We present a rigorous theoretical description of excitonic dynamics in molecular light-harvesting aggregates photoexcited by weak-intensity radiation of arbitrary properties. While the interaction with light is included up to the second order, the treatment of the excitation–environment coupling is exact and results in an exact expression for the reduced excitonic density matrix that is manifestly related to the spectroscopic picture of the photoexcitation process. This expression takes fully into account the environmental reorganization processes triggered by the two interactions with light. This is particularly important for slow environments and/or strong excitation–environment coupling. Within the exponential decomposition scheme, we demonstrate how our result can be recast as the hierarchy of equations of motion (HEOM) that explicitly and consistently includes the photoexcitation step. We analytically describe the environmental reorganization dynamics triggered by a delta-like excitation of a single chromophore, and demonstrate how our HEOM, in appropriate limits, reduces to the Redfield equations comprising a pulsed photoexcitation and the nonequilibrium Förster theory. We also discuss the relation of our formalism to the combined Born–Markov–HEOM approaches in the case of excitation by thermal light.

I. INTRODUCTION

Recent years have seen vigorous interest in unveiling the basic physical mechanisms governing the electronic solar energy conversion in photosynthetic systems. The developments in this field are expected to provide new ways of improving the light-to-charge conversion in artificial systems, e.g., organic photovoltaics (OPVs). A thorough understanding of the solar energy conversion in molecular light-harvesting systems calls for a detailed description of light absorption, excitation energy transfer (EET), charge separation, and charge transport. Our current understanding of these steps has been shaped by ultrafast spectroscopy experiments, which can provide insights into the dynamics of electronic excitations on time scales as short as a couple of femtoseconds. Such experiments, therefore, can also temporally resolve nuclear motions provoked by photoexcitation, i.e., nuclear reorganization processes, which take place on ~10–100 fs time scales. Moreover, photosynthetic EET falls into the so-called intermediate regime in which the energy scales representative of electronic couplings, excitation–environment couplings, and static disorder in local transition energies are comparable to one another. Therefore, a proper interpretation of ultrafast experimental signatures necessitates development of explicitly time-dependent theoretical approaches that can accurately capture the non-Markovian dynamical interplay between temporal evolution of electronic excitations and their environment. Examples of such methods include hierarchical equations of motion (HEOM) and some wavefunction-based methods.

Apart from the nonperturbative treatment of the interaction with the environment, a comprehensive theoretical analysis of the dynamics of electronic excitations created during ultrafast spectroscopy experiments should explicitly consider the exciting radiation field. However, the explicit inclusion of the photoexcitation process has received only a limited attention so far. The photoexcitation is commonly assumed to be infinitely short, i.e., delta-like, so that it instantaneously produces excited-state populations, whose further evolution on ultrashort time scales is followed. On the other hand, theoretical methods of nonlinear spectroscopy, which explicitly keep track of the interaction with exciting pulses, have been employed in conjunction with, e.g., HEOM, to examine certain features of spectroscopic signals. However, there has not been much discussion on how to explicitly include the photoexcitation and respect the nonperturbative treatment of the excitation–environment coupling. The importance of the photoexcitation step is typically discussed within the debate on the relevance of the results of ultrafast experiments for the photosynthetic operation in vivo. It is argued that, due to different properties of natural Sunlight compared to laser pulses employed in experiments, photoexcitation of photosynthetic complexes under natural conditions triggers different dynamics from the one observed in ultrafast experiments. Nevertheless, under the common assumption that the electronic system is initially unexcited, any nontrivial dynamics under both excitation conditions is ultimately induced by the interaction with the radiation. In a nonlinear spectroscopy experiment, the signal depends on the appropriate power of the exciting field, i.e., the
perturbation expansion in the interaction with radiation is appropriate. Similarly, the weakness of the excitation of photosynthetic complexes under natural conditions makes the second-order treatment of the interaction with light plausible. Indeed, it has been shown that the excited-state dynamics of a molecular system weakly driven by light of arbitrary properties is completely determined by the first-order radiation correlation function and the reduced evolution superoperator. It can be said that the information required for constructing the dynamics under arbitrary (weak) driving can only be obtained by ultrafast spectroscopy, which provides access to the reduced evolution superoperator. However, the analysis conducted in Ref. 20 is quite general and does not provide any details on the form and properties of this superoperator. Certainly, it should contain information about the nonequilibrium evolution of the environment taking place between consecutive interactions with light. Along these lines, attempts were made to examine the importance of these dynamical environmental effects for the second-order light-induced dynamics by augmenting the usual quantum master equation by terms that depend on the delay between the two interactions. The analysis of the second-order photoinduced dynamics in Ref. 28 suggested that the nonequilibrium bath evolution between the two interactions with light is reflected in the so-called photoinduced correlation term. Let us note that the analyses conducted in Refs. 20–28 are essentially perturbative in the excitation–environment coupling.

On the other hand, in the field of ultrafast semiconductor optics, the photoexcitation step and the nonequilibrium dynamics of thus induced electronic excitations are typically studied within the density matrix (DM) theory complemented with the so-called dynamics controlled truncation (DCT) scheme. The DCT scheme classifies DMs according to the lowest power with which they scale in the exciting field and, therefore, provides a recipe to analyze the dynamics up to any given order in the exciting field in terms of a finite number of electronic DMs. A DCT-based approach has been recently applied by one of us to study exciton generation and subsequent charge separation in photoexcited OPVs. However, the truncation of the environment-assisted branch of the hierarchy within the DCT scheme still has to be performed separately and it is commonly done in a low order in the excitation–environment coupling.

While the explicit inclusion of the light–matter coupling is typically accompanied by a perturbative treatment of the excitation–environment coupling, there are also studies concentrating on a (numerically) exact treatment of the latter, at the expense of a less transparent inclusion of the former. When the semiclassical description of light–matter interaction is appropriate, the time-dependent electric field can be straightforwardly incorporated in the HEOM formalism, whose relation to the spectroscopic picture of sequential interactions with light is not manifest. When the quantum description of light–matter interaction is in place, the interaction with the radiation is treated from the standpoint of quantum optics, using the so-called hybrid master-equation–HEOM approach. In essence, the interaction with radiation appears in form of Markovian corrections to HEOM equations. In the end, there are also studies that propose a numerically exact treatment of both the couplings to environment and radiation, which, however, comes with a complex formalism and huge computational costs.

In this work, we build on results of Ref. 21. Our approach is based on the two cornerstones of the theory of photosynthetic excitons. Section II introduces the Frenkel exciton model of a molecular light-harvesting aggregate, while the theory of nonlinear spectroscopy is employed in Sec. III to shed new light on the existing approaches to include semiclassical light–matter coupling into the HEOM formalism. Section IV presents the central result of our analysis. There, we perform a second-order treatment of the light–matter coupling and a nonperturbative treatment of the excitation–environment coupling to obtain an expression for weak light-induced excitonic dynamics that is manifestly related to the spectroscopic picture, and fully includes the dynamical interplay between nonequilibrium electronic dynamics and environmental reorganization processes. The exact result that we obtain does not allow easy analytical manipulations, and we demonstrate how it can be recast as HEOM, both in the case of semiclassical (Sec. V) and quantum (Sec. VI) treatment of the interaction with light. In addition, we analytically solve for the environmental reorganization dynamics triggered by a delta-like excitation of a single molecule (Sec. V A), and relate our results to existing approaches, such as the Redfield theory with photoexcitation (Sec. V B), the nonequilibrium Förster theory (Sec. V C), and hybrid Born–Markov–HEOM approaches (Sec. VI). These discussions further emphasize the advantages of our method, which are once again summarized in the concluding Sec. VII.

II. MODEL HAMILTONIAN

The system of interest consists of a molecular aggregate $M$ that is in contact with the thermal bath $B$ representing its environment and with the radiation $R$. The total Hamiltonian reads

$$H = H_M + H_B + H_R + H_{M-B} + H_{M-R}. \quad (1)$$

The electronic excitations of the aggregate are described within the Frenkel exciton model:

$$H_M = \sum_j \varepsilon_j B_j^\dagger B_j + \sum_{jk} J_{jk} B_k^\dagger B_k. \quad (2)$$

In Eq. (2), $\varepsilon_j$ are the so-called site energies, while $J_{jk}$ are resonance couplings (we take $J_{kk} = 0$). The operators $B_j$ and $B_j^\dagger$ describe the destruction and creation of an...
excitation on site \( j \), respectively, and they obey Pauli\footnote{29,43,45} commutation relations\footnote{29,43,45}. The environment is assumed to be composed of sets of independent harmonic oscillators associated to each site

\[
H_B = \sum_{\xi} \hbar \omega_{\xi} b_{\xi}^\dagger b_{\xi}. \tag{3}
\]

The oscillators are labeled by site index \( j \) and mode index \( \xi \) and phonon creation and annihilation operators \( b_{\xi}^\dagger \) and \( b_{\xi} \) satisfy Bose commutation relations. The interaction of aggregate excitations and the environment is taken to be linear in mode displacements and local to each chromophore (Holstein-like coupling\footnote{29,43,45}).

\[
H_{M-B} = \sum_{\xi} B_j^\dagger B_j g_{j\xi} \left( b_{\xi}^\dagger + b_{\xi} \right) \equiv \sum_j B_j^\dagger B_j u_j, \tag{4}
\]

where \( u_j \) is the collective environment coordinate associated with chromophore \( j \). The coupling constants \( g_{j\xi} \) may be related to the displacement of the equilibrium configuration of mode \( \xi \) between the ground and excited electronic state of chromophore \( j \)\footnote{29,43,45}. The coupling between aggregate excitations and the radiation is taken in the dipole and rotating-wave approximations

\[
H_{M-R} = -\mu_{eg} \cdot \mathbf{E}^{(+)} - \mu_{ge} \cdot \mathbf{E}^{(-)}. \tag{5}
\]

The dipole-moment operator \( \mu \) is assumed to be a purely electronic operator \( \mu = \sum_j \mathbf{d}_j \left( B_j^\dagger + B_j \right) = \mu_{eg} + \mu_{ge} \), where transition dipole moment \( \mathbf{d}_j \) of chromophore \( j \) does not depend on environmental coordinates (Condron approximation), part \( \mu_{eg} \) contains only operators \( B^\dagger \), while \( \mu_{ge} \) contains only operators \( B \). \( \mathbf{E}^{(\pm)} \) denotes the positive- and negative-frequency parts of the (time-independent) operator of the (transversal) electric field, so that we treat both electronic excitations and the radiation generating them on quantum level.

We assume that, at the initial instant \( t_0 \) of our dynamics, the total statistical operator \( W(t_0) \) representing the state of the combined system of aggregate excitations, environment, and radiation, can be factorized as follows

\[
W(t_0) = |g\rangle \langle g| \otimes \rho_B^g \otimes \rho_R. \tag{6}
\]

In Eq. \ref{eq:6}, the aggregate is taken to be initially unexcited, the state of the environment is adapted to the collective electronic ground state \( |g\rangle \) of the aggregate \( T = (k_B \beta)^{-1} \) is the temperature,

\[
\rho_B^g = \frac{\exp(-\beta H_B)}{\text{Tr}_B \exp(-\beta H_B)}, \tag{7}
\]

while \( \rho_R \) describes the state of the radiation.

### III. EQUATIONS OF MOTION: SEMICLASSICAL TREATMENT OF LIGHT–MATTER INTERACTION

The excitation by an arbitrary time-dependent (classical) electric field \( \mathbf{E}(t) \) can be incorporated into the HEOM formalism by taking that the total purely electronic Hamiltonian is \( H_M + H_{M-R}(t) \).\footnote{38,39} Here, \( H_{M-R}(t) \) is obtained from \( H_{M-R} \) in Eq. \ref{eq:5} by replacing electric-field operators \( \mathbf{E}^{(\pm)} \) by the corresponding time-dependent quantities \( \mathbf{E}^{(\pm)}(t) \). Indeed, all the steps in the derivation conducted in Ref. \ref{47} can be repeated to obtain equations of motion for the reduced DM (RDM) \( \rho(t) \equiv \sigma(t) \) and auxiliary DMs (ADMs) \( \sigma_n(t) \). ADMs are fully specified by vector \( n \) of non-negative integers \( n_{j,m} \)

\[
n = \left\{ (n_{0,0}, n_{0,1}, \ldots), (n_{N-1,0}, n_{N-1,1}, \ldots) \right\}. \tag{8}
\]

The index \( j = 0, \ldots, N - 1 \) enumerates chromophores, while index \( m \), in principle, does not have an upper limit and is related to the following expansion of the bath correlation function in terms of exponentially decaying factors \( t > 0 \)

\[
C_j(t) = \text{Tr}_B \left\{ u_j^{(+)\dagger}(t) u_j(0) \rho_B^g \right\} = \sum_{m} c_{j,m} e^{-\mu_{j,m} t}. \tag{9}
\]

The time dependence of the collective coordinate \( u_j^{(+)\dagger}(t) \) in Eq. \ref{eq:9} is with respect to the free-photon Hamiltonian, Eq. \ref{eq:3}. While expansion coefficients \( c_{j,m} \) may be complex, the decay rates \( \mu_{j,m} \) are assumed to be real and positive. We note that, apart from the exponential decomposition scheme [Eq. \ref{eq:9}] adopted in this work, there are other decompositions of \( C_j(t) \) from which a HEOM approach may be derived\footnote{38,44}. The bath correlation function is commonly expressed in terms of the so-called spectral density \( J_j(\omega) \),

\[
J_j(\omega) = \frac{\hbar}{\pi} \int_{-\infty}^{+\infty} \text{d}\omega J_j(\omega) e^{i\omega t} \frac{e^{i\beta \omega}}{e^{\beta \omega} - 1}, \tag{10}
\]

which conveniently combines information on the density of environmental-mode states and the respective coupling strengths to electronic excitations\footnote{38,44}.

The equation of motion for ADM \( \sigma_n(t) \) reads as\footnote{47}

\[
\partial_t \sigma_n(t) = -\frac{i}{\hbar} \left[ H_M, \sigma_n(t) \right] + \frac{i}{\hbar} \left[ \mu_{eg} \mathbf{E}^{(+)\dagger}(t) + \mu_{ge} \mathbf{E}^{(-)\dagger}(t), \sigma_n(t) \right] - \sum_{m} \sum_{j} n_{j,m} \mu_{j,m} \sigma_n(t) + i \sum_{m} \sum_{j} \left[ V_j, \sigma_{n_j}^{(+)}(t) \right] + i \sum_{j} \sum_{n} n_{j,n} \left( \frac{c_{j,m}}{\hbar^2} V_j \sigma_{n_j}^{(-)}(t) - \frac{c_{j,n}^{*}}{\hbar^2} \sigma_{n_j}^{(-)}(t) V_j \right), \tag{11}
\]

where \( V_j = B_j^\dagger B_j \). Since the coupling to the radiation is explicitly included in the electronic Hamiltonian, the HEOM in Eq. \ref{eq:11} treats nonperturbatively not only the...
interaction with the bath, as usually, but also that with light. Keeping in mind that our formulation of the model Hamiltonian supports states with an arbitrary number of excitations, the result embodied in Eq. (11) is quite general. In principle, it can describe in great detail a nonlinear spectroscopy experiment of an arbitrary order. However, once we fix the highest order in the electric field we are interested in, there will be many elements of the DMs that do not contribute to the optical response up to that order. In other words, solving coupled equations (11) as they stand, we obtain much more information than necessary to reconstruct the optical response up to a given order. Moreover, we lack the intuitive physical picture characteristic of nonlinear spectroscopy, which is in terms of Liouville pathways, block structure of the statistical operator and evolution superoperator, etc. In order to circumvent these deficiencies, it is enough to make a projection of the dynamics on relevant excitonic subspaces. For example, in the third-order spectroscopy experiment, it would be enough to consider subspaces containing at most one excitation. This is discussed in greater detail further in this section and in Sec. SI of the Supplementary Material. Practically, the appropriate reduction to obtain the second-order response consists in the following replacements in the model Hamiltonian

\[
B_j \rightarrow |g, j\rangle, \quad B_j^\dagger \rightarrow |j\rangle\langle g|, \quad B_j^\dagger B_k \rightarrow |j\rangle\langle k|. \tag{12}
\]

In Eq. (12), \(|j\rangle\) is the collective singly excited state featuring a selective excitation of site \(j\).

