REGULARITY OF FULLY NON-LINEAR ELLIPTIC EQUATIONS
ON HERMITIAN MANIFOLDS. II

RIRONG YUAN

ABSTRACT. In this paper we investigate the solvability and regularity of solutions
to Dirichlet problem for a class of fully non-linear elliptic equations with gradient
terms on Hermitian manifolds. Some significantly new features of the regularity
assumptions on the boundary and boundary data are obtained, which reveal
how the shape of the boundary influences such regularity assumptions. Such new
features follow from quantitative boundary estimates which specifically enable us
to apply a blow-up argument to derive the gradient estimate when the boundary
is holomorphically flat. Also, a direct proof of gradient estimate is obtained un-
der suitable assumptions. Interestingly, the subsolutions are constructed when the
background space is moreover a product of a closed Hermitian manifold with a
compact Riemann surface supposing boundary. Finally we also study the regularity
and solvability of the solution to Dirichlet problem for Monge-Ampère equation for
\((n - 1)\)-plurisubharmonic functions associated to Gauduchon’s conjecture.

1. INTRODUCTION

Let \((M, J, \omega)\) be a compact Hermitian manifold of complex dimension \(n \geq 2\) possibly with boundary, and 
\(\omega = \sqrt{-1} g_{ij} dz^i \wedge d\bar{z}^j\) denote the Kähler form being compatible with complex structure \(J\).

This paper is primarily devoted to investigating second order fully nonlinear elliptic equations of the form

\[
F(\mathfrak{g}[u]) := f(\lambda(\mathfrak{g}[u])) = \psi \text{ in } M.
\]

In addition if \(M\) has boundary \(\partial M\), \(\bar{M} := M \cup \partial M\), we study equation (1.1) with the prescribing boundary data

\[
u = \varphi \text{ on } \partial M.
\]

Here \(\psi\) and \(\varphi\) are sufficiently smooth functions, \(\lambda(\mathfrak{g}[u])\) are eigenvalues of \(\mathfrak{g}[u]\) with respect to \(\omega\), and the real (1, 1)-form in the equation has the form

\[
\mathfrak{g}[u] = \tilde{\chi} + \sqrt{-1} \partial u \wedge \eta^{1,0} + \sqrt{-1} \eta^{1,0} \wedge \partial u + \sqrt{-1} \partial \bar{\partial} u,
\]

where \(\tilde{\chi}\) is a smooth real (1,1)-form and \(\eta^{1,0} = \eta_i dz^i\) is a smooth (1,0)-form on the background Hermitian manifold. Here, we write \(\eta_i = \bar{\eta}_i\). For simplicity, we denote

\[
\chi[u] := \chi(z, \partial u, \bar{\partial} u) = \tilde{\chi} + \sqrt{-1} \partial u \wedge \eta^{1,0} + \sqrt{-1} \eta^{1,0} \wedge \partial u.
\]

The deformation of this type is reasonable and applicable, since one may apply it to deform Aeppli cohomology class so that it obeys prescribed appropriate property. (See also Remark 4.13 below). Moreover, the form \(\chi[u]\) satisfies (3.11) below and then automatically satisfies the assumption (1.6) in [82], which plays a key role in the proof of global second order estimate.

The study of equations generated by symmetric functions of eigenvalues goes back to the work of Caffarelli-Nirenberg-Spruck [11] concerning the Dirichlet problem in bounded domains of \(\mathbb{R}^n\), and to the work of Ivochkina [54] which considers some special cases. As in [11], \(f\) is a smooth symmetric function defined in an open symmetric and convex cone \(\Gamma\) with vertex at the origin, \(\Gamma_n \subseteq \Gamma \subset \mathbb{R}^n\) and the boundary \(\partial \Gamma \neq \emptyset\),
where \( \Gamma_n := \{ \lambda \in \mathbb{R}^n : \sigma_k(\lambda) > 0 \text{ for each } 1 \leq k \leq n \} \), and
\[
\sigma_k(\lambda) = \sum_{1 \leq i_1 < i_2 < \cdots < i_k \leq n} \lambda_{i_1} \cdots \lambda_{i_k}.
\]

