#### Abstract

We consider stochastic differential equations driven by a general Lévy processes (SDEs) with infinite activity and the related, via the Feynman-Kac formula, Dirichlet problem for parabolic integro-differential equation (PIDE). We approximate the solution of PIDE using a numerical method for the SDEs. The method is based on three ingredients: (i) we approximate small jumps by a diffusion; (ii) we use restricted jump-adaptive time-stepping; and (iii) between the jumps we exploit a weak Euler approximation. We prove weak convergence of the considered algorithm and present an in-depth analysis of how its error and computational cost depend on the jump activity level. Results of some numerical experiments, including pricing of barrier basket currency options, are presented.

AMS 2000 subject classification. Primary 65C30; secondary 60H10, 35R09, 60H35, 60J75.
Keywords. SDEs driven by Lévy processes, jump processes, integro-differential equations, Feynman-Kac formula, weak approximation of stochastic differential equations.

## 1 Introduction

Stochastic differential equations driven by Lévy processes (SDEs) have become a very important modelling tool in finance, physics, and biology (see e.g. [1, 4, 6, 23]). Successful use of SDEs relies on effective numerical methods. In this paper, we are interested in weak-sense approximation of SDEs driven by general Lévy processes in which the noise has both the Wiener process and Poisson processes components including the case of infinite jump activity.

Let $G$ be a bounded domain in $\mathbb{R}^{d}, Q=\left[t_{0}, T\right) \times G$ be a cylinder in $\mathbb{R}^{d+1}, \Gamma=\bar{Q} \backslash Q$ be the part of the cylinder's boundary consisting of the upper base and lateral surface, $G^{c}=\mathbb{R}^{d} \backslash Q$ be the complement of $G$ and $Q^{c}:=\left(t_{0}, T\right] \times G^{c} \cup\{T\} \times \bar{G}$. Consider the Dirichlet problem for the parabolic integro-differential equation (PIDE):

$$
\begin{align*}
\frac{\partial u}{\partial t}+L u+c(t, x) u+g(t, x) & =0, \quad(t, x) \in Q  \tag{1.1}\\
u(t, x) & =\varphi(t, x), \quad(t, x) \in Q^{c},
\end{align*}
$$

[^0]where the integro-differential operator $L$ is of the form
\[

$$
\begin{align*}
& L u(t, x):=\frac{1}{2} \sum_{i, j=1}^{d} a^{i j}(t, x) \frac{\partial^{2} u}{\partial x^{i} \partial x^{j}}(t, x)+\sum_{i=1}^{d} b^{i}(t, x) \frac{\partial u}{\partial x^{i}}(t, x)  \tag{1.2}\\
& +\int_{\mathbb{R}^{m}}\left\{u(t, x+F(t, x) z)-u(t, x)-\langle F(t, x) z, \nabla u(t, x)\rangle \mathbf{I}_{|z| \leq 1}\right\} \nu(\mathrm{d} z)
\end{align*}
$$
\]

$a(t, x)=\left(a^{i j}(t, x)\right)$ is a $d \times d$-matrix; $b(t, x)=\left(b^{1}(t, x), \ldots, b^{d}(t, x)\right)^{\top}$ is a $d$-dimensional vector; $c(t, x), g(t, x)$, and $\varphi(t, x)$ are scalar functions; $F(t, x)=\left(F^{i j}(t, x)\right)$ is a $d \times m$-matrix; and $\nu(z), z \in \mathbb{R}^{m}$, is a Lévy measure such that $\int_{\mathbb{R}^{m}}\left(|z|^{2} \wedge 1\right) \nu(\mathrm{d} z)<\infty$. We allow $\nu$ to be of infinite intensity, i.e. we may have $\nu(B(0, r))=\infty$ for some $r>0$, where as usual for $x \in \mathbb{R}^{d}$ and $s>0$ we write $B(x, s)$ for the open ball of radius $s$ centred at $x$.

The Feynman-Kac formula provides a probabilistic representations of the solution $u(t, x)$ to (1.1) in terms of a system of Lévy-driven SDEs (see Section 2), which can be viewed as a system of characteristics for this PIDE. A weak-sense approximation of the SDEs together with the Monte Carlo technique gives us a numerical approach to evaluating $u(t, x)$, which is especially effective in higher dimensions.

There has been a considerable amount of research on weak-sense numerical methods for Lévy-type SDEs of finite and infinite activity (see e.g. [10-14, 16, 19 22] and references therein). Our approach is most closely related to [12]. As in [3, 11, 12], we replace small jumps with an appropriate Brownian motion, which makes the numerical solution of SDEs with infinite activity of the Lévy measure feasible in practice. There are three main differences between our approach and that of [12]. First, we use restricted jump-adapted time-stepping while in [12] jump-adapted time-stepping was used. Here by jump-adapted we mean that time discretization points are located at jump times $\tau_{k}$ and between the jumps the remaining diffusion process is effectively approximated [11, 12]. By restricted jump-adapted time-stepping, we understand the following. We fix a time-discretization step $h>0$. If the jump time increment $\delta$ for the next time step is less than $h$, we set the time increment $\theta=\delta$, otherwise $\theta=h$, i.e., our time steps are defined as $\theta=\delta \wedge h$. We note that this is a different time-stepping strategy to commonly used ones in the literature including the finite-activity case (i.e., jump-diffusion). For example, in the finite activity case it is common [13, 19, 20] to simulate $\tau_{k}$ before the start of simulations and then superimpose those random times on a grid with some constant or variable finite, small time-step $h$. Our time-stepping approach is more natural for the problem under consideration than both commonly used strategies; its benefits are discussed in Section 3, with the infinite activity case discussed in more detail in Subsections 3.5 and 4.2. Restricting $\delta$ by $h$ is beneficial for accuracy when jumps are rare (e.g. in the jump-diffusion case) and it is also beneficial for convergence rates (measured in the average number of steps) in the case of $\alpha$-stable Lévy measure with $\alpha \in(1,2)$ (see Sections 3 and 4 . Second, in comparison with [12] we explicitly show (singular) dependence of the numerical integration error of our algorithm on the parameter $\epsilon$ which is the cut-off for small jumps replaced by the Brownian motion. Third, in comparison with the literature we consider the Dirichlet problem for PIDEs, though we also comment on the Cauchy case in Subsection 3.4, which is novel with respect to the use of restricted time-stepping and dependence of the algorithm's error on $\epsilon$.

The paper is organised as follows. In Section 2, we write down a probabilistic representation for the solution $u(t, x)$ of (1.1), we state assumptions used throughout the paper, and we consider the approximation $u^{\epsilon}(t, x)$ that solves an auxiliary Dirichlet problem corresponding to the system of characteristics with jumps cut-off by $\epsilon$. In Section 3, we introduce the numerical algorithm which approximates $u^{\epsilon}(t, x)$. The algorithm uses the restricted jump-adapted timestepping and approximates the diffusion by a weak Euler scheme. In this section we also obtain and discuss the weak-sense error estimate for the algorithm. In Section 4, we illustrate our theoretical findings by three numerical examples, including an application of our algorithm to pricing an FX barrier basket option whose underlyings follow an exponential Lévy model.

## 2 Preliminaries

Let $\left(\Omega, \mathcal{F},\left\{\mathcal{F}_{t}\right\}_{t_{0} \leq t \leq T}, P\right)$ be a filtered probability space satisfying the usual hypotheses. The operator $L$ defined in (1.2), on an appropriate domain, is the generator of the $d$-dimensional process $X_{t_{0}, x}(t)$ given by

$$
\begin{equation*}
X_{t_{0}, x}(t)=x+\int_{t_{0}}^{t} b(s, X(s-)) \mathrm{d} s+\int_{t_{0}}^{t} \sigma(s, X(s-)) \mathrm{d} w(s)+\int_{t_{0}}^{t} \int_{\mathbb{R}^{d}} F(s, X(s-)) z \hat{N}(\mathrm{~d} z, \mathrm{~d} s) \tag{2.1}
\end{equation*}
$$

where the $d \times d$ matrix $\sigma(s, x)$ is defined through $\sigma(s, x) \sigma^{\top}(s, x)=a(s, x) ; w(t)=\left(w^{1}(t), \ldots, w^{d}(t)\right)^{\top}$ is a standard $d$-dimensional Wiener process; and $\hat{N}$ is a Poisson random measure on $[0, \infty) \times \mathbb{R}^{m}$ with intensity measure $\nu(\mathrm{d} z) \times \mathrm{d} s, \int_{\mathbb{R}^{m}}\left(|z|^{2} \wedge 1\right) \nu(\mathrm{d} z)<\infty$, and compensated small jumps, i.e.,

$$
\hat{N}([0, t] \times B)=\int_{[0, t] \times B} N(\mathrm{~d} z, \mathrm{~d} s)-t \nu(B \cap\{|z| \leq 1\}), \quad \text { for all } t \geq 0 \text { and } B \in \mathcal{B}\left(\mathbb{R}^{m}\right)
$$

Remark 2.1. Often [2, 21] a simpler model of the form

$$
\begin{equation*}
X(t)=x+\int_{t_{0}}^{t} F(s, X(s-)) \mathrm{d} Z(s) \tag{2.2}
\end{equation*}
$$

where $Z(t), t \geq t_{0}$, is an $m$-dimensional Lévy process with the characteristic exponent

$$
\psi(\xi)=\mathrm{i}(\mu, \xi)-\frac{1}{2}(\xi, \sigma \xi)+\int_{|z| \leq 1}\left[\mathrm{e}^{\mathrm{i}(\xi, z)}-1-\mathrm{i}(\xi, z)\right] \nu(\mathrm{d} z)+\int_{|z|>1}\left[\mathrm{e}^{\mathrm{i}(\xi, z)}-1\right] \nu(\mathrm{d} z)
$$

is considered instead of the general SDEs (2.1). The equation (2.2) is obtained as a special case of (2.1) by setting $b(t, x)=\mu F(t, x)$ and $\sigma(t, x)=\sigma F(t, x)$.

When the solution $u$ of 1.1$)$ is regular enough, for example $u \in C^{1,2}\left(\left[t_{0}, T\right] \times \mathbb{R}^{d}\right)$, it can be shown, see e.g. [2], that $u$ has the following probabilistic representation

$$
\begin{equation*}
u(t, x)=\mathbb{E}\left[\varphi\left(\tau_{t, x}, X_{t, x}\left(\tau_{t, x}\right)\right) Y_{t, x, 1}\left(\tau_{t, x}\right)+Z_{t, x, 1,0}\left(\tau_{t, x}\right)\right], \quad(t, x) \in Q \tag{2.3}
\end{equation*}
$$

where $\left(X_{t, x}(s), Y_{t, x, y}(s), Z_{t, x, y, z}(s)\right)$ for $s \geq t$, solves the system of SDEs consisting of (2.1) and

$$
\begin{equation*}
d Y=c(s, X(s-)) Y d s, \quad Y_{t, x, y}(t)=y \tag{2.4}
\end{equation*}
$$

$$
\begin{equation*}
d Z=g(s, X(s-)) Y d s, \quad Z_{t, x, y, z}(t)=z \tag{2.5}
\end{equation*}
$$

and $\tau_{t, x}=\inf \left\{s \geq t:\left(s, X_{t, x}(s)\right) \notin Q\right\}$ is the fist exit-time of the space-time Lévy process $\left(s, X_{t, x}(s)\right)$ from the space-time cylinder $Q$.

If one can simulate trajectories of $\left\{\left(s, X_{t, x}(s), Y_{t, x, 1}(s), Z_{t, x, 1,0}(s)\right) ; s \geq 0\right\}$ then the solution of the Dirichlet problem for PIDE (1.1) can be estimated by applying the Monte Carlo technique to (2.3). This approach however is not generally implementable for Lévy measures of infinite intensity, that is when $\nu(B(0, r))=\infty$ for some $r>0$. The difficulty arises from the presence of an infinite number of small jumps in any finite time interval, and can be overcome by replacing these small jumps by an appropriate diffusion exploiting the idea of the method developed in [3, 11], which we apply here. Alternatively, the issue can be overcome if one can simulate directly from the increments of Lévy process. We will not discuss this case in this paper as we only assume that one has access to the Lèvy measure.

### 2.1 Approximation of small jumps by diffusion

We will now consider the approximation of (2.1) discussed above, where small jumps are replaced by an appropriate diffusion. In the case of the whole space (the Cauchy problem for a PIDE) such an approximation was considered in [3, 11].

Let $\gamma_{\epsilon}$ be an $m$-dimensional vector with the components

$$
\begin{equation*}
\gamma_{\epsilon}^{i}=\int_{\epsilon \leq|z| \leq 1} z^{i} \nu(\mathrm{~d} z) ; \tag{2.6}
\end{equation*}
$$

and $B_{\epsilon}$ is an $m \times m$ matrix with the components

$$
\begin{equation*}
B_{\epsilon}^{i j}=\int_{|z|<\epsilon} z^{i} z^{j} \nu(\mathrm{~d} z) \tag{2.7}
\end{equation*}
$$

while $\beta_{\epsilon}$ be obtained from the formula $\beta_{\epsilon} \beta_{\epsilon}^{\top}=B_{\epsilon}$.
Remark 2.2. In many practical situations (see e.g. [6]), where the dependence among the components of $X(t)$ introduced through the structure of the SDEs is enough, we can allow the components of the driving Poisson measure to be independent. This amounts to saying that $\nu$ is concentrated on the axes, and as a result $B_{\epsilon}$ will be a diagonal matrix.

We shall consider the modified jump-diffusion $\widetilde{X}_{t_{0}, x}(t)=\widetilde{X}_{t_{0}, x}^{\epsilon}(t)$ defined as

$$
\begin{align*}
\widetilde{X}_{t_{0}, x}(t)= & x+\int_{t_{0}}^{t}\left[b(s, \widetilde{X}(s-))-F(s, \widetilde{X}(s-)) \gamma_{\epsilon}\right] \mathrm{d} s+\int_{t_{0}}^{t} \sigma(s, \widetilde{X}(s-)) \mathrm{d} w(s)  \tag{2.8}\\
& +\int_{t_{0}}^{t} F(s, \widetilde{X}(s-)) \beta_{\epsilon} \mathrm{d} W(s)+\int_{t_{0}}^{t} \int_{|z| \geq \epsilon} F(s, \widetilde{X}(s-)) z N(\mathrm{~d} z, \mathrm{~d} s),
\end{align*}
$$

where $W(t)$ is a standard $m$-dimensional Wiener process, independent of $N$ and $w$. We observe that, in comparison with (2.1), in 2.8 jumps less than $\epsilon$ in magnitude are replaced by the additional diffusion part. In this way, the new Lévy measure has finite activity allowing us to simulate its events exactly, i.e. in a practical way.