Therefore, to obtain the second-order response, we should calculate the expectation values \(\langle g|\sigma_n(t)|g\rangle\), \(y_{ee,n}(t) = \langle e|\sigma_n(t)|e\rangle\), and \(\langle e|\sigma_n(t)|\bar{e}\rangle\), where \(|e\rangle\) is an arbitrary basis of singly excited states (the notation is similar to that in Ref. [29]. If \(n = 0\), these three expectation values respectively represent the ground-state population, optical coherences, and singly excited-state populations and intraband coherences. Since the electronic subsystem starts from \(|g\rangle\langle g|\), and since the light–matter coupling \(H_{M-R}\) is the only part of the Hamiltonian that can cause transitions from the ground state to singly excited states, the following scaling relations hold [19]

\[
n_{g,n}(t) = \delta_{n,0} + \sum_{k=1}^{+\infty} n_{g,n}^{(2k)}(t) \propto \mathcal{E}^{2k}, \tag{13a}
\]

\[
y_{ee,n}(t) = \sum_{k=0}^{+\infty} y_{ee,n}^{(2k+1)}(t) \propto \mathcal{E}^{2k+1}, \tag{13b}
\]

\[
n_{ee,n}(t) = \sum_{k=1}^{+\infty} n_{ee,n}^{(2k)}(t) \propto \mathcal{E}^{2k}. \tag{13c}
\]

In other words, optical coherences are dominantly linear in the applied field, while excited-state populations are at least quadratic in the applied field. The environmental assistance, which actually enters through vector \(n_{g,0}\) does not affect the scaling laws [13, 25].

Formulating equations of motion for \(y_{e,n}(t)\) and \(n_{ee,n}(t)\) actually enables us to formulate operator equations for sectors \(eg\) and \(ee\) of \(\sigma_n(t)\). Namely, using Eqs. (13) and keeping only terms that are at most of the second order in the applied field, we form the following equations for the \(eg\) sector \(\sigma_{eg,n}(t)\) and for the \(ee\) sector \(\sigma_{ee,n}(t)\)

\[
\partial_t \sigma_{eg,n}(t) = -\frac{i}{\hbar}[H_M, \sigma_{eg,n}(t)] - \left(\sum_j \sum_m n_{j,m} \mu_{j,m}\right) \sigma_{eg,n}(t) + \delta_{n,0} \mathcal{E}^{(+)}(t) \mu_{eg} + i \sum_j \sum_m V_j \sigma_{eg,n_j,m}(t) + i \sum_j \sum_m \frac{c_{j,m}}{\hbar^2} V_j \sigma_{eg,n_j,m}(t), \tag{14}
\]

\[
\partial_t \sigma_{ee,n}(t) = -\frac{i}{\hbar}[H_M, \sigma_{ee,n}(t)] - \left(\sum_j \sum_m n_{j,m} \mu_{j,m}\right) \sigma_{ee,n}(t) + \frac{i}{\hbar} \mathcal{E}^{(+)}(t) \mu_{eg} \sigma_{eg,n}^\dagger(t) - \frac{i}{\hbar} \sigma_{eg,n}(t) \mu_{ge} \mathcal{E}^{(-)}(t) + i \sum_j \sum_m \left[V_j, \sigma_{ee,n_j,m}(t)\right] + i \sum_j \sum_m n_{j,m} \frac{c_{j,m}}{\hbar^2} V_j \sigma_{ee,n_j,m}(t) - i \sum_j \sum_m n_{j,m} \frac{c_{j,m}^*}{\hbar^2} \sigma_{ee,n_j,m}(t) V_j, \tag{15}
\]

where now \(V_j \rightarrow |j\rangle\langle j|\). By reducing our dynamics to the subspace containing at most one excitation, we transform Eq. (11) into coupled equations describing evolution of optical coherences [Eq. (14)] and excited-state populations and intraband coherences [Eq. (15)]. The crucial step in the transformation is the application of scaling laws in Eqs. (14), which ensure that our dynamics is consistently up to the second order in the exciting field.

Instead of the path we have taken, one could have started from the model Hamiltonian in which the low-density replacements of Eq. (12) are performed, and solved Eq. (11) without ever considering the scaling laws in Eqs. (13). In that case, one would in principle obtain the solution that is exact to all orders in the exciting field. However, this exactness is only apparent, because the proper treatment of higher orders in the exciting field requires enlarging the space on which the Hamiltonian is formulated, as we discuss in more detail in Sec. SI
of the Supplementary Material. Temporal evolutions of higher-order sectors of the DM (which are not taken into account) would then influence evolutions of optical coherences, excited-state populations, and intraband coherences. For example, as demonstrated in Ref. 29, already in the third order in the electric field, equations of motion for optical coherences are coupled to equations of motion for biexcitonic amplitudes (coherences between the ground state and doubly excited states), meaning that a separate equation governing the evolution of $|jk\rangle\langle g|$ block of $\sigma_n(t)$ has to be formulated. This discussion emphasizes that, once we treat the photogeneration step explicitly, we should be aware of the close connection between the largest order in the exciting field we include and the space on which the dynamics has to be formulated. Should we limit ourselves to the Frenkel Hamiltonian for the singly excited states and, at the same time, explicitly describe the excitation generation by light, we should do that only up to the second order in the applied field.

Let us conclude this section by noting that the results we have presented so far rely heavily on the form of the light–matter interaction Hamiltonian in the semiclassical approximation. If we want to treat light quantum mechanically, too, the results of Ref. 29 suggest that, up to the second order in the exciting field, the only information we need about light is its first-order (two-point) correlation function (indices $i, j$ label Cartesian components of a vector)

$$G_{ij}^{(1)}(\tau_2, \tau_1) = \text{Tr}_R \left\{ \left\{ E^{(-)}(\tau_2) \right\}_i \left\{ E^{(+)}(\tau_1) \right\}_j \rho_R \right\}. \quad (16)$$

In the developments presented up to now, such a quantity does not directly enter Eqs. (11), (14), and (15). However, for (classical, transform-limited) pulses, this correlation function factorizes into products of expectation values of single electric-field operators, which define classical values of the electric field:

$$G_{ij}^{(1)}(\tau_2, \tau_1) = \mathcal{E}_{ij}^{(-)}(\tau_2) \mathcal{E}_{ij}^{(+)}(\tau_1), \quad (17a)$$

$$\mathcal{E}_{ij}^{(\pm)}(\tau) = \text{Tr}_R \left\{ \left\{ E^{(\pm)}(\tau) \right\}_i \rho_R \right\}. \quad (17b)$$

As will be demonstrated in more detail in Sec. IV, it is precisely this factorization that enables us to formulate Eqs. (11) and (15) as they stand.

IV. GENERAL THEORY OF WEAK LIGHT-INDUCED DYNAMICS

This section presents the central result of our exact description of the dynamics triggered by weak light of arbitrary properties. While the derivation is elementary in all its steps, it is cumbersome and thus presented in Sec. II of the Supplementary Material. Here, we only analyze the final result for the reduced excited-state density matrix

$$\rho_{ee}^{(I)}(t) = \int_{t_0}^t dt_2 \int_{t_0}^{t_2} dt_1 \mathcal{U}_{\text{red}}^{(I)}(t, t_2, \tau_1) A^{(I)}(\tau_2, \tau_1) +$$

$$+ \int_{t_0}^t dt_2 \int_{t_0}^{t_2} dt_1 A^{(I)+}(\tau_2, \tau_1) \mathcal{U}_{\text{red}}^{(I)}(t, t_2, \tau_1). \quad (18)$$

In Eq. (18), superscript $(I)$ denotes the interaction picture with respect to $H_M$, $\tau_1$ and $\tau_2$ are the instants at which the interaction with the radiation occurs, and the purely electronic operator $A^{(I)}(\tau_2, \tau_1)$ reads as

$$A^{(I)}(\tau_2, \tau_1) = \frac{1}{\hbar^2} \sum_{i,j} G_{ij}^{(1)}(\tau_2, \tau_1) \times$$

$$\times \left\{ \left\{ \mu_{ij}^{(1)}(\tau_1) \right\}_j |g\rangle \langle \mu_{ij}^{(1)}(\tau_2) \right\}_i. \quad (19)$$

The arrow above the reduced propagator sign indicates the direction of its action on the corresponding operator. The reduced propagator acting on the right reads as $(T$ is the chronological time-ordering sign)

$$\mathcal{U}_{\text{red}}^{(I)}(t, \tau_2, \tau_1) = T \exp \left[ \mathcal{W}_c(\tau_2, \tau_1) + \mathcal{W}_p(t, \tau_2) + \mathcal{W}_{c-p}(t, \tau_2, \tau_1) \right], \quad (20a)$$

$$\mathcal{W}_c(\tau_2, \tau_1) = -\frac{1}{\hbar^2} \sum_j \int_{\tau_1}^{\tau_2} ds_2 \int_{\tau_1}^{s_2} ds_1 V_j^{(I)}(s_2) C_j(s_2 - s_1) V_j^{(I)*}(s_1), \quad (20b)$$

$$\mathcal{W}_p(t, \tau_2) = -\frac{1}{\hbar^2} \sum_j \int_{\tau_2}^{t} ds_2 \int_{\tau_2}^{s_2} ds_1 V_j^{(I)}(s_2) C_j(s_2 - s_1) V_j^{(I)*}(s_1) + i C_j(s_2 - s_1) V_j^{(I)}(s_1), \quad (20c)$$

$$\mathcal{W}_{c-p}(t, \tau_2, \tau_1) = -\frac{1}{\hbar^2} \sum_j \int_{\tau_2}^{t} ds_2 \int_{\tau_1}^{s_2} ds_1 V_j^{(I)}(s_2) C_j(s_2 - s_1) V_j^{(I)*}(s_1). \quad (20d)$$

In Eq. (20), $C_j^{\sigma/f}$ denote the real and imaginary part of the bath correlation function $C_j$ [Eq. (9)], whereas
the interaction instants
the interaction with light, i.e., it explicitly depends on
duced evolution superoperator that is compatible with
that, here, we provide an exact expression for the re-
principal novelty compared
of arbitrary properties. The principal novelty compared
with the radiation and due to absorptions and emissions of elementary envi-
mental excitations\textsuperscript{44,55} In this discussion, we assume
that the instants $\tau_1$ and $\tau_2$ are fixed. We further fo-
cus on the first-order term of the reduced evolution su-
peroperator [Eq. (20a)] and we also fix instants $s_1$ and
$s_2$ [Eqs. (20b)–(20d)] that describe a single environment-
tally assisted process. In Figs. (a) and (c) we present the
three primitive diagrams corresponding to the hyperop-
erators in Eqs. (20b)–(20d), respectively. The diagram in
Fig. (a) describes a single-phonon-assisted process during
which the electronic subsystem is in a state of optical coherence. The diagram in Fig. (b) describes a single-phonon-assisted process during which the electronic subsystem is entirely in the excited-state manifold. The single-phonon-assisted process represented by the primitive diagram in Fig. (c) starts when the electronic subsystem is in a state of optical coherence, and ends when it is entirely in the excited-state manifold. There, the phonon propagator straddles two temporal sectors defined by the interactions with the radiation. These so-called straddling evolutions\textsuperscript{44,55} fully capture the nonequilibrium dynamics of the bath during different periods of photoinduced evolution. They are intimately connected to the quantum coherence between electronic excitations and environment and their presence is crucial to accurately describe photoinduced electronic dynamics.

Let us point out another viewpoint on the result embodied in Eq. (18). Due to the assumption of the initially unexcited system, any nontrivial dynamics is ultimately induced by the interaction with the radiation because the environment alone cannot cause transitions from the ground- to the excited-state manifold. This is reflected by the fact that hyperoperator $V^C$ in Eqs. (20b) and (20d) acts after the first and before the second interaction with the radiation, while hyperoperators $V^{x/s}_j$ in Eqs. (20a) and (20c) act after both interactions with radiation, see also Figs. (a) and (c). Therefore, Eq. (18) can be reformulated by introducing a global time-ordering sign as follows

\begin{equation}
\rho^{(t)}_{ee}(t) = \int_{t_0}^{t} d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \frac{1}{\hbar^2} \sum_{i,j} G^{(1)}_{ij}(\tau_2, \tau_1) \times 
\times T \left\{ \exp \left[ \overleftrightarrow{W}_c(\tau_2, \tau_1) + \overleftrightarrow{W}_p(t, \tau_2) + \overleftrightarrow{W}_{c-p}(t, \tau_2, \tau_1) \right] V^C \right\}_{i} \left\{ \mu^{(t)}_{eg}(\tau_2) \right\}_{j}^{C} |g\rangle \langle g| + \text{H.c.} \right\}
\end{equation}

In Eq. (21), we introduced hyperoperator $V^C$ as $V^C O = OV$, for any operators $V$ and $O$. This viewpoint will be useful in our discussion in Sec. III where we emphasize the similarities between the descriptions of the second-order photoexcitation process starting from the ground state and the Förster energy transfer from an excited

The RDM evolution can be conveniently represented in terms of diagrams showing how the state of electronic excitations changes due to interactions with radiation and due to absorptions and emissions of elementary environmental excitations\textsuperscript{44,55} In this discussion, we assume
that the instants $\tau_1$ and $\tau_2$ are fixed. We further fo-
focus on the first-order term of the reduced evolution su-
peroperator [Eq. (20a)] and we also fix instants $s_1$ and
$s_2$ [Eqs. (20b)–(20d)] that describe a single environment-
tally assisted process. In Figs. (a) and (c) we present the
three primitive diagrams corresponding to the hyperop-
erators in Eqs. (20b)–(20d), respectively. The diagram in
Fig. (a) describes a single-phonon-assisted process during
which the electronic subsystem is in a state of optical coherence. The diagram in Fig. (b) describes a single-phonon-assisted process during which the electronic subsystem is entirely in the excited-state manifold. The single-phonon-assisted process represented by the primitive diagram in Fig. (c) starts when the electronic subsystem is in a state of optical coherence, and ends when it is entirely in the excited-state manifold. There, the phonon propagator straddles two temporal sectors defined by the interactions with the radiation. These so-called straddling evolutions\textsuperscript{44,55} fully capture the nonequilibrium dynamics of the bath during different periods of photoinduced evolution. They are intimately connected to the quantum coherence between electronic excitations and environment and their presence is crucial to accurately describe photoinduced electronic dynamics.

