) \int_{\partial \Omega}|u|^{p} \mathrm{~d} s \leq(1+\varepsilon) \delta^{p} \int_{\Omega}|\nabla u|^{p} \mathrm{~d} x+\left(c_{\varepsilon}+(1+\varepsilon)(p-1) \delta^{-q}\right) \int_{\Omega}|u|^{p} \mathrm{~d} x
$$

which holds by density for all $u \in W^{1, p}(\Omega)$ and can be transformed into

$$
\int_{\Omega}|\nabla u|^{p} \mathrm{~d} x-\frac{1-\varepsilon}{1+\varepsilon} \delta^{-p} \int_{\partial \Omega}|u|^{p} \mathrm{~d} s \geq-\delta^{-p}\left(\frac{1}{1+\varepsilon} c_{\varepsilon}+(p-1) \delta^{-q}\right) \int_{\Omega}|u|^{p} \mathrm{~d} x
$$

For $\delta=\left(\frac{1+\varepsilon}{1-\varepsilon} \alpha\right)^{-1 / p}$ it takes the form

$$
\int_{\Omega}|\nabla u|^{p} \mathrm{~d} x-\alpha \int_{\partial \Omega}|u|^{p} \mathrm{~d} s \geq\left((1-p)\left(\frac{1+\varepsilon}{1-\varepsilon}\right)^{q} \alpha^{q}-\frac{1}{1-\varepsilon} c_{\varepsilon} \alpha\right) \int_{\Omega}|u|^{p} \mathrm{~d} x .
$$

Therefore,

$$
\begin{equation*}
\Lambda(\alpha) \geq(1-p)\left(\frac{1+\varepsilon}{1-\varepsilon}\right)^{q} \alpha^{q}-\frac{1}{1-\varepsilon} c_{\varepsilon} \alpha \tag{3}
\end{equation*}
$$

and then $\liminf _{\alpha \rightarrow+\infty} \alpha^{-q} \Lambda(\alpha) \geq(1-p)\left(\frac{1+\varepsilon}{1-\varepsilon}\right)^{q}$. As $\varepsilon \in(0,1)$ can be taken arbi-

Now assume that $\Omega$ is of class $C^{1, \lambda}$. By Lemma 2, the map $\mu$ in the preceding computations can be assumed $C^{0, \lambda}$. The idea of an improved remainder estimate is to apply the standard mollifying procedure to construct $\mu_{\varepsilon}$ and then to control the constant $c_{\varepsilon}$ in the above computations using the modulus of continuity of $\mu$. Namely, let $\rho \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ be non-negative, supported in the unit ball centered at the origin, with $\int \rho=1$. For $t>0$ consider the function $\rho_{t}: x \mapsto t^{-n} \rho\left(t^{-1} x\right)$ and then the $C^{\infty}$ vector field $m_{t}:=\mu \star \rho_{t} \in C^{\infty}\left(\mathbb{R}^{n}, \mathbb{R}^{n}\right)$, with $\star$ being the convolution product. One has

$$
\nabla \cdot m_{t}(x)=\frac{1}{t^{n+1}} \int_{\mathbb{R}^{n}} \mu(y) \cdot(\nabla \rho)\left(\frac{x-y}{t}\right) \mathrm{d} y=\frac{1}{t} \int_{|z|<1} \mu(x-t z) \cdot \nabla \rho(z) \mathrm{d} z
$$

so that $\left\|\nabla \cdot m_{t}\right\|_{L^{\infty}(\Omega)} \leq a t^{-1}$ with $a:=\|\mu\|_{L^{\infty}\left(\Omega_{1}, \mathbb{R}^{n}\right)}\|\nabla \rho\|_{L^{1}\left(\mathbb{R}^{n}, \mathbb{R}^{n}\right)}$, where we denote $\Omega_{1}:=\{x+z: x \in \Omega,|z|<1\}$. Furthermore,

$$
m_{t}(x)-\mu(x)=\int_{\mathbb{R}^{n}}(\mu(x-y)-\mu(x)) \rho_{t}(y) \mathrm{d} y=\int_{|z|<1}(\mu(x-t z)-\mu(x)) \rho(z) \mathrm{d} z
$$