Moreover, \( f \) satisfies the following fundamental conditions:

(1.4) \[
f_i := f_{\lambda_i}(\lambda) = \frac{\partial f}{\partial \lambda_i}(\lambda) > 0 \text{ in } \Gamma, \quad 1 \leq i \leq n,
\]

(1.5) \( f \) is concave in \( \Gamma \),

(1.6) \[
\delta_{\psi,f} := \inf_{M} \psi - \sup_{\partial \Gamma} f > 0,
\]

where
\[
\sup f := \sup_{\partial \Gamma} \lim_{\lambda_{0} \rightarrow \lambda_{0}} f(\lambda).
\]

In order to study equation (1.1) within the framework of elliptic equations, we shall look for solutions in the class of \( C^2 \)-admissible functions \( u \) satisfying \( \lambda(g[u]) \in \Gamma \). The constant \( \delta_{\psi,f} \) measures whether or not the equation is degenerate. More explicitly, if \( \delta_{\psi,f} > 0 \) (respectively, \( \delta_{\psi,f} \) vanishes) then the equation is called non-degenerate (respectively, degenerate). Moreover, \( \sup_M \psi < \sup_{\Gamma} f \) is necessary for the solvability of equation (1.1) within the framework of elliptic equations, which is automatically satisfied when \( \sup_{\Gamma} f = +\infty \) or there is a subsolution satisfying (1.8) or (1.9).

If the boundary is supposed to be holomorphically flat\(^*\) in the sense that there exist holomorphic coordinates \((z_1, \cdots, z_n)\) such that \( \partial M \) is locally given by \( \Re(z_n) = 0 \), as in [84], we assume

(1.7) \[
\text{For each } \sigma < \sup_{\Gamma} f \text{ and } \lambda \in \Gamma, \quad \lim_{t \rightarrow +\infty} f(t\lambda) > \sigma,
\]

so that one can apply Székelyhidi’s [72] Liouville type theorem extending a result of Dinew-Kołodziej [24] to set up gradient estimate by using a blow-up argument. Such a condition is satisfied by many symmetric functions arising from differential geometry and fully nonlinear equations, including homogenous functions of degree one with \( f|_{\Gamma} > 0 \), or the functions with \( \Gamma = \Gamma_n \). We remark further that, from the viewpoint of geometry, it is natural to study functions being of the form \( f(t\lambda) = H(t,f(\lambda)) \) when one rescales \( \omega \) by \( t^{-1} \omega \), where \( \frac{\partial H}{\partial \sigma}(t,\sigma) > 0 \) for \( t > 0 \) and \( \sigma \in (\sup_{\partial \Gamma} f, \sup_{\Gamma} f) \).

A notion of subsolution is used to study fully nonlinear equations of this type. For the Dirichlet problem, we call \( u \) an admissible subsolution if it is an admissible function \( u \in C^2(\bar{M}) \) satisfying

(1.8) \[
f(\lambda(g[u])) \geq \psi \text{ in } \bar{M}, \text{ and } u = \varphi \text{ on } \partial M.
\]

Such an admissible subsolution is a key ingredient in deriving a priori estimates, especially the boundary estimate for the Dirichlet problem (cf. [44, 52, 37]), moreover, it relaxes geometric restrictions to boundary and so plays important roles in some

\(^*\)See also [13] for Cartan’s theorem on characterization of real analytic Levi flat hypersurfaces.
geometric problems (cf. [14, 47, 49]). Condition (1.14) is introduced in this paper to construct the admissible subsolutions when the background space is a product of a closed Hermitian manifold with a compact Riemann surface with boundary.