Let us point out another viewpoint on the result embodied in Eq. (18). Due to the assumption of the initially unexcited system, any nontrivial dynamics is ultimately induced by the interaction with the radiation because the environment alone cannot cause transitions from the ground- to the excited-state manifold. This is reflected by the fact that hyperoperator $V^C$ in Eqs. (20b) and (20d) acts after the first and before the second interaction with the radiation, while hyperoperators $V^{x/s}_j$ in Eqs. (20a) and (20c) act after both interactions with radiation, see also Figs. (a) and (c). Therefore, Eq. (18) can be reformulated by introducing a global time-ordering sign as follows

\begin{equation}
\rho^{(t)}_{ee}(t) = \int_{t_0}^{t} d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \frac{1}{\hbar^2} \sum_{i,j} G^{(1)}_{ij}(\tau_2, \tau_1) \times 
\times T \left\{ \exp \left[ \overleftrightarrow{W}_c(\tau_2, \tau_1) + \overleftrightarrow{W}_p(t, \tau_2) + \overleftrightarrow{W}_{c-p}(t, \tau_2, \tau_1) \right] V^C \right\}_{i} \left\{ \mu^{(t)}_{eg}(\tau_2) \right\}_{j}^{C} |g\rangle \langle g| + \text{H.c.} \right\}
\end{equation}

In Eq. (21), we introduced hyperoperator $V^C$ as $V^C O = OV$, for any operators $V$ and $O$. This viewpoint will be useful in our discussion in Sec. III where we emphasize
donor to an unexcited acceptor.

Even though the result embodied in Eqs. (18)–(20) is remarkable, it is not very useful for actual computations, principally due to the time-ordering sign that renders analytical manipulations difficult. Nevertheless, whenever the bath correlation function \( C_f(t) \) can be represented in the form given in Eq. (4), Eq. (18) can be recast as an infinite hierarchy of equations of motion for the RDM and ADMs. However, the details of this procedure now depend on the form of operator \( A(I)(\tau_2, \tau_1) \) [Eq. (19)], i.e., on the temporal and statistical properties of the radiation.

V. EXCITATION BY WEAK (COHERENT) LASER PULSES

As has been recently discussed in Refs. 52 and 53, a pulse of light may be understood as a classical-like state of the electromagnetic field, whose energy density is localized and which can be specified by the spatial position around which it is localized, propagation direction, polarization, and spectral distribution. In essence, the quantum state representing the classical pulse whose bandwidth is determined by its spectral distribution is a coherent state which, as first realized by Glauber, is specified by the spatial position of the electromagnetic field, whose energy density is localized and which can be specified by the spatial position around which it is localized, propagation direction, polarization, and spectral distribution. In essence, the quantum state representing the classical pulse whose bandwidth is determined by its spectral distribution is a coherent state which, as first realized by Glauber, is specified by the spatial position around which it is localized, propagation direction, polarization, and spectral distribution.

The manipulations that are necessary to recast Eqs. (23) and (19) as the HEOM presented in Eqs. (14) and (15), respectively, proceed as usually. For the sake of completeness, here, we only present the definitions of ADMs (in the interaction picture) for optical coherences

\[
\sigma_{eg,n}^{(I)}(t) = \int_{t_0}^{t} d\tau T \left\{ \prod_j \prod_m \left[ \int_{\tau}^{t_0} ds \, e^{-\mu_{j,m}(t-s)} \frac{\epsilon_{j,m}}{\hbar^2} V_j^{(I)}(s)^{C} \right]^{n_{j,m}} U_{eg}^{(I)}(t, \tau) \right\} \frac{i}{\hbar} \mu_{eg}^{(I)}(\tau) \mathcal{E}^{(+)}(\tau) |g\rangle \langle g|, \tag{23}\]

and for excited-state populations and intraband coherences (\( \epsilon_{j,m} \) denote the real/imaginary part of complex coefficients \( \epsilon_{j,m} \))

\[
\sigma_{ec,n}^{(I)}(t) = \int_{t_0}^{t} d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 T \left\{ \prod_j \prod_m \left[ \int_{\tau_2}^{t} ds \, e^{-\mu_{j,m}(t-s)} \left( \frac{\epsilon_{j,m}}{\hbar^2} V_j^{(I)}(s)^{C} \frac{i}{\hbar^2} - \frac{\epsilon_{j,m}}{\hbar^2} V_j^{(I)}(s)^{C} \right) + \int_{\tau_1}^{\tau_2} ds \, e^{-\mu_{j,m}(t-s)} \frac{\epsilon_{j,m}}{\hbar^2} V_j^{(I)}(s)^{C} \right]^{n_{j,m}} \mathcal{U}_{eg}^{(I)}(t, \tau_2, \tau_1) \right\} A(I)(\tau_2, \tau_1) + \text{H.c.} \tag{26}\]

Before discussing the relation of the HEOM embodied in Eqs. (14) and (15) to existing theories of the dynamics of electronic excitations induced by weak laser pulses, let us briefly comment on the way in which the photoexcitation enters the HEOM. The electric field explicitly enters the hierarchy for optical coherences only on the level of
RDM, see Eq. (14). Environmentally assisted optical coherences then act as source terms for environmentally assisted excited-state populations and intraband coherences, see Eq. (15). Moreover, the source term for the \( ee \) sector of ADM characterized by vector \( n \) comprises only the \( eg \) sector of ADM characterized by the same vector \( n \). The hierarchy is schematically presented in Fig. 2 for \( N = 2 \) chromophores and \( K = 1 \) term in the decomposition of the bath correlation function \( C_j(t) \) in Eq. (9).

![Fig. 2](image)

**FIG. 2.** Schematic representation of the HEOM for optical coherences and excited-state populations and intraband coherences in the case of excitation by a weak laser pulse. For the sake of simplicity, the aggregate comprises \( N = 2 \) chromophores and only \( K = 1 \) term in the exponential decomposition of the bath correlation function \( C_j(t) \) is taken into account. Individual DMs are represented by circles, while the driving by the electric field \( \mathcal{E}(t) \), which directly affects only the optical-coherence RDM, is presented by the straight horizontal arrow. \( D \) denotes the level of the hierarchy, and each DM is accompanied by the corresponding vector \( n \), see Eq. (5). Curved dashed arrows represent hierarchical links between optical-coherence DMs, while curved solid arrows represent hierarchical links between excited-state DMs. The fact that DM \( \sigma_{eg,n}(t) \) acts as the source term in the EOM for \( \sigma_{ee,n}(t) \) is reflected in the diagram by the presence of curved dash-dotted arrows pointing from \( \sigma_{eg,n}(t) \) towards \( \sigma_{ee,n}(t) \).

### A. Impulsive Photoexcitation of Pure-Dephasing Spin–Boson Model: Analytical Results

Let us now concentrate on the case of only one chromophore. The Hamiltonian, Eq. (1), then reads as

\[
H = \varepsilon_e |e\rangle \langle e| + \sum_\xi \hbar \omega_\xi b_\xi^\dagger b_\xi \\
+ \sum_\xi g_\xi |e\rangle \langle e| (b_\xi^\dagger + b_\xi) \\
- d_{eg} \cdot \left( \mathcal{E}^{(+)}(t) |e\rangle \langle g| + \mathcal{E}^{(-)}(t) |g\rangle \langle e| \right).
\]

Equation (27) is actually the pure-dephasing spin–boson Hamiltonian (or the independent-boson Hamiltonian, see Ref. 54), in which \( \varepsilon_e \) is the energy splitting between the two local energy levels (the ground state \( |g\rangle \) and the singly excited state \( |e\rangle \)), and there is no tunneling between the two levels. The hyperoperators appearing in the reduced evolution superoperator [Eqs. (20)] are time-independent, meaning that the time-ordering signs are not effective. This circumstance enables us to obtain analytical insights into the photoexcitation dynamics of the pure-dephasing spin–boson model in the impulsive limit.

The waveform of the positive-frequency part of the electric field is taken to be

\[
\mathcal{E}^{(+)}(t) = e \mathcal{E}_0 \delta(t) e^{-i\Omega_p t},
\]

where vector \( e \) defines the polarization of the pulse, \( \Omega_p \) is its central frequency, and \( \mathcal{E}_0 \) is its amplitude. If the initial instant is \( t_0 < 0 \), the excited-state RDM for \( t > 0 \) reads as

\[
\rho_{ee}(t) = \frac{1}{\hbar^2} |(d_{eg} \cdot e) \mathcal{E}_0|^2 |e\rangle \langle e| \equiv P_e |e\rangle \langle e|.
\]

At the same time, the optical-coherence RDM

\[
\rho_{eg}(t) = \frac{1}{\hbar^2} (d_{eg} \cdot e) \mathcal{E}_0 e^{-i\varepsilon_e t / \hbar} e^{-g(t)} |e\rangle \langle g|
\]

exponentially decays to zero on a time scale determined by the temporal behavior of the lineshape function

\[
g(t) = \frac{1}{\hbar^2} \int_0^t ds_2 \int_0^{s_2} ds_1 C(s_1).
\]

In a certain sense, Eqs. (29) and (30) formally demonstrate that the propagation scheme adopted in, e.g., Ref. 47, is physically sensible. Namely, optical coherences generated upon impulsive photoexcitation quickly decay to zero and, more importantly, they do not act as sources for excited-state populations and intraband coherences for \( t > 0 \), see Eqs. (28), (15) and (14). Therefore, upon a delta-like photoexcitation, it is justified to propagate only the excited-state dynamics. The reduced propagator for the excited-state sector, Eq. (20), then becomes the reduced propagator used in Ref. 47.

Although the excited-state RDM does not evolve in time, the impulsive photoexcitation triggers environmental reorganization processes, whose dynamics is encoded in ADMs. Using the definition of the first-tier excited-state ADM in Eq. (20) and specializing to the single-chromophore case and impulsive excitation, we obtain

\[
\sigma_{ee,m_n}(t) = -2 e^{i \varepsilon_m / \hbar} \frac{1}{\mu_n} P_e |e\rangle \langle e|.
\]

In essence, the only nontrivial contribution comes from the anticommutator with \( |e\rangle \langle e| \), which produces a factor of 2. A similar analysis can be conducted for \( d \)-th tier \((d \geq 1)\) excited-state ADM with the final result

\[
\sigma_{ee,m_{n_1}...m_d}(t) = (-2)^d \prod_{p=1}^d \left( \frac{e^{i \varepsilon_{m_p} / \hbar} - 1 - e^{-\mu_{m_p} t}}{\mu_{m_p}} \right) P_e |e\rangle \langle e|.
\]
Therefore, within the pure-dephasing spin–boson model, we can analytically compute the nonequilibrium environmental dynamics initiated by a delta-like photoexcitation. The result embodied in Eq. \ref{eq:29} becomes particularly interesting in the archetypal case of overdamped Brownian oscillator spectral density

\[ J(\omega) = 2\lambda \frac{\omega \gamma}{\omega^2 + \gamma^2}, \]

when only the coefficient \( c_0 \) connected to the Drude pole \( \mu_0 = \gamma \) has an imaginary part [see also Eq. \ref{eq:10}]

\[ c_0 = \lambda \cdot \hbar \gamma \left[ \cot \left( \frac{\beta \hbar \gamma}{2} \right) - i \right]. \]

In this case, the only excited-state ADMs which exhibit a nontrivial temporal evolution are the ones featuring an exclusive excitation of the Drude pole. After performing suitable rescalings, which ensure that ADMs are dimensionless and indeed decay to zero in high enough hierarchical orders,\textsuperscript{57} we finally obtain for \( d \geq 0 \)

\[ \langle \epsilon | \sigma_{ec,0_1 \ldots m_d}^{resc}(t) \epsilon \rangle / P_e = \delta_{m_1,0} \ldots \delta_{m_d,0} \times \]

\[ \times \frac{\alpha_d}{\sqrt{d!}} \left( \frac{\lambda}{\hbar \gamma} \right)^{d/2} \left[ 1 + \cot^2 \left( \frac{\beta \hbar \gamma}{2} \right) \right]^{-d/4} \left( 1 - e^{-\gamma t} \right)^d. \]

(36)

In Fig. \ref{fig:3} we present the time evolution of the RDM and first four nontrivial ADMs that is predicted by Eq. \ref{eq:36}. The numerical computations of the dynamics of impulsively photoexcited spin–boson model performed in Ref.\textsuperscript{17} (see Fig. 1 and the corresponding discussion) employed the high-temperature approximation, in which the expansion of the bath correlation function [Eq. \ref{eq:9}] contains only the Drude contribution (term with \( m = 0 \)). Interestingly, our analytical result [Eq. \ref{eq:39}] demonstrates that, in that case, the high-temperature approximation actually gives an exact solution.

Let us also note that the procedure outlined can be repeated to obtain optical-coherence ADMs. However, judging by Eq. \ref{eq:25}, there will be no restrictions on \( m \)'s that can be excited. This is not at variance with constraints present in Eq. \ref{eq:36} because, in the impulsive limit, optical coherences are not sources for purely excited-state dynamics.

\[ \text{FIG. 3. (Color online) Time evolution of the RDM and first four nontrivial ADMs following the impulsively excited of the pure-dephasing spin–boson model. The spectral density of the excitation–environment interaction is assumed to be of the Drude–Lorentz type, see Eq. \ref{eq:29}. The results are obtained using Eq. \ref{eq:36} with the following values of model parameters: reorganization energy } \lambda = 100 \text{ cm}^{-1}, \text{ bath relaxation time } \gamma^{-1} = 100 \text{ fs, temperature } T = 300 \text{ K.} \]

\[ \text{pulsively photoexcited spin–boson model performed in Ref.}\textsuperscript{17} (see Fig. 1 and the corresponding discussion) employed the high-temperature approximation, in which the } \]

\[ \text{expansion of the bath correlation function [Eq. } \ref{eq:9} \text{] contains only the Drude contribution (term with } m = 0 \text{). Interestingly, our analytical result [Eq. } \ref{eq:39} \text{] demonstrates that, in that case, the high-temperature approximation actually gives an exact solution.} \]

\[ \text{Let us also note that the procedure outlined can be repeated to obtain optical-coherence ADMs. However, judging by Eq. } \ref{eq:25}, \text{ there will be no restrictions on } m \text{'s that can be excited. This is not at variance with constraints present in Eq. } \ref{eq:36} \text{ because, in the impulsive limit, optical coherences are not sources for purely excited-state dynamics.} \]

\[ \text{B. Redfield Theory with Photoexcitation} \]

Here, we discuss how, in the limit of weak excitation–environment interaction, our results for \( \rho_{ec}(t) \) and \( \rho_{eg}(t) \) reduce to the results of Ref.\textsuperscript{29} and \textsuperscript{35} where the photoexcitation is treated up to the second order in the optical field, while the environment-induced relaxation processes are described within the Redfield theory. Our strategy is similar to the one used in Ref.\textsuperscript{17} to accomplish a similar goal.