As $\mu$ is $C^{0, \lambda}$, with a suitable $b>0$ one has $|\mu(x-t z)-\mu(x)| \leq b|t z|^{\lambda}$ and then $\left|m_{t}(x)-\mu(x)\right| \leq b t^{\lambda}$ for all $x \in \bar{\Omega}$ and $t>0$. Hence, if for $t \in\left(0, b^{-1 / \lambda}\right)$ one sets $\varepsilon:=b t^{\lambda} \in(0,1)$ and $\mu_{\varepsilon}:=m_{t}$, then in $\bar{\Omega}$ one has $\left|\mu_{\varepsilon}-\mu\right| \leq \varepsilon$ and $\left|\nabla \cdot \mu_{\varepsilon}\right| \leq c_{\varepsilon}:=c \varepsilon^{-1 / \lambda}$ with $c:=a b^{1 / \lambda}$, and the inequality (3) takes the form

$$
\Lambda(\alpha) \geq(1-p)\left(\frac{1+\varepsilon}{1-\varepsilon}\right)^{q} \alpha^{q}-\frac{1}{1-\varepsilon} c \varepsilon^{-1 / \lambda} \alpha \text { for all } \alpha>0 \text { and } \varepsilon \in(0,1)
$$

Now we take $\varepsilon=\varepsilon(\alpha)$ with $\lim _{\alpha \rightarrow+\infty} \varepsilon(\alpha)=0$, then by applying Taylor expansions one arrives at $\Lambda(\alpha) \geq(1-p) \alpha^{q}+O\left(\varepsilon \alpha^{q}+\varepsilon^{-1 / \lambda} \alpha\right)$. To optimize the last summand we now set $\varepsilon:=\alpha^{\lambda(1-q) /(\lambda+1)}$, which gives $\Lambda(\alpha) \geq(1-p) \alpha^{q}+O\left(\alpha^{k}\right)$ with $k:=\frac{q+\lambda}{1+\lambda}$ for large $\alpha$.

Proof of Lemma 园, The idea is very standard: one first construct an explicit extension near each point of the boundary, then these constructions are glued together using a partition of unity. The local construction is also very simple: informally, in a compact coordinate patch over which the boundary of the domain is given by a graph $y=\phi(x)$, the local extension can be defined by $\mu(x, y)=\nu(x, \phi(x))$.

Let us describe the above procedure in a detailed rigorous way. By the usual definition of a $C^{1}$ domain, see e.g. [5, Def. 1.2.1.1], each point of $\partial \Omega$ admits an open neighborhood $V$ with the following properties:

- the set $V$ is a hyperparallelepiped, i.e. there exist orthogonal coordinates $y=\left(y_{1}, \ldots, y_{n}\right)$ and strictly positive numbers $a_{1}, \ldots, a_{n}$ such that $V=$ $\left\{y: y^{\prime} \in V^{\prime}, y_{n} \in\left(-a_{n}, a_{n}\right)\right\}$ with $V^{\prime}:=\left(-a_{1}, a_{1}\right) \times \cdots \times\left(-a_{n-1}, a_{n-1}\right)$ and $y^{\prime}:=\left(y_{1}, \ldots, y_{n-1}\right)$,
- there exists a $C^{1}$ function $\varphi: V^{\prime} \rightarrow \mathbb{R}$ with $\left|\varphi\left(y^{\prime}\right)\right| \leq \frac{1}{2} a_{n}$ for all $y^{\prime} \in V^{\prime}$ and such that $\Omega \cap V=\left\{y \in V: y_{n}<\varphi\left(y^{\prime}\right)\right\}$ and $\partial \Omega \cap V=\left\{y \in V: y_{n}=\varphi\left(y^{\prime}\right)\right\}$.
The map $\nu_{0}: V \ni y \mapsto\left(1+\left|\nabla \varphi\left(y^{\prime}\right)\right|^{2}\right)^{-\frac{1}{2}}\left(-\partial_{1} \varphi\left(y^{\prime}\right), \ldots,-\partial_{n-1} \varphi\left(y^{\prime}\right), 1\right) \in \mathbb{R}^{n}$ is clearly continuous, and for $y \in \partial \Omega \cap V$, i.e. for $y_{n}=\varphi\left(y^{\prime}\right)$, it coincides with the outer
unit normal $\nu$. Hence, the map $\nu_{0}$ is a continuous extension of $\nu: \partial \Omega \cap V \rightarrow \mathbb{R}^{n}$ to the whole of $V$, and it satisfies pointwise $\left|\nu_{0}\right|=1$ by construction. If $\Omega$ is of class $C^{1, \lambda}$, then one can additionally assume that $\varphi \in C^{1, \lambda}\left(V^{\prime}, \mathbb{R}\right)$, and then $\partial_{j} \varphi \in C^{0, \lambda}\left(V^{\prime}, \mathbb{R}\right)$. Simple manipulations with Hölder continuous functions, see e.g. 3, Sec. 1.2], show that $\nu_{0} \in C^{0, \lambda}\left(V, \mathbb{R}^{n}\right)$.

