# On a class of Lebesgue-Ljunggren-Nagell type equations 

Andrzej Dąbrowski, Nursena Günhan and Gökhan Soydan

Abstract. Given odd, coprime integers $a, b(a>0)$, we consider the Diophantine equation $a x^{2}+b^{2 l}=4 y^{n}, x, y \in \mathbb{Z}, l \in \mathbb{N}$, $n$ odd prime, $\operatorname{gcd}(x, y)=1$. We completely solve the above Diophantine equation for $a \in\{7,11,19,43,67,163\}$, and $b$ a power of an odd prime, under the conditions $2^{n-1} b^{l} \not \equiv \pm 1(\bmod a)$ and $\operatorname{gcd}(n, b)=1$. For other square-free integers $a>3$ and $b$ a power of an odd prime, we prove that the above Diophantine equation has no solutions for all integers $x, y$ with $(\operatorname{gcd}(x, y)=1), l \in \mathbb{N}$ and all odd primes $n>3$, satisfying $2^{n-1} b^{l} \not \equiv \pm 1(\bmod a), \operatorname{gcd}(n, b)=1$, and $\operatorname{gcd}(n, h(-a))=1$, where $h(-a)$ denotes the class number of the imaginary quadratic field $\mathbb{Q}(\sqrt{-a})$.

Key words: Diophantine equation, Lehmer number, Fibonacci number, class number, modular form, elliptic curve

2010 Mathematics Subject Classification: 11D61, 11B39

## 1 Introduction

The Diophantine equation $x^{2}+C=y^{n}(x \geq 1, y \geq 1, n \geq 3)$ has a rich history. Lebesgue proved that this equation has no solution when $C=1$, and Cohn solved the equation for several values of $1 \leq C \leq 100$. The remaining values of $C$ in the above range were covered by Mignotte and de Weger, and finally by Bugeaud, Mignotte and Siksek. Barros in his PhD thesis considered the range $-100 \leq C \leq-1$. Also, several authors (Abu Muriefah, Arif, Dąbrowski, Le, Luca, Pink, Soydan, Togbé, Ulas,...) became interested in the case where only the prime factors of $C$ are specified. Surveys of these
and many others topics can be found in [2] and [5]. Some people studied the more general equation $a x^{2}+C=2^{i} y^{n}, a>0$ and $i \leq 2$.

Given odd, coprime integers $a, b(a>0)$, we consider the Diophantine equation

$$
\begin{equation*}
a x^{2}+b^{2 l}=4 y^{n}, \quad x, y \in \mathbb{Z}, l, n \in \mathbb{N}, n \text { odd prime }, \operatorname{gcd}(x, y)=1 \tag{1}
\end{equation*}
$$

If $a \equiv 1 \bmod 4$, then reducing modulo 4 we trivially obtain that the equation (1) has no solution.

It is known (due to Ljunggren [18]) that the Diophantine equation $a x^{2}+$ $1=4 y^{n}, n \geq 3$, has no positive solution with $y>1$ such that $a \equiv 3(\bmod 4)$ and the class number of the quadratic field $\mathbb{Q}(\sqrt{-a})$ is not divisible by $n$. When $a=3$, then $3 x^{2}+1=4 y^{n}$ has the only positive solution $(x, y)=(1,1)$.

As our first result, we completely solve the equation (1) for $a \in\{7,11,19$, $43,67,163\}$, under the conditions $2^{n-1} b^{l} \not \equiv \pm 1(\bmod a)$ and $\operatorname{gcd}(n, b)=1$.

Theorem 1 Fix $p \in\{7,11,19,43,67,163\}$ and $b= \pm q^{r}$, with $q$ an odd prime different from $p$ and $r \geq 1$.
(i) The Diophantine equation

$$
\begin{equation*}
p x^{2}+b^{2 l}=4 y^{n}, l \in \mathbb{N}, \operatorname{gcd}(x, y)=1 \tag{2}
\end{equation*}
$$

has no solutions ( $p, x, y, b, l, n$ ) with integers $x, y$ and primes $n>3$, satisfying the conditions $2^{n-1} b^{l} \not \equiv \pm 1(\bmod p)$ and $\operatorname{gcd}(n, b)=1$.
(ii) If $n=3$ and $p \neq 7$, then the equation (2) has no solutions ( $p, x, y, b, l, 3$ ) satisfying the conditions $4 b^{l} \not \equiv \pm 1(\bmod p)$ and $\operatorname{gcd}(3, b)=1$.
(iii) If $n=3$ and $p=7$, then the equation (2) leads to 6 infinite families of solutions, corresponding to solutions of Pell-type equations (4), (5), (6), (7), and satisfying the conditions $4 b^{l} \not \equiv \pm 1(\bmod 7)$ and $\operatorname{gcd}(3, b)=1$.