If we assume that the characteristic decay time of the bath correlation function \( C_j(t) \) is short compared to the time scales of the dynamics we are interested in, we can employ the Markov approximation to reduce Eqs. \ref{eq:18} and \ref{eq:19} to a system of coupled second-order equations for the excited-state and optical-coherence sectors of the RDM.\textsuperscript{29} The final result is commonly written in the exciton basis \{\( |x\rangle \}\, defined by \( H_M|x\rangle = \hbar \omega_x|x\rangle \), and assumes the form of Redfield equations with photoexcitation. The optical coherence \( y_{x'}(t) = \langle x|\rho_{eg}(t)|x'\rangle \) evolves according to

\[ \partial_t y_{x'}(t) = -i \omega_x y_{x'}(t) + \frac{i}{\hbar} \mu_x : \mathcal{E}^{(+)}(t) - \sum_{x'} \left( \sum_{x} \prod_{x'} \Gamma_{xx'x'}(t) y_{x'}(t) \right), \]

(37)

while exciton populations and interexciton coherences \( n_{xx}(t) = \langle x|\rho_{ec}(t)|x\rangle \) obey

\[ \partial_t n_{xx}(t) = -i (\omega_x - \omega_x) n_{xx}(t) - \frac{i}{\hbar} \mu_x : \mathcal{E}^{(-)}(t) y_{x'}(t) + \frac{i}{\hbar} \gamma_x(t) \mu_x : \mathcal{E}^{(+)}(t) - \sum_{x'} \prod_{x' x} \mathcal{R}_{xx'x'}(t) \]

(38)

In Eq. \ref{eq:37}, the damping matrix \( \Gamma_{xx'x'} \) is defined as

\[ \Gamma_{xx'} = \sum_{j} \langle j| j'| \langle x'| x \rangle \langle x'| x}\rangle \times \int_{0}^{+\infty} ds \frac{C_{j}(s)}{s^{2}} e^{(\omega_x - \omega_x)s} \]
See Eq. (34), whose parameters action is assumed to be the Drude–Lorentz spectral density, represented by the motion lines below chromophore numbers (mophore is in contact with its thermal bath (schematically and the electronic coupling is $J_{01}$) strongly coupled to relatively slow nuclear motions runs into more serious difficulties than those caused by neglecting renormalizations of transition frequencies or approximating the secular approximation. Moreover, as the following discussion demonstrates, the application of Eqs. (37) and (38) to describe laser-induced dynamics of electronic excitations that are strongly coupled to relatively slow nuclear motions runs into more serious difficulties than those caused by neglecting renormalizations of transition frequencies or applying the secular approximation.

In Figs. (4a1)–(4d2) we compare the photoinduced electronic dynamics of a dimer (see Fig. 3) treated by our HEOM formalism incorporating the photoexcitation [Eqs. (14) and (15) and the Redfield formalism incorporating the photoexcitation [Eqs. (37) and (38)]. Relevant parameters of the model dimer are summarized in the caption of Fig. 4.

For the weakest excitation–environment coupling, see Figs. (4a1) and (4a2), the results predicted by the two approaches are quite similar, as expected. However, as the excitation–environment coupling is increased, the dynamics predicted by the Redfield theory deviates both qualitatively (e.g., absence of oscillatory features) and quantitatively from the numerically exact results, see Figs. (4b1)–(4d2). The reasons for such deviations are summarized in the following.

Firstly, the relaxation tensor employed in Eqs. (37) and (38) is time-independent, i.e., it cannot accurately capture the very first steps of the nuclear reorganization dynamics initiated by photoexcitation. In the derivation of Eqs. (37) and (38), we obtained time-local equations because we ceased to keep track of the exact instants of the interaction with light by formally setting the difference between the observation instant $t$ and the last instant of the interaction with light $\tau$ to infinity. Such an approximation is reasonable whenever the bath correlation time and/or the excitation–environment coupling are small enough. These conditions are typically satisfied in ultrafast semiconductor optics,30–32 which explains the success of methods relying on equations such as Eqs. (37) and (38) to describe ultrafast semiconductor dynamics. On the other hand, in view of the intermediate regime to which photosynthetic EET belongs,3,12 transient features of light-triggered nuclear reorganization dynamics become crucial to properly characterize electronic dynamics in photosynthetic aggregates. In other words, one has to keep track of the exact instants $\tau_1$ and $\tau_2$ of the interaction with light, which our formalism manifestly does. One may hope to partially cure the deficiencies of the dynamics predicted by Eqs. (37) and (38) by replacing the time-independent Redfield tensor by its time-dependent counterpart, see, e.g., Ref. 27. However, as argued in the Supporting Information to Ref. 28, such a replacement in a time-local equation for RDM would have to rely on the rather arbitrary instant $t_0$ in which we prescribe the initial condition [Eq. (6)], which would give a reasonable description only in the limit of impulsive excitation at $t_0$. For pulses of finite duration, the correct description of ultrafast dynamics has to be on the time-nonlocal level.

Secondly, the derivation presented in the Supplementary Material suggests that Eqs. (37) and (38) neglect the nonequilibrium dynamics of the bath in the period between the two interactions with light. Again, our formalism manifestly includes such dynamics through the HEOM for optical coherences. On the other hand, the change in the bath state in the period between the two interactions with the light can be partially taken into account, even on the time-local level, through the so-called photoinduced correlation term that was identified...
in Ref. 62 (and also, in a more specialized setting, in Ref. 27). In the language of the standard density matrix theory, the photoinduced correlation term arises from the combined action of the environmental assistance and the interaction with the exciting field. While the neglect of

such a term can be justified in semiconductor optics, its effect on the dynamics may be nontrivial in the case of slow bath and/or strong excitation–environment coupling.

with \( H_{DA} = J_{DA}(|A\rangle\langle D| + |D\rangle\langle A|) \) being the DA electronic coupling.

C. Nonequilibrium Generalization of Förster Theory

As pointed out in Ref. 47, the Förster limit cannot be directly obtained from the analytical results presented there, simply because the initial environmental density matrix \( \rho_B^0 \) is assumed to describe the equilibrium of environmental modes when there are no electronic excitations in the system. However, in the following, we demonstrate how, under appropriate approximations, the results of Ref. 47, i.e., our results in the limit of ultrashort excitation, lead to the nonequilibrium generalization of the Förster theory proposed in Refs. 60 and 61.

Let us limit our discussion to an aggregate containing two chromophores, see Fig. 4, one acting as the excitation donor (\( D \), chromophore 0 in Fig. 4), and the other acting as the excitation acceptor (\( A \), chromophore 1 in Fig. 4). Let us focus on the first-order term. The first summation on the right-hand side of Eq. (45) describes the combined action of the environmental assistance and the first interaction \( H_{DA} \) takes place at instant \( \tau \). Upon making the approximation

\[
\rho_{ee}^{(1)}(t) = T \exp \left[ \tilde{W}_{p}(t, 0) |D\rangle\langle D| \right],
\]

where we have dropped out the normalization constant similar to \( P_c \) in Eq. (29). We are interested in the rate at which the population of \( A \),

\[
P_A(t) = \langle A | \tilde{U}_{DA}(t, 0) \rho_{ee}^{(1)}(t) \tilde{U}_{DA}^\dagger(t, 0) |A\rangle,
\]

changes. In the last equation, a tilde over operator denotes the interaction picture with respect to the electronic Hamiltonian of the noninteracting chromophores \( (\epsilon_D |D\rangle\langle D| + \epsilon_A |A\rangle\langle A|) \), and

\[
\tilde{U}_{DA}(t, 0) = T \exp \left[ -\frac{i}{\hbar} \int_0^t ds \tilde{H}_{DA}(s) \right]
\]

We then partition the integration domain in \( \tilde{W}_{p}(t, 0) \) as follows [\( \tilde{F}_p(s_2, s_1) \) denotes the hyperoperator under integral signs in Eq. (28)]

\[
\tilde{W}_{p}(t, 0) = \int_\tau^t ds_2 \int_0^{s_2} ds_1 \tilde{F}_p(s_2, s_1) + \int_\tau^t ds_2 \int_0^{s_2} ds_1 \tilde{F}_p(s_2, s_1) + \int_\tau^t ds_2 \int_0^\tau ds_1 \tilde{F}_p(s_2, s_1).
\]
FIG. 5. (Color online) Time evolution of the optical coherence modulus [(a1)-(d1)] and population [(b2)-(d2)] of site 0 following a pulsed photoexcitation of the model dimer (see Fig. 4). The computation is performed using the HEOM formalism incorporating the photoexcitation [Eqs. (14) and (15), solid curves] and the Redfield theory incorporating the photoexcitation [Eqs. (37) and (38), dash-dotted curves], while the envelope of the photoexcitation is represented by shaded areas. The transition dipole moment of site 1 is assumed to be perpendicular to the polarization vector of the exciting field, whereas the magnitude of the projection of the transition dipole moment of site 0 onto the polarization vector is $d_{eg}$. The waveform of the excitation is $E(t) = E_0 \exp\left(-i\Omega_p t - t^2/(2\tau_p^2)\right)/\tau_p \sqrt{2\pi}$, where the duration of the pulse is $\tau_p = 20$ fs, while the central frequency $\Omega_p$ is tuned to the vertical transition frequency of site 0. The temperature is set to $T = 300$ K, while the bath relaxation time is $\gamma = 100$ fs. The reorganization energy assumes the following values: $\lambda = 2$ cm$^{-1}$ in (a1) and (a2), $\lambda = 20$ cm$^{-1}$ in (b1) and (b2), $\lambda = 100$ cm$^{-1}$ is (c1) and (c2), and $\lambda = 500$ cm$^{-1}$ in (d1) and (d2).
we conclude that the corresponding contribution is equal to zero (cf. Sec. [VA]). The second summand in Eq. (45) is effective after the first interaction $H_{DA}$, when the electronic state is that of $D/A$ coherence, $|D\rangle\langle A|$. It is then easily checked that [see also Eq. (31)]

$$
T \left[ \bar{H}_{DA}(t) C \int_\tau^t ds_2 \int_\tau^{s_2} \bar{F}_p(s_2, s_1) C \bar{H}_{DA}(\tau) \right] |D\rangle \langle D| \approx -J^2_{DA} e^{-i(\varepsilon_D - \varepsilon_A)(t - \tau)} \left[ g_D(t - \tau) + g_A^*(t - \tau) \right] |A\rangle \langle A|. \tag{46}
$$

We may anticipate that, after the resummation, this term produces the well-known factors characteristic of donor emission ($e^{-g_D(t-\tau)}$) and acceptor absorption ($e^{-g_A(t-\tau)}$). In the third summand in Eq. (45), one superoperator acts before, and the other after, the first interaction $H_{DA}$. This summand is expected to take into account corrections to the aforementioned donor emission factor due to the fact that donor environment has not yet adapted to the electronic excited state. In greater detail,

$$
T \left[ \bar{H}_{DA}(t) C \int_\tau^t ds_2 \int_\tau^{s_2} \bar{F}_p(s_2, s_1) C \bar{H}_{DA}(\tau) \right] |D\rangle \langle D| \approx -J^2_{DA} e^{-i(\varepsilon_D - \varepsilon_A)(t - \tau)} \frac{2i}{\hbar^2} \int_\tau^t ds_2 \int_0^\tau ds_1 C_D(s_2 - s_1) |A\rangle \langle A|. \tag{47}
$$

One can convince themselves that the final result for the excitation transfer rate $k_{AD}^E(t)$ in this limit reads as

$$
k_{AD}^E(t) = \frac{2J^2_{DA}}{\hbar^2} \int_0^t d\tau \operatorname{Re} \left\{ \exp \left( i(\varepsilon_D - \varepsilon_A)(t - \tau) - g_D^*(t - \tau) - g_A(t - \tau) + \frac{2i}{\hbar^2} \int_\tau^t ds_2 \int_0^\tau ds_1 C_D(s_2 - s_1) \right) \right\}. \tag{48}
$$

To enable a direct comparison with Eq. (20) or Eq. (24) of Ref. [60], one should perform change of variables $t - \tau = \tau'$ and calculate all bath correlation functions by definition, starting from the general expression for $u_j$ [Eq. (5)].

### VI. EXCITATION BY WEAK INCOHERENT LIGHT

Here, we study in more detail the excitation by (weak) incoherent light, for which the factorized part [Eq. (17)] of the first-order light correlation function [Eq. (16)] identically vanishes. The HEOM, as formulated here, lends on the exponential decomposition of the environmental correlation function $C_j(t)$, see Eq. (9). Therefore, it may be expected that, if we can expand $G^{(1)}_{ij}(\tau_2 - \tau_1)$ as a weighted sum of exponential factors, we can proceed to formulate HEOM in the usual manner. We concentrate on thermal (chaotic) light whose propagation direction and polarization are well defined. It is known that quantum and classical theory predict the same form of the first-order light correlation function for such light.

$$
G^{(1)}(\tau) = I_0 \exp \left( i\omega_c \tau - \tau/\tau_c \right). \tag{49}
$$

In Eq. (49), $I_0$ is the intensity, $\omega_c$ is the central frequency, while $\tau_c$ is the coherence time of the radiation. In view of the well defined polarization, we omit subscripts $i,j$ labeling Cartesian coordinates of the electric field. This form of the first-order radiation correlation function has been used to gain insight into the dynamics of open systems and closed quantum systems weakly driven by light. Here, motivated by the aforementioned exponential decomposition, we show how the following light correlation function

$$
G^{(1)}(\tau) = \sum_i I_{0,i} \exp \left( i\omega_{c,i} \tau - \tau/\tau_{c,i} \right) \tag{50}
$$

can be used to recast Eq. (18) as HEOM.

For incoherent light, optical coherences defined in Eq. (28) are exactly equal to zero. Nevertheless, the general scheme of the hierarchy is still analogous to that we outlined in the case of classical excitation, see Fig. 2. One can introduce the following objects that act in the $eg$ sector and are thus analogous to optical coherences, cf. Eq. (29),

$$
\rho_{eg,l}^{(i)}(t) = \int_{t_0}^t d\tau U_{\text{red}}^{(i)}(t, \tau) \frac{i}{\hbar} \mu_{eg,l}(\tau) |g\rangle \langle g| \times I_{0,i} \exp \left[ i\omega_{c,i}(t - \tau) - (t - \tau)/\tau_{c,i} \right], \tag{51}
$$

where the dipole-moment operator $\mu_{eg}$ is the projection of $\tilde{\mu}_{eg}$ on the polarization direction. These optical coherence-like objects are counted by index $l$ appearing in Eq. (50). In other words, each term in the exponential decomposition of the first-order radiation correlation function adds a new layer to the HEOM for "optical coherences", which reads as

$$
\delta_l \sigma_{eg,l,n}(t) = -\frac{i}{\hbar} \left[ H_{\text{M}}, \sigma_{eg,l,n}(t) \right] \\
+ \left( i\omega_{c,l} - \tau_{c,l}^{-1} \right) \sigma_{eg,l,n}(t) \\
- \sum_j \sum_m n_{j,m} \{ H_{j,m} \} \sigma_{eg,l,n}(t) \\
+ \delta_{n,0} \frac{i}{\hbar} I_{0,l} \tilde{\mu}_{eg} \\
+ i \sum_j \sum_m V_j \sigma_{eg,l,n_j^+(t)} \\
+ 1 \sum_j \sum_m c_{j,m} \frac{\hbar}{2} V_j \sigma_{eg,l,n_j^-(t)}. \tag{52}
$$
Nevertheless, the HEOM for singly excited-state populations and intraband coherences does not feature any additional layers stemming from the decomposition in Eq. \( \text{[60]} \) and it reads as

\[
\begin{align*}
\partial_t \sigma_{ee,n}(t) &= -\frac{i}{\hbar} [H_{M}, \sigma_{ee,n}(t)] \\
&- \left( \sum_j n_{j,m} \mu_{j,m} \right) \sigma_{ee,n}(t) \\
&+ \frac{i}{\hbar} \rho_{eg} \left( \sum_l \sigma_{eg,l,n}(t) \right) - \frac{i}{\hbar} \left( \sum_l \sigma_{eg,l,n}(t) \right) \mu_{ge} \\
&+ i \sum_j n_{j,m} \left[ V_j, \sigma_{ee,n_{j,m}}(t) \right] \\
&+ i \sum_j \sum_m n_{j,m} \frac{e_{j,m}}{\hbar^2} V_j' \sigma_{ee,n_{j,m}}(t) \\
&- i \sum_j \sum_m n_{j,m} \frac{e^*_{j,m}}{\hbar^2} \sigma_{ee,n_{j,m}}(t) V_j.
\end{align*}
\]  

(53)