Recently, influenced by the work of Guan [38], an extended notion of a subsolution was proposed by Székelyhidi [72]. Following Székelyhidi, a $C^2$ function $u$ is a $C^1$-subsolution of equation (1.1), if for each point $z \in \bar{M}$ the set $(\lambda(\mathfrak{g}(u)(z)) + \Gamma_n) \cap \partial \Gamma_{\psi(z)}$ is bounded, where $\partial \Gamma_{\sigma} = \{ \lambda \in \Gamma : f(\lambda) = \sigma \}$ denotes the level hypersurface. Namely,

\begin{equation}
\lim_{t \to +\infty} f(\lambda(\mathfrak{g}(u)(z)) + t e_i) > \psi, \text{ in } \bar{M} \text{ for each } i = 1, \cdots, n,
\end{equation}

where $e_i$ is the $i$-th standard basis vector. The notion of a $C$-subsolution turns out to be applicable for the setting of closed manifolds (cf. [72, 73, 20]). For the $J$-flow introduced by Donaldson [26] and by Chen [15] independently, it is exactly same as the condition (1.6) of Song-Weinkove [70] (see Fang-Lai-Ma [28] for its extension to complex inverse $\sigma_k$ flow). It would be worthwhile to note that an admissible subsolution is indeed a $C$-subsolution. Also, we apply the $C$-subsolutions of rescaled equations to derive in Theorem 6.7 the gradient estimate directly for some equations.

The most important equation of this type is perhaps the complex Monge-Ampère equation corresponding to $f(\lambda) = (\sigma_n(\lambda))^{\frac{1}{n}}$ that is closely related to Calabi’s conjecture. In his celebrated work [81], Yau proved Calabi’s conjecture and obtained Calabi-Yau theorem on the prescribed volume form which in particular implies each closed Kähler manifold of vanishing first Chern class endows with a Ricci flat Kähler metric. Yau also showed in the same paper that every closed Kähler manifold of $c_1(M) < 0$ admits a unique Kähler-Einstein metric in the original Kähler class, which was also proved independently by Aubin [2]. Another fundamental work concerning complex Monge-Ampère equation was done by Bedford-Taylor [3, 4] on weak solutions and pluripotential theory, and by Caffarelli-Kohn-Nirenberg-Spruck [10] who treated with Dirichlet problem for complex Monge-Ampère equation on a strictly pseudoconvex domain in $\mathbb{C}^n$ ($\chi = 0$, $\eta^{1,0} = 0$). Since then complex Monge-Ampère equation and more general fully nonlinear elliptic equations on complex manifolds have been studied extensively in literature (cf. [14, 15, 20, 24, 26, 28, 37, 40, 42, 45, 47, 53, 56, 70, 71, 72, 75, 76, 86, 87] and references therein).

Due to the importance and interest of Calabi-Yau theorem in Kähler geometry, algebraic geometry and mathematical physics, some generalizations of Calabi-Yau theorem for other special non-Kähler metrics, including Gauduchon and balanced metrics introduced in [34, 62], have been studied by many specialists over the past several decades. We are also guided towards in Section 8 the study of Dirichlet problem of Monge-Ampère equation for $(n-1)$-plurisubharmonic functions associated with Gauduchon’s conjecture, which is very different from that of Dirichlet problem (1.1)-(1.2). More precisely, we show Dirichlet problem (8.5) is solvable, provided that there is a subsolution and the background space is moreover a product of a closed Hermitian manifold with a compact Riemann surface with boundary. Furthermore,
such subsolutions are constructed if the factor of the background product manifold supposes a balanced metric.

1.1. Main results. The primary procedure to solve the Dirichlet problem is to prove gradient estimate, which is, however, open for general equations. In this paper we achieve it and solve Dirichlet problem under appropriate assumptions.

**Theorem 1.1.** Let $\partial M \subset C^\infty$ be pseudoconcave in the sense that Levi form of $\partial M$ is nonpositive, $\psi \in C^\infty(M)$ and $\varphi \in C^\infty(\partial M)$. Suppose, in addition to (1.4), (1.5), (1.6), that Dirichlet problem (1.1)-(1.2) admits an admissible subsolution $u \in C^{2,1}(M)$. Suppose in addition that one of the following three conditions is satisfied

1. The function $f$ satisfies (1.7), and $\partial M$ is further assumed to be holomorphically flat.
2. $(M, \omega)$ is a compact Kähler manifold with nonnegative orthogonal bisectional curvature.
3. The corresponding cone of $f$ is $\Gamma_n$, and there is $w \in C^2(\bar{M})$ such that

$$\lim_{t \to +\infty} f\left(\frac{1}{3}(\lambda(g|w|) + te_i)\right) \geq \psi \text{ for each } i, \text{ in } \bar{M}.$$  