Remarks. (i) The Diophantine equation (2) has many solutions (infinitely many?) satisfying the conditions $2^{n-1} b^{l} \equiv \pm 1(\bmod p)$ and $\operatorname{gcd}(n, b)=$ 1. Examples include $(p, x, y, b, l, n) \in\{(7, \pm 1,2, \pm 11,1,5),(11, \pm 1,3, \pm 31,1,5),(7, \pm 7,2, \pm 13,1,7)$, $(19, \pm 1,5, \pm 559,1,7),(11, \pm 253,3, \pm 67,1,11),(19, \pm 2531,5, \pm 8579,1,11)$, $(7, \pm 1,2, \pm 181,1,13),(11, \pm 1801,3, \pm 21929,1,17),(7, \pm 457,2, \pm 797,1,19)$, ( $7, \pm 967,2, \pm 5197,1,23)\}$.
(ii) If $b$ is divisible by at least two different odd primes, then the Diophantine equation (2) may have solutions satisfying the conditions $2^{n-1} b^{l} \not \equiv$ $\pm 1(\bmod p)$. Examples include
$(p, x, y, b, l, n) \in\{(7,103820535541,4,10341108537,1,37)$,
$(7,4865,46,1320267,1,7),(19,315003,49,909715,1,7)$, $(19,581072253,49,3037108805,1,11)\}$.
(iii) Write the equation (2) as $p x^{2}+b^{2 l}=4 y\left(y^{(n-1) / 2}\right)^{2}$ (compare [18, p.116]). Now using $4 y=u^{2}+p v^{2}$, taking $u= \pm 1$, and multiplying the equation by $p$, we arrive at the equation

$$
\begin{equation*}
X^{2}-p\left(1+p v^{2}\right) Y^{2}=-p b^{2 l} \tag{3}
\end{equation*}
$$

If $b= \pm 1$, we obtain the equation ( $7^{\prime}$ ) in [18]. Ljunggren used an old result by Mahler to deduce that, if $p>3$, then (3) has no solution with $Y>1$ such that any prime divisor of $Y$ divides $p\left(1+p v^{2}\right)$ as well.
(iv) Question: may we extend Ljunggren's idea to prove non-existence of solutions of our equation for some $b^{l}$ ?

For a family of positive square-free integers $a$ with $h(-a)>1$ we can prove the following result (a variant of the results by Bugeaud [9] and Arif and Al-Ali [3] in a case of the equation $\left.a x^{2}+b^{2 l+1}=4 y^{n}\right)$. Let $h(-a)$ denote the class number of the imaginary quadratic field $\mathbb{Q}(\sqrt{-a})$.

Theorem 2 Fix a positive square-free integer a, different from 3, 7, 11, 19, 43, 67, 163, and $b= \pm q^{r}$, with $q$ an odd prime not dividing a and $r \geq$ 1. Then the Diophantine equation (1) has no solutions $(a, x, y, b, l, n)$, with integers $x, y$ and primes $n>3$ satisfying the conditions $\operatorname{gcd}(n, h(-a))=1$, $2^{n-1} b^{l} \not \equiv \pm 1(\bmod a)$, and $\operatorname{gcd}(n, b)=1$.

Remarks. (i) There are a lot of positive square-free integers $a$ with $\operatorname{rad}(h(-a)) \mid 6$ (hypothetically, infinitely many): 18 values of $a$ with $h(-a)=$ 2,54 values of $a$ with $h(-a)=4,31$ values of $a$ with $h(-a)=6$, etc. Here $\operatorname{rad}(m)$ denotes the radical of a positive integer $m$, i.e. the product of all prime divisors of $m$.
(ii) For fixed $a$ and $b$ we can (in some cases) use MAGMA 8 to solve the Diophantine equation $a x^{2}+b^{2 l}=4 y^{3}$ (applying SIntegralPoints subroutine of MAGMA to associated families of elliptic curves). In a general case, one can try to prove a variant of Dahmen's result [14] saying that the above equation has no solution for a positive proportion of $l$ 's, not divisible by 3 .
(iii) The following variant of a result by Laradji, Mignotte and Tzanakis (see [16, Theorem 2.3]) follows immediately from out Theorem 2 (note that always $h(-p)<p)$. Let $p, q$ be odd primes with $p \equiv 3(\bmod 8)$ and $p>3$. Then the Diophantine equation $p x^{2}+q^{2 l}=4 y^{p}$ has no solution $(x, y, l)$ with positive integers $x, y, l$ satisfying $\operatorname{gcd}(x, y)=1$.
(iv) Dieulefait and Urroz [15] used the method of Galois representations attached to $\mathbb{Q}$-curves to solve the Diophantine equation $3 x^{2}+y^{4}=z^{n}$. The authors suggest that their method can be applied to solve this type of equations with 3 replaced by other values of $a$. We expect that their method can be extended to the case $a x^{2}+y^{4}=4 z^{n}$ with small $a$ as well.
(v) We can solve the Diophantine $a x^{2}+b^{2 l}=4 y^{n}$ for relatively small values of $a>0$ (at least) in positive integers $x, y, l, n, \operatorname{gcd}(x, y)=1, n \geq 7$ a prime dividing $l$, by using the Bennett-Skinner strategy [4]. We treat some examples in Section 3. Let us also mention that the smallest positive integer $a$ with $h(-a)=7$ is 71 , and one needs to consider newforms of weight 2 and level 10082.
(vi) Pink [21] used estimates for linear forms in two logarithms in the complex and the $p$-adic case, to give an explicit bound for the number of solutions of the Diophantine equation $x^{2}+\left(p_{1}^{\alpha_{1}} \cdots p_{s}^{\alpha_{s}}\right)^{2}=2 y^{n}$ in terms of $s$ and $\max \left\{p_{1}, \cdots, p_{s}\right\}$. We can prove analogous result concerning the equations $p x^{2}+\left(p_{1}^{\alpha_{1}} \cdots p_{s}^{\alpha_{s}}\right)^{2}=4 y^{n}$, with $p \in\{7,11,19,43,67,163\}$.