Our results embodied in Eqs. \( \text{[52]} \) and \( \text{[53]} \) are significant because they provide a viable route towards a description of excitonic dynamics triggered by thermal light. This description consistently combines both specific temporal and statistical properties of the radiation and a nonperturbative treatment of the excitation–environment interactions. Namely, propagating HEOM for "optical coherence" \( \tau_c \) is at least an order of magnitude shorter than the time scales typical for electronic couplings and nuclear reorganization processes (which assume values \( \sim 10 - 100 \text{ cm}^{-1} \)). We may then argue that we can disregard the nonequilibrium environmental dynamics taking place between the two interactions with the radiation, which was crucial to correctly describe excitonic dynamics induced by a pulsed photoexcitation, see the discussion accompanying Fig. 1(c) and Figs. 5(a1)–5(d2). In other words, we may assume that both interactions with the radiation occur essentially at the same instant, which means that Eq. \( \text{[49]} \) should be replaced by

\[ G^{(1)}(\tau) = 2I_0 \tau_c \delta(\tau). \]  

(54)

This is the so-called white-noise model (WNM) of the radiation \( \text{[36]} \). In this case, one has to propagate only the HEOM for excited-state populations and interband coherences and Eq. \( \text{[53]} \) should be replaced by

\[
\begin{align*}
\partial_t \sigma_{ee,n}(t) &= -\frac{i}{\hbar} [H_{M}, \sigma_{ee,n}(t)] \\
&- \left( \sum_j n_{j,m} \mu_{j,m} \right) \sigma_{ee,n}(t) \\
&+ \frac{2I_0 \tau_c}{\hbar^2} \mu_{eg} |g\rangle \langle g| \mu_{ge} \\
&+ i \sum_j \sum_m n_{j,m} \left[ V_j, \sigma_{ee,n_{j,m}}(t) \right] \\
&+ i \sum_j \sum_m n_{j,m} \frac{e_{j,m}}{\hbar^2} V_j' \sigma_{ee,n_{j,m}}(t) \\
&- i \sum_j \sum_m n_{j,m} \frac{e^*_{j,m}}{\hbar^2} \sigma_{ee,n_{j,m}}(t) V_j.
\end{align*}
\]  

(55)

In Figs. 6(a) and 6(b) we confront the dynamics of the dimer described in Fig. 4 that is triggered by suddenly turned on incoherent light and governed by Eqs. \( \text{[52]} \) and \( \text{[53]} \) (label "full") and Eq. \( \text{[55]} \) (label "WNM") for different values of light coherence time \( \tau_c \). Figure 6(a) presents the dimensionless source term for the total excited-state population for \( G^{(1)}(\tau) \) given in Eq. \( \text{[49]} \) (curves labeled as "full")

\[ S_{\text{full}}(t) = \frac{i}{\hbar} T_{YM} \left\{ \mu_{eg} \sigma^1_{eg,0}(t) - \sigma_{eg,0}(t) \mu_{ge} \right\} \]  

(56)

and for \( G^{(1)}(\tau) \) given in Eq. \( \text{[51]} \) (the curve labeled as "WNM")

\[ S_{\text{WNM}} = \frac{2I_0 \tau_c}{\hbar^2} T_{YM} \left\{ \mu_{eg} |g\rangle \langle g| \mu_{ge} \right\}. \]  

(57)

The value of \( \tau_c \) determines the time scale on which the source term for the total excited-state population \( S_{\text{full}}(t) \) reaches a constant value upon a sudden turn-on of incoherent radiation, see Fig. 6(a). For the shortest \( \tau_c \) examined, the source term \( S_{\text{full}}(t) \) saturates within the initial
The larger is the coherence time \( \tau_c \), the more pronounced \( \gamma \tau_c \) of the dynamics and the value it reaches excel-
ently agrees with the source term \( S_{\text{WNM}} \) predicted by the WNM of the radiation. This is also reflected in Fig. 6(b), in which the total exciton populations predicted by the two models display a perfect agreement for the shortest \( \tau_c \). As \( \tau_c \) is increased, so that it becomes comparable to the time scales of nuclear reorganization processes, the agreement between the results predicted by Eqs. (52) and (53) and Eq. (55) deteriorates, see Figs. 6(a) and 6(b), because the WNM cannot capture the nonequilibrium bath dynamics between the two interactions with the radiation. The larger is the coherence time \( \tau_c \), the more pronounced are the deviations of the exact dynamics from the WNM results.

We now turn our attention to the dynamics of interexciton coherences, which is displayed in Figs. 6(a)–6(d) for different values of the reorganization energy \( \lambda \).

The initial (sub-picosecond) oscillatory dynamics of the interexciton coherence that is clearly observed for lower values of \( \lambda \), see Figs. 6(a) and 6(b), is directly related to the oscillations displayed by the populations in the site basis upon an ultrafast excitation, see Figs. 5(b1)–5(d2). As the reorganization energy is increased, the oscillatory features gradually disappear, cf. Figs. 6(b1)–6(d2), and certain steady behavior of the interexciton coherence, similar to a steady increase in the total exciton population observed in Fig. 6 sets in. In Figs. 6(b)–6(d), we see that the imaginary part of the interexciton coherence saturates in \( \sim 1 \) ps after the excitation start. On the other hand, the real part of the interexciton coherence in Fig. 6(b) exhibits a steady increase for \( t \gtrsim 1.25 \) ps, while the corresponding start of the steady increased is shifted to \( \sim 0.75 \) ps and \( \sim 1.5 \) ps in Figs. 6(c) and 6(d), respectively. The time scale on which the steady increase of the interexciton coherence sets in is intimately related to the time scale on which the populations in the site basis [see Figs. 5(b2)–5(d2)] reach their limiting values following a very short photoexcitation. By virtue of basis transformation, the latter is closely connected to the time scale of the dephasing of the interexciton coherence generated by a very short photoexcitation. Therefore, the oscillatory features under incoherent illumination originate from the sudden turn-on of the excitation at \( t = 0 \) and they disappear on the time scale on which the interexciton coherence dephases after a short photoexcitation. We note, in passing, that the magnitude of the interexciton coherence becomes much larger than populations, which is also in line with previous studies.\(^{24,41,66,69}\) The light-induced coherences observed in Figs. 7(a) and 7(b) are not expected to be directly relevant to excitation harvesting under natural conditions, which proceeds via nonequilibrium steady states.\(^{24}\) Such states arise from a combination of the steady increase in populations and coherences [see Fig. 7(b) and Figs. 7(a)–7(d)] due to continuous generation and the steady excitation decay by trapping at the reaction center and recombination. What may be relevant for the efficiency of light harvesting driven by incoherent light are the relations among the RDM elements that establish themselves on time scales typical for excitation trapping and recombination, which are generally much longer than the time scales covered in this study. Further development of this idea is the topic of the accompanying paper.\(^{24}\)

This section explicitly deals with incoherent light whose first-order correlation function is of the form given in Eqs. (14) and (15). In the literature, it is common to formulate equations similar to Eq. (15), which tacitly lean on the WNM in which the source term describing the generation of state \( |e\rangle \) (from the ground state) by incoherent sunlight is given in terms of the number of
FIG. 7. (Color online) Dynamics of the real (solid lines) and imaginary (dashed lines) parts of the interexciton coherence [in units of $\gamma_\tau I_0 d_0^2/(\hbar \gamma)^2$] in the model dimer (see Fig. 4) for different values of the reorganization energy: (a) $\lambda = 2 \text{ cm}^{-1}$, (b) $\lambda = 20 \text{ cm}^{-1}$, (c) $\lambda = 100 \text{ cm}^{-1}$, and (d) $\lambda = 500 \text{ cm}^{-1}$. Light coherence time is $\tau_c = 1.3$ fs.

VII. CONCLUSION

We have conducted a detailed theoretical investigation of the dynamics of electronic excitations in molecular aggregates induced by weak radiation of arbitrary properties. Starting from initially unexcited aggregate, our approach combines a perturbative treatment of the coupling to radiation with an exact treatment of the excitation–environment coupling in a manner that is manifestly compatible with the spectroscopic view of the photoexcitation. We express the reduced excited-state dynamics entirely in terms of the first-order radiation correlation function and the reduced evolution superoperator, for which we provide an exact expression within the Frenkel exciton model. The changes that the state of electronic excitations undergoes due to the photoexcitation and the interaction with the environment can be conveniently represented diagrammatically, in terms of elementary processes assisted by single quanta of environmental excitations. The fact that our general expression for the excited-state dynamics explicitly keeps track of the instants at which the two interactions with light occur means that the corresponding differential equation is time-nonlocal. Within the exponential decomposition scheme, we outline how this temporal nonlocality can be circumvented by setting up a suitable HEOM scheme that explicitly takes into account the photoexcitation step. Such developments, however, turn out to heavily depend on radiation properties.

In the case of excitation by transform-limited pulses, when the radiation correlation function factorizes into product of (classical) electric fields at two interaction in-
stant, we relate HEOM arising from our results to the HEOM obtained by considering the (semiclassical) light–material coupling as a part of the aggregate Hamiltonian. The insights from nonlinear spectroscopy and semiconductor optics analyzed using the DCT scheme turn out to be crucial in establishing that relationship. Namely, the order in which the light–matter coupling is taken into account determines the subspace of the excitation Fock space on which the photoinduced dynamics should be formulated, and vice versa. We demonstrate that the second-order response to light should be formulated on the subspace containing at most one excitation.

We analyze in detail the dynamics triggered by an impulsive excitation of a single chromophore, where we provide analytical results for environmental reorganization dynamics, which is encoded in ADMs. We further identify the approximations under which our general result reduces to the widely employed Redfield theory with photoexcitation and nonequilibrium Förster theory. Our comparison between the dynamics predicted by HEOM and Redfield theory with photoexcitation further corroborates the advantages of our approach, which exactly describes light-induced environmental reorganization processes and fully takes into account the nonequilibrium evolution of the bath between the two interactions with light.

In the case of excitation by thermal light, we compare our approach to the widely used hybrid Born–Markov–HEOM approach, which treats the light–matter coupling within quantum-optical approximations. Since we employ the exponential decomposition scheme, the formulation of HEOM relies on an exponential decomposition of the radiation correlation function. We obtain that the HEOM thus obtained is not significantly more numerically expensive than the HEOM as it is usually formulated. This is because additional layers stemming from the decomposition of radiation correlation function exist only in its optical-coherence-like part, which may be solved completely independently from its excited-state part. This paves the way towards viable computations of the dynamics triggered by natural incoherent light that respects both specific properties of the radiation and the need for a nonperturbative treatment of excitation–environment coupling.

We believe that, despite its unfavorable numerical cost, the approach outlined here can be useful in further investigations of light–induced dynamics in both photosynthetic light-harvesting aggregates and OPVs. In particular, in both types of systems the relation of the insights gained in ultrafast spectroscopies to the actual operation under natural Sunlight illumination has provoked long-standing debates. Therefore, our method stands a chance of bridging these two standpoints and establishing a new viewpoint on energy conversion in these systems, the tasks that are under way in our research groups.

SUPPLEMENTARY MATERIAL

See supplementary material for: (a) a more detailed discussion of the second-order response to excitation by coherent light; (b) a detailed derivation of the exact evolution superoperator; (c) derivation of the Redfield equation comprising photoexcitation; (d) a discussion of the quantum-optical limit in the case of excitation by incoherent light.

SI. SECOND-ORDER RESPONSE WITHIN SEMICLASSICAL TREATMENT OF LIGHT–MATTER INTERACTION

In this section, we explain in greater detail why, when we study the second-order response, we can safely limit ourselves to the subspace containing at most one excitation.

The full density matrix $W(t)$ describing the combined system of aggregate excitations and environment can be expanded in powers $n$ of the exciting field

$$W(t) = \sum_{n=0}^{+\infty} W^{(n)}(t), \text{ where } W^{(n)}(t) \propto \mathcal{E}^n. \quad (S1)$$

According to the expansion theorem of Ref. [1], the $n$th order contribution $W^{(n)}(t)$ may be expanded in terms of states containing a definite number of excitations as follows

$$W^{(n)}(t) = \sum_{n'=0}^{n} \sum_{\kappa' \kappa} |n', \kappa', t\rangle \langle n - n', \kappa, t| \rho_B(n, n', \kappa, \kappa', t). \quad (S2)$$

Here, $|n', \kappa', t\rangle$ is a number state containing $n'$ excitations characterized by quantum numbers that are collectively denoted as $\kappa'$, while its explicit time dependence stems from the time dependence of the exciting field. In that sense, state $|n', \kappa', t\rangle$ is not normalized, but rather scales as $\mathcal{E}^{n'}$. The expansion coefficients $\rho_B(n, n', \kappa, \kappa', t)$ are purely environmental operators.

Using the expansion theorem, it can be shown that the second-order response is fully formulated in terms of the following generating functions:

$$Y_{\alpha\beta}^j = \langle B_j \hat{F}^{\alpha\beta} \rangle, \quad (S3)$$

$$N_{ij}^{\alpha\beta} = \langle B_i B_j \hat{F}^{\alpha\beta} \rangle, \quad (S4)$$

where

$$\hat{F}^{\alpha\beta} = \exp \left( \sum_{j \xi} \alpha_{j \xi} b_j^{\dagger} \right) \exp \left( \sum_{j \xi} \beta_{j \xi} b_j \right). \quad (S5)$$

$Y_{\alpha\beta}^j$ is the generating function for (environment-assisted) optical coherences, while $N_{ij}^{\alpha\beta}$ is the generating function for (environment-assisted) singly excited-state populations and intraband coherences. A more elaborate analysis shows that (environment-assisted) biexcitonic amplitudes, $\langle B_i B_j \hat{F}^{\alpha\beta} \rangle$, which also scale as $O(\mathcal{E}^2)$, do not contribute to the second-order response, so that they are omitted from further discussions.

a) Electronic mail: veljko.jankovic@ipb.ac.rs
b) Electronic mail: mancal@karlov.mff.cuni.cz
Let us now recall that the excitation annihilation operator $B_j$ may be expanded in terms of number states so that it manifestly connects subspaces accommodating different numbers of excitons:

$$B_j = |0\rangle\langle 1, j| + \sum_{k \neq j} |1, k\rangle\langle 2, k| + \ldots \quad (S6)$$

Then,

$$Y_j^\alpha\beta = \sum_{n=0}^{+\infty} \sum_{n'=0}^{n} \sum_{\kappa'\kappa} \text{Tr}_M \{ B_j|n', \kappa', t\rangle\langle n - n', \kappa, t| \} \text{Tr}_B \{ \hat{F}_{\alpha\beta} \rho_B(n, n', \kappa, \kappa', t) \}$$

$$= \sum_{n=0}^{+\infty} \sum_{n'=0}^{n} \sum_{\kappa'\kappa} \langle 1, j|n', \kappa', t\rangle\langle n - n', \kappa, t|0\rangle \text{Tr}_B \{ \hat{F}_{\alpha\beta} \rho_B(n, n', \kappa, \kappa', t) \} +$$

$$+ \sum_{n=0}^{+\infty} \sum_{n'=0}^{n} \sum_{\kappa'\kappa} \sum_{k \neq j} \langle 2, kj|n', \kappa', t\rangle\langle n - n', \kappa, t|1, k\rangle \text{Tr}_B \{ \hat{F}_{\alpha\beta} \rho_B(n, n', \kappa, \kappa', t) \} + \ldots \quad (S7)$$

We see that the summand containing $\langle 1, j|n', \kappa', t\rangle\langle n - n', \kappa, t|0\rangle$ is nonzero iff $n = n' = 1$, i.e., in the first order in the exciting field. The summand containing $\langle 2, kj|n', \kappa', t\rangle\langle n - n', \kappa, t|1, k\rangle$ is nonzero iff $n' = 2$ and $n = 3$, i.e., in the third order in the optical field. Therefore, the expansion of the excitation annihilation operator in number states actually reflects the contributions to $Y_j^\alpha\beta$ that are linear, cubic, etc. in the exciting field, as predicted by the central theorem of the DCT scheme. The fact that the environment has no impact on scaling relations is apparent in our discussion. Up to the second order in the exciting field, contributions to $B_j$ that involve a state containing more than one particle do not contribute to the response.