The boundary $\partial \Omega$ is compact and can be covered by finitely many open hyperparallelepipeds $V_{1}, \ldots, V_{m}$ with the above properties, and we denote by $\nu_{j}$ continuous maps $V_{j} \rightarrow \mathbb{R}^{n}$ extending $\nu: \partial \Omega \cap V_{j} \rightarrow \mathbb{R}^{n}$ and satisfying $\left|\nu_{j}\right| \leq 1$, which exist due to the preceding construction. As $\Omega, V_{1}, \ldots, V_{m}$ form a finite open covering of $\bar{\Omega}$, one can find a subordinated partition of unity, i.e. $C^{\infty}$ functions $\psi_{0}, \ldots, \psi_{m}: \mathbb{R}^{n} \rightarrow[0,1]$ with $\operatorname{supp} \psi_{0} \subset \Omega, \operatorname{supp} \psi_{j} \subset V_{j}$ for $j=1, \ldots, m$, and $\psi_{0}+\cdots+\psi_{m}=1$ in $\bar{\Omega}$. We define $\mu: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ by $\mu:=\psi_{1} \nu_{1}+\cdots+\psi_{m} \nu_{m}$, which is continuous as each summand is a continuous function. For $x \in \partial \Omega$ we have $\psi_{0}(x)=0$ and $\left(\psi_{j} \nu_{j}\right)(x)=\psi_{j}(x) \nu(x)$ for $j=1, \ldots, m$, which yields

$$
\mu(x)=\left(\psi_{1} \nu_{1}\right)(x)+\cdots+\left(\psi_{m} \nu_{m}\right)(x)=\left(\psi_{0}(x)+\psi_{1}(x)+\ldots \psi_{m}(x)\right) \nu(x)=\nu(x)
$$

and shows that $\mu$ is an extension of $\nu$. Finally, for any $x \in \bar{\Omega}$ we have

$$
\begin{aligned}
|\mu(x)| & \leq\left|\left(\psi_{1} \nu_{1}\right)(x)\right|+\cdots+\left|\left(\psi_{m} \nu_{m}\right)(x)\right| \\
& =\psi_{1}(x)\left|\nu_{1}(x)\right|+\cdots+\psi_{m}(x)\left|\nu_{m}(x)\right| \\
& \leq \psi_{1}(x)+\cdots+\psi_{m}(x)=1-\psi_{0}(x) \leq 1
\end{aligned}
$$

If $\Omega$ is $C^{1, \lambda}$, then one can assume $\nu_{j} \in C^{0, \lambda}\left(V_{j}, \mathbb{R}^{n}\right)$, and then $\mu \in C^{0, \lambda}\left(\mathbb{R}^{n}, \mathbb{R}^{n}\right)$.
2.2. Upper bound. The upper bound was already obtained in [7, Prop. 6.2] using a minor variation of a construction by Giorgi and Smits in [4, Thm. 2.3]. As the argument is very simple, we repeat it here in order to have a self-contained presentation. Set $\beta:=\frac{q}{p}$ and consider the function $u: x \mapsto e^{\beta x_{1}}$ and the vector field $F: x \mapsto e^{p \beta x_{1}} e_{1}$ with $e_{1}:=(1,0, \ldots, 0)$, then

$$
\int_{\partial \Omega}|u|^{p} \mathrm{~d} s=\int_{\partial \Omega} e^{p \beta x_{1}} \mathrm{~d} s=\int_{\partial \Omega} F \cdot e_{1} \mathrm{~d} s=\int_{\partial \Omega} F \cdot \nu \mathrm{~d} s+\int_{\partial \Omega} e^{p \beta x_{1}}\left(1-e_{1} \cdot \nu\right) \mathrm{d} s
$$