## 2 Proofs of Theorems 1 and 2

## Proof of Theorem 1 .

Below in the proof, $b$ is a power of an odd prime $q \neq p$.
As the class number of $\mathbb{Q}(\sqrt{-p})$ with $p \in\{7,11,19,43,67,163\}$ is 1 , we have the following factorization

$$
\frac{b^{l}+x \sqrt{-p}}{2} \cdot \frac{b^{l}-x \sqrt{-p}}{2}=y^{n} .
$$

Now we have

$$
\frac{b^{l}+x \sqrt{-p}}{2}=\left(\frac{u+v \sqrt{-p}}{2}\right)^{n}
$$

where $u, v$ are odd rational integers. Note that necessarily $\operatorname{gcd}(u, v)=1$. Equating real parts we get

$$
2^{n-1} b^{l}=u \sum_{r=0}^{(n-1) / 2}\binom{n}{2 r} u^{n-2 r-1}(-p)^{r} v^{2 r}
$$

As $u$ is odd, its possible values are among divisors of $b^{l}$. Here, we assume that $2^{n-1} b^{l} \not \equiv \pm 1(\bmod p)$.
(i) If $u= \pm 1$, then $2^{n-1} b^{l}=\sum_{r=0}^{(n-1) / 2}\binom{n}{2 r}(-p)^{r} v^{2 r}$, and in particular $2^{n-1} b^{l} \equiv \pm 1(\bmod p)$, a contradiction.
(ii) If $u \neq \pm 1, \pm b^{l}$, then $q$ divides $p v n$. Since $\operatorname{gcd}(u, v)=\operatorname{gcd}(p, b)=1$, then $q$ divides $n$, a contradiction.
(iii) Assume $u= \pm b^{l}$. Put $\alpha=\frac{v \sqrt{p}+b^{l} i}{2}$. Then $(\alpha+\bar{\alpha})^{2}=v^{2} p, \alpha \bar{\alpha}=$ $\frac{1}{4}\left(v^{2} p+b^{2 l}\right)$, and $\alpha / \bar{\alpha}$ is not a root of unity. Hence $(\alpha, \bar{\alpha})$ is a Lehmer pair. Note that $\frac{\alpha^{n}-\bar{\alpha}^{n}}{\alpha-\bar{\alpha}}= \pm 1$. On the other hand, using [7] we obtain that $\frac{\alpha^{n}-\bar{\alpha}^{n}}{\alpha-\bar{\alpha}}$ has primitive divisors for $n=11$ and all primes $n>13$, and hence our equation has no solution for $n=11$ and for primes $n>13$. Let us consider the cases $n \in\{3,5,7,13\}$ separately. Let us stress that the data in [7] are given for equivalence classes of $n$-detective Lehmer pairs: two Lehmer pairs $\left(\alpha_{1}, \beta_{1}\right),\left(\alpha_{2}, \beta_{2}\right)$ are equivalent (we write $\left.\left(\alpha_{1}, \beta_{1}\right) \sim\left(\alpha_{2}, \beta_{2}\right)\right)$ if $\alpha_{1} / \alpha_{2}=$ $\beta_{1} / \beta_{2} \in\{ \pm 1, \pm i\}$.
$\underline{n=3}$. According to [7], we have two possibilities: (a) $\frac{v \sqrt{p}+u i}{2} \sim \frac{\sqrt{1+\lambda}+\sqrt{1-3 \lambda}}{2}$, $\lambda \neq 1$, or (b) $\frac{v \sqrt{p}+u i}{2} \sim \frac{\sqrt{3^{k}+\lambda}+\sqrt{3^{k}-3 \lambda}}{2}, k>0,3 \nmid \lambda$.