Consequently, we can approximate the solution of $u(t, x)$ the PIDE (1.1) by

$$
\begin{equation*}
u(t, x) \approx u_{\epsilon}(t, x):=\mathbb{E}\left[\varphi\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right) \tilde{Y}_{t, x, 1}\left(\widetilde{\tau}_{t, x}\right)+\widetilde{Z}_{t, x, 1,0}\left(\widetilde{\tau}_{t, x}\right)\right], \quad(t, x) \in Q \tag{2.9}
\end{equation*}
$$

where $\widetilde{\tau}_{t, x}=\inf \left\{s \geq t:\left(s, \widetilde{X}_{t, x}(s)\right) \notin Q\right\}$ is the fist exit time of the space-time Lévy process $\left(s, \widetilde{X}_{t, x}(s)\right)$ from the space-time cylinder $Q$ and $\left(\widetilde{X}_{t, x}(s), \widetilde{Y}_{t, x, y}(s), \widetilde{Z}_{t, x, y, z}(s)\right)_{s \geq 0}$ solves the system of SDEs consisting of 2.8 along with

$$
\begin{align*}
d \tilde{Y} & =c(s, \widetilde{X}(s-)) \tilde{Y} d s, \quad \widetilde{Y}_{t, x, y}(t)=y  \tag{2.10}\\
d \widetilde{Z} & =g(s, \widetilde{X}(s-)) \tilde{Y} d s, \quad \widetilde{Z}_{t, x, y, z}(t)=z \tag{2.11}
\end{align*}
$$

Since the new Lévy measure has finite activity, we can derive a constructive weak scheme for 2.8, 2.10-2.11) (see Section 3). By using this method together with the Monte Carlo technique, we will arrive at an implementable approximation of $u_{\epsilon}(t, x)$ and hence of $u(t, x)$.

We will next show that indeed $u_{\epsilon}$ defined in 2.9 is a good approximation to the solution of (1.1). Before proceeding, we need to formulate appropriate assumptions.

### 2.2 Assumptions

First, we make the following assumptions on the coefficients of the problem (1.1) which will guarantee, see e.g. [2], that the SDEs (2.1), (2.4)-(2.5) and (2.8), 2.10)-(2.11) have unique adapted, càdlàg solutions with finite moments.

Assumption 2.1. (Lipschitz condition) There exists a constant $K>0$ such that for all $x_{1}$, $x_{2} \in \mathbb{R}^{d}$ and all $t \in\left[t_{0}, T\right]$,

$$
\begin{align*}
\left|b\left(t, x_{1}\right)-b\left(t, x_{2}\right)\right|^{2}+\| \sigma\left(t, x_{1}\right)- & \sigma\left(t, x_{2}\right) \|^{2}+\left|c\left(t, x_{1}\right)-c\left(t, x_{2}\right)\right|^{2}+\left|g\left(t, x_{1}\right)-g\left(t, x_{2}\right)\right|^{2} \\
& +\int_{\mathbb{R}^{d}}\left\|F\left(t, x_{1}\right)-F\left(t, x_{2}\right)\right\|^{2}|z|^{2} \nu(\mathrm{~d} z) \leq K\left|x_{1}-x_{2}\right|^{2} \tag{2.12}
\end{align*}
$$

Assumption 2.2. (Growth condition) There exists a constant $K>0$ such that for all $x \in \mathbb{R}^{d}$ and all $t \in\left[t_{0}, T\right]$,

$$
\begin{align*}
|b(t, x)|^{2}+\|\sigma(t, x)\|^{2}+|g(t, x)|^{2}+\int_{\mathbb{R}^{d}}\|F(t, x)\|^{2}|z|^{2} \nu(\mathrm{~d} z) & \leq K(1+|x|)^{2}  \tag{2.13}\\
|c(t, x)| & \leq K \tag{2.14}
\end{align*}
$$

In order to streamline the presentation and avoid lengthy technical discussions (see Remark 2.3), we will make the following assumption regarding the regularity of solutions to (1.1).

Assumption 2.3. The Dirichlet problem (1.1) admits a classical solution $u(\cdot, \cdot) \in C^{l, m}\left(\left[t_{0}, T\right] \times\right.$ $\mathbb{R}^{d}$ ) with some $l \geq 1$ and $m \geq 2$.

In addition to the PIDE problem (1.1), we also consider the PIDE problem for $u^{\epsilon}$ from (2.9) [2]:

$$
\begin{equation*}
\frac{\partial u^{\epsilon}}{\partial t}+L_{\epsilon} u^{\epsilon}+c(t, x) u^{\epsilon}+g(t, x)=0, \quad(t, x) \in Q \tag{2.15}
\end{equation*}
$$

$$
u^{\epsilon}(t, x)=\varphi(t, x), \quad(t, x) \in Q^{c},
$$

where

$$
\begin{gather*}
L_{\epsilon} v(t, x):=\frac{1}{2} \sum_{i, j=1}^{d}\left[a^{i j}(t, x)+\left(F(t, x) B_{\epsilon}(t, x) F^{\top}(t, x)\right)^{i j}\right] \frac{\partial^{2} v}{\partial x^{i} \partial x^{j}}(t, x)  \tag{2.16}\\
+\sum_{i=1}^{d}\left(b^{i}(t, x)-\sum_{j=1}^{m} F^{i j}(t, x) \gamma_{\epsilon}^{j}\right) \frac{\partial v}{\partial x^{i}}(t, x)+\int_{|z| \geq \epsilon}\{v(t, x+F(t, x) z)-v(t, x)\} \nu(\mathrm{d} z) .
\end{gather*}
$$

Again, for simplicity (but see Remark [2.3), we impose the following conditions on the solution $u_{\epsilon}$ of the above Dirichlet problem.

Assumption 2.4. The auxiliary Dirichlet problem 2.15) admits a classical solution $u^{\epsilon}(\cdot, \cdot) \in$ $C^{l, m}\left(\left[t_{0}, T\right] \times \mathbb{R}^{d}\right)$ with some $l \geq 1$ and $m \geq 2$.

Finally, we also require that $u^{\epsilon}$ and its derivatives do not grow faster than a polynomial function at infinity.

Assumption 2.5 (Smoothness and growth). There exist constants $K>0$ and $q \geq 1$ such that for all $x \in \mathbb{R}^{d}$, all $t \in\left[t_{0}, T\right]$ and $\epsilon>0$, the solution $u^{\epsilon}$ of the PIDE problem (2.15) and its derivatives satisfy

$$
\begin{equation*}
\left|\frac{\partial^{l+j}}{\partial t^{l} \partial x^{i_{1}} \cdots \partial x^{i_{j}}} u^{\epsilon}(t, x)\right| \leq K\left(1+|x|^{q}\right), \tag{2.17}
\end{equation*}
$$

where $0 \leq 2 l+j \leq 4, \sum_{k=1}^{j} i_{k}=j$, and $i_{k}$ are integers from 0 to $j$.
Remark 2.3. Sufficient conditions guaranteeing Assumptions 2.3, 2.4 and 2.5 consist in sufficient smoothness of the coefficients, the boundary $\partial G$, and the function $\varphi$ and in appropriate compatibility of $\varphi$ and $g$ (see e.g. [8, 9, (15)).

### 2.3 Closeness of $u^{\epsilon}(t, x)$ and $u(t, x)$

We now state and prove the theorem on closeness of $u^{\epsilon}(t, x)$ and $u(t, x)$. In what follows we use the same letters $K$ and $C$ for various positive constants independent of $x, t$, and $\epsilon$.

Theorem 2.4. Let Assumptions 2.1, 2.2 and 2.3 hold, the latter with $l=1$ and $m=3$. Then for $0 \leq \epsilon<1$

$$
\begin{equation*}
\left|u^{\epsilon}(t, x)-u(t, x)\right| \leq K \int_{|z| \leq \epsilon}|z|^{3} \nu(\mathrm{~d} z), \quad(t, x) \in Q, \tag{2.18}
\end{equation*}
$$

where $K>0$ does not depend on $t, x, \epsilon$.
Proof. We have $\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right) \in Q^{c}$ and $\varphi\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right)=u\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right)$, and

$$
\begin{equation*}
u^{\epsilon}(t, x)-u(t, x)=\mathbb{E}\left[u\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right) \widetilde{Y}_{t, x, 1}\left(\widetilde{\tau}_{t, x}\right)+\widetilde{Z}_{t, x, 1,0}\left(\widetilde{\tau}_{t, x}\right)\right]-u(t, x) \tag{2.19}
\end{equation*}
$$

By Ito's formula, we get

$$
\begin{equation*}
u\left(s, \widetilde{X}_{t, x}(s)\right) \widetilde{Y}_{t, x, 1}(s)+\widetilde{Z}_{t, x, 1,0}(s) \tag{2.20}
\end{equation*}
$$

$$
\begin{aligned}
& =u(t, x)+\int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[\frac{\partial}{\partial t} u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)+\frac{1}{2} \sum_{i, j=1}^{d} a^{i j}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) \frac{\partial^{2} u}{\partial x^{i} \partial x^{j}}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right. \\
& +\left\langle b\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right), \nabla u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right\rangle-\left\langle F\left(s, \widetilde{X}^{\prime}(s-)\right) \gamma_{\epsilon}, \nabla u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right\rangle \\
& \left.+c\left(s, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)+g\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right] \mathrm{d} s^{\prime} \\
& +\frac{1}{2} \int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right) \sum_{i, j=1}^{d}\left(F\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) B_{\epsilon} F^{\top}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right)^{i j} \frac{\partial^{2} u}{\partial x^{i} \partial x^{j}}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) \mathrm{d} s^{\prime} \\
& +\int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[\sigma\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) \nabla u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right)\right]^{\top} \mathrm{d} w\left(s^{\prime}\right) \\
& +\int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[F\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) \beta_{\epsilon} \nabla u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right)\right]^{\top} \mathrm{d} W\left(s^{\prime}\right) \\
& +\int_{t}^{s} \int_{|z| \geq \epsilon} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[u\left(s^{\prime}, \widetilde{X}(s-)+F\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) z\right)-u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}\right)\right)\right] N\left(\mathrm{~d} z, \mathrm{~d} s^{\prime}\right) .
\end{aligned}
$$

Since $u(t, x)$ solves (1.1) and recalling (2.6), we obtain from (2.20):

$$
\begin{align*}
& u\left(s, \widetilde{X}_{t, x}(s)\right) \widetilde{Y}_{t, x, 1}(s)+\widetilde{Z}_{t, x, 1,0}(s)-u(t, x)  \tag{2.21}\\
& =-\int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[\left\langle F(s, \widetilde{X}(s-)) \gamma_{\epsilon}, \nabla u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right\rangle\right. \\
& +\int_{\mathbb{R}^{m}}\left\{u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)+F\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) z\right)-u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right. \\
& \left.\left.-\left\langle F\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) z, \nabla u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right\rangle \mathbb{1}_{|z| \leq 1}\right\} \nu(\mathrm{~d} z)\right] \mathrm{d} s^{\prime} \\
& +\frac{1}{2} \int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right) \sum_{i, j=1}^{d}\left(F\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) B_{\epsilon} F^{\top}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right)^{i j} \frac{\partial^{2} u}{\partial x^{i} \partial x^{j}}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) \mathrm{d} s^{\prime} \\
& +\int_{t}^{s} \widetilde{Y}_{t, x, y}\left(s^{\prime}\right)\left[\sigma\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) \nabla u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right)\right]^{\top} \mathrm{d} w\left(s^{\prime}\right) \\
& +\int_{t}^{s} \widetilde{Y}_{t, x, y}\left(s^{\prime}\right)\left[F\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) \beta_{\epsilon} \nabla u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right)\right]^{\top} \mathrm{d} W\left(s^{\prime}\right) \\
& +\int_{t}^{s} \int_{|z| \geq \epsilon} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[u\left(s^{\prime}, \widetilde{X}(s-)+F\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) z\right)-u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}\right)\right)\right] N\left(\mathrm{~d} z, \mathrm{~d} s^{\prime}\right) \\
& =\frac{1}{2} \int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right) \sum_{i, j=1}^{d}\left(F\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) B_{\epsilon} F^{\top}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right)^{i j} \frac{\partial^{2} u}{\partial x^{i} \partial x^{j}}\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) \mathrm{d} s^{\prime} \\
& -\int_{t}^{s} \int_{|z|<\epsilon} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)+F\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) z\right)-u\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right. \\
& \left.-\left\langle F\left(s^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right) z, \nabla u\left({ }^{\prime}, \widetilde{X}_{t, x}\left(s^{\prime}-\right)\right)\right\rangle\right] \nu(\mathrm{d} z) \mathrm{d} s^{\prime} \\
& +\int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[\sigma\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) \nabla u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right)\right]^{\top} \mathrm{d} w\left(s^{\prime}\right) \\
& +\int_{t}^{s} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[F\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) \beta \beta_{\epsilon} \nabla u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right)\right]^{\top} \mathrm{d} W\left(s^{\prime}\right) \\
& +\int_{t}^{s} \int_{|z| \geq \epsilon} \widetilde{Y}_{t, x, 1}\left(s^{\prime}\right)\left[u\left(s^{\prime}, \widetilde{X}(s-)+F\left(s^{\prime}, \widetilde{X}\left(s^{\prime}-\right)\right) z\right)-u\left(s^{\prime}, \widetilde{X}\left(s^{\prime}\right)\right)\right] \\
& \quad \times\left(N\left(\mathrm{~d} z, \mathrm{~d} s^{\prime}\right)-\nu(\mathrm{d} z) \mathrm{d} s^{\prime}\right) . \tag{2.22}
\end{align*}
$$

Replacing $s$ with the stopping time $\widetilde{\tau}_{t, x}$ in 2.21) (cf. 2.19), taking expectations of the resulting left- and right-hand sides of 2.21 and using the martingale property, we arrive at

$$
\begin{align*}
& \mathbb{E}\left[u\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right) \widetilde{Y}_{t, x, 1}\left(\widetilde{\tau}_{t, x}\right)+\widetilde{Z}_{t, x, 1,0}\left(\widetilde{\tau}_{t, x}\right)\right]-u(t, x)  \tag{2.23}\\
& =\mathbb{E} \int_{t}^{\widetilde{\tau}_{t, x}} \widetilde{Y}_{t, x, 1}(s)\left[\frac{1}{2} \sum_{i, j=1}^{d}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) B_{\epsilon} F^{\top}\left(s, \widetilde{X}_{t, x}(s-)\right)\right)^{i j} \frac{\partial^{2} u}{\partial x^{i} \partial x^{j}}\left(s, \widetilde{X}_{t, x}(s-)\right)\right. \\
& -\int_{|z|<\epsilon}\left(u\left(s, \widetilde{X}_{t, x}(s-)+F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)-u\left(s, \widetilde{X}_{t, x}(s-)\right)\right. \\
& \left.\left.-\left\langle F\left(s, \widetilde{X}_{t, x}(s-)\right) z, \nabla u\left(s, \widetilde{X}_{t, x}(s-)\right)\right\rangle\right) \nu(\mathrm{d} z)\right] \mathrm{d} s
\end{align*}
$$