Using the quantity

$$
I(\alpha):=\int_{\partial \Omega} e^{p \beta x_{1}}\left(1-e_{1} \cdot \nu\right) \mathrm{d} s>0
$$

and the divergence theorem we arrive at

$$
\int_{\partial \Omega}|u|^{p} \mathrm{~d} s=\int_{\Omega} \nabla \cdot F \mathrm{~d} s+I(\alpha)=p \beta \int_{\Omega}|u|^{p} \mathrm{~d} x+I(\alpha),
$$

and then

$$
\begin{align*}
\Lambda(\alpha) & \leq\left(\int_{\Omega}|\nabla u|^{p} \mathrm{~d} x-\alpha \int_{\partial \Omega}|u|^{p} \mathrm{~d} s\right) / \int_{\Omega}|u|^{p} \mathrm{~d} x \\
& \leq\left(\beta^{p} \int_{\Omega}|u|^{p} \mathrm{~d} x-p \beta \alpha \int_{\Omega}|u|^{p} \mathrm{~d} x-\alpha I(\alpha)\right) / \int_{\Omega}|u|^{p} \mathrm{~d} x  \tag{4}\\
& =\beta^{p}-p \beta \alpha-K(\alpha) \equiv(1-p) \alpha^{q}-K(\alpha)
\end{align*}
$$

where

$$
\begin{equation*}
K(\alpha):=\alpha \int_{\partial \Omega} e^{p \beta x_{1}}\left(1-e_{1} \cdot \nu\right) \mathrm{d} s / \int_{\Omega} e^{p \beta x_{1}} \mathrm{~d} x>0 \tag{5}
\end{equation*}
$$

which implies $\Lambda(\alpha)<(1-p) \alpha^{q}$ and concludes the proof of Theorem 1

## 3. More on remainder estimates

We continue using the notation of subsection 2.2 and remark that the term $K(\alpha)$ was kept intentionally, as this allows one to discuss the optimality of the remainders. We restrict our attention to two-dimensional domains.

Proposition 3. For any $\lambda \in(0,1)$ one can find a bounded $C^{1, \lambda}$ domain $\Omega \subset \mathbb{R}^{2}$ and $a$ constant $c_{\lambda}>0$ such that for large $\alpha$ there holds

$$
\left|\Lambda(\alpha)-(1-p) \alpha^{q}\right| \geq c_{\lambda} \alpha^{m}, \quad m:=\frac{p-\frac{2 \lambda}{\lambda+1}}{p-1} \equiv \frac{q+(2-q) \lambda}{1+\lambda} \in(1, q)
$$

Proof. Let $\delta>0$. As the function $t \mapsto|t|^{1+\lambda}$ is $C^{1, \lambda}$ on any finite interval, one can find a bounded $C^{1, \lambda}$ domain $\Omega \subset \mathbb{R}^{2}$ such that

$$
\Omega \cap\left\{\left(x_{1}, x_{2}\right): x_{1}>-\delta\right\}=\left\{\left(x_{1}, x_{2}\right):-\delta<x_{1}<-\left|x_{2}\right|^{1+\lambda}\right\}
$$

First, there holds

$$
\int_{\partial \Omega} e^{p \beta x_{1}}\left(1-e_{1} \cdot \nu\right) \mathrm{d} s \geq \int_{\partial \Omega \cap\left\{x_{1}>-\delta\right\}} e^{p \beta x_{1}}\left(1-e_{1} \cdot \nu\right) \mathrm{d} s
$$

Using the parametrization $(0, \delta) \ni t \mapsto\left(-t, \pm t^{1 /(1+\lambda)}\right)$ of $\partial \Omega \cap\left\{x_{1}>0, \pm x_{2}>0\right\}$ and assuming that $\delta$ is chosen small enough and that $\alpha$ is large enough, we get