In the case (a) we have four subcases: (i) $1+\lambda=v^{2} p$ and $1-3 \lambda=-u^{2}$ or (ii) $1+\lambda=-v^{2} p$ and $1-3 \lambda=u^{2}$ or (iii) $1+\lambda=-u^{2}$ and $1-3 \lambda=v^{2} p$ or (iv) $1+\lambda=u^{2}$ and $1-3 \lambda=-v^{2} p$.

In the subcase (i) we obtain a contradiction reducing the second equation modulo 3.

In the subcase (ii) we obtain relation $u^{2}=3 p v^{2}+4$. If $p \neq 7$, then reducing this equation modulo 8 , we obtain $1 \equiv 5(\bmod 8)$, a contradiction. Now the case $p=7$ leads to Pell-type equation

$$
\begin{equation*}
u^{2}-21 v^{2}=4 \tag{4}
\end{equation*}
$$

Using the assumption $u$ and $v$ are odd for our equation, any solution to (4) is given by

$$
\frac{u_{t}+v_{t} \sqrt{21}}{2}=\left(\frac{u_{0}+v_{0} \sqrt{21}}{2}\right)^{t}
$$

where $\left(u_{0}, v_{0}\right)=(5,1)$ is minimal solution and $3 \nmid t$. Thus an infinite family of solutions of equation (1) is given by

$$
\left(x_{t}, y_{t}, b_{t}^{l}, n\right)=\left(\frac{3 u_{t}^{2} v_{t}-7 v_{t}^{3}}{4}, \frac{7 v_{t}^{2}+u_{t}^{2}}{4}, \frac{u_{t}^{3}-21 u_{t} v_{t}^{2}}{4}, 3\right)
$$

(see [12, Proposition 6.3.16] for the details about the equation (4)).
In the subcase (iii), note that $4+3 u^{2}=v^{2} p$, and hence $7 \equiv 3(\bmod 8)$ if $p \neq 7$, a contradiction. If $p=7$, then we need to consider the Diophantine equation

$$
\begin{equation*}
7 v^{2}-3 u^{2}=4 \tag{5}
\end{equation*}
$$

Such an equation has 3 infinite families of solutions $(v, u) \in\{(s+3 r, s+$ $7 r),(-s+3 r, s-7 r),(4 s+18 r, 6 s+28 r)\}$, where $s^{2}-21 r^{2}=1$. But since $u$ and $v$ are odd, one gets 2 infinite families of solutions $(v, u) \in\{(s+3 r, s+$ $7 r),(-s+3 r, s-7 r)\}$ for the equation (5). Any solution to the equation $s^{2}-21 r^{2}=1$ is given by

$$
s_{t}+r_{t} \sqrt{21}=\left(s_{0}+r_{0} \sqrt{21}\right)^{t}
$$

where $\left(s_{0}, r_{0}\right)=(55,12)$ is minimal solution. Thus 2 infinite families of solutions of equation (1) are given by

$$
\begin{aligned}
x_{t} & =-3 r_{t} s_{t}^{2}+63 r_{t}^{3}+21 s_{t} r_{t}^{2}-s_{t}^{3} \\
y_{t} & =2 s_{t}^{2}+14 s_{t} r_{t}+28 r_{t}^{2} \\
b_{t}^{l} & =-5 s_{t}^{3}-63 s_{t}^{3} r_{t}-231 s_{t} r_{t}^{2}-245 r_{t}^{3}
\end{aligned}
$$

or

$$
\begin{aligned}
x_{t} & =-3 s_{t}^{2} r_{t}+s_{t}^{3}-21 s_{t} r_{t}^{2}+63 r_{t}^{3} \\
y_{t} & =2 s_{t}^{2}-14 s_{t} r_{t}+28 r_{t}^{2} \\
b_{t}^{l} & =-5 s_{t}^{3}+63 s_{t}^{2} r_{t}-231 s_{t} r_{t}^{2}+245 r_{t}^{3}
\end{aligned}
$$

with $n=3$. (see [1, Theorems 4.5.1, 4.5.2] for details about the equation (5)).

In the subcase (iv) note that $4+v^{2} p=3 u^{2}$, and hence $7 \equiv 3(\bmod 8)$ if $p \neq 7$, a contradiction. If $p=7$, then reducing $4+7 v^{2}=3 u^{2}$ modulo 7 we obtain $\square=-\square$, a contradiction.

In the case (b) we have four subcases: (i) $3^{k}+\lambda=v^{2} p$ and $3^{k}-3 \lambda=-u^{2}$ or (ii) $3^{k}+\lambda=-v^{2} p$ and $3^{k}-3 \lambda=u^{2}$ or (iii) $3^{k}+\lambda=-u^{2}$ and $3^{k}-3 \lambda=v^{2} p$ or (iv) $3^{k}+\lambda=u^{2}$ and $3^{k}-3 \lambda=-v^{2} p$.