By Taylor's expansion, we get

$$
\begin{align*}
& u\left(s, \widetilde{X}_{t, x}(s-)+F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)-u\left(s, \widetilde{X}_{t, x}(s-)\right)  \tag{2.24}\\
& =\left\langle F\left(s, \widetilde{X}_{t, x}(s-)\right) z, \nabla u\left(s, \widetilde{X}_{t, x}(s-)\right)\right\rangle \\
& +\frac{1}{2} \sum_{i, j=1}^{d}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{i}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{j} \frac{\partial^{2} u}{\partial x^{i} \partial x^{j}}\left(s, \widetilde{X}_{t, x}(s-)\right) \\
& +\frac{1}{6} \sum_{i, j, k=1}^{d}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{i}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{j}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{k} \\
& \times \frac{\partial^{3} u}{\partial x^{i} \partial x^{j} \partial x^{k}}\left(s, \widetilde{X}_{t, x}(s-)+\theta F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)
\end{align*}
$$

where $\theta \in[0,1]$. Recalling (2.7), we obtain from $(2.23)-(2.24)$ :

$$
\begin{align*}
& \mathbb{E}\left[u\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right) \widetilde{Y}_{t, x, 1}\left(\widetilde{\tau}_{t, x}\right)+\widetilde{Z}_{t, x, 1,0}\left(\widetilde{\tau}_{t, x}\right)\right]-u(t, x)  \tag{2.25}\\
& =-\frac{1}{6} \mathbb{E} \int_{t}^{\widetilde{\tau}_{t, x}} \widetilde{Y}_{t, x, 1}(s) \int_{|z|<\epsilon} \sum_{i, j, k=1}^{d}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{i}\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{j} \\
& \times\left(F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right)^{k} \frac{\partial^{3} u}{\partial x^{i} \partial x^{j} \partial x^{k}}\left(s, \widetilde{X}_{t, x}(s-)+\theta F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right) \nu(\mathrm{d} z) \mathrm{d} s .
\end{align*}
$$

By definition of $\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}(s-) \in G$ for $s \leq \widetilde{\tau}_{t, x}$, then we have

$$
\begin{align*}
\left|F\left(s, \widetilde{X}_{t, x}(s-)\right)\right| & \leq \max _{t_{0} \leq s \leq T, x \in \bar{G}}|F(s, x)| \leq K  \tag{2.26}\\
\left|\widetilde{X}_{t, x}(s-)+\theta F\left(s, \widetilde{X}_{t, x}(s-)\right) z\right| & \leq \max _{x \in \bar{G}}|x|+\epsilon \max _{t_{0} \leq s \leq T, x \in \bar{G}}|F(s, x)| \leq K
\end{align*}
$$

where $K>0$ does not depend on $\epsilon, t, x, s$, noting that $|z|<\epsilon$. Using Assumption 2.3, (2.25)(2.26)

$$
\begin{align*}
& \left|\mathbb{E}\left[u\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right) \tilde{Y}_{t, x, 1}\left(\widetilde{\tau}_{t, x}\right)+\widetilde{Z}_{t, x, 1,0}\left(\widetilde{\tau}_{t, x}\right)\right]-u(s, x)\right|  \tag{2.27}\\
\leq & K \int_{t_{0}}^{T} \mathbb{E} \tilde{Y}_{t, x, 1}(s) \chi_{\widetilde{\tau}_{t, x}>s} \mathrm{~d} s \cdot \int_{|z|<\epsilon}|z|^{3} \nu(\mathrm{~d} z) .
\end{align*}
$$

Since $c\left(s, \widetilde{X}_{t, x}(s)\right)$ is bounded on the set $\left\{\widetilde{\tau}_{t, x}>s\right\}, \mathbb{E} \widetilde{Y}_{t, x, 1}(s) \chi_{\widetilde{\tau}_{t, x}>s}$ is bounded which together with (2.27) implies 2.18).

Example 2.1 (Tempered $\alpha$-stable Process). For $\alpha \in(0,2)$ consider an $\alpha$-stable process with Lévy measure given by $\nu(\mathrm{d} z)=z^{-1-\alpha} \mathrm{d} z$. Then

$$
\int_{|z| \leq \epsilon}|z|^{3} \nu(\mathrm{~d} y)=\frac{\epsilon^{3-\alpha}}{3-\alpha}
$$

Similarly, for a tempered stable distribution which has Lévy measure given by

$$
\nu(\mathrm{d} z)=\left(\frac{C_{+} \mathrm{e}^{-\lambda_{+} z}}{z^{1+\alpha}} \mathbf{1}_{z>0}+\frac{C_{-} \mathrm{e}^{-\lambda_{-} z}}{z^{1+\alpha}} \mathbf{1}_{z<0}\right) \mathrm{d} z
$$

for $\alpha \in(0,2)$ and $C_{+}, C_{-}, \lambda_{+}, \lambda_{-}>0$ we find that the error from approximating the small jumps by diffusion as in Theorem 2.4 is of the order $O\left(\epsilon^{3-\alpha}\right)$.

## 3 Weak approximation of jump-diffusions in bounded domains

In this section we propose and study a numerical algorithm which weakly approximates the solutions of the jump-diffusion (2.8), 2.10-2.11 with finite intensity of jumps in a bounded domain, i.e., approximates $u^{\epsilon}(t, x)$ from $(2.9)$. In Section 3.1 we formulate the algorithm based on a simplest random walk. We analyse the one-step error of the algorithm in Section 3.2 and the global error in Section 3.3. In Section 3.4 we comment on how the global error can be estimated in the Cauchy case. In Section 3.5 we combine the convergence result of Section 3.3 with Theorem 2.4 to get error estimates in the case of infinite activity of jumps.

### 3.1 Algorithm

Let us describe an algorithm for simulating a Markov chain that approximates a trajectory of (2.8), (2.10)-(2.11). In what follows we assume that we can exactly sample increments $\delta$ between jump times with the intensity

$$
\begin{equation*}
\lambda_{\epsilon}:=\int_{|z|>\epsilon} \nu(\mathrm{d} z) \tag{3.1}
\end{equation*}
$$

and jump sizes $J_{\epsilon}$ are distributed according to the density

$$
\begin{equation*}
\rho_{\epsilon}(z):=\frac{\nu(z) \mathbf{I}_{|z|>\epsilon}}{\lambda_{\epsilon}} \tag{3.2}
\end{equation*}
$$

Remark 3.1. There are known methods for simulating jump times and sizes for many standard distributions. In general, if there exists an explicit expression for the jump size density, one can construct a rejection method to sample jump sizes. An overview with regard to simulation of jump times and sizes can be found in [6, 7].

In what follows we also require the following to hold.

Assumption 3.1 (Moments of $J$ ). There exists a constant $K>0$ independent of $\epsilon$ such that

$$
\mathbb{E}\left|J_{\epsilon}\right|^{p} \equiv \frac{1}{\lambda_{\epsilon}} \int_{|z|>\epsilon}|z|^{p} \nu(d z) \leq K
$$

for sufficiently large $p \geq 2$.
We also note that

$$
\begin{equation*}
\frac{\gamma_{\epsilon}^{2}}{\lambda_{\epsilon}} \leq K \tag{3.3}
\end{equation*}
$$

where $K>0$ is a constant independent of $\varepsilon$.
We now describe the algorithm. Fix a time-discretization step $h>0$ and suppose the current position of the chain is $(t, x, y, z)$. If the jump time increment $\delta<h$, we set $\theta=\delta$, otherwise $\theta=h$, i.e. $\theta=\delta \wedge h$.

In the case $\theta=h$, we apply the weak explicit Euler approximation with the simplest simulation of noise to the system (2.8), (2.10)-(2.11) with no jumps:

$$
\begin{align*}
\widetilde{X}_{t, x}(t+\theta) & \approx X=x+\theta \cdot\left(b(t, x)-F(t, x) \gamma_{\epsilon}\right)+\sqrt{\theta} \cdot\left(\sigma(t, x) \xi+F(t, x) \beta_{\epsilon} \eta\right),  \tag{3.4}\\
\widetilde{Y}_{t, x, y}(t+\theta) & \approx Y=y+\theta \cdot c(t, x) y  \tag{3.5}\\
\widetilde{Z}_{t, x, y, z}(t+\theta) & \approx Z=z+\theta \cdot g(t, x) y \tag{3.6}
\end{align*}
$$

where $\xi=\left(\xi^{1}, \ldots, \xi^{d}\right)^{\top}, \eta=\left(\eta^{1}, \ldots, \eta^{m}\right)^{\top}$, with $\xi^{1}, \ldots, \xi^{d}$ and $\eta^{1}, \ldots, \eta^{m}$ mutually independent random variables, taking the values $\pm 1$ with equal probability. In the case of $\theta<h$, we replace (3.4) by the following explicit Euler approximation

$$
\begin{align*}
\widetilde{X}_{t, x}(t+\theta) \approx & X=x+\theta \cdot\left(b(t, x)-F(t, x) \gamma_{\epsilon}\right)+\sqrt{\theta} \cdot\left(\sigma(t, x) \xi+F(t, x) \beta_{\epsilon} \eta\right)  \tag{3.7}\\
& +F(t, x) J_{\epsilon} .
\end{align*}
$$

Let $\left(t_{0}, x_{0}\right) \in Q$. We aim to find the value $u^{\epsilon}\left(t_{0}, x_{0}\right)$, where $u^{\epsilon}(t, x)$ solves the problem (2.15). Introduce a discretization of the interval $\left[t_{0}, T\right]$, for example the equidistant one:

$$
h:=\left(T-t_{0}\right) / L .
$$

To approximate the solution of the system (2.8), we construct a Markov chain $\left(\vartheta_{k}, X_{k}, Y_{k}, Z_{k}\right)$ which stops at a random step $\varkappa$ when $\left(\vartheta_{k}, X_{k}\right)$ exits the domain $Q$. The algorithm is formulated as Algorithm 3.1 below.

Remark 3.2. We note [17, [18] that in the diffusion case (i.e., when there is no jump component in the noise which drives SDEs) solving Dirichlet problems for parabolic or elliptic PDEs requires to complement a random walk inside the domain $G$ with a special approximation near the boundary $\partial G$. In contrast, in the case of Dirichlet problems for PIDEs we do not need a special construction near the boundary since the boundary condition is defined on the whole complement $G^{c}$. Here, when the chain $X_{k}$ exits $G$, we know the exact value of the solution $u\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right)=\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right)$ at the exit point $\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right)$, while in the diffusion case when a chain exits $G$, we do not know the exact value of the solution at the exit point and need an approximation.

```
Algorithm 3.1 Algorithm for (2.8), (2.10)-(2.11).
    Output: \(\bar{\vartheta}_{\varkappa}, X_{\varkappa}, Y_{\varkappa}, Z_{\varkappa}\)
    Initialize: \(\vartheta_{0}=t_{0}, X_{0}=x_{0}, Y_{0}=1, Z_{0}=0, k=0\).
    Simulate: \(\xi_{k}\) and \(\eta_{k}\) with i.i.d. components taking values \(\pm 1\) with probability \(1 / 2\) and
    independently \(I_{k} \sim \operatorname{Bernoulli}\left(1-e^{-\lambda_{\epsilon} h}\right)\).
    if \(I_{k}=0\), then
        Set: \(\theta_{k}=h\)
        Evaluate: \(X_{k+1}, Y_{k+1}, Z_{k+1}\) according to (3.4 - 3.6) with \(t=\vartheta_{k}, \theta=\theta_{k}, \xi=\xi_{k}\),
    \(\eta=\eta_{k}, x=X_{k}, y=Y_{k}, z=Z_{k}\).
    else
        Sample: \(\delta_{k}\) according to the density \(\frac{\lambda_{\epsilon} e^{-\lambda_{\epsilon} x}}{1-e^{-\lambda_{\epsilon} h}}\) with finite support [0, \(h\) ].
        Set: \(\theta_{k}=\delta_{k}\)
        Sample: jump size \(J_{\epsilon, k}\) according to the density (3.2).
        Evaluate: \(X_{k+1}, Y_{k+1}\) and \(Z_{k+1}\) according to (3.7), (3.5), (3.6) with \(t=\vartheta_{k}, \theta=\theta_{k}\),
    \(\xi=\xi_{k}, \eta=\eta_{k}, J_{\epsilon}=J_{\epsilon, k}, x=X_{k}, y=Y_{k}, z=Z_{k}\).
    end if
    Set: \(\vartheta_{k+1}=\vartheta_{k}+\theta_{k}\).
    if \(\vartheta_{k+1} \geq T\) or \(X_{k+1} \notin G\) then
        Set: \(X_{\varkappa}=X_{k+1}, Y_{\varkappa}=X_{k+1}, Z_{\varkappa}=Z_{k+1}, \varkappa=k+1\)
        if \(\vartheta_{k+1}<T\) then Set: \(\bar{\vartheta}_{\varkappa}=\vartheta_{k+1}\)
        else Set: \(\bar{\vartheta}_{\varkappa}=T\)
        end if
        STOP
    else
        Set: \(k=k+1\) and GOTO 2 ,
    end if
```

Due to this fact, Algorithm 3.1 is somewhat simpler than algorithms for Dirichlet problems for parabolic or elliptic PDEs (cf. [17, 18] and references therein).