In a similar vein,

$$B_1^i B_j = |1, i\rangle\langle 1, j| + \sum_{k \neq i, k \neq j} |2, ik\rangle\langle 2, jk| + \ldots \quad (S8)$$

Combining Eqs. (S2), (S4), and (S8), we conclude that all contributions to $B_1^i B_j$ involving states that accommodate more than a single excitation are at least of the fourth order in the exciting field, and, therefore, do not contribute to the second-order response.

If we are to study the second-order response, we can limit our description to subspaces that contain up to one excitation. On the other hand, as described in the main text, once we formulate the model Hamiltonian in the subspace containing at most one excitation, we can consistently formulate the dynamics only up to the second order in the exciting field.
II. DERIVATION OF THE EXACT EVOLUTION SUPEROPERATOR

Here, we present the derivation of the exact evolution superoperator for a weakly driven excitonic aggregate. In the interaction picture, the total DM $W^{(I)}(t)$ of the combined system comprising the molecular aggregate, its environment, and the radiation field, evolves according to

$$\partial_t W^{(I)}(t) = -\frac{i}{\hbar} \left[ H_{M-B}^{(I)}(t) + H_{M-R}^{(I)}(t), W^{(I)}(t) \right],$$  \hspace{1cm} (S9)

with the factorized initial condition $W^{(I)}(t_0) = W(t_0)$ given in the main text. Here, we define the interaction picture with respect to the non-interacting Hamiltonian

$$H_0 = H_M + H_B + H_R,$$  \hspace{1cm} (S10)

so that for any operator $O$ in the Schrödinger picture, the corresponding operator in the interaction picture with respect to $H_0$ reads as

$$O^{(I)}(t) = U_0^\dagger(t, t_0) O U_0(t, t_0),$$
$$U_0(t, t_0) = \exp \left[ -\frac{i}{\hbar} H_0 (t - t_0) \right].$$  \hspace{1cm} (S11a, S11b)

The formal solution to Eq. (S9) is

$$W^{(I)}(t) = \sum_{n=0}^{\infty} \left( -\frac{i}{\hbar} \right)^n \int_{t_0}^{t} d\tau_n \cdots \int_{t_0}^{\tau_2} d\tau_1 \left[ H_{M-B}^{(I)}(\tau_n) + H_{M-R}^{(I)}(\tau_n), \ldots, \left[ H_{M-B}^{(I)}(\tau_1) + H_{M-R}^{(I)}(\tau_1), W(t_0) \right] \right].$$  \hspace{1cm} (S12)

Let us now focus on the case of weak interaction with the radiation by keeping in Eq. (S12) only contributions that contain no more than two interaction Hamiltonians $H_{M-R}$. At the same time, as discussed in Sec. S1, this means that we can safely reduce our description to the subspace containing at most one excitation and consequently make the replacements $B_j \to |g\rangle \langle j|, B_j^\dagger \to |j\rangle \langle g|$ in the model Hamiltonian. The specific form of the initial condition, as well as the fact that any nontrivial dynamics is ultimately induced by $H_{M-R}$, enable us to separately treat different electronic sectors ($gg, eg, ge,$ and $ee$) of the total DM. By electronic sectors $gg, eg,$ and $ee$ of the total DM, we understand here its parts that, after appropriate reductions, contain information on the ground-state population, optical coherences, and excited-state populations and intraband coherences, respectively. After a straightforward analysis, we obtain the following results for the $eg$ sector

$$W^{(I)}_{eg}(t) = -\frac{i}{\hbar} \int_{t_0}^{t} d\tau \ U_{M-B}^{(I)}(t, \tau) H_{M-R}^{(I)}(\tau) W(t_0),$$  \hspace{1cm} (S13)

for the $gg$ sector

$$W^{(I)}_{gg}(t) = W(t_0) - \frac{i}{\hbar} \int_{t_0}^{t} d\tau \ H_{M-R}^{(I)}(\tau) W^{(I)}(\tau)$$
$$+ \frac{i}{\hbar} \int_{t_0}^{t} d\tau \ W^{(I)}_{eg} \left( \tau \right) H_{M-R}^{(I)}(\tau),$$  \hspace{1cm} (S14)

and for the $ee$ sector

$$W^{(I)}_{ee}(t) = \int_{t_0}^{t} d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \ U_{M-B}^{(I)}(t, \tau_2) U_{M-B}(\tau_2, \tau_1) \left( \frac{1}{\hbar^2} H_{M-R}^{(I)}(\tau_1) W(t_0) H_{M-R}^{(I)}(\tau_2) \right) U_{M-B}^{(I)}(t, \tau_2)$$
$$+ \int_{t_0}^{t} d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \ U_{M-B}^{(I)}(t, \tau_2) \left( \frac{1}{\hbar^2} H_{M-R}(\tau_2) W(t_0) H_{M-R}(\tau_1) \right) U_{M-B}^{(I)}(\tau_2, \tau_1) U_{M-B}(t, \tau_2).$$  \hspace{1cm} (S15)

In Eqs. (S13) and (S15),

$$U_{M-B}^{(I)}(s_2, s_1) = T \exp \left[ -\frac{i}{\hbar} \int_{s_1}^{s_2} ds \ H_{M-B}^{(I)}(s) \right],$$  \hspace{1cm} (S16)
where $T$ denotes the chronological time ordering. The result embodied in Eq. (S15) can be interpreted in terms of double-sided Feynman diagrams. The two summands on the right-hand side of Eq. (S15) represent the two Liouville pathways from $|g\rangle \langle g|$ to $|e\rangle \langle e|$, which differ by the time order of the interactions with the bra and ket. These two summands are complex conjugates of one another, so that $W_{ee}^{(I)}(t)$ is a Hermitian operator. Therefore, in further discussions, it will be enough to perform manipulations with the first summand only.

Let us note that the total number of excitations, which is given by the (total) trace of $W(t)$ or $W^{(I)}(t)$, is conserved. This is most easily proven by rewriting Eqs. (S15) and (S14) as differential equations.

The RDM containing excited-state populations and intraband coherences is obtained by performing partial traces with respect to the radiation and the thermal bath

$$
\rho_{ee}^{(I)}(t) = \text{Tr}_B \left\{ \text{Tr}_R \left\{ W_{ee}^{(I)}(t) \right\} \right\} .
$$

Let us concentrate on reducing the first term on the right-hand side of Eq. (S15). The partial trace over radiation is computed straightforwardly, since radiation operators enter Eq. (S15) only through the two

$$
\frac{1}{\hbar^2} \text{Tr}_R \left\{ H_{M-R}^{(I)} W(t_0) H_{M-R}^{(I)}(\tau_2) \right\} = A^{(I)}(\tau_2, \tau_1) \rho_B^g .
$$

where the purely electronic operator $A^{(I)}(\tau_2, \tau_1)$ is defined as

$$
A^{(I)}(\tau_2, \tau_1) = \frac{1}{\hbar^2} \sum_{i,j} G_{ij}^{(I)}(\tau_2, \tau_1) \left\{ \mu_{eg}^{(I)}(\tau_1) \right\}_j \langle g| \langle g| \left\{ \mu_{ge}^{(I)}(\tau_2) \right\}_i .
$$

In Eq. (S19), the sums over $i$ and $j$ are performed over Cartesian components of the electric field, whereas $G_{ij}^{(I)}(\tau_2, \tau_1)$ is defined in the main text. Therefore, in the limit of weak aggregate–radiation interaction, the radiation enters the reduced dynamics of excited-state populations and intraband coherences only via its first-order correlation function, which is defined in the main text. Therefore, in the limit of weak aggregate–radiation interaction, the radiation enters the reduced dynamics of excited-state populations and intraband coherences only via its first-order correlation function, which is defined in the main text. Therefore, in the limit of weak aggregate–radiation interaction, the radiation enters the reduced dynamics of excited-state populations and intraband coherences only via its first-order correlation function, which is defined in the main text.

To simplify further discussion, we concentrate on the following operator

$$
w_{ee}^{(I)}(t, \tau_2, \tau_1) = U_{M-B}^{(I)}(t, \tau_2) U_{M-B}^{(I)}(\tau_2, \tau_1) A^{(I)}(\tau_2, \tau_1) \rho_B^g U_{M-B}^{(I)\dagger}(t, \tau_2) ,
$$

whose partial trace over bath has to be computed. The operator $w_{ee}^{(I)}(t, \tau_2, \tau_1)$ describes the state of electronic excitations and the environment at time $t$ when we assume that the first interaction with the radiation takes place at $\tau_1$ from the left, while the second interaction occurs at $\tau_2$ from the right. Upon expanding $U_{M-B}^{(I)}$ in powers of $H_{M-B}^{(I)}$, we obtain

$$
w_{ee}^{(I)}(t, \tau_2, \tau_1) = \sum_{n=0}^{+\infty} \left( \frac{i}{\hbar} \right)^n \frac{1}{n!} \left( \frac{-i}{\hbar} \right)^m \frac{1}{m!} \int_{\tau_2}^{t} dq_1 \cdots \int_{\tau_2}^{t} dq_1 \int_{\tau_1}^{\tau_2} ds_m \cdots \int_{\tau_1}^{\tau_2} ds_1
$$

$$
T \left[ H_{M-B}^{(I)}(q_n) \cdots H_{M-B}^{(I)}(q_1) \right] T \left[ H_{M-B}^{(I)}(s_m) \cdots H_{M-B}^{(I)}(s_1) \right] A^{(I)}(\tau_2, \tau_1) \rho_B^g ,
$$

where hyperoperators with superscripts $\times$ and $C$ have the same meaning as in the main text. The index $n$ controls the order of expansion of the combination $U_{M-B}^{(I)}(t, \tau_2) \cdots U_{M-B}^{(I)}(t, \tau_2)$, and the instants at which individual excitation–environment interactions take place are denoted as $q_1, \ldots, q_n$. Similarly, index $m$ controls the order of expansion of $U_{M-B}^{(I)}(\tau_2, \tau_1)$, and the respective instants are $s_1, \ldots, s_m$. We now use the explicit form of the excitation–environment coupling

$$
H_{M-B}^{(I)}(s_1) = \sum_{l_1} V^{(I)}_{l_1}(s_1) u^{(I)}_{l_1}(s_1) ,
$$

(S22)
where \( V_{l_1}^{(1)}(s_1) \) is a purely electronic operator, while \( u_{l_1}^{(1)}(s_1) \) is a purely environmental operator. Let us focus in the following on the operator under sums and integrals in Eq. (S21). Since \( A^{(1)}(\tau_2, \tau_1) \) is a purely electronic, while \( \rho_B^g \) is a purely environmental operator, we can write

\[
T \left[ H_{M-B}^{(l)}(q_n)^x \ldots H_{M-B}^{(l)}(q_1)^x \right] T \left[ H_{M-B}^{(l)}(s_m)^C \ldots H_{M-B}^{(l)}(s_1)^C \right] A^{(1)}(\tau_2, \tau_1) \rho_B^g = \\
\sum_{j_0 \ldots j_l} \sum_{l_0 \ldots l_1} T \left[ \left( V_{j_0}^{(l)}(q_n) u_{j_0}^{(l)}(q_n) \right) \ldots \left( V_{j_l}^{(l)}(q_1) u_{j_l}^{(l)}(q_1) \right) \right] \times \\
T \left[ V_{l_0}^{(l)}(s_m)^C \ldots V_{l_1}^{(l)}(s_1)^C \right] A^{(1)}(\tau_2, \tau_1) T \left[ u_{l_0}^{(l)}(s_m)^C \ldots u_{l_1}^{(l)}(s_1)^C \right] \rho_B^g 
\]

(S23)

where, in each term of the sum, the superoperators from the outermost layer act on an operator that is factorized into a purely electronic and purely environmental part. At this point, the following identity is useful

\[
(Vu)^x O_V O_u = \frac{1}{2} \left( Vu^o + Vu^x \right) O_V O_u, 
\]

(S24)

where \( O_V \) and \( O_u \) are arbitrary operators such that \( V \) can act on \( O_V \) only, while \( u \) can act on \( O_u \) only. The last identity enables us to rewrite Eq. (S23) as follows

\[
T \left[ H_{M-B}^{(l)}(q_n)^x \ldots H_{M-B}^{(l)}(q_1)^x \right] T \left[ H_{M-B}^{(l)}(s_m)^C \ldots H_{M-B}^{(l)}(s_1)^C \right] A^{(1)}(\tau_2, \tau_1) \rho_B^g = \\
\frac{1}{2^n} \sum_{j_0 \ldots j_l} \sum_{l_0 \ldots l_1} T \left[ \left( V_{j_0}^{(l)}(q_n)^{x_n} u_{j_0}^{(l)}(q_n)^{x_n} + V_{j_l}^{(l)}(q_1)^{x_l} u_{j_l}^{(l)}(q_1)^{x_l} \right) \ldots \left( V_{j_l}^{(l)}(q_1)^{x_l} u_{j_l}^{(l)}(q_1)^{x_l} + V_{j_0}^{(l)}(q_n)^{x_n} u_{j_0}^{(l)}(q_n)^{x_n} \right) \right] \times \\
T \left[ V_{l_0}^{(l)}(s_m)^C \ldots V_{l_1}^{(l)}(s_1)^C \right] A^{(1)}(\tau_2, \tau_1) T \left[ u_{l_0}^{(l)}(s_m)^C \ldots u_{l_1}^{(l)}(s_1)^C \right] \rho_B^g 
\]

(S25)

Each term under multiple sums over \( j_0 \) and \( l_0 \) has \( 2^n \) summands and, in each of them, the superoperators from the outermost layer can be written as

\[ V_{j_0}^{(l)}(q_n)^{x_n} u_{j_0}^{(l)}(q_n)^{x_n} \ldots V_{j_l}^{(l)}(q_1)^{x_l} u_{j_l}^{(l)}(q_1)^{x_l} \]

where \( \sigma_i \in \{x, \circ\} \), \( \circ = \circ \), and vice versa. Moreover, since all instants \( q_n, \ldots, q_1 \) are certainly later than all instants \( s_m, \ldots, s_1 \), we can merge the two time-ordering signs (one ordering \( q \) and the other ordering \( s \)) into a single time-ordering sign. Having all these transformations performed, we are left with

\[
T \left[ H_{M-B}^{(l)}(q_n)^x \ldots H_{M-B}^{(l)}(q_1)^x \right] T \left[ H_{M-B}^{(l)}(s_m)^C \ldots H_{M-B}^{(l)}(s_1)^C \right] A^{(1)}(\tau_2, \tau_1) \rho_B^g = \\
\frac{1}{2^n} \sum_{j_0 \ldots j_l} \sum_{l_0 \ldots l_1} \sum_{\sigma_n \ldots \sigma_1} T \left[ \left( V_{j_0}^{(l)}(q_n)^{x_n} \ldots V_{j_l}^{(l)}(q_1)^{x_l} \right) \left( V_{l_0}^{(l)}(s_m)^C \ldots V_{l_1}^{(l)}(s_1)^C \right) \right] A^{(1)}(\tau_2, \tau_1) \times \\
T \left[ u_{l_0}^{(l)}(s_m)^C \ldots u_{l_1}^{(l)}(s_1)^C \right] \rho_B^g 
\]

(S26)