In the subcase (i) note that $3 v^{2} p=u^{2}+4 \cdot 3^{k}$, hence necessarily $k=1$ (otherwise $3 \mid \operatorname{gcd}(u, v)$ ). Therefore $v^{2} p=3 t^{2}+4$, where $u=3 t$. If $p \neq 7$, then reducing this equation modulo 8 , we obtain $3 \equiv 7(\bmod 8)$, a contradiction. If $p=7$, then we need to consider the Diophantine equation

$$
\begin{equation*}
7 v^{2}-3 t^{2}=4 \tag{6}
\end{equation*}
$$

As in subcase (iii) of part (a) Such an equation has 3 infinite families of solutions $(v, u) \in\{(s+3 r, 3(s+7 r)),(-s+3 r, 3(s-7 r)),(4 s+18 r, 3(6 s+$ $28 r))\}$, where $s^{2}-21 r^{2}=1$. But since $u$ and $v$ are odd, one obtains 2 infinite families of solutions $(v, u) \in\{(s+3 r, 3(s+7 r)),(-s+3 r, 3(s-7 r))$ for the equation (6). Any solution to the equation $s^{2}-21 r^{2}=1$ is given by

$$
s_{t}+r_{t} \sqrt{21}=\left(s_{0}+r_{0} \sqrt{21}\right)^{t}
$$

where $\left(s_{0}, r_{0}\right)=(55,12)$ is minimal solution. Thus 2 infinite families of solutions of equation (1) are given by

$$
\begin{aligned}
x_{t} & =567 s_{t} r_{t}^{2}+99 r_{t} s_{t}^{2}+5 s_{t}^{3}+945 r_{t}^{3} \\
y_{t} & =4 s_{t}^{2}+42 s_{t} r_{t}+126 r_{t}^{2} \\
b_{t}^{l} & =-9 s_{t}^{3}-63 s_{t}^{2} r_{t}+189 s_{t} r_{t}^{2}+1323 r_{t}^{3}
\end{aligned}
$$

or

$$
\begin{aligned}
x_{t} & =-567 s_{t} r_{t}^{2}+99 r_{t} s_{t}^{2}-5 s_{t}^{3}+945 r_{t}^{3} \\
y_{t} & =4 s_{t}^{2}-42 s_{t} r_{t}+126 r_{t}^{2} \\
b_{t}^{l} & =-9 s_{t}^{3}+63 s_{t}^{2} r_{t}+189 s_{t} r_{t}^{2}-1323 r_{t}^{3}
\end{aligned}
$$

with $n=3$.
In the subcase (ii) note that $4 \cdot 3^{k}+3 p v^{2}=u^{2}$, hence necessarily $k=1$ (otherwise $3 \mid \operatorname{gcd}(u, v)$ ). Therefore $4=3 t^{2}-p v^{2}$, where $u=3 t$. If $p \neq 7$, then reducing this equation modulo 8 , we obtain $4 \equiv 0(\bmod 8)$, a contradiction. Now reducing $4=3 t^{2}-7 v^{2}$ modulo 7 , we obtain $\square=-\square$, a contradiction again.

In the subcase (iii) note that $3 t^{2} p=u^{2}+4$, where $v=3 t$. Now reducing modulo 3 , we obtain a contradiction.

In the subcase (iv) note that $u^{2}=3 p t^{2}+4$, where $v=3 t$. If $p \neq 7$, then reducing this equation modulo 8 , we obtain $1 \equiv 5(\bmod 8)$, a contradiction. Now the case $p=7$ leads to Pell-type equation

$$
\begin{equation*}
u^{2}-21 t^{2}=4 \tag{7}
\end{equation*}
$$

Since $u$ and $v$ are odd, one gets that $t$ is odd for the equation (7). So, any solution to (7) is given by

$$
\frac{u_{m}+t_{m} \sqrt{21}}{2}=\left(\frac{u_{0}+t_{0} \sqrt{21}}{2}\right)^{m}
$$

where $\left(u_{0}, t_{0}\right)=(5,1)$ is minimal solution and $3 \nmid m$. Thus an infinite family of solutions of equation (1) is given by

$$
\left(x_{m}, y_{m}, b_{m}^{l}, n\right)=\left(\frac{3 u_{m}^{2} v_{m}-7 v_{m}^{3}}{4}, \frac{7 v_{m}^{2}+u_{m}^{2}}{4}, \frac{u_{m}^{3}-21 u_{m} v_{m}^{2}}{4}, 3\right),
$$

with $v_{m}=3 t_{m}$.
$\underline{n=5}$. According to [7], we have two possibilities to consider: (a) $\frac{v \sqrt{p}+u i}{2} \sim$ $\frac{\sqrt{F_{k-2 \epsilon}}+\sqrt{F_{k-2 \epsilon}-4 F_{k}}}{2}, k \geq 3, \epsilon= \pm 1$, or (b) $\frac{v \sqrt{p}+u i}{2} \sim \frac{\sqrt{L_{k-2 \epsilon}}+\sqrt{L_{k-2 \epsilon}-4 F_{k}}}{2}$, $k \neq 1, \epsilon= \pm 1$. Here $F_{m}$ and $L_{m}$ denote $m$-th Fibonacci and Lucas number respectively.