### 3.2 One-step error

In this section we consider the one-step error of Algorithm 3.1. The one step of this algorithm takes the form for $(t, x) \in Q$ :

$$
\begin{align*}
X & =x+\theta\left(b(t, x)-F(t, x) \gamma_{\epsilon}\right)+\sqrt{\theta}\left(\sigma(t, x) \xi+F(t, x) \beta_{\epsilon} \eta\right)+\mathbf{I}(\delta<h) F(t, x) J_{\epsilon},  \tag{3.8}\\
Y & =y+\theta c(t, x) y  \tag{3.9}\\
Z & =z+\theta g(t, x) y . \tag{3.10}
\end{align*}
$$

Before we state and prove an error estimate for the one-step of Algorithm 3.1, we need to introduce some additional notation. For brevity let us write $b=b(t, x), \sigma=\sigma(t, x), F=F(t, x)$, $g=g(t, x), c=c(t, x), J=J_{\epsilon}$. Let us define the intermediate points $Q_{i}$ and their differences $\Delta_{i}$, for $i=1, \ldots, 4$ :

$$
\begin{align*}
& \Delta_{1}=\theta^{1 / 2}\left[\sigma \xi+F \beta_{\epsilon} \eta\right],  \tag{3.11}\\
& \Delta_{2}=\theta\left[b-F \gamma_{\epsilon}\right],
\end{align*}
$$

$$
\begin{aligned}
\Delta_{3} & =\mathbf{I}(\delta<h) F J, \\
Q_{1} & =x+\Delta_{1}+\Delta_{2}+\Delta_{3}=X, \\
Q_{2} & =x+\Delta_{2}+\Delta_{3}, \\
Q_{3} & =x+\Delta_{3}, \\
Q_{4} & =x,
\end{aligned}
$$

where $x \in G$. Note that $Q_{i}, i=1, \ldots, 3$, can be outside $G$.
Lemma 3.3 (Moments of intermediate points $Q_{i}$ ). Under Assumptions 2.1 and 3.1, there is $K>0$ independent of $\epsilon$ and $h$ such that for $p \geq 1$ :

$$
\begin{align*}
& \mathbb{E}\left[\left|Q_{i}\right|^{2 p} \mid \theta, t, x\right] \leq K\left(1+\theta^{2 p} \gamma_{\epsilon}^{2 p}\right), i=1,2,  \tag{3.12}\\
& \mathbb{E}\left[\left|Q_{i}\right|^{2 p} \mid \theta, t, x\right] \leq K, i=3,4, \tag{3.13}
\end{align*}
$$

where $Q_{i}$ are defined in (3.11).
Proof. It is not difficult to see that the points $Q_{i}, i=1,2$, are of the following form

$$
Q_{i}=x+c_{1} \theta^{1 / 2}\left[\sigma \xi+F(t, x) \beta_{\epsilon} \eta\right]+\theta\left[b(t, x)-F(t, x) \gamma_{\epsilon}\right]+\mathbf{I}(\theta<h) F(t, x) J_{\epsilon},
$$

where $c_{1}$ is either 0 or 1 . It is obvious that $\xi$ and $\eta$ and their moments are all bounded. The functions $b(t, x), \sigma(t, x)$ and $F(t, x)$ are bounded as $(t, x) \in Q$, and for $x \in G,|x|^{2 p}$ is also bounded. Recall that sufficiently high moments of $J_{\epsilon}$ are bounded due to Assumption 3.1. Then, using the Cauchy-Schwarz inequality, we can show that

$$
\begin{aligned}
\mathbb{E}\left[\left|Q_{i}\right|^{2 p} \mid \theta, t, x\right] & \leq|x|^{2 p}+K \theta^{p}+K \theta^{2 p}\left[1+\gamma_{\epsilon}^{2 p}\right]+K \mathbf{I}(\theta<h) \mathbb{E}\left|J_{\epsilon}\right|^{2 p} \\
& \leq K\left(1+\theta^{2 p} \gamma_{\epsilon}^{2 p}\right) .
\end{aligned}
$$

Hence, we obtained (3.12). The bound (3.13) is shown analogously.
It is not difficult to prove the following technical lemma.
Lemma 3.4 (Moments of $\theta$ ). For integer $p \geq 2$, we have

$$
\mathbb{E} \theta^{p} \leq K \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{p}},
$$

where $K>0$ depends on $p$ but is independent of $\lambda_{\epsilon}$ and $h$.
Now we prove an estimate for the one-step error.
Theorem 3.5 (One-step error of Algorithm 3.1). Under Assumption 2.4 with $l=2, m=4$ and Assumptions 2.1, 2.5 and 3.1 the one-step error of Algorithm 3.1 given by

$$
R(t, x, y, z):=u^{\epsilon}(t+\theta, X) Y+Z-u^{\epsilon}(t, x) y-z
$$

satisfies the bound

$$
\begin{equation*}
|\mathbb{E}[R(t, x, y, z)]| \leq K\left(1+\gamma_{\epsilon}^{2}\right) \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}} y, \tag{3.14}
\end{equation*}
$$

where $K>0$ is a constant independent of $h$ and $\epsilon$.
Proof. For any smooth function $v(t, x)$, we write $D_{l} v_{n}=\left(D_{l} v\right)\left(t, Q_{n}\right)$ for the $l$-th time derivative and $\left(D_{l}^{k} v\right)(t, x)\left[f_{1}, \ldots, f_{k}\right]$ for the $l$-th time derivative of the $k$-th spatial directional derivative evaluated in the direction $\left[f_{1}, \ldots, f_{k}\right]$. For example, if $k=2$ and $l=1$,

$$
D_{1}^{2} v\left[f_{1}, f_{2}\right]=\sum_{i=1}^{d} \sum_{j=1}^{d} f_{1, i} f_{2, j} \frac{\partial^{3} v}{\partial t x_{i} x_{j}} .
$$

We will also use the following short notation

$$
D_{l}^{k} v_{i}\left[f_{1}, \ldots, f_{k}\right]:=\left(D_{l}^{k} v\right)\left(t, Q_{i}\right)\left[f_{1}, \ldots, f_{k}\right] .
$$

The final aim of this theorem is to achieve an error estimate explicitly capturing the (singular) dependence of the one-step error on $\epsilon$. To this end, we split the error into several parts according to the intermediate points $Q_{i}$ defined in (3.11).

Using (3.8) and (3.11), we have

$$
\begin{aligned}
u^{\epsilon}(t+\theta, X) & =u^{\epsilon}\left(t+\theta, Q_{1}\right) \\
& =u^{\epsilon}\left(t+\theta, x+\mathbf{I}(\delta<h) F J+\theta\left(b-F \gamma_{\epsilon}\right)+\theta^{1 / 2}\left(\sigma \xi+F \beta_{\epsilon} \eta\right)\right) \\
& =u^{\epsilon}\left(t+\theta, x+\Delta_{1}+\Delta_{2}+\Delta_{3}\right)
\end{aligned}
$$

To precisely account for the factor $\gamma_{\epsilon}$ and powers of $\theta$ in the analysis of the one-step error, we use multiple Taylor expansions of $u^{\epsilon}(t+\theta, X)$. We obtain

$$
\begin{align*}
u^{\epsilon}(t+\theta, X)= & u^{\epsilon}\left(t, Q_{1}\right)+\theta D_{1} u_{1}^{\epsilon}+R_{11}  \tag{3.15}\\
= & u^{\epsilon}\left(t, Q_{2}\right)+D^{1} u_{2}^{\epsilon}\left[\Delta_{1}\right]+\frac{1}{2} D^{2} u_{2}^{\epsilon}\left[\Delta_{1}, \Delta_{1}\right] \\
+ & \frac{1}{6} D^{3} u_{2}^{\epsilon}\left[\Delta_{1}, \Delta_{1}, \Delta_{1}\right]+\theta D_{1} u_{2}^{\epsilon}+\theta D_{1}^{1} u_{2}^{\epsilon}\left[\Delta_{1}\right] \\
& +R_{11}+R_{12}+R_{13} \\
= & u^{\epsilon}\left(t, Q_{3}\right)+D^{1} u_{3}^{\epsilon}\left[\Delta_{2}\right]+D^{1} u_{2}^{\epsilon}\left[\Delta_{1}\right]+\frac{1}{2} D^{2} u_{3}^{\epsilon}\left[\Delta_{1}, \Delta_{1}\right]+\frac{1}{6} D^{3} u_{2}^{\epsilon}\left[\Delta_{1}, \Delta_{1}, \Delta_{1}\right] \\
& +\theta D_{1} u_{3}^{\epsilon}+\theta D_{1}^{1} u_{2}^{\epsilon}\left[\Delta_{1}\right]+R_{11}+R_{12}+R_{13}+R_{14}+R_{15}+R_{16} \\
= & u^{\epsilon}\left(t, Q_{3}\right)+D^{1} u_{4}^{\epsilon}\left[\Delta_{2}\right]+D^{1} u_{2}^{\epsilon}\left[\Delta_{1}\right]+\frac{1}{2} D^{2} u_{4}^{\epsilon}\left[\Delta_{1}, \Delta_{1}\right] \\
& +\frac{1}{6} D^{3} u_{2}^{\epsilon}\left[\Delta_{1}, \Delta_{1}, \Delta_{1}\right]+\theta D_{1} u_{4}^{\epsilon}+\theta D_{1}^{1} u_{2}^{\epsilon}\left[\Delta_{1}\right]+R_{1},
\end{align*}
$$

where the remainders are as follows

$$
R_{11}=\frac{1}{2} \theta^{2} \int_{0}^{1} s D_{2} u^{\epsilon}\left(t+(1-s) \theta, Q_{1}\right) d s,
$$

$$
\begin{aligned}
R_{12} & =\frac{1}{24} \int_{0}^{1} s^{3} D^{4} u^{\epsilon}\left(t, s Q_{2}+(1-s) Q_{1}\right)\left[\Delta_{1}, \Delta_{1}, \Delta_{1}, \Delta_{1}\right] d s, \\
R_{13} & =\frac{1}{2} \theta \int_{0}^{1} s^{2} D_{1}^{2} u^{\epsilon}\left(t, s Q_{2}+(1-s) Q_{1}\right)\left[\Delta_{1}, \Delta_{1}\right] d s, \\
R_{14} & =\frac{1}{2} \int_{0}^{1} s D^{2} u^{\epsilon}\left(t, s\left(Q_{3}+(1-s) Q_{2}\right)\left[\Delta_{2}, \Delta_{2}\right] d s,\right. \\
R_{15} & =\frac{1}{2} \int_{0}^{1} s^{2} D^{3} u^{\epsilon}\left(t, s\left(Q_{3}\right)+(1-s) Q_{2}\right)\left[\Delta_{1}, \Delta_{1}, \Delta_{2}\right] d s, \\
R_{16} & =\theta \int_{0}^{1} s D_{1}^{1} u^{\epsilon}\left(t, s\left(Q_{3}\right)+(1-s) Q_{2}\right)\left[\Delta_{2}\right] d s, \\
R_{17} & =\int_{0}^{1} s D^{2} u^{\epsilon}\left(t, s\left(Q_{4}\right)+(1-s) Q_{3}\right)\left[\Delta_{2}, \Delta_{3}\right] d s, \\
R_{18} & =\frac{1}{2} \int_{0}^{1} s D^{3} u^{\epsilon}\left(t, s\left(Q_{4}\right)+(1-s) Q_{3}\right)\left[\Delta_{1}, \Delta_{1}, \Delta_{3}\right] d s, \\
R_{19} & =\theta \int_{0}^{1} s D_{1}^{1} u^{\epsilon}\left(t, s\left(Q_{4}\right)+(1-s) Q_{3}\right)\left[\Delta_{3}\right] d s, \\
R_{1} & =R_{11}+R_{12}+R_{13}+R_{14}+R_{15}+R_{16}+R_{17}+R_{18}+R_{19} .
\end{aligned}
$$

Using (3.15), (3.9)-(3.10), and the fact that $\xi$ and $\eta$ have mean zero and that components of $\xi$, $\eta, \theta, J$ are mutually independent, we obtain

$$
\begin{align*}
\mathbb{E} & {\left[u^{\epsilon}(t+\theta, X) Y+Z\right] }  \tag{3.16}\\
= & \mathbb{E}\left[\left(u^{\epsilon}\left(t, Q_{3}\right)+D^{1} u_{4}^{\epsilon}\left[\Delta_{2}\right]+\frac{1}{2} D^{2} u_{4}^{\epsilon}\left[\Delta_{1}, \Delta_{1}\right]+\theta D_{1} u_{4}^{\epsilon}\right)(y+\theta c y)\right. \\
& \left.+z+\theta g y+y(1+\theta c) R_{1}\right] .
\end{align*}
$$

The following elementary formulas are needed for future calculations:

$$
\begin{gather*}
\mathbb{E}\left(D^{2} u^{\epsilon}\left[\Delta_{1}, \Delta_{1}\right] \mid \theta\right)  \tag{3.17}\\
=\theta \sum_{i, j=1}^{d}\left[a^{i j}(t, x)+\left(F(t, x) B_{\epsilon}(t, x) F^{\top}(t, x)\right)^{i j}\right] \frac{\partial^{2} u^{\epsilon}}{\partial x^{i} \partial x^{j}} \\
=: \theta\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}, \\
u^{\epsilon}\left(t, Q_{3}\right)-u^{\epsilon}(t, x)=u^{\epsilon}(t, x+\mathbf{I}(\theta<h) F J)-u^{\epsilon}(t, x) \\
=\mathbf{I}(\theta<h)\left[u^{\epsilon}(t, x+F J)-u^{\epsilon}(t, x)\right], \\
\mathbb{E}[\theta]=\frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}, \\
\mathbb{E}\left[\theta^{2}\right]=2 \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}}, \\
\mathbb{E}[\mathbf{I}(\theta<h)]=1-e^{-\lambda_{\epsilon} h}, \\
\mathbb{E}[\mathbf{I}(\theta<h) \theta]=\frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}} .
\end{gather*}
$$

Also, $\mathbb{E} v(J)$ for some $v(z)$ will mean

$$
\mathbb{E}[v(J)]=\mathbb{E}\left[v\left(J_{\epsilon}\right)\right]=\frac{1}{\lambda_{\epsilon}} \int_{|s|>\epsilon} v(s) \nu(d s)
$$

Noting that $u_{4}^{\epsilon}=u^{\epsilon}(t, x)=u^{\epsilon}$ and using (3.16), (3.11), (3.17) and (2.15), we obtain

$$
\begin{aligned}
& \mathbb{E} R:=\mathbb{E}\left[u^{\epsilon}(t+\theta, X) Y+Z-u^{\epsilon} y-z\right] \\
& =\mathbb{E}\left[\theta\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}\right)(y+\theta c y)+\theta g y\right. \\
& \left.+u^{\epsilon}(t, x+\mathbf{I}(\theta<h) F J)(y+\theta c y)-u^{\epsilon} y\right]+y \mathbb{E}\left[(1+\theta c) R_{1}\right] \\
& =\mathbb{E}\left[\theta\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}+c u^{\epsilon}+g\right) y\right. \\
& \left.+\left[u^{\epsilon}(t, x+\mathbf{I}(\theta<h) F J)-u^{\epsilon}\right)\right] y \\
& +\theta^{2}\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}\right) c y \\
& \left.+\theta\left[u^{\epsilon}(t, x+\mathbf{I}(\theta<h) F J)-u^{\epsilon}\right] c y\right]+y \mathbb{E}\left[(1+\theta c) R_{1}\right] \\
& =\mathbb{E}\left[\theta\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}+c u^{\epsilon}+g\right) y\right. \\
& \left.+\mathbf{I}(\theta<h)\left[u^{\epsilon}(t, x+F J)-u^{\epsilon}\right)\right] y \\
& +\theta^{2}\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}\right) c y \\
& \left.+\theta \mathbf{I}(\theta<h)\left[u^{\epsilon}(t, x+F J)-u^{\epsilon}\right] c y\right]+y \mathbb{E}\left[(1+\theta c) R_{1}\right] \\
& =\mathbb{E}[\theta]\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}+c u^{\epsilon}+g\right) y \\
& +\mathbb{E}\left[\mathbf{I}(\theta<h)\left[u^{\epsilon}(t, x+F J)-u^{\epsilon}(t, x)\right] y\right]+y \mathbb{E}\left[R_{1}(1+\theta c)+R_{2}\right] \\
& =\frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}+c u^{\epsilon}(t, x)+g\right) y \\
& +\left(1-e^{-\lambda_{\epsilon} h}\right) \mathbb{E}\left[u^{\epsilon}(t, x+F J)-u^{\epsilon}(t, x)\right] y+y \mathbb{E}\left[R_{0}\right] \\
& =\frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}+c u^{\epsilon}(t, x)+g\right) y \\
& +\frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} \int\left\{u^{\epsilon}(t, x+F s)-u^{\epsilon}(t, x)\right\} \nu(d s) y+y \mathbb{E}\left[R_{0}\right] \\
& =y \mathbb{E}\left[R_{0}\right],
\end{aligned}
$$

where

$$
\begin{gathered}
R_{0}=R_{1}(1+\theta c)+R_{2} \\
R_{2}=R_{21}+R_{22}
\end{gathered}
$$

and

$$
\begin{aligned}
& R_{21}=\theta^{2}\left(D_{1} u^{\epsilon}+D^{1} u^{\epsilon}\left[b-F \gamma_{\epsilon}\right]+\frac{1}{2}\left(a+F B_{\epsilon} F^{T}\right): \nabla \nabla u^{\epsilon}\right) c, \\
& R_{22}=\theta \mathbf{I}(\theta<h)\left[u^{\epsilon}(t, x+F J)-u^{\epsilon}(t, x)\right] c .
\end{aligned}
$$