$$
\begin{aligned}
& \int_{\partial \Omega \cap\left\{x_{1}>-\delta\right\}} e^{p \beta x_{1}}\left(1-e_{1} \cdot \nu\right) \mathrm{d} s \\
& =2 \int_{0}^{\delta} e^{-p \beta t}\left(1-\frac{t^{-\lambda /(1+\lambda)}}{\sqrt{1+\left(\frac{1}{1+\lambda}\right)^{2} t^{-2 \lambda /(1+\lambda)}}}\right) \sqrt{1+\left(\frac{1}{1+\lambda}\right)^{2} t^{-2 \lambda /(1+\lambda)}} \mathrm{d} t \\
& =2 \int_{0}^{\delta} e^{-p \beta t}\left(\sqrt{1+\left(\frac{1}{1+\lambda}\right)^{2} t^{-2 \lambda /(1+\lambda)}}-t^{-\lambda /(1+\lambda)}\right) \mathrm{d} t \\
& =\frac{2}{1+\lambda} \int_{0}^{\delta} e^{-p \beta t} t^{-\lambda /(1+\lambda)}\left(\sqrt{1+(1+\lambda)^{2} t^{2 \lambda /(1+\lambda)}}-1\right) \mathrm{d} t \\
& \geq \frac{2}{1+\lambda} \int_{0}^{\delta} e^{-p \beta t} t^{-\lambda /(1+\lambda)}\left(\frac{1}{4}(1+\lambda)^{2} t^{2 \lambda /(1+\lambda)}\right) \mathrm{d} t \\
& \quad=\frac{1+\lambda}{2} \int_{0}^{\delta} e^{-p \beta t} t^{\lambda /(1+\lambda)} \mathrm{d} t \geq \frac{1+\lambda}{2} \int_{0}^{\infty} e^{-p \beta t} t^{\lambda /(1+\lambda)} \mathrm{d} t-e^{-\delta \beta} \\
& =\frac{1+\lambda}{2} \Gamma\left(\frac{1+2 \lambda}{1+\lambda}\right)(p \beta)^{-(1+2 \lambda) /(1+\lambda)}-e^{-\delta \beta}
\end{aligned}
$$

Therefore,

$$
\int_{\partial \Omega} e^{p \beta x_{1}}\left(1-e_{1} \cdot \nu\right) \mathrm{d} s \geq \frac{1+\lambda}{2} \Gamma\left(\frac{1+2 \lambda}{1+\lambda}\right)(p \beta)^{-(1+2 \lambda) /(1+\lambda)}-e^{-\delta \beta}
$$

In addition,

$$
\int_{\Omega} e^{p \beta x_{1}} \mathrm{~d} x \leq \int_{\Omega \cap\left\{x_{1} \in(-\delta, 0)\right\}} e^{p \beta x_{1}} \mathrm{~d} x+|\Omega| e^{-p \delta \beta},
$$

while the first summand on the right-hand side is estimated as

$$
\int_{\Omega \cap\left\{x_{1}>-\delta\right\}} e^{p \beta x_{1}} \mathrm{~d} x=\int_{-\delta}^{0} \int_{-\left|x_{1}\right|^{1 /(1+\lambda)}}^{\left|x_{1}\right|^{1 /(1+\lambda)}} e^{p \beta x_{1}} \mathrm{~d} x_{2} \mathrm{~d} x_{1}
$$

$$
\begin{aligned}
& =2 \int_{0}^{\delta} t^{1 /(1+\lambda)} e^{-p \beta t} \mathrm{~d} t \leq 2 \int_{0}^{\infty} t^{1 /(1+\lambda)} e^{-p \beta t} \mathrm{~d} t \\
& =2(p \beta)^{-(2+\lambda) /(1+\lambda)} \int_{0}^{\infty} t^{1 /(1+\lambda)} e^{-t} \mathrm{~d} t=2 \Gamma\left(\frac{2+\lambda}{1+\lambda}\right)(p \beta)^{-(2+\lambda) /(1+\lambda)}
\end{aligned}
$$

Putting these estimates into the expression (5) for $K(\alpha)$ one sees that for a suitable $c_{\lambda}>0$ we have, as $\alpha$ is large,

$$
K(\alpha) \geq c_{\lambda} \alpha \beta^{(1-\lambda) /(1+\lambda)} \equiv c_{\lambda} \alpha^{m}, \quad m:=\left(p-\frac{2 \lambda}{\lambda+1}\right) /(p-1)
$$

and the claim follows from the above inequality (4).
Corollary 4. For any $r<q$ one can find a bounded $C^{1}$ domain $\Omega \subset \mathbb{R}^{2}$ and $a$ constant $c_{r}>0$ satisfying $\left|\Lambda(\alpha)-(1-p) \alpha^{q}\right| \geq c_{r} \alpha^{r}$ for large $\alpha$.
Proof. Given a value of $r$, one can find a sufficiently small $\lambda \in(0,1)$ to have $\left(p-\frac{2 \lambda}{\lambda+1}\right) /(p-1) \geq r$. For this value of $\lambda$ one applies Proposition 3