In the case (a) we have four subcases: (i) $v^{2} p=F_{k-2 \epsilon}-4 F_{k}$ and $-u^{2}=$ $F_{k-2 \epsilon}$ or (ii) $-v^{2} p=F_{k-2 \epsilon}-4 F_{k}$ and $u^{2}=F_{k-2 \epsilon}$ or (iii) $v^{2} p=F_{k-2 \epsilon}$ and $-u^{2}=F_{k-2 \epsilon}-4 F_{k}$ or (iv) $-v^{2} p=F_{k-2 \epsilon}$ and $u^{2}=F_{k-2 \epsilon}-4 F_{k}$.

In the subcase (i) we obtain $F_{k-2 \epsilon}=-u^{2}<0$, a contradiction.
In the subcase (ii), due to the fundamental work by Ljunggren [17] [19] (see also [11, Section 2]) we can find all solutions to the equation $u^{2}=F_{k-2 \epsilon}$ ( $k \geq 3, \epsilon= \pm 1$ ). Ljunggren has proved that the only squares in the Fibonacci sequence are $F_{0}=0, F_{1}=F_{2}=1$, and $F_{12}=144$.

The case $k-2 \epsilon=1$ gives $k=3, \epsilon=1, u^{2}=1$, hence using the first equation from (ii) we obtain $-v^{2} p=-7$, i.e. $p=7, v^{2}=1$. This case gives the solution $\left(p, x, y, b^{l}, n\right)=(7, \pm 1,2, \pm 11,5)$ which contradicts with $2^{n-1} b^{l} \not \equiv \pm(\bmod p)$.

The case $k-2 \epsilon=2$, gives $k=4, \epsilon=1, u^{2}=1$, hence using the first equation from (ii) we obtain $-v^{2} p=-11$, i.e. $p=11, v^{2}=1$. This case
gives the solution $\left(p, x, y, b^{l}, n\right)=(11, \pm 1,3, \pm 31,5)$, which is impossible since $2^{n-1} b^{l} \equiv \pm 1(\bmod p)$.

The case $k-2 \epsilon=12$, gives $k=14, \epsilon=1, u^{2}=144$ or $k=10, \epsilon=-1$, $u^{2}=144$. The first possibility gives $-v^{2} p=-2^{2} \cdot 11 \cdot 31$, i.e. $p=11 \cdot 31$, $v^{2}=4$. The second possibility gives $-v^{2} p=-2^{2} \cdot 19$, i.e. $p=19, v^{2}=4$. This case gives no solution satisfying $\operatorname{gcd}(x, b)=1$ (note that both $u$ and $v$ are even).

In the subcase (iii), let us note that $u^{2}=-\left(F_{k-2 \epsilon}-4 F_{k}\right)=F_{k}+F_{k+2 \epsilon}$. Now a short look at the paper by Luca and Patel (see [20, Theorem 1], and their calculations in Section 5) shows that $k=4, \epsilon=-1$ is the only possibility. But then $F_{6}=8=v^{2} p$, a contradiction.

In the subcase (iv) we obtain $F_{k-2 \epsilon}=-v^{2} p<0$, a contradiction.
In the case (b) we have four subcases: (i) $v^{2} p=L_{k-2 \epsilon}-4 L_{k}$ and $-u^{2}=$ $L_{k-2 \epsilon}$ or (ii) $-v^{2} p=L_{k-2 \epsilon}-4 L_{k}$ and $u^{2}=L_{k-2 \epsilon}$ or (iii) $v^{2} p=L_{k-2 \epsilon}$ and $-u^{2}=L_{k-2 \epsilon}-4 L_{k}$ or (iv) $-v^{2} p=L_{k-2 \epsilon}$ and $u^{2}=L_{k-2 \epsilon}-4 L_{k}$.

In the subcase (i) we obtain $L_{k-2 \epsilon}=-u^{2}<0$, a contradiction.
In the subcase (ii) we can find all solutions to the equation $u^{2}=L_{k-2 \epsilon}$, $(k \neq 1, \epsilon= \pm 1)$. By the work by Cohn [13] we know all solutions: $L_{1}=1^{2}$ and $L_{3}=2^{2}$.

The case $k-2 \epsilon=1$, gives $k=3, \epsilon=1, u^{2}=1$, hence using the first equation from (ii) we obtain $-v^{2} p=-13$, i.e. $p=13, v^{2}=1$. The case $k-2 \epsilon=3$, gives $k=5, \epsilon=1, u^{2}=4$, hence using the first equation from (ii) we obtain $-v^{2} p=-40$, i.e. $p=10, v^{2}=4$. None of these two cases lead to solution of our Diophantine equation (13 is congruent to 1 modulo 4 , while 10 is even).