It is clear that many of the terms in $R$ are only non-zero in the case $\theta<h$, i.e. when a jump occurs. We rearrange the terms in $R_{0}$ according to their degree in $\theta$ :

$$
\begin{aligned}
R_{0}= & \underbrace{R_{17}+R_{18}+R_{19}+R_{22}}_{\mathbf{I}(\theta<h) \theta \text {-terms }}+\underbrace{R_{11}+R_{12}+R_{13}+R_{14}+R_{15}+R_{16}+R_{21}}_{\theta^{2} \text { - terms }} \\
& +\underbrace{\theta c\left(R_{17}+R_{18}+R_{19}\right)}_{\left(\mathbf{I}(\theta<h) \theta^{2}\right. \text {-terms }}+\underbrace{\theta c\left(R_{11}+R_{12}+R_{13}+R_{14}+R_{15}+R_{16}\right)}_{\theta^{3} \text { - terms }}
\end{aligned}
$$

Now to estimate the terms in the error $R_{0}$, we observe that (i) $\int_{|s|>\epsilon} s \nu(d s)=\gamma_{\epsilon}+\int_{|s|>1} s \nu(d s)$ with the latter integral bounded and, in particular, $|\mathbb{E}[J]| \leq K\left(1+\left|\gamma_{\epsilon}\right|\right) / \lambda_{\epsilon} ;($ ii $) \mathbb{E}[J]^{2 p}, p \geq 1$, are bounded; (iii) the terms $R_{17}, R_{18}, R_{19}, R_{21}$ and $R_{22}$ contain derivatives of $u^{\epsilon}$ evaluated at or between the points $Q_{3}$ and $Q_{4}$ and in their estimation Assumption 2.5 and (3.13) from Lemma 3.3 are used; (iv) the terms $R_{11}, R_{12}, R_{13}, R_{14}, R_{15}$ and $R_{16}$ contain derivatives of $u^{\epsilon}$ evaluated at or between the points $Q_{1}$ and $Q_{2}$ and in their estimation Assumption 2.5, (3.12) from Lemma 3.3, and Lemma 3.4 are used; (v) $\gamma_{\epsilon}^{2} / \lambda_{\epsilon}$ is bounded by a constant independent of $\epsilon$. As a result, we obtain

$$
\begin{aligned}
& \left|\mathbb{E}\left[R_{17}+R_{18}+R_{19}+R_{22}\right]\right| \leq K_{1} \frac{\left(1+\gamma_{\epsilon}^{2}\right)}{\lambda_{\epsilon}} \mathbb{E}[\mathbf{I}(\theta<h) \theta] \\
& \left|\mathbb{E}\left[\theta\left(R_{17}+R_{18}+R_{19}\right)\right]\right| \leq K_{2} \frac{\left(1+\gamma_{\epsilon}^{2}\right)}{\lambda_{\epsilon}} \mathbb{E}\left[\mathbf{I}(\theta<h) \theta^{2}\right] \leq K_{3} \frac{\left(1+\gamma_{\epsilon}^{2}\right)}{\lambda_{\epsilon}} \mathbb{E}[\mathbf{I}(\theta<h) \theta] \\
& \left.\left|\mathbb{E}\left[\left(R_{11}+R_{12}+R_{13}+R_{14}+R_{15}+R_{16}+R_{21}\right)\right]\right| \leq K_{4}\left(1+\gamma_{\epsilon}^{2}\right)\left(\mathbb{E}\left[\theta^{2}\right]+\gamma_{\epsilon}^{q} \mathbb{E} \theta^{q+2}\right)\right) \\
& \leq K_{5}\left(1+\gamma_{\epsilon}^{2}\right) \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}}
\end{aligned}
$$

and

$$
\begin{aligned}
& \left.\left|\mathbb{E}\left[\theta\left(R_{11}+R_{12}+R_{13}+R_{14}+R_{15}+R_{16}\right)\right]\right| \leq K_{6}\left(1+\gamma_{\epsilon}^{2}\right)\left(\mathbb{E}\left[\theta^{3}\right]+\gamma_{\epsilon}^{q} \mathbb{E} \theta^{q+3}\right)\right) \\
& \quad \leq K_{7}\left(1+\gamma_{\epsilon}^{2}\right) \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{3}} \leq K_{8}\left(1+\gamma_{\epsilon}^{2}\right) \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}}
\end{aligned}
$$

where all constants $K_{i}>0$ are independent of $h$ and $\epsilon$ and $q \geq 1$.
Overall we obtain

$$
\begin{aligned}
|\mathbb{E}[R]| & \leq\left(K_{1}+K_{3}\right) \frac{\left(1+\gamma_{\epsilon}^{2}\right)}{\lambda_{\epsilon}} y \mathbb{E}[\mathbf{I}(\theta<h) \theta]+\left(K_{5}+K_{8}\right)\left(1+\gamma_{\epsilon}^{2}\right) y \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}} \\
& \leq K\left\{\frac{1}{\lambda_{\epsilon}} \mathbb{E}[\mathbf{I}(\theta<h) \theta]+\frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}}\right\}\left(1+\gamma_{\epsilon}^{2}\right) y \\
& =2 K\left(1+\gamma_{\epsilon}^{2}\right) \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}} y .
\end{aligned}
$$

Remark 3.6. We note the following two asymptotic regimes for the one-step error (3.14). For $\lambda_{\epsilon} h<1$ (in practice, this occurs only when $\lambda_{\epsilon}$ is small or moderate like it is in jump-diffusions),
we can expand the exponent in (3.14) and obtain that the one-step error is of order $O\left(h^{2}\right)$ :

$$
|\mathbb{E}[R(t, x, y, z)]| \leq K\left(1+\gamma_{\epsilon}^{2}\right) h^{2} y
$$

When $\lambda_{\epsilon}$ is very large (e.g., for small $\epsilon$ in the infinite activity case) then the term with $e^{-\lambda_{\epsilon} h}$ can be neglected and we get

$$
|\mathbb{E}[R(t, x, y, z)]| \leq K \frac{1+\gamma_{\epsilon}^{2}}{\lambda_{\epsilon}^{2}} y
$$

The usefulness of a more precise estimate (3.14) is that it includes situations in between these two asymptotic regimes and also allows to consider an interplay between $h$ and $\epsilon$ (see Section 3.5).

### 3.3 Global error

In this section we obtain an estimate for the global weak-sense error of Algorithm 3.1. We first estimate average number of steps $\mathbb{E} \varkappa$ of Algorithm 3.1.

Lemma 3.7 (Number of steps). The average number of steps $\varkappa$ for the chain $X_{k}$ from Algorithm 3.1 satisfies the following bound

$$
E \varkappa \leq \frac{\left(T-t_{0}\right) \lambda_{\epsilon}}{1-e^{-\lambda_{\epsilon} h}}+1 .
$$

Proof. It is obvious that if we replace the bounded domain $G$ in Algorithm 3.1 with the whole space $\mathbb{R}^{d}$ (i.e., replace the Dirichlet problem by the Cauchy one), then the corresponding number of steps $\varkappa^{\prime}$ of Algorithm 3.1 is not less than $\varkappa$. Hence it is sufficient to get an estimate for $E \varkappa^{\prime}$. Let $\delta_{1}, \delta_{2}, \ldots$ be the interarrival times of the jumps, $\theta_{i}=\delta_{i} \wedge h$ for $i \geq 0$, and $S_{k}=\sum_{i=0}^{k-1} \theta_{i}$ for $k \geq 0$. Then

$$
\varkappa \leq \varkappa^{\prime}:=\inf \left\{l: S_{l} \geq T-t_{0}\right\} .
$$

Introduce the martingale: $\widetilde{S}_{0}=0$ and $\widetilde{S}_{k}:=S_{k}-k \mathbb{E} \theta$ for $k \geq 1$. Since $\theta_{i} \leq h$ we have that $\widetilde{S}_{\varkappa^{\prime}-1} \leq S_{\varkappa^{\prime}-1}<T-t_{0}$ almost surely and thus by the optional stopping theorem we obtain

$$
\mathbb{E} \widetilde{S}_{\varkappa^{\prime}-1}=\mathbb{E} \widetilde{S}_{0}=0
$$

Therefore

$$
\mathbb{E} \widetilde{S}_{\varkappa^{\prime}-1}=\mathbb{E}\left[\varkappa^{\prime}-1\right] \cdot \mathbb{E}[\theta]
$$

and we conclude

$$
\begin{aligned}
\mathbb{E} \varkappa & \leq \mathbb{E} \varkappa^{\prime}=\mathbb{E}\left[\varkappa^{\prime}-1\right]+1 \\
& =\frac{\mathbb{E} S_{\varkappa^{\prime}-1}}{\mathbb{E} \theta}+1 \leq \frac{\left(T-t_{0}\right) \lambda_{\epsilon}}{1-\mathrm{e}^{-\lambda_{\epsilon} h}}+1
\end{aligned}
$$

We also need the following auxiliary lemma.
Lemma 3.8 (Boundedness of $Y_{k}$ in Algorithm 3.1). The chain $Y_{k}$ defined in (3.5) is uniformly
bounded by a deterministic constant:

$$
Y_{k} \leq e^{\bar{c}\left(T-t_{0}+h\right)}
$$

where $\bar{c}=\max _{(t, x) \in \bar{Q}} c(t, x)$.
Proof. From (3.5), we can express $Y_{k}$ via previous $Y_{k-1}$ and get the required estimate as follows:

$$
\begin{aligned}
Y_{k} & =Y_{k-1}\left(1+\theta_{k} c\left(t_{k-1}, x_{k-1}\right) \leq Y_{k-1}\left(1+\theta_{k} \bar{c}\right)\right. \\
& \leq Y_{k-1} e^{\bar{c} \theta_{k-1}} \leq Y_{k-2} e^{\bar{c}\left(\theta_{k}+\theta_{k-1}\right)} \leq Y_{0} e^{\bar{c}\left(\vartheta_{k}-t_{0}\right)} \leq e^{\bar{c}\left(T-t_{0}+h\right)}
\end{aligned}
$$

Now we prove the convergence theorem for Algorithm 3.1.

Theorem 3.9 (Global error of Algorithm 3.1). Under Assumption 2.4 with $l=2, m=4$ and Assumptions 2.1, 2.5 and 3.1, the global error of Algorithm 3.1 satisfies the following bound

$$
\begin{align*}
& \left|\mathbb{E}\left[\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}\right]-u^{\epsilon}\left(t_{0}, x_{0}\right)\right|  \tag{3.18}\\
& \leq K\left(1+\gamma_{\epsilon}^{2}\right)\left(\frac{1}{\lambda_{\epsilon}}-h \frac{e^{-\lambda_{\epsilon} h}}{1-e^{-\lambda_{\epsilon} h}}\right)+K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}
\end{align*}
$$

where $K>0$ is a constant independent of $h$ and $\epsilon$.
Proof. Recall (see 2.9)):

$$
u^{\epsilon}(t, x)=\mathbb{E}\left[\varphi\left(\widetilde{\tau}_{t, x}, \widetilde{X}_{t, x}\left(\widetilde{\tau}_{t, x}\right)\right) \widetilde{Y}_{t, x, 1}\left(\widetilde{\tau}_{t, x}\right)+\widetilde{Z}_{t, x, 1,0}\left(\widetilde{\tau}_{t, x}\right)\right]
$$

The global error

$$
\mathbf{R}:=\left|\mathbb{E}\left[\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}\right]-u^{\epsilon}\left(t_{0}, x_{0}\right)\right|
$$

can be written as

$$
\begin{align*}
\mathbf{R} & =\left|\mathbb{E}\left[\mathbf{I}\left(\vartheta_{\varkappa} \geq T\right)\left(\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}-u^{\epsilon}\left(\vartheta_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}\right)+u^{\epsilon}\left(\vartheta_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}-v\left(t_{0}, x_{0}\right)\right]\right|  \tag{3.19}\\
& \leq\left|\mathbb{E}\left[\mathbf{I}\left(\vartheta_{\varkappa} \geq T\right)\left(\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}-u^{\epsilon}\left(\vartheta_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}\right)\right]\right|+\left|\mathbb{E}\left[u^{\epsilon}\left(\vartheta_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}-u^{\epsilon}\left(t_{0}, x_{0}\right)\right]\right|
\end{align*}
$$

Using Lemma 3.8, Assumption 2.5 and Lemmas 3.3 and 3.4 as well as that $\bar{\vartheta}_{\varkappa}-\vartheta_{\varkappa} \leq \theta_{\varkappa}$, we have for the first term in 3.19 :

$$
\begin{equation*}
\mathbb{E}\left[\mathbf{I}\left(\vartheta_{\varkappa} \geq T\right)\left(\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}-u^{\epsilon}\left(\vartheta_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}\right)\right] \leq K E\left[\theta_{\varkappa}\left(1+\gamma_{\epsilon}^{q} \theta_{\varkappa}^{q}\right)\right] \leq K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} \tag{3.20}
\end{equation*}
$$

where $K>0$ does not depend on $h$ or $\varepsilon$.
For the second term in (3.19), we exploit ideas from [18] to re-express the global error. We get using Theorem 3.5 and Lemmas 3.8 and 3.7;

$$
\begin{align*}
& \left|\mathbb{E}\left[u^{\epsilon}\left(\vartheta_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}-u^{\epsilon}\left(t_{0}, x_{0}\right)\right]\right|  \tag{3.21}\\
& =\left|\mathbb{E}\left[\sum_{k=0}^{\varkappa-1} \mathbb{E}\left[u^{\epsilon}\left(\vartheta_{k+1}, X_{k+1}\right) Y_{k+1}+Z_{k+1}-u^{\epsilon}\left(\vartheta_{k}, X_{k}\right) Y_{k}-Z_{k} \mid \vartheta_{k}, X_{k}, Y_{k}, Z_{k}\right]\right]\right|
\end{align*}
$$

$$
\begin{aligned}
& =\left|\mathbb{E}\left[\sum_{k=0}^{\varkappa-1} \mathbb{E}\left[R\left(\vartheta_{k}, X_{k}, Y_{k}, Z_{k}\right) \mid \vartheta_{k}, X_{k}, Y_{k}, Z_{k}\right]\right]\right| \\
& \leq \mathbb{E}\left[\sum_{k=0}^{\varkappa-1} \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}} K\left(1+\gamma_{\epsilon}^{2}\right) Y_{k}\right] \\
& \leq K \frac{1+\gamma_{\epsilon}^{2}}{\lambda_{\epsilon}^{2}}\left(1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)\right) \mathbb{E} \varkappa \\
& \leq K\left(1+\gamma_{\epsilon}^{2}\right)\left(\frac{1}{\lambda_{\epsilon}\left(1-e^{\left.-\lambda_{\epsilon} h\right)}\right.}-h \frac{e^{-\lambda_{\epsilon} h}}{1-e^{-\lambda_{\epsilon} h}}\right)\left(T-t_{0}\right) \\
& \leq K\left(1+\gamma_{\epsilon}^{2}\right)\left(\frac{1}{\lambda_{\epsilon}}-h \frac{e^{-\lambda_{\epsilon} h}}{1-e^{-\lambda_{\epsilon} h}}\right),
\end{aligned}
$$

where, as usual constants $K>0$ are changing from line to line. Combining (3.19)-3.21), we arrive at (3.18).