We have thus reduced the problem to the computation of the following trace over the environment

\[
\text{Tr}_B \left\{ T \left[ u_{j_0}^{(l)}(q_n)^{x_n} \ldots u_{j_l}^{(l)}(q_1)^{x_l} \right] u_{l_0}^{(l)}(s_m)^C \ldots u_{l_1}^{(l)}(s_1)^C \right\} \rho_B^g 
\]

(S27)

It is clear that this trace may give a nontrivial result only when \( n + m \) is even, \( n + m = 2k \), where \( k = 1, 2, \ldots \). Let us now start from the simplest case \( n + m = 2 \), in which we face the following possibilities:

1. \( n = 2 \) and \( m = 0 \): environmental assistance is characteristic for the electronic subsystem in the excited-state manifold

\[
\text{Tr}_B \left\{ T \left[ u_{j_2}^{(l)}(q_2)^{x_2} u_{j_1}^{(l)}(q_1)^{x_1} \right] \right\} \rho_B^g = \theta(q_2 - q_1) \delta_{j_2 j_1} \cdot 2^2 \left( \delta_{\sigma_2,\circ} \delta_{\sigma_1,\circ} C_{j_2}^{f r}(q_2 - q_1) + \delta_{\sigma_2,\circ} \delta_{\sigma_1,\times} i C_{j_1}^{f t}(q_2 - q_1) \right) + \\
\theta(q_1 - q_2) \delta_{j_2 j_1} \cdot 2^2 \left( \delta_{\sigma_2,\circ} \delta_{\sigma_1,\circ} C_{j_1}^{f r}(q_1 - q_2) + \delta_{\sigma_2,\times} \delta_{\sigma_1,\circ} C_{j_1}^{f t}(q_1 - q_2) \right) 
\]

(S28)
The corresponding contribution to the partial trace over environment of Eq. (S21) then reads as

$$
\left[ \text{Tr}_B u^{(I)}_{ee,1}(t, \tau_2, \tau_1) \right]_{n=2, m=0} = -\frac{1}{\hbar^2} \sum_j \int_0^t dq_2 \int_0^{q_2} dq_1 \times
$$

$$
\times V_j^{(I)}(q_2) \times C^{(I)}_j(q_2 - q_1) V_j^{(I)}(q_1) \times + \text{i} C^{(I)}_j(q_2 - q_1) V_j^{(I)}(q_1) \times \right) \Lambda^{(I)}(\tau_2, \tau_1)
\equiv \mathcal{W}^p_{c}(t, \tau_2) \Lambda^{(I)}(\tau_2, \tau_1),
$$

which is the familiar form that has been obtained when the propagation is considered only within the excited-state manifold.\(^9\)

2. \(n = 0\) and \(m = 2\): environmental assistance is characteristic for the electronic subsystem in the state of optical coherence

$$
\text{Tr}_B \left\{ T \left[ u^{(I)}_{12}(s_2) C^{(I)}_{11}(s_1) \right] \rho^g_B \right\} = \theta(s_2 - s_1) \delta_{12,1} C_{11}(s_2 - s_1) + \theta(s_1 - s_2) \delta_{12,1} C_{11}(s_1 - s_2)
\equiv \delta_{12,1} C_{11}(|s_2 - s_1|).
$$

(S30)

The corresponding contribution to the partial trace over environment of Eq. (S21) then reads as

$$
\left[ \text{Tr}_B u^{(I)}_{ee,1}(t, \tau_2, \tau_1) \right]_{n=0, m=2} = -\frac{1}{\hbar^2} \sum_l \int_0^{\tau_2} ds_2 \int_0^{s_2} ds_1 V^{(I)}_{12}(s_2) C_l(s_2 - s_1) V^{(I)}_{11}(s_1) \Lambda^{(I)}(\tau_2, \tau_1)
\equiv \mathcal{W}^c_{ee}(\tau_2, \tau_1) \Lambda^{(I)}(\tau_2, \tau_1).
$$

(S31)

3. \(n = 1\) and \(m = 1\): environmental assistance straddles over periods in which electronic subsystem is in different states: it starts when the electronic subsystem is in the state of optical coherence, and ends when the electronic subsystem is in the excited-state manifold; here, we obtain the elementary contribution to the so-called straddled evolution

$$
\text{Tr}_B \left\{ T \left[ u^{(I)}_{11}(q_1) \sigma^a u^{(I)}_{11}(s_1) \right] \rho^g_B \right\} = \delta_{\sigma_1, \sigma} \delta_{j_1, l_1} \cdot 2 C_{j_1}(q_1 - s_1).
$$

(S32)

Note that \(T\) sign in the last equation can safely be omitted, since we are sure that \(q_1 \geq s_1\). The corresponding contribution to the partial trace over environment of Eq. (S21) then reads as

$$
\left[ \text{Tr}_B u^{(I)}_{ee,1}(t, \tau_2, \tau_1) \right]_{n=1, m=1} = -\frac{1}{\hbar^2} \sum_j \int_0^t dq_1 \int_0^{\tau_2} ds_1 V_j^{(I)}(q_1) \times C_j(q_1 - s_1) V_j^{(I)}(s_1) \times \Lambda^{(I)}(\tau_2, \tau_1)
\equiv \mathcal{W}^c_{e-p}(t, \tau_2, \tau_1) \Lambda^{(I)}(\tau_2, \tau_1).
$$

(S33)

The above analysis conducted in the lowest order of the perturbation expansion gives us basic building blocks from which higher-order contributions are constructed. This is possible by virtue of the Wick’s theorem

$$
\text{Tr}_B \left\{ T \left[ u^{(I)}_{j_2k}(q_{2k}) \ldots u^{(I)}_{j_1}(q_1) \right] \rho^g_B \right\} = \prod_{a,p-p} \text{Tr}_B \left\{ T \left[ u^{(I)}_{j_b}(q_b) u^{(I)}_{j_a}(q_a) \right] \rho^g_B \right\},
$$

(S34)

which expresses the (equilibrium) expectation value of the product of \(2k\) nuclear displacement operators \(u\) as a sum over all possible pairings (a.p.p.) of products of \(k\) (equilibrium) expectation values of two nuclear displacement operators. A similar identity also holds on the hyperoperator level, which is relevant to our discussion [see Eq. (S27)]. Namely, since all hyperoperators \(u^\pi\), where \(\pi \in \{\times, o, C\}\) are linear in nuclear displacement \(u\), we can use Eq. (S34) to establish the following identity

$$
\text{Tr}_B \left\{ T \left[ u^{(I)}_{j_2k}(q_{2k}) \pi^{2k} \ldots u^{(I)}_{j_1}(q_1) \pi^1 \right] \rho^g_B \right\} = \prod_{a,p-p} \text{Tr}_B \left\{ T \left[ u^{(I)}_{j_b}(q_b) \pi^a u^{(I)}_{j_a}(q_a) \pi^a \right] \rho^g_B \right\}.
$$

(S35)

Equation (S35) provides us with a general recipe to compute the partial trace in Eq. (S27) and, eventually, evaluate the contribution to Eq. (S21) in arbitrary perturbation order defined by values of \(n\) and \(m\). The form of Eq. (S35) suggests that all the contributions are indeed expressed in terms of the three elementary (lowest-order) contributions
that we have evaluated. However, we should still convince ourselves that all these contributions can be resummed into the form of a time-ordered exponential that presented in the main body of the manuscript.

Since this demonstration is rather formal and not particularly insightful, we only make its sketch for \( n + m = 2k \), \( k \geq 1 \). There, we have \( 2k + 1 \) different possibilities for \( n \) and \( m \). In the sketch, we make use of the so-called polynomial expansion, which states that, for mutually commuting entities \( x_c, x_p, x_{c-p} \) we have

\[
(x_c + x_p + x_{c-p})^k = \sum_{l_c, l_p, l_{c-p} \geq 0, l_c + l_p + l_{c-p} = k} \frac{k!}{l_c! l_p! l_{c-p}!} x_c^{l_c} x_p^{l_p} x_{c-p}^{l_{c-p}}.
\] (S36)

The commutativity in our case is ensured by the presence of the global time-ordering sign.

1. \( n = 2k, m = 0 \)

The application of Wick’s theorem [Eq. (S35)] produces \((2k - 1)!!\) terms, and it turns out that all of them are the same. In essence, this follows from the fact that all integrals over \( q_{2k}, \ldots, q_1 \) are over the same interval \([\tau_2, t]\) and that \( T \) sign enables us to permute at will the hyperoperators it affects. All the contributions contain environmental assistance in the form characteristic for the electronic subsystem in the excited-state manifold. Even though the Heaviside functions in Eq. (S28) order the integration variables in pairs, they do not enforce the global order, so that \( T \) sign cannot be removed.

The factor \( 2^{−2k} \) (appearing in front of sums by \( js \) and \( ls \)) is cancelled by the factor \((2^2)^k\) that emerges from \( k \) factors of the type given in Eq. (S28). Then, the total prefactor is

\[
\frac{1}{(2k)!} \cdot (2k - 1)!! = \frac{1}{k!} \cdot \frac{1}{2^k},
\]

where \((k!)^{-1}\) is indicative of the \( k \)-th order in the expansion of an exponential, whereas \((1/2)^k\) compensates for two equivalent time orderings in Eq. (S28). In Fig. 1 we give the corresponding diagrams for \( k = 2 \).

![FIG. 1. Diagrams representing different contributions in the fourth-order in \( H_{M-B} \) when \( n = 4 \) and \( m = 0 \). Their sum can be understood as the square of the primitive diagram in Fig. 1(b) of the main body of the manuscript. For simplicity, here, we omit information on the state of the electronic subsystem (\( |g\) or \( |e\)\).](image)

2. \( n = 2k - 1, m = 1 \)

Here, we have one environmental assistance that is mixed (straddled), as in Eq. (S32), and \((k - 1)\) assistances that are characteristic for the electronic system in the excited-state manifold, as in Eq. (S28). All the terms produced by the application of Wick’s theorem again turn out to be the same. The factor \( 2^{−(2k-1)} \) (appearing in front of sums by \( js \) and \( ls \)) is cancelled by the factor \((2^2)^{k-1} \cdot 2\) which stems from \((k - 1)\) factors similar to that in Eq. (S28) and one factor similar to that in Eq. (S32). The overall prefactor

\[
\frac{1}{(2k - 1)!} \cdot \frac{1}{1!} \cdot (2k - 1)!! = \frac{1}{2^{k-1}} \cdot k \cdot \frac{1}{k!}
\]

is then combined with the appropriate term as follows. The factor \((1/2)^{k-1}\) compensates for two equivalent time orderings in each of \((k - 1)\) factors analogous to Eq. (S28) (the straddled assistance, by its definition, features a definite time ordering), factor \( k \) reflects the fact that there are \( k \) equivalent ways of choosing the straddled building block (this is the polynomial coefficient \( k!/(l_c! l_p! l_{c-p}!) \) for \( l_c = 0, l_p = k - 1, l_{c-p} = 1 \)), while \((k!)^{-1}\) is again indicative of the \( k \)-th order in the expansion of an exponential. In Fig. 2 we give the corresponding diagrams for \( k = 2 \).
FIG. 2. Diagrams representing different contributions in the fourth-order in $H_{M-B}$ when $n = 3$ and $m = 1$. Their sum can be understood as twice the product of the primitive diagrams in Figs. 1(b) and 1(c) of the main body of the manuscript. For simplicity, here, we omit information on the state of the electronic subsystem ($|g\rangle$ or $|e\rangle$).

3. $n = 2k - 2$, $m = 2$

Here, we may have

(a) $(k-1)$ population-like assistances and 1 coherence-like assistance; the number of such terms, which are all mutually identical, is

$$(2(k-1)-1)!! = (2k-3)!!;$$

(b) $(k-2)$ population-like assistances and 2 straddled assistances; the number of such terms, which are all mutually identical, is

$$(2k-2)(2k-3)(2k-2-1)!! = (2k-2)(2k-3)!!.$$  

Of course, the total number of terms produced by the application of Wick’s theorem is $(2k-1)!!$. Let us briefly comment on the way how the prefactors combine.

(a) the prefactor $2^{-2k}$ (appearing in front of sums over $j$s and $l$s) is cancelled by the factor $(2^2)^{k-1}$ stemming from $(k-1)$ terms like that in Eq. $(S28)$; the overall prefactor

$$\frac{1}{(2k-2)!} \cdot \frac{1}{2!} \cdot (2k-3)!! = \frac{1}{2^k} \cdot \frac{1}{k}$$

is combined with the appropriate terms as follows. The factor $(1/2)^k$ compensates for two equivalent time orderings in each of $(k-1)$ factors analogous to Eq. $(S28)$ and the remaining factor analogous to Eq. $(S30)$; factor $k$ is again the polynomial coefficient $k!/(l_c!l_p!l_{c-p}!)$ for $l_c = 1, l_p = k-1, l_{c-p} = 0$;

(b) the prefactor $2^{-2k}$ (appearing in front of sums over $j$s and $l$s) is cancelled by the product $(2^2)^{k-2} \cdot 2^2$ originating from $(k-2)$ factors like that in Eq. $(S28)$ and 2 factors like that in Eq. $(S32)$; in the overall prefactor

$$\frac{1}{(2k-2)!} \cdot \frac{1}{2!} \cdot (2k-2)(2k-3)!! = \frac{1}{2^{k-2}} \cdot \binom{k}{2} \frac{1}{k!};$$

$(1/2)^{k-2}$ compensates for two equivalent time orderings [Eq. $(S28)$], while $\binom{k}{2}$ is the polynomial coefficient $k!/(l_c!l_p!l_{c-p}!)$ for $l_c = 0, l_p = k-2, l_{c-p} = 2$.

In Figs. 3(a) and 3(b) we give the corresponding diagrams for $k = 2$.

In a similar manner, one can analyze the remaining terms in order $2k$. The main result of such an analysis is the presence of the factor $1/k!$, as well as the corresponding polynomial factor $k!/(l_c!l_p!l_{c-p}!)$, in each of these terms. Therefore, the resummation produces the time-ordered exponential that is presented in the main text.
FIG. 3. Diagrams representing different contributions in the fourth-order in $H_{M-B}$ when $n = 2$ and $m = 2$. The diagram in (a) corresponds to the contribution analyzed under point (a) of the discussion and can be understood as twice the product of primitive diagrams in Figs. 1(a) and 1(b) of the main body of the manuscript. The two diagrams in (b) correspond to the contributions analyzed under point (b) of the discussion and can be understood as the square of the primitive diagram in Fig. 1(c) of the main body of the manuscript. For simplicity, here, we omit information on the state of the electronic subsystem ($|g⟩$ or $|e⟩$).