In the subcase (iii), let us note that $L_{k}+L_{k-2 \epsilon}=5 F_{k-\epsilon}$. Therefore we need to determine all $k$ such that $5 F_{k-\epsilon}$ is a square. Again, the paper by Bugeaud, Mignotte and Siksek [10] shows that the only possibility is $5 F_{5}=5^{2}$. But then $v^{2} p=L_{4}=7$ in case $\epsilon=1$ or $v^{2} p=L_{6}=18$ in case $\epsilon=-1$. In the first case we obtain $p=7$, but then $u^{2}=65$, a contradiction. The second case gives a contradiction by trivial observation.

In the subcase (iv) we obtain $L_{k-2 \epsilon}=-v^{2} p<0$, a contradiction.
$\underline{n=7}$. According to [7] we have six equivalence classes of 7 -defective Lehmer pairs. Two of them, $\left(\frac{1-\sqrt{-7}}{2}, \frac{1+\sqrt{-7}}{2}\right)$ and $\left(\frac{1-\sqrt{-19}}{2}, \frac{1+\sqrt{-19}}{2}\right)$, come from our Lehmer pairs, giving $\left(p, x, y, b^{l}, n\right) \in\{(7, \pm 7,2, \pm 13,7),(19, \pm 1,5$, $\pm 559,7)\}$, which are impossible since $2^{n-1} b^{l} \equiv \pm 1(\bmod p)$.
$\underline{n=13}$. The unique 13 -detective equivalence class $\left(\frac{1-\sqrt{-7}}{2}, \frac{1+\sqrt{-7}}{2}\right)$ leads to the solution $\left(p, x, y, b^{l}, n\right)=(7, \pm 1,2, \pm 181,13)$, which contradicts with $2^{n-1} b^{l} \not \equiv \pm 1(\bmod p)$.

Proof of Theorem ,
In this case, thanks to [6, Lemma 1], we can follow the same lines as in the proof of Theorem 1 for $n>3$.

## 3 Method via Galois representations and modular forms

We will consider the Diophantine equation $a x^{2}+b^{2 k}=4 y^{n}$, for $a \in\{3,7,11,15\}$ in positive integers $x, y, k, n, \operatorname{gcd}(x, y)=1, n \geq 7$ a prime dividing $k$. We will apply the Bennett-Skinner strategy [4], in particular we will use the results we need from [4]. We can compute systems of Hecke eigenvalues for conjugacy classes of newforms using MAGMA (or use Stein's Modular Forms Database provided the level is $\leq 7248$ ).

Remarks. (a) If $a \equiv 3 \bmod 8$, then $y$ is necessarily odd: if $y$ is even, then reducing modulo 8 we obtain that the left hand side is congruent to 4 modulo 8 , while the right hand side is congruent to 0 modulo 8 , a contradiction.
(b) If $a \equiv 7 \bmod 8$, then $y$ is necessarily even.
(i) The Diophantine equation $3 x^{2}+b^{2 k}=4 y^{n}$ has no solution $(x, y, k, n)$, $x y \neq 1, n \geq 7$ prime dividing $k$.

We will consider a more general Diophantine equation $X^{n}+4 Y^{n}=3 Z^{2}$ ( $n \geq 7$ a prime) and use [4]. We are in case (iii) of [4, p.26], hence $\alpha \in\{1,2\}$. From Lemma 3.2 it follows, that we need to consider the newforms of weight 2 and levels $N \in\{36,72\}$.
a) There is only one newform of weight 2 and level 36 , corresponding to an elliptic curve $E$ of conductor 36 with complex multiplication by $\mathbb{Q}(\sqrt{-3})$. Here we will apply [4, Subsection 4.4], to prove that $a b= \pm 1$. Assume (a.a) that $a b \neq \pm 1$. Then (using Prop. 4.6 (b)) holds, hence if $n=7$ or 13, $n$ splits in $K=\mathbb{Q}(\sqrt{-3})$ and $E(K)$ is infinite for all elliptic curves of conductor $2 n$. One checks that both primes 7 and 13 split in $K$. Now using Cremona's online tables we check, that all elliptic curves of conductor $126=2 \times 7 \times 3^{2}$ have rank zero, and all elliptic curves of conductor $234=2 \times 13 \times 3^{2}$, which
are quadratic twists by 3 of quadratic curves of conductor 26 , have rank zero too.
b) There is only one newform of weight 2 and level 72 , corresponding to isogeny class of elliptic curves of conductor 72 , with $j$-invariant $u / 3^{v}$, with $v>0$ and $u$ some non-zero integer prime to 3 . To eliminate such an elliptic curve we use [4, Prop. 4.4].
(ii) The Diophantine equation $7 x^{2}+b^{2 k}=4 y^{n}$ has no solution $(x, y, k, n)$, $n \geq 7$ prime dividing $k$.