Remark 3.10 (Error estimate and convergence). Note that the error estimate in Theorem 3.9 gives us the expected results in the limiting cases (see also Remark 3.6). If $\lambda_{\epsilon} h<1$, we obtain:

$$
\mathbf{R} \leq K\left(1+\gamma_{\epsilon}^{2}\right) h,
$$

which is expected for weak convergence in the jump-diffusion case.
If $\lambda_{\epsilon}$ is large (meaning that almost always $\theta<h$ ), the error is tending to

$$
\mathbf{R} \leq K\left(1+\gamma_{\epsilon}^{2}\right) \frac{1}{\lambda_{\epsilon}},
$$

as expected (cf. [11).
We also remark that for any fixed $\lambda_{\epsilon}$, we have first order convergence when $h \rightarrow 0$.
Remark 3.11. In the case of symmetric measure $\nu(z)$ we have $\gamma_{\epsilon}=0$ and hence the global error (3.18) becomes

$$
\begin{align*}
& \left|\mathbb{E}\left[\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}\right]-u^{\epsilon}\left(t_{0}, x_{0}\right)\right|  \tag{3.22}\\
& \leq K\left(\frac{1}{\lambda_{\epsilon}}-h \frac{e^{-\lambda_{\epsilon} h}}{1-e^{-\lambda_{\epsilon} h}}\right)+K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} .
\end{align*}
$$

### 3.4 Remark on the Cauchy problem

Let us set $G=\mathbb{R}^{d}$ in 2.15 and hence consider the Cauchy problem for the PIDE:

$$
\begin{align*}
\frac{\partial u^{\epsilon}}{\partial t}+L_{\epsilon} u^{\epsilon}+c(t, x) u^{\epsilon}+g(t, x) & =0, & & (t, x) \in Q,  \tag{3.23}\\
u^{\epsilon}(T, x) & =\varphi(t, x), & & x \in \mathbb{R}^{d} .
\end{align*}
$$

In this case Algorithm 3.1 stops only when $\vartheta_{\varkappa} \geq T$ as there is no spatial boundary. Theorem 3.5 remains valid for the Cauchy problem, although in this case one should replace the constant $K$
in the right-hand side of the bound (3.14) with a function $K(x)>0$ satisfying

$$
K(x) \leq \widetilde{K}\left(1+|x|^{2 q}\right)
$$

with some constants $\widetilde{K}>0$ and $q \geq 1$. Consequently, to prove an analogue of the global convergence Theorem 3.9 , we need to prove boundedness of moments $\mathbb{E} X_{k}^{2 p}$. Let

$$
X_{k} \equiv X_{\varkappa} \text { for all } k \geq \varkappa
$$

Lemma 3.12. Under Assumptions 2.1, 2.2, and 3.1, we have for $X_{k}$ from Algorithm 3.1:

$$
\begin{equation*}
\mathbb{E}\left|X_{k}\right|^{2 p} \leq K\left(1+|x|^{2 p}\right) \tag{3.24}
\end{equation*}
$$

with some constants $K>0$ and $p \geq 1$.

Proof. As usual, in this proof $K>0$ is a constant independent of $\epsilon$ and $h$ which can change from line to line in derivations. We first prove the lemma for an integer $p \geq 1$.

We have

$$
\begin{align*}
& \left|X_{k+1}\right|^{2 p}=\left|\left(X_{k+1}-X_{k}\right)+X_{k}\right|^{2 p} \leq\left|X_{k}\right|^{2 p}+\mathbb{I}_{\varkappa \geq k+1}\left|X_{k}\right|^{2 p-2}  \tag{3.25}\\
& \quad \times\left[2 p\left(X_{k}, X_{k+1}-X_{k}\right)+p(2 p-1)\left|X_{k+1}-X_{k}\right|^{2}\right]+K \sum_{l=3}^{2 p}\left|X_{k}\right|^{2 p-l}\left|X_{k+1}-X_{k}\right|^{l} .
\end{align*}
$$

For $\varkappa>k$ :

$$
\begin{gathered}
X_{k+1}-X_{k}=\theta_{k+1}\left(b\left(\vartheta_{k}, X_{k}\right)-F\left(\vartheta_{k}, X_{k}\right) \gamma_{\epsilon}\right)+\sqrt{\theta_{k+1}}\left(\sigma\left(\vartheta_{k}, X_{k}\right) \xi_{k}+F\left(\vartheta_{k}, X_{k}\right) \beta_{\epsilon} \eta\right) \\
+\mathbf{I}\left(\delta_{k+1}<h\right) F\left(\vartheta_{k}, X_{k}\right) J_{\epsilon, k+1} .
\end{gathered}
$$

Then

$$
\begin{aligned}
\mathbb{E}\left(X_{k+1}-X_{k} \mid X_{k}\right) & =\mathbb{I}_{\varkappa>k}\left(b\left(\vartheta_{k}, X_{k}\right)-F\left(\vartheta_{k}, X_{k}\right) \gamma_{\epsilon}\right) \mathbb{E} \theta_{k+1} \\
& +\mathbb{I}_{\varkappa>k} F\left(\vartheta_{k}, X_{k}\right) \mathbb{E}\left(\mathbf{I}\left(\delta_{k+1}<h\right) J_{\epsilon, k+1}\right) \\
& =\mathbb{I}_{\varkappa>k} \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}\left[b\left(\vartheta_{k}, X_{k}\right)+F\left(\vartheta_{k}, X_{k}\right) \int_{|s|>1} s \nu(d s)\right],
\end{aligned}
$$

where we used

$$
\begin{aligned}
& -\gamma_{\epsilon} \mathbb{E} \theta_{k+1}+\mathbb{E}\left(\mathbf{I}\left(\delta_{k+1}<h\right) J_{\epsilon, k+1}\right) \\
& =-\gamma_{\epsilon} \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}+\left(1-e^{-\lambda_{\epsilon} h}\right)\left[\frac{\gamma_{\epsilon}}{\lambda_{\epsilon}}+\frac{1}{\lambda_{\epsilon}} \int_{|s|>1} s \nu(d s)\right] \\
& =\frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} \int_{|s|>1} s \nu(\mathrm{~d} s) .
\end{aligned}
$$

By the linear growth Assumption 2.2 and Assumption 3.1, we get

$$
\begin{align*}
& \left|\mathbb{E}\left[\left|X_{k}\right|^{2 p-2}\left(X_{k}, X_{k+1}-X_{k}\right)\right]\right|  \tag{3.26}\\
& \leq K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}\left(\mathbb{E} \mathbf{I}_{\varkappa>k}(\omega)\left|X_{k}\right|^{2 p-2}+\mathbb{E} \mathbf{I}_{\varkappa>k}(\omega)\left|X_{k}\right|^{2 p}\right) \\
& \leq K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} \mathbb{E} \mathbf{I}_{\varkappa>k}(\omega)\left|X_{k}\right|^{2 p}
\end{align*}
$$

using that $\mathbb{E} \mathbf{I}_{\varkappa>k}(\omega)\left|X_{k}\right|^{2 p-2} \leq \mathbb{E} \mathbf{I}_{\varkappa>k}(\omega)\left|X_{k}\right|^{2 p}$. Further,

$$
\begin{aligned}
\mathbb{E}\left(\left|X_{k+1}-X_{k}\right|^{2} \mid X_{k}\right) \leq & \mathbf{I}_{\varkappa>k}\left(a\left(\vartheta_{k}, X_{k}\right)+F\left(\vartheta_{k}, X_{k}\right) B_{\epsilon} F^{\top}\left(\vartheta_{k}, X_{k}\right)\right) \mathbb{E} \theta_{k+1} \\
& +2 \mathbf{I}_{\varkappa>k}\left(b\left(\vartheta_{k}, X_{k}\right)-F\left(\vartheta_{k}, X_{k}\right) \gamma_{\epsilon}\right)^{2} \mathbb{E} \theta_{k+1}^{2} \\
& +2 \mathbf{I}_{\varkappa>k} F\left(\vartheta_{k}, X_{k}\right) F^{\top}\left(\vartheta_{k}, X_{k}\right) \mathbb{E}\left(\mathbf{I}\left(\delta_{k+1}<h\right) J_{\epsilon, k+1}^{2}\right)
\end{aligned}
$$

and thus

$$
\begin{align*}
\left|\mathbb{E}\left[\left|X_{k}\right|^{2 p-2}\left|X_{k+1}-X_{k}\right|^{2}\right]\right| \leq & K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}\left(\mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p-2}+\mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p}\right)  \tag{3.27}\\
& +K \frac{1-e^{-\lambda_{\epsilon} h}\left(1+\lambda_{\epsilon} h\right)}{\lambda_{\epsilon}^{2}}\left(1+\gamma_{\epsilon}^{2}\right)\left(\mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p-2}+\mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p}\right) \\
& +K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}\left(\mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p-2}+\mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p}\right) \\
\leq & K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} \mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p}
\end{align*}
$$

using that

$$
\mathbb{E} J_{\epsilon, k+1}^{2}=\frac{1}{\lambda_{\epsilon}} \int_{|s|>\epsilon} s^{2} \nu(d s)=\frac{B_{\epsilon}}{\lambda_{\epsilon}}+\frac{1}{\lambda_{\epsilon}} \int_{|s|>1} s^{2} \nu(d s)
$$

and that $\frac{\gamma_{\epsilon}^{2}}{\lambda_{\epsilon}}$ is bounded.
For the last term in 3.25 , observe that

$$
\left|X_{k}\right|^{2 p-l}\left|X_{k+1}-X_{k}\right|^{l} \leq \theta_{k+1}\left[\frac{2 p-l}{2 p}\left|X_{k}\right|^{2 p}+\frac{l}{2 p}\left|X_{k+1}-X_{k}\right|^{2 p} \frac{1}{\theta_{k+1}^{2 p / l}}\right], l=3, \ldots, 2 p
$$

Then one can show that

$$
\begin{equation*}
\sum_{l=3}^{2 p} \mathbb{E}\left|X_{k}\right|^{2 p-l}\left|X_{k+1}-X_{k}\right|^{l} \leq K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} \mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p} \tag{3.28}
\end{equation*}
$$

Combining (3.25)-3.28), we get

$$
\mathbb{E}\left|X_{k+1}\right|^{2 p} \leq \mathbb{E}\left|X_{k}\right|^{2 p}+K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}} \mathbb{E} \mathbf{I}_{\varkappa>k}\left|X_{k}\right|^{2 p}=\mathbb{E}\left|X_{k}\right|^{2 p}+K \mathbb{E}\left[\theta_{k+1} \mathbb{I}_{\varkappa>k}\left|X_{k}\right|^{2 p}\right]
$$

whence

$$
\begin{equation*}
\mathbb{E}\left|X_{\varkappa}\right|^{2 p} \leq\left|x_{0}\right|^{2 p}+K \mathbb{E} \sum_{k=0}^{\varkappa-1} \theta_{k+1}\left|X_{k}\right|^{2 p} \tag{3.29}
\end{equation*}
$$

Introduce a continuous time piece-wise constant process

$$
\widetilde{U}(t)=\left|X_{k}\right|^{2 p} \text { for } t \in\left[\vartheta_{k}, \vartheta_{k+1}\right), \quad k=0, \ldots, \varkappa-1
$$

and

$$
\widetilde{U}(t)=\left|X_{\varkappa}\right|^{2 p} \text { for } t \geq \vartheta_{\varkappa}
$$

Then we can write 3.29 as

$$
\begin{aligned}
E \widetilde{U}\left(\vartheta_{\varkappa}\right) & =E \widetilde{U}(T+h) \leq\left|x_{0}\right|^{2 p}+K E \int_{t_{0}}^{\vartheta_{\varkappa}} \widetilde{U}(t) d s \\
& \leq\left|x_{0}\right|^{2 p}+K \int_{t_{0}}^{T+h} E \widetilde{U}(t) d s
\end{aligned}
$$

By Gronwall's inequality, we get

$$
E \widetilde{U}\left(\vartheta_{\varkappa}\right) \leq e^{K\left(T+h-t_{0}\right)}\left|x_{0}\right|^{2 p}
$$

implies (3.24) for integer $p \geq 1$. Then, by Jensen's inequality, (3.24) holds for non-integer $p \geq 1$ as well.

Based on the discussion before Lemma 3.12 and on the moments estimate 3.24 of Lemma 3.12 , it is not difficult to show that the global error estimate 3.18 for Algorithm 3.1 also holds in the Cauchy problem case.

### 3.5 The case of infinite intensity of jumps

In this section we combine the previous results, Theorem 2.4 and 3.9 , to obtain an overall error estimate for solving the problem (1.1) in the case of infinite intensity of jumps by Algorithm 3.1 . We obtain

$$
\begin{align*}
& \left|\mathbb{E}\left[\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}\right]-u\left(t_{0}, x_{0}\right)\right|  \tag{3.30}\\
& \leq K\left(1+\gamma_{\epsilon}^{2}\right)\left(\frac{1}{\lambda_{\epsilon}}-h \frac{e^{-\lambda_{\epsilon} h}}{1-e^{-\lambda_{\epsilon} h}}\right)+K \frac{1-e^{-\lambda_{\epsilon} h}}{\lambda_{\epsilon}}+K \int_{|z| \leq \epsilon}|z|^{3} \nu(\mathrm{~d} z),
\end{align*}
$$

where $K>0$ is independent of $h$ and $\epsilon$.
Let us consider an $\alpha$-stable process as in Example 2.1, i.e., for $\alpha \in(0,2)$ the Lévy measure

$$
\nu(\mathrm{d} z) \sim|z|^{-1-\alpha} \mathrm{d} z
$$

where we are focusing our attention on the singularity near zero. Then

$$
\lambda_{\epsilon}=\int_{|z| \geq \epsilon} \nu(\mathrm{d} z) \sim \epsilon^{-\alpha}
$$

$$
\begin{aligned}
\gamma_{\epsilon}^{2}= & {\left[\int_{\epsilon \leq|z| \leq 1} z^{i} \nu(\mathrm{~d} z)\right]^{2} \sim \epsilon^{2-2 \alpha} } \\
& \int_{|z| \leq \epsilon}|z|^{3} \nu(\mathrm{~d} y) \sim \epsilon^{3-\alpha}
\end{aligned}
$$

Hence

$$
\begin{align*}
& \left|\mathbb{E}\left[\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}\right]-u\left(t_{0}, x_{0}\right)\right|  \tag{3.31}\\
& \leq K\left[\left(1+\epsilon^{2-2 \alpha}\right)\left(\epsilon^{\alpha}-h \frac{e^{-\epsilon^{-\alpha} h}}{1-e^{-\epsilon^{-\alpha} h}}\right)+\epsilon^{\alpha}\left(1-e^{-\epsilon^{-\alpha} h}\right)+\epsilon^{3-\alpha}\right] .
\end{align*}
$$

Let us measure the computational cost of Algorithm 3.1 in terms of the average number of steps (see Lemma 3.7). Since

$$
E \varkappa \leq \frac{\left(T-t_{0}\right) \lambda_{\epsilon}}{1-e^{-\lambda_{\epsilon} h}} \leq K \frac{\epsilon^{-\alpha}}{1-e^{-\epsilon^{-\alpha} h}}
$$

we choose to use the cost associated with the average number of steps as

$$
C:=\frac{\epsilon^{-\alpha}}{1-e^{-\epsilon^{-\alpha} h}} .
$$

We fix a tolerance level $\rho_{\text {tol }}$ and require $\epsilon$ and $h$ to be so that

$$
\rho_{\text {tol }}=\rho(\epsilon, h):=\left(1+\epsilon^{2-2 \alpha}\right)\left(\epsilon^{\alpha}-\frac{h e^{-\epsilon^{-\alpha} h}}{1-e^{-\epsilon^{-\alpha} h}}\right)+\epsilon^{\alpha}\left(1-e^{-\epsilon^{-\alpha} h}\right)+\epsilon^{3-\alpha} .
$$

Note that since we are using the Euler scheme for SDE approximation, the decrease of $\rho_{t o l}$ in terms of cost cannot be faster than linear. We now consider three cases of $\alpha$.