Finally, let us present the expression for the reduced evolution superoperator $U_{\text{red}}^{(I)}(t, \tau_2, \tau_1)$ that acts on the left ($T$ denotes antichronological time order)

$$U_{\text{red}}^{(I)}(t, \tau_2, \tau_1) = T \exp \left[ \hat{W}_c(\tau_2, \tau_1) + \hat{W}_p(t, \tau_2) + \hat{W}_{c-p}(t, \tau_2, \tau_1) \right], \quad (S37a)$$

$$\hat{W}_c(\tau_2, \tau_1) = -\frac{1}{\hbar^2} \sum_j \int_{\tau_1}^{\tau_2} ds_2 \int_{s_2}^{s_1} ds_1 C_{V_j}^{(II)}(s_1) C_j(s_1 - s_2) C_{V_j}^{(I)}(s_2), \quad (S37b)$$

$$\hat{W}_p(t, \tau_2) = -\frac{1}{\hbar^2} \sum_j \int_t^{\tau_2} ds_2 \int_{s_2}^{s_1} ds_1 \left( C_j^r(s_1 - s_2) \times V_j^{(I)}(s_1) + i C_j^a(s_1 - s_2) \circ V_j^{(I)}(s_1) \right) \times V_j^{(I)}(s_2), \quad (S37c)$$

$$\hat{W}_{c-p}(t, \tau_2, \tau_1) = -\frac{1}{\hbar^2} \sum_j \int_t^{\tau_2} ds_2 \int_{s_2}^{s_1} ds_1 C_{V_j}^{(II)}(s_1) \times C_j(s_1 - s_2) \times V_j^{(I)}(s_2). \quad (S37d)$$

In Eqs. (S37), we define hyperoperators $\times/\circ/C$ acting on the left (which is suggested by the position of the superscript) by the following equalities valid for any operator $O$

$$O \times V_j = [O, V_j], \quad (S38a)$$

$$O \circ V_j = \{O, V_j\}, \quad (S38b)$$

$$O C V_j = O V_j. \quad (S38c)$$
SIII. DERIVATION OF THE REDFIELD EQUATION COMPRISING PHOTOEXCITATION

We start from the central result of our analysis

\[
\rho_{ee}^{(I)}(t) = \int_{t_0}^{t} dt_2 \int_{t_0}^{t_2} dt_1 \tilde{\mathcal{U}}_{red}^{(I)}(t, t_2, \tau_1) A^{(I)}(t_2, \tau_1) + \text{H.c.} \tag{S39}
\]

and specialize to the case of excitation by a weak laser pulse. Taking time derivative of Eq. \((S39)\), we obtain

\[
\partial_t \rho_{ee}^{(I)}(t) = -\frac{i}{\hbar} \rho_{eg}^{(I)}(t) \mu_{ge}^{(I)}(t) \cdot \mathcal{E}^{(-)}(t) + \int_{t_0}^{t} dt_2 \int_{t_0}^{t_2} dt_1 \partial_t \tilde{\mathcal{U}}_{red}^{(I)}(t, t_2, \tau_1) A^{(I)}(t_2, \tau_1) + \text{H.c.} \tag{S40}
\]

The time derivative of the reduced evolution superoperator reads as

\[
\partial_t \tilde{\mathcal{U}}_{red}^{(I)}(t, t_2, \tau_1) = -\sum_j V_j^{(I)}(t) \times \\
\times T \left\{ \int_{t_0}^{t_2} ds \frac{C_j(s)}{\hbar^2} V_j^{(I)}(t - s)^\times + \int_{t_2}^{t - \tau_1} ds \frac{C_j(s)}{\hbar^2} V_j^{(I)}(t - s) C \right\} \tilde{\mathcal{U}}_{red}^{(I)}(t, t_2, \tau_1) \tag{S41}
\]

If we now assume that the characteristic decay time of the bath correlation function \(C_j(t)\) is short compared to the time scales of the dynamics we are interested in, we can formally set \(t - \tau_2 \rightarrow +\infty\). Then, the second integral on the right-hand side of Eq. \((S41)\) is equal to zero, while in the first integral we can invoke Markovian approximation, which enables us to formally move hyperoperators \(V_j^{(I)}(t - s)^\times/\circ\) in front of the \(T\) sign. Transferring back to the Schrödinger picture, we obtain

\[
\partial_t \rho_{ee}(t) = -\frac{i}{\hbar} [H_M, \rho_{ee}(t)] - \frac{i}{\hbar} \rho_{eg}(t) \mu_{ge} \cdot \mathcal{E}^{(-)}(t) + \frac{i}{\hbar} \mathcal{E}^{(+)}(t) \cdot \mu_{eg} \rho_{eg}(t) - \sum_j V_j^{\times} \left[ \Lambda_j \rho_{ee}(t) - \rho_{ee}(t) \Lambda_j^\dagger \right], \tag{S42}
\]

where

\[
\Lambda_j = \int_{0}^{+\infty} ds \frac{C_j(s)}{\hbar^2} e^{-iH_M s/\hbar} V_j e^{iH_M s/\hbar}. \tag{S43}
\]

In an analogous manner, we obtain the following second-order equation for optical coherences

\[
\partial_t \rho_{eg}(t) = -\frac{i}{\hbar} [H_M, \rho_{eg}(t)] + \frac{i}{\hbar} \mu_{eg} \cdot \mathcal{E}^{(+)}(t) |g\rangle \langle g| - \sum_j V_j \Lambda_j \rho_{eg}(t). \tag{S44}
\]

Further manipulations towards the Redfield equation take place in the excitonic basis \(\{|x\}\). These are quite standard and result in Eqs. (37) and (38) of the main text.
SIV. EXCITATION BY WEAK INCOHERENT LIGHT: LEVEL OF QUANTUM OPTICAL MASTER EQUATIONS

Here, we demonstrate in more detail how the excitation by weak incoherent light should be handled on the level of quantum optical master equations to produce the HEOM. We start from the general expression for $\rho^{(f)}_{ee}(t)$ [Eq. (S39)] in which we insert the following the radiation correlation function:

$$G_{ij}^{(1)}(\tau_2, \tau_1) = \delta_{ij} \frac{\hbar}{6\pi^2 \varepsilon_0 c^3} \int_0^{+\infty} d\omega \frac{\omega^3}{e^{\beta \hbar \omega} - 1} e^{i\omega(\tau_2 - \tau_1)}$$  \hspace{1cm} (S45)

to obtain

$$\rho^{(f)}_{ee}(t) = \int_{t_0}^{t} d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \, \mathcal{U}^{(f)}_{\text{red}}(t, \tau_2, \tau_1) \frac{1}{\hbar^2} \left[ \mu^{(f)}_{ee}(\tau_1) \cdot \mu^{(f)}_{ee}(\tau_2) \right] \frac{\hbar}{6\pi^2 \varepsilon_0 c^3} \int_0^{+\infty} d\omega \, \omega^3 n_{\text{BE}}(\omega, T_R) e^{i\omega(\tau_2 - \tau_1)} + \text{H.c.}$$  \hspace{1cm} (S46)

The radiation correlation function in Eq. (S45) is computed for the three-dimensional photon gas at temperature $T_R = (k_B \beta_R)^{-1}$, and $n_{\text{BE}}(\omega, T_R) = (e^{\beta \hbar \omega} - 1)^{-1}$.

As is usual when the interaction of matter with electromagnetic radiation is treated on the quantum optical level, further developments should be conducted in the eigenbasis of $H_M$, i.e., in the excitonic basis $\{|x\}\}$, whose basis vectors satisfy $H_M|x\rangle = \hbar \omega_x |x\rangle$. Introducing time intervals $t_1 = \tau_2 - \tau_1$ and $t_2 = t - \tau_2$, and transferring to the excitonic basis, we obtain

$$\rho^{(f)}_{ee}(t) = \frac{1}{\hbar^2} \sum_{\bar{x} \bar{x}} (\mu_{\bar{x}} \cdot \mu_{\bar{x}}) \int_{t_0}^{t-t_0} dt_2 e^{i\omega_x(t-t_2-t_0)} e^{-i\omega_x(t_2-t_0)} \int_0^{+\infty} d\omega \frac{\hbar}{6\pi^2 \varepsilon_0 c^3} \omega^3 n_{\text{BE}}(\omega, T_R) \times$$

$$\times \int_0^{t-t_0} dt_1 e^{i(\omega-\omega_x)t_1} \mathcal{U}^{(f)}_{\text{red}}(t, t-t_2-t-t_1 |\bar{x}\rangle \langle x|) + \text{H.c.}$$  \hspace{1cm} (S47)

Further steps are inspired by the Weisskopf–Wigner approximation. Namely, the integral over $t_1$ contains the phase factor $e^{i(\omega-\omega_x)t_1}$ that exhibits oscillatory behaviour unless $\omega \approx \omega_x$. By employing this approximation in Eq. (S47), the integral over $\omega$ reduces to

$$\int_0^{+\infty} d\omega \, e^{i\omega t_1} = \pi \delta(t_1) + i \mathcal{P} \left( \frac{1}{t_1} \right),$$  \hspace{1cm} (S48)

where $\mathcal{P}$ denotes the Cauchy principal value. In the spirit of Weisskopf–Wigner approximation, the part containing the principal-value sign is neglected, and the integration over $t_1$ is performed to arrive at

$$\rho^{(f)}_{ee}(t) = \sum_{\bar{x} \bar{x}} (\mu_{\bar{x}} \cdot \mu_{\bar{x}}) \int_{t_0}^{t} dt_2 \, \frac{\omega_x^3}{6\pi \varepsilon_0 \hbar c^3} n_{\text{BE}}(\omega, T_R) \mathcal{U}^{(f)}_{\text{red}}(t, \tau_2, \tau_2) e^{i\omega_x(\tau_2-t_0)} |\bar{x}\rangle \langle x| e^{-i\omega_x(\tau_2-t_0)} + \text{H.c.}$$  \hspace{1cm} (S49)

where we have also restored the interaction instant $\tau_2$ as the integration variable. It is now apparent that the quantum-optical limit is intimately connected to the white-noise model considered in the main text. In both cases, the coherence time of the radiation is assumed to be negligible compared to other relevant time scales in the problem, so that both interactions with the radiation take place at the same instant $\tau_2$.

The Hermitian conjugate of the first summand in the last equation is easily calculated by noting that the exact reduced propagator $\mathcal{U}^{(f)}_{\text{red}}(t, \tau_2, \tau_2)$, which actually propagates only the excited-state sector of the reduced density matrix, satisfies

$$A^\dagger \mathcal{U}^{(f)}_{\text{red}}(t, \tau_2, \tau_2) = \mathcal{U}^{(f)}_{\text{red}}(t, \tau_2, \tau_2) A,$$  \hspace{1cm} (S50)

for arbitrary purely electronic operator $A$. Introducing the spontaneous emission rate $\Gamma_x$ from excitonic state $|x\rangle$

$$\Gamma_x = \frac{1}{4\pi \varepsilon_0} \frac{4\omega_x^3 |\mu_x|^2}{3\hbar c^3},$$  \hspace{1cm} (S51)
the final result for the excited-state sector of the RDM in the interaction picture reads as

$$\rho^{(1)}_{ee}(t) = \int_{t_0}^{t} dt_2 \, \tilde{U}_{\text{red}}^{(1)}(t, t_2, T_2) \times$$

$$\times \sum_{x} \left[ \frac{\mu_x \cdot \mu_x^*}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R) + \frac{\mu_x \cdot \mu_x^* - i}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R) \right] e^{i \omega_x (t_2 - t_0)} |\bar{x}\rangle \langle x| e^{-i \omega_x (t_2 - t_0)}. \tag{S52}$$

One can now formulate in the usual manner the HEOM that replaces Eq. (S52). In doing so, we immediately realize that only the equation of motion for RDM has the source term describing the generation of excitations from the ground state, while ADMs do not possess such a term. In greater detail, the interaction-picture ADM labeled by vector \( n \) assumes the form

$$\sigma^{(1)}_{ee, n}(t) = \int_{t_0}^{t} dt_2 T \left\{ \prod_{j} \prod_{m} \left[ \int_{t_2}^{t} ds \, e^{-\nu_{j,m}(t-s)} \left( \frac{\epsilon_{j,m}}{\hbar^2} V_{j}^{(1)}(s) \times - \frac{\epsilon_{j,m}}{\hbar^2} V_{j}^{(1)}(s) \right) \right]^{n_{j,m}} \left[ U_{\text{red}}^{(1)}(t, t_2, \tau_2) \right] \right\} \times$$

$$\times \sum_{x} \left[ \frac{\mu_x \cdot \mu_x^*}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R) + \frac{\mu_x \cdot \mu_x^* - i}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R) \right] e^{i \omega_x (t_2 - t_0)} |\bar{x}\rangle \langle x| e^{-i \omega_x (t_2 - t_0)} \tag{S53}$$

while its equation of motion reads as

$$\partial_t \sigma_{ee, n}(t) = -\frac{i}{\hbar} [H_M, \sigma_{ee, n}(t)] - \left( \sum_j \sum_m n_{j,m} \mu_{j,m} \right) \sigma_{ee, n}(t)$$

$$+ \delta_{n,0} \sum_{xx} \left[ \frac{\mu_x \cdot \mu_x^*}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R) |\bar{x}\rangle \langle x| + \delta_{n,0} \sum_{xx} \left[ \frac{\mu_x \cdot \mu_x^* - i}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R) |\bar{x}\rangle \langle x| \right) \right] \times$$

$$\times \sum_{j} \sum_m \left[ V_{j}, \sigma_{ee, n_{j,m}^+}(t) \right] + i \sum_j \sum_m \left[ \epsilon_{j,m} V_{j} \sigma_{ee, n_{j,m}^-}(t) - \epsilon_{j,m} \sigma_{ee, n_{j,m}^-}(t) V_{j} \right]. \tag{S54}$$

In Eq. (S53), the generation of excited-state populations and intraband coherences from the ground state is described by the source terms containing excitonic dipole moments, spontaneous emission rates, and photon occupation numbers. The rate at which the population of excitonic state \( |\bar{x}\rangle \) is generated from the ground state assumes the familiar form

$$\left( \partial_t n_{xx}(t) \right)_{\text{source}} = \Gamma_x n_{\text{BE}}(\omega_x, T_R), \tag{S55}$$

where the spontaneous emission rate \( \Gamma_x \) is multiplied by the Bose–Einstein factor, which is characteristic for the absorption of one photon of energy \( \hbar \omega_x \). The rate at which the intraband coherence between excitonic states \( |\bar{x}\rangle \) and \( |x\rangle \) \((\bar{x} \neq x)\) is generated from the ground state contains factors \( \mu_x \cdot \mu_x \) describing the alignment of the corresponding transition dipole moments

$$\left( \partial_t n_{\bar{x}x}(t) \right)_{\text{source}} = \frac{\mu_x \cdot \mu_x^*}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R) + \frac{\mu_x \cdot \mu_x^* - i}{|\mu_x|^2} \frac{1}{2} \Gamma_x n_{\text{BE}}(\omega_x, T_R). \tag{S56}$$

Interestingly, these source terms are present exclusively in the equation for the RDM, as indicated by the presence of the Kronecker delta \( \delta_{n,0} \). At first sight, this is very different from the description of the light–matter interaction on the quantum-optical level in, e.g., Ref. 14, which is inspired by the combined Born–Markov–HEOM approach developed in Ref. 13. There, each level of the hierarchy contains source terms similar to the ones we encounter in Eq. (S53) on the level of the RDM. Moreover, the quantum-optical source terms in Ref. 14 also feature the radiative recombination terms, which deplete excited-state populations and increase the ground-state population.

The reason for such differences lies in the fact that our treatment of the photoexcitation process starts from the unexcited system and is consistently up to the second order in the exciting field. Within our approximations, the ground-state population is always close to 1, while the excited-state populations are at least quadratic in the weak exciting field and are much smaller than 1, compared to the scaling laws under semiclassical light–matter interactions [Eqs. (13)] presented in the main text. We have already used similar arguments in the main text to transform the HEOM that does not take into account scaling laws to the HEOM that is consistently up to the second order in the optical field. Here, on the quantum-optical level, the generation rate of excited-state populations, Eq. (S55), implicitly contains our assumption that, at all times, the ground-state population differs from 1 by a quantity that is at least quadratic in the exciting field. Similar terms for higher-tier ADOs are absent in our treatment simply because their ground-state expectation values are approximately 0 at all times. In a similar vein, our treatment cannot capture radiative recombination from excited states because that process is at least of the fourth order in the field.