We need to consider the newforms of weight 2 and level $N=98$.
There are two Galois conjugacy classes of forms of weight 2 and level 98. We will use numbering as in Stein's tables: we have $a_{3}\left(f_{2}\right)= \pm \sqrt{2}$ and we can use [4, Prop. 4.3] to eliminate $f_{2}$. On the other hand, the form $f_{1}$ corresponds to an elliptic curve of conductor 98 , with $j$-invariant $u / 7^{v}$, with $v>0$ and $u$ some non-zero integer prime to 7 . To eliminate such an elliptic curves we use [4, Prop. 4.4].
(iii) The Diophantine equation $11 x^{2}+b^{2 k}=4 y^{n}$ has no solution $(x, y, k, n)$, $n \geq 7, n \neq 11,13$ prime dividing $k$.

We need to consider the newforms of weight 2 and levels $N \in\{484,968\}$.
a) There are five Galois conjugacy classes of forms of weight 2 and level 484. We have $a_{3}\left(f_{1}\right)=1, a_{3}\left(f_{4}\right)=\frac{1 \pm \sqrt{33}}{2}$, and we can use [4, Prop. 4.3] to eliminate $f_{1}$ and $f_{4}$. To eliminate $f_{2}$ and $f_{3}$ we need to consider coefficients $a_{3}$ and $a_{5}$ : we have $a_{3}\left(f_{2}\right)=a_{3}\left(f_{3}\right)=\frac{-3 \pm \sqrt{5}}{2}$ and $a_{5}\left(f_{2}\right)=a_{5}\left(f_{3}\right)=\frac{-1 \pm \sqrt{5}}{2}$ (we cannot avoid $n=29$ when considering only $a_{3}$ ). Finally, $a_{7}\left(f_{5}\right)= \pm 2 \sqrt{3}$, and we can use [4, Prop. 4.3] to eliminate $f_{5}$ when $n \geq 7$ and $n \neq 13$.
b) There are fourteen Galois conjugacy classes of forms of weight 2 and level 968. We have $a_{3}\left(f_{1}\right)=-3, a_{5}\left(f_{2}\right)=a_{5}\left(f_{3}\right)=3, a_{3}\left(f_{4}\right)=a_{3}\left(f_{5}\right)=1$, $a_{3}\left(f_{6}\right)=a_{3}\left(f_{7}\right)= \pm 2 \sqrt{5}, a_{3}\left(f_{10}\right)=\frac{1 \pm \sqrt{17}}{2}$, and we can easily use [4, Prop. 4.3] to eliminate $f_{1}, \ldots, f_{7}$, and $f_{10}$. Now considering $a_{3}$ and $a_{13}$ for both newforms $f_{8}, f_{9}$, and $a_{3}$ and $a_{5}$ for both newforms $f_{13}, f_{14}$, and using [4, Prop. 4.3], we can eliminate these four forms when $n \geq 7$ and $n \neq 11$.
(iv) The Diophantine equation $15 x^{2}+b^{2 k}=4 y^{n}$ has no solution $(x, y, k, n)$, $n \geq 7$ prime dividing $k$.

We need to consider the newforms of weight 2 and level $N=450$.
There are seven Galois conjugacy classes of forms of weight 2 and level 450. We have $a_{11}\left(f_{3}\right)=a_{11}\left(f_{7}\right)=3$, and we can use [4, Prop. 4.3] to
eliminate $f_{3}$ and $f_{7}$. The forms $f_{2}$ and $f_{6}$ correspond to elliptic curves of conductor 450 (named $C$ and $A$ respectively in Cremona's tables), with $j$ invariants $u / 3^{v}$, with $v>0$ and $u$ some non-zero integer prime to 3 ; the forms $f_{1}$ and $f_{5}$ correspond to elliptic curves of conductor 450 (named $F$ and $E$ respectively in Cremona's tables), with $j$-invariants $u / 5^{v}$, with $v>0$ and $u$ some non-zero integer prime to 5 ; the form $f_{4}$ corresponds to elliptic curve $G$ of conductor 450, with $j$-invariant $u /\left(3^{v} 5^{w}\right)$, with $v, w>0$ and $u$ some non-zero integer prime to 15 . To eliminate all these elliptic curves we use [4, Prop. 4.4]

## Acknowledgments

We would like to thank Professor Mike Bennett for providing us with some references. Andrzej Dąbrowski would like to thank Professor Gökhan Soydan for inviting him to the Friendly Workshop on Diophantine Equations and Related Problems (Bursa Uludağ University, Bursa, July 6-8, 2019), where this work started. This workshop was partially supported by TÜBİTAK (the Scientific and Technological Research Council of Turkey) under Project No: 117F287.