The case $\alpha=1$. We have

$$
\rho(\epsilon, h)=2\left(\epsilon-\frac{h e^{-\epsilon^{-1} h}}{1-e^{-\epsilon^{-1} h}}\right)+\epsilon\left(1-e^{-\epsilon^{-1} h}\right)+\epsilon^{2}=O(\epsilon)
$$

and by choosing sufficiently small $\epsilon$ we can reach the required $\rho_{\text {tol }}$. It is optimal to take $h=\infty$ (in practice, taking $h=T-t_{0}$ ) and the cost is then $C=1 / \epsilon$. Hence $\rho_{t o l}$ is inversely proportional to $C$, and convergence is linear in cost (to reduce $\rho_{\text {tol }}$ twice, we need to double $C$ ).

The case $\alpha \in(0,1)$. We have

$$
\rho(\epsilon, h) \leq \epsilon^{2-\alpha}+2 \epsilon^{\alpha}+\epsilon^{3-\alpha}=O\left(\epsilon^{\alpha}\right) .
$$

Again, it is optimal to take $h=\infty$ and we have linear convergence in cost.
The case $\alpha \in(1,2)$. If we take $h=\infty$, then $\rho(\epsilon, h)=O\left(\epsilon^{2-\alpha}\right)$ and the convergence order in terms of cost is $2 / \alpha-1$, which is very slow (e.g., for $\alpha=3 / 2$, the order is $1 / 3$ and for $\alpha=1.9$, the order is $\approx 0.05$ ). Let us now take $h=\epsilon^{\ell}$ with $\ell \geq \alpha$. Then

$$
\rho(\epsilon, h) \leq \epsilon^{2-2 \alpha} h+2 h+\epsilon^{3-\alpha}=\epsilon^{2-2 \alpha+\ell}+\epsilon^{\ell}+\epsilon^{3-\alpha}
$$

and $C \approx 1 / h=\epsilon^{-\ell}$. The optimal $\ell=1+\alpha$, for which $\rho(\epsilon, h)=O\left(\epsilon^{3-\alpha}\right)$ and the convergence
order in terms of cost is $(3-\alpha) /(1+\alpha)$, which is much better (e.g., for $\alpha=3 / 2$, the order is $3 / 5$ and it cannot be smaller than $1 / 3$ for any $\alpha \in(1,2))$. Note that in the case of symmetric measure $\nu(z)$ (see Remark 3.11), convergence is linear in cost for $\alpha \in(1,2)$.

To conclude, for $\alpha \in(0,1]$ we have first order convergence and there is no benefit of restricting jump adapted steps by $h$ (see a similar result in the case of the Cauchy problem and not restricted jump-adapted steps in [12]). However, in the case of $\alpha \in(1,2)$, it is beneficial to use restricted jump-adapted steps to get the order of $(3-\alpha) /(1+\alpha)$. We also recall that restricted jump-adapted steps should typically be used for jump-diffusions (the finite activity case when there is no singularity of $\lambda_{\epsilon}$ and $\gamma_{\epsilon}$ ) because jump time increments $\delta$ typically take too large values and to control the error at every step we should truncate those times at a sufficiently small $h>0$ for a satisfactory accuracy.

## 4 Numerical experiments

In this section we illustrate the theoretical results of Section 3. In particular, we display the behaviour in the case of infinite intensity of jumps for different regimes of $\alpha$. We showcase numerical tests of Algorithm 3.1 in three different examples: (i) a non-singular Lévy measure (Example 4.1), (ii) a singular Lévy measure which is similar to that of Example 2.1 (see Example 4.2), and (iii) pricing a foreign-exchange (FX) barrier basket option where the underlying model is of exponential Lévy-type (Example 4.3).

As it is usual for weak approximation (see e.g. [18]), in simulations we compliment Algorithm 3.1 by the Monte Carlo techniques and evaluate $u\left(t_{0}, x\right)$ or $u^{\epsilon}\left(t_{0}, x\right)$ as

$$
\begin{equation*}
\bar{u}\left(t_{0}, x\right):=\mathbb{E}\left[\varphi\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}\right) Y_{\varkappa}+Z_{\varkappa}\right] \simeq \hat{u}=\frac{1}{M} \sum_{m=1}^{M}\left[\varphi\left(\bar{\vartheta}_{\varkappa}^{(m)}, X_{\varkappa}^{(m)}\right) Y_{\varkappa}^{(m)}+Z_{\varkappa}^{(m)}\right] \tag{4.1}
\end{equation*}
$$

where $\left(\bar{\vartheta}_{\varkappa}^{(m)}, X_{\varkappa}^{(m)}, Y_{\varkappa}^{(m)}, Z_{\varkappa}^{(m)}\right)$ are independent realisations of $\left(\bar{\vartheta}_{\varkappa}, X_{\varkappa}, Y_{\varkappa}, Z_{\varkappa}\right)$. The Monte Carlo error of (4.1) is

$$
\sqrt{D_{M}}:=\frac{(\operatorname{Var} f(\bar{X}(T)))^{1 / 2}}{M^{1 / 2}} \simeq \sqrt{\bar{D}_{M}}
$$

where

$$
\bar{D}_{M}=\frac{1}{M}\left[\frac{1}{M} \sum_{m=1}^{M}\left[\Xi^{(m)}\right]^{2}-\left(\frac{1}{M} \sum_{m=1}^{M} \Xi^{(m)}\right)^{2}\right]
$$

and $\Xi^{(m)}=\varphi\left(\bar{\vartheta}_{\varkappa}^{(m)}, X_{\varkappa}^{(m)}\right) Y_{\varkappa}^{(m)}+Z_{\varkappa}^{(m)}$. Then $\bar{u}\left(t_{0}, x\right)$ falls in the corresponding confidence interval $\hat{u} \pm 2 \sqrt{\bar{D}_{M}}$ with probability 0.95 .

### 4.1 Example with a non-singular Lévy measure

In this subsection, we illustrate Algorithm 3.1 in the case of a simple non-singular Lévy measure (i.e., the jump-diffusion case), where there is no need to replace small jumps and hence we directly approximate $u\left(t_{0}, x\right)$ rather than $u^{\epsilon}\left(t_{0}, x\right)$. Consequently, the numerical integration error does not depend on $\epsilon$. We recall (see Theorem 3.9) that Algorithm 3.1 has first order of
convergence in $h$.
Example 4.1 (Non-singular Lévy measure). To construct this and the next example, we use the same recipe as in [17, 18]: we choose the coefficients of the problem (1.1) so that we can write down its solution explicitly. Having the exact solution is very useful for numerical tests.

Consider the problem (1.1) with $d=3, G=U_{1}$ which is the open unit ball centred at the origin in $\mathbb{R}^{3}$, and with the coefficients

$$
\begin{align*}
a^{11}(t, x) & =1.21-x_{2}^{2}-x_{3}^{2}, \quad a^{22}=1, \quad a^{33}=1,  \tag{4.2}\\
a^{i j} & =0, i \neq j, \\
b & =0
\end{align*}
$$

with the boundary condition

$$
\begin{equation*}
\varphi(t, x)=\left(1-\frac{1}{2} \mathrm{e}^{T-t}\right)\left(1.21-x_{1}^{4}-x_{2}^{4}\right) \tag{4.5}
\end{equation*}
$$

and with the Lévy measure density

$$
\nu(\mathrm{d} z)= \begin{cases}C_{-} \mathrm{e}^{-\mu|z|} \mathrm{d} z, & \text { if } z<0, \\ C_{+} \mathrm{e}^{-\mu|z|} \mathrm{d} z, & \text { if } z>0,\end{cases}
$$

where $C_{-}$and $C_{+}$are some positive constants.
It is not difficult to verify that this problem has the solution

$$
u(t, x)=\left(1-\frac{1}{2} \mathrm{e}^{T-t}\right)\left(1.21-x_{1}^{4}-x_{2}^{4}\right) .
$$

and we also find

$$
\begin{aligned}
\lambda & =\int_{|z|>0} \nu(\mathrm{~d} z)=\int_{\mathbb{R}} \nu(\mathrm{d} z)=\frac{C_{+}+C_{-}}{\mu}, \\
\rho(z) & =\frac{C_{-} \mathrm{e}^{-\mu|z|} \mathbf{I}_{\{z<0\}}+C_{+} \mathrm{e}^{-\mu|z|} \mathbf{I}_{\{z>0\}}}{\lambda} .
\end{aligned}
$$

We simulated jump sizes by analytically inverting the cumulative distribution function corresponding to the density $\rho(z)$ and making use of uniform random numbers in the standard manner.

Figure 1: Non-singular Lévy measure example: dependence of the error $e$ on $h$, the error bars show the Monte Carlo error. The parameters used are $T=1, C_{+}=30, C_{-}=$ $1.0, \mu=3.0, f=0.1, M=40000000$ and $\hat{u}$ is evaluated at the point $(0,0)$.

Table 1: Non-singular Lévy measure example. The parameters are the same as in Figure 1 The column $\hat{\varkappa}$ gives the sample average of the number of steps together with its Monte Carlo error.

| $h$ | $\hat{u}$ | $2 \sqrt{\hat{D}_{M}}$ | $e$ | $\hat{\varkappa}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0.1 | 0.9367 | 0.0004 | 0.0507 | $7.72 \pm 0.0037$ |
| 0.05 | 0.9612 | 0.0004 | 0.0262 | $11.04 \pm 0.0056$ |
| 0.025 | 0.9742 | 0.0004 | 0.0133 | $17.85 \pm 0.0096$ |
| 0.01 | 0.9821 | 0.0003 | 0.0054 | $37.85 \pm 0.0217$ |
| 0.005 | 0.9850 | 0.0003 | 0.0024 | $70.90 \pm 0.0416$ |

Here the absolute error $e$ is given by

$$
\begin{equation*}
e=|\hat{u}-u| . \tag{4.6}
\end{equation*}
$$

The expected convergence order $O(h)$ can be clearly seen in Figure 1 and Table 1 .

### 4.2 Example with a singular Lévy measure

In this subsection, we confirm dependence of the error of Algorithm 3.1 on the cut-off parameter $\epsilon$ for jump sizes and on the parameter $\alpha$ of the Lévy measure as well as associated computational costs which were derived in Section 3.5,

Example 4.2 (Singular Lévy measure). Consider the problem (1.1) with $d=3, G=U_{1}$ which is the open unit ball centred at the origin in $\mathbb{R}^{3}$, and with the coefficients as in 4.2, 4.3), and

$$
\begin{align*}
g(t, x):= & \frac{1}{2} e^{T-t}\left(1.21-x_{1}^{4}-x_{2}^{4}\right)+6\left(1-\frac{1}{2} e^{T-t}\right)\left[x_{1}^{2}\left(1.21-x_{2}^{2}-x_{3}^{2}\right)+x_{2}^{2}\right]  \tag{4.7}\\
& +\left(1-\frac{1}{2} e^{T-t}\right)\left[\left(C_{+}-C_{-}\right) f\left(\frac{4}{\mu}+\frac{4}{\mu^{2}}\right)\left(x_{1}^{3}+x_{2}^{3}\right)\right. \\
& +\left(C_{+}+C_{-}\right) f^{2}\left(\frac{6}{2-\alpha}+\frac{6}{\mu}+\frac{12}{\mu^{2}}+\frac{12}{\mu^{3}}\right)\left(x_{1}^{2}+x_{2}^{2}\right) \\
& +\left(C_{+}-C_{-}\right) f^{3}\left(\frac{4}{3-\alpha}+\frac{4}{\mu}+\frac{12}{\mu^{2}}+\frac{24}{\mu^{3}}+\frac{24}{\mu^{4}}\right)\left(x_{1}+x_{2}\right) \\
& \left.+\left(C_{+}+C_{-}\right) f^{4}\left(\frac{2}{4-\alpha}+\frac{2}{\mu}+\frac{8}{\mu^{2}}+\frac{24}{\mu^{3}}+\frac{48}{\mu^{4}}+\frac{48}{\mu^{5}}\right)\right],
\end{align*}
$$

with the boundary condition (4.5), and with the Lévy measure density

$$
\nu(\mathrm{d} z)= \begin{cases}C_{-} \mathrm{e}^{-\mu(|z|-1)} \mathrm{d} z, & \text { if } z<-1,  \tag{4.8}\\ C_{-}|z|^{-(\alpha+1)} \mathrm{d} z, & \text { if }-1 \leq z<0, \\ C_{+}|z|^{-(\alpha+1)} \mathrm{d} z, & \text { if } 0<z \leq 1, \\ C_{+} \mathrm{e}^{-\mu(|z|-1)} \mathrm{d} z, & \text { if } z>1,\end{cases}
$$

where $C_{-}, C_{+}$, and $\mu$ are some positive constants and $\alpha \in(0,2)$.
Note that $C_{-} \neq C_{+}$gives an asymmetric jump measure and the Lévy process has infinite activity and variation.

It is not difficult to verify that this problem has the following solution

$$
u(t, x)=\left(1-\frac{1}{2} \mathrm{e}^{T-t}\right)\left(1.21-x_{1}^{4}-x_{2}^{4}\right) .
$$

Other quantities needed for the algorithm take the form

$$
\begin{gathered}
\gamma_{\epsilon}=\left(C_{+}-C_{-}\right) \frac{1-\epsilon^{1-\alpha}}{1-\alpha}, \quad \alpha \neq 1, \\
B_{\epsilon}=\left(C_{+}+C_{-}\right) \frac{\epsilon^{2-\alpha}}{2-\alpha}, \\
\beta_{\epsilon}=\sqrt{B_{\epsilon}}=\sqrt{\left(C_{+}+C_{-}\right) \frac{\epsilon^{2-\alpha}}{2-\alpha}}, \\
\lambda_{\epsilon}=\int_{|z|>\epsilon} \nu(\mathrm{d} z)=\left(C_{+}+C_{-}\right)\left(\frac{1}{\mu}+\frac{\epsilon^{-\alpha}-1}{\alpha}\right), \\
\rho_{\epsilon}(z)=\frac{1}{\lambda_{\epsilon}}\left[C_{-} \mathrm{e}^{-\mu(|z|-1)} \mathbf{I}_{\{z<-1\}}+C_{-}|z|^{-(\alpha+1)} \mathbf{I}_{\{-1 \leq z<-\epsilon\}}\right. \\
\left.+C_{+}|z|^{-(\alpha+1)} \mathbf{I}_{\{\epsilon<z \leq 1\}}+C_{+} \mathrm{e}^{-\mu(|z|-1)} \mathbf{I}_{\{z>1\}}\right],
\end{gathered}
$$

In this example, the absolute error $e$ is given by

$$
\begin{equation*}
e=\left|\hat{u}^{\epsilon}-u\right| \tag{4.9}
\end{equation*}
$$

For the case of $\alpha=0.5$, we can clearly see in Figure 2 and Table 2 that the error is of order $O\left(\epsilon^{\alpha}\right)=O\left(\epsilon^{0.5}\right)$ as expected. We also observe linear convergence in computational cost (measured in average number of steps). In addition we note that choosing a smaller time step, e.g. $h=0.1$, does not change the behaviour in this case which is in accordance with our prediction of Section 3.5

Numerical results for the case $\alpha=1.5$ are given in Figures 4 and 5. As is shown in Section 3.5, convergence (in terms of computational costs) can be improved in the case of $\alpha \in(1,2)$ by choosing $h=\epsilon^{1+\alpha}$. In Figure 5, for all $\epsilon$ it can be seen that choosing a smaller (but optimally chosen) step parameter $h$ results in quicker convergence (i.e., for the same cost, we can achieve a better result if $h$ is chosen in an optimal way) and naturally in a smaller error.

We recall that if the jump measure is symmetric, i.e. $C_{-}=C_{+}$in the considered example,

Figure 2: Singular Lévy measure example, the case $\alpha=0.5$ : dependence of the error $e$ on $\epsilon$, the error bars show the Monte Carlo error. The parameters used are $T=1, C_{+}=$ $0.1, C_{-}=1.0, \mu=3.0, f=0.2, M=$ 40000000 and $\hat{u}$ is evaluated at the point $(0,0)$.

Figure 3: Singular Lévy measure example, the case $\alpha=0.5$ : dependence of the error $e$ on the average number of steps (computational costs). The parameters are the same as in Figure 2 .

Table 2: Singular Lévy measure example for $\alpha=0.5$ and $h=1$. The parameters are the same as in Figure 2. The column $\hat{\varkappa}$ gives the sample average of the number of steps together with its Monte Carlo error.

| $\epsilon$ | $\hat{u}$ | $2 \sqrt{\hat{D}_{M}}$ | $e$ | $\lambda_{\epsilon}$ | $\gamma_{\epsilon}$ | $\hat{\varkappa}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.0025 | 0.9610 | 0.0004 | 0.0265 | 42.2 | -1.71 | $17.10 \pm 0.0096$ |
| 0.001 | 0.9713 | 0.0004 | 0.0162 | 67.7 | -1.74 | $25.78 \pm 0.0149$ |
| 0.0005 | 0.9761 | 0.0004 | 0.0113 | 96.6 | -1.76 | $35.45 \pm 0.0208$ |
| 0.00025 | 0.9795 | 0.0003 | 0.0080 | 137.3 | -1.77 | $48.96 \pm 0.0290$ |
| 0.0001 | 0.9822 | 0.0003 | 0.0052 | 218.2 | -1.78 | $75.53 \pm 0.0452$ |
| 0.00005 | 0.9841 | 0.0003 | 0.0033 | 309.3 | -1.79 | $105.32 \pm 0.0633$ |
| 0.000025 | 0.9850 | 0.0003 | 0.0024 | 438.2 | -1.79 | $147.07 \pm 0.0888$ |
| 0.00001 | 0.9858 | 0.0003 | 0.0016 | 693.9 | -1.79 | $229.51 \pm 0.1393$ |

then $\gamma_{\epsilon}=0$ and the numerical integration error of Algorithm 3.1 is no longer singular (see Theorem 3.9 and Remark 3.11). Consequently (see Section 3.5), in this case the computational cost depends linearly on $\epsilon$ even for $\alpha=1.5$, which is confirmed on Figure 6.

### 4.3 FX option pricing under a Lévy-type currency exchange model

In this subsection, we demonstrate the use of Algorithm 3.1 for pricing financial derivatives where underliers follow a Lévy process. We apply the algorithm to estimate the price of a foreign exchange (FX) barrier basket option. A barrier basket option gives the holder the right to buy or sell a certain basket of assets (here foreign currencies) at a specific price $K$ at maturity $T$ in the case when a certain barrier event has occurred. The most used barrier-type options are knock-in and knock-out options. This type of option becomes active (or inactive) in the case of the underlying price $S(t)$ reaching a certain threshold (the barrier) $B$ before reaching its maturity. In most cases barrier option prices cannot be given explicitly and therefore have

Figure 4: Singular Lévy measure example, the case $\alpha=1.5$ : dependence of the error $e$ on $\epsilon$, the error bars show the Monte Carlo error. The parameters used are $T=1, C_{+}=1.0, C_{-}=25.0, \mu=$ $3.0, f=1.0, M=100000000$ and $\hat{u}$ is evaluated at the point $(0,0)$.

Figure 5: Singular Lévy measure example, the case $\alpha=1.5$ : dependence of the error $e$ on the average number of steps (computational costs), the error bars show the Monte Carlo error. The parameters are the same as in Figure 4 .
to be approximated.
Example 4.3 (Barrier basket option pricing). Let us consider the case with five currencies: GBP, USD, EUR, JPY and CHF and let us assume the domestic currency is GBP. We denote the corresponding spot exchange rates as

$$
\begin{aligned}
& S_{1}(t)=S_{U S D G B P}(t), \\
& S_{2}(t)=S_{E U R G B P}(t), \\
& S_{3}(t)=S_{J P Y G B P}(t), \\
& S_{4}(t)=S_{C H F G B P}(t),
\end{aligned}
$$

where $S_{F O R D O M}(t)$ describes the amount of domestic currency DOM one pays/receives for one unit of foreign currency FOR (for more details see [5, 24]). We assume that under a risk-neutral measure $\mathbb{Q}$ the dynamics for the spot exchange rates can be written as

$$
S_{i}(t)=S_{i}\left(t_{0}\right) \exp \left(\left(r_{G B P}-r_{i}\right)\left(t-t_{0}\right)+X_{i}(t)\right), \quad i=1,2,3,4,
$$

where $r_{i}$ are the corresponding short rates of USD, EUR, JPY, CHF and $r_{G B P}$ is the short rate for GBP, which are for simplicity assumed to be constant; and $X(t)$ is a 4-dimensional Lévy process similar to (2.1) with a single jump noise:

$$
\begin{equation*}
X(t)=\int_{t_{0}}^{t} b(t, X(s-)) d s+\int_{t_{0}}^{t} \sigma(s, X(s-)) d W^{\mathbb{Q}}(t)+\int_{t_{0}}^{t} \int_{\mathbb{R}} F(s, S(s-)) z \tilde{N}(d z, d s) . \tag{4.10}
\end{equation*}
$$

Figure 6: Dependency of $\epsilon$ on error plot for a simulation example with symmetric singular Lévy measure for $\alpha=1.5$. The parameters used are $T=1, C_{+}=$ $0.5, C_{-}=0.5, \mu=3.0, f=1.0, M=100000000$ and $\hat{u}$ is evaluated at the point $(0,0)$.

Here $W(t)=\left(W_{1}(t), W_{2}(t), W_{3}(t), W_{4}(t)\right)^{\top}$ is a 4-dimensional standard Wiener process. As $\nu(z)$, we choose the Lévy measure with density (4.8) as in Example 4.2 and we take $F(t, x)=$ $\left(f_{1}, f_{2}, f_{3}, f_{4}\right)^{\top}$ and we will assume that $\sigma(s, x)$ is a constant $4 \times 4$ matrix.

Under the measure $\mathbb{Q}$ all the discounted assets $\hat{S}_{i}(t)=e^{-r_{G B P}(t)} S_{i}(t)=S_{i}\left(t_{0}\right) \exp \left(-r_{i}(t-\right.$ $\left.\left.t_{0}\right)+X_{i}(t)\right)$ have to be martingales on the domestic market (therefore discounted by the domestic interest rate) to avoid arbitrage. Using the Ito formula for Lévy processes, we can derive the SDEs for $\widetilde{S}_{i}$

$$
\begin{aligned}
\frac{d \widetilde{S}_{i}}{\widetilde{S}_{i}}= & {\left[-r_{i}+b_{i}(t, X(s-))+\frac{1}{2} \sum_{j=1}^{4} \sigma_{i j}+\int_{\mathbb{R}}\left(e^{f_{i} z}-1-f_{i} z \mathbf{I}_{|z|<1}\right) \nu(d z)\right] d t } \\
& +\sum_{j=1}^{4} \sigma_{i j} d W_{j}^{\mathbb{Q}}(t)+\int_{\mathbb{R}} f_{i} z \tilde{N}(d z, d s)
\end{aligned}
$$

Hence, for all $\widetilde{S}_{i}$ to be martingales, the drift component $b_{i}$ has to be so that

$$
\begin{aligned}
b_{i} & =r_{i}-\frac{1}{2} \sum_{j=1}^{4} \sigma_{i j}-\int_{\mathbb{R}}\left(e^{f_{i} z}-1-f_{i} z \mathbf{I}_{|z|<1}\right) \nu(d z) \\
& =r_{i}-\frac{1}{2} \sum_{j=1}^{4} \sigma_{i j}-\frac{C_{-}}{\mu+f_{i}} e^{-f_{i}}-\frac{C_{+}}{\mu-f_{i}} e^{f_{i}}-\frac{C_{+}-C_{-}}{\mu}-I_{i}\left(\alpha, C_{+}, C_{-}\right),
\end{aligned}
$$

where

$$
I_{i}\left(\alpha, C_{+}, C_{-}\right)=\sum_{n=2}^{\infty} \frac{\left(C_{+}+C_{-}(-1)^{n}\right) f_{i}^{n}}{n!(n-\alpha)}
$$

We also note that

$$
\int_{|z|>1} e^{f_{i} z} \nu(d z)<\infty
$$

is satisfied by (4.8).
Let us consider an international company based in the UK. If it wants to protect itself against large FX rate fluctuations, they could hedge their exposure for each foreign currency on its own. Alternatively, they could use a knock-in barrier basket option to protect themselves against all the currency exposure they have, which is in most cases a cheaper way. The value for such a (down-and-in) put option can be written as

$$
\begin{equation*}
P_{t_{0}}(T, K)=\exp ^{-r_{G B P}\left(T-t_{0}\right)} \mathbb{E}\left[\mathbf{I}_{\operatorname{tin}_{0} \leq t \leq T} S(t)<B \max \left(K-\sum_{i=1}^{n} w_{i} S_{i}(T), 0\right)\right], \tag{4.11}
\end{equation*}
$$

where $\mathbf{I}_{t_{0} \leq t \leq T} \min _{T(t)<B}=1$ if for any of the underlying exchange rates $S_{i}(t)<B_{i}, t_{0} \leq t \leq T$, otherwise it is zero.

We use Algorithm 3.1 together with the Monte Carlo technique to evaluate this barrier basket option price 4.11). In Table 3, market data for the 4 currency pairs are given, and in Table 4 the option and model parameters are provided, which are used in simulations here.

Table 3: Market data for 4 currency pairs. Here $\sigma_{i}$ are volatilities for the corresponding pairs and $\rho_{i j}$ are the correlation coefficients for the corresponding two pairs.

| Market data |  |  | Correlation data $\rho_{i j}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| currency pair $i$ | $S_{i}(0)$ | $r_{i}$ | $\sigma_{i}$ | USDGBP | EURGBP | JPYGBP |
| USDGBP | 0.81 | 0.02 | 0.095 |  |  |  |
| EURGBP | 0.88 | 0.00 | 0.089 | 0.87 |  |  |
| JPYGBP | 0.0075 | -0.011 | 0.071 | 0.94 | 0.77 |  |
| CHFGBP | 0.90 | 0.075 | 0.110 | 0.86 | 0.93 | 0.96 |
|  | $r_{G B P}$ | 0.01 |  |  |  |  |

Table 4: Option and model parameters for Example 4.3

| Option parameter |  |  |  |  | Model parameter |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| currency pair | Barrier $B_{i}$ | $w_{i}$ |  |  | jump factor $f_{i}$ | $\alpha$ | 1.5 |
| USDGBP | 0.50 | 0.20 | $t_{0}$ | 0.0 | 0.10 | $C_{+}$ | 0.3 |
| EURGBP | 0.60 | 0.25 | $T$ | 1.0 | 0.15 | $C_{-}$ | 1.2 |
| JYNGBP | 0.0045 | 0.45 | $K$ | 0.5 | 0.05 | $\mu$ | 3.0 |
| CHFGBP | 0.55 | 0.10 |  |  | 0.12 | $M$ | $10^{6}$ |

To find the matrix $\sigma=\left\{\sigma_{i j}\right\}$ used in the model (4.10), we form the matrix $a$ using the volatility $\sigma_{i}$ and correlation coefficient data from Table 3 in the usual way, i.e., $a_{i i}=\sigma_{i}^{2}$ and $a_{i j}=\sigma_{i} \sigma_{j} \rho_{i j}$ for $i \neq j$. Then the matrix $\sigma$ is the solution of $\sigma \sigma^{\top}=a$ obtained by the Cholesky decomposition.

The results of the simulations are presented in Figure 7 for different choices of $\epsilon$ and different choices of $h$. In Figure 8, it can be seen, that (similar to Example 4.2) by choosing the step size $h$ optimally results in a better approximation for the same cost.

In this example we demonstrated that Algorithm 3.1 can be successfully used to price a FX barrier basket option involving 4 currency pairs following a exponential Lévy model. In particular, we note that the algorithm is easy to implement and it gives sufficient accuracy with

Figure 7: Dependence of the approximate price of the FX barrier basket option on $\epsilon$ for different choices of $h$. The error bars show the Monte Carlo error.

Figure 8: Dependence of the approximate price of the FX barrier basket option on average number of steps (computational costs) for different choices of $h$. The error bars show the Monte Carlo error.
relatively small computational costs. Moreover, application of Algorithm 3.1 can be easily extended to other multi-dimensional barrier option (and other types of options and not only on FX markets), while other approximation techniques such as finite difference methods or Fourier transform methods typically cannot cope with higher dimensions.