Then the Dirichlet problem admits a unique smooth admissible solution $u$ with

$$\sup_M \Delta u \leq C,$$

where $\Delta$ is the complex Laplacian operator with respect to $\omega$, $C$ is a uniformly positive constant depending on $\partial M$ up to its third order derivatives, $|\varphi|_{C(M)}$, $\sup_M |\nabla \psi|$, $\inf_{z \in M} \inf_{\xi \in T_{1,0}^1 M, |\xi|=1} \partial \bar{\partial} \psi(\xi, \bar{\xi})$ and other known data but not on $(\delta_{\psi,f})^{-1}$. In particular, if $\partial M$ is holomorphically flat and $\varphi \equiv$ constant then $C$ depends on $\partial M$ up to second order derivatives and other known data.

**Remark 1.2.** Throughout this paper we say a constant $C$ does not depend on $(\delta_{\psi,f})^{-1}$ if it remains uniformly bounded as $\delta_{\psi,f}$ tends to zero, while we say a constant $\kappa$ depends not on $\delta_{\psi,f}$ if $\kappa$ has a uniformly positive lower bound as $\delta_{\psi,f} \to 0$. Moreover, in the theorems, we assume that the function $\varphi$ is extended to $\bar{M}$ with the same regularity, still denoted $\varphi$.

We can study degenerate equations by applying approximation, since the estimate is independent of $(\delta_{\psi,f})^{-1}$ when $\partial M$ is pseudoconcave. For purpose of solving degenerate equation, condition (3) should be replaced by a slightly stronger condition:

(3) The corresponding cone $\Gamma$ of $f$ is $\Gamma_n$, and there is $w \in C^2(\bar{M})$ such that

$$\lim_{t \to +\infty} f\left(\frac{1}{3}(\lambda(g|w|) + te_i)\right) > \psi \text{ for each } i, \text{ in } \bar{M}.$$  

**Theorem 1.3.** Let $\psi \in C^{1,1}(\bar{M})$, $\varphi \in C^{2,1}(\partial M)$ and $f \in C^\infty(\Gamma) \cap C(\bar{\Gamma})$, $\bar{\Gamma} = \Gamma \cup \partial \Gamma$. Suppose there is a strictly admissible subsolution satisfying for some $\delta_0 > 0$

$$f(\lambda(g|u|)) \geq \psi + \delta_0 \text{ in } \bar{M}, \ u = \varphi \text{ on } \partial M.$$
Suppose in addition that \( u \in C^{2,1}(\bar{M}) \) and \( \partial M \) is smooth pseudoconcave boundary. Then Dirichlet problem (1.1)-(1.2) for degenerate equations with (1.4), (1.5) and \( \delta_{\psi,j} = 0 \) supposes a (weak) solution \( u \in C^{1,\alpha}(\bar{M}) \), \( \forall 0 < \alpha < 1 \), with \( \lambda(\mathcal{g}[u]) \in \bar{\Gamma} \) and \( \Delta u \in L^\infty(\bar{M}) \), provided that one of (1), (2), (3)' holds.

For purpose of investigating the equations on complex manifolds with less regular boundary, we need to seek those manifolds which allow us to apply Theorem 1.1 to do the submanifold/domain approximation.

Clearly, there are two types of complex manifolds that fulfill the request. That is \( M = X \times S \) (or more generally \( M \) is as mentioned in Theorem 1.6 below), or the manifold whose boundary is strictly pseudoconcave. For the equations on such manifolds, the boundary estimates in Theorems 4.2, 4.3 and 4.4 enable us to further weaken the regularity assumptions on \( \varphi \) and \( \partial M \), since the corresponding structure (near the boundary) of such manifolds is stable under the approximation.

Without specific clarification we assume throughout this paper that \( X \) is a closed complex manifold and \( S \) is a compact Riemann surface with boundary, and \( \nu \) denotes the unit inner normal vector along the boundary.

**Theorem 1.4.** Suppose \( M = X \times S \) (or more generally \( M \) is as mentioned in Theorem 1.6 below but with \( \partial M_i \) converge to \( \partial M \) in the \( C^{2,1} \) norm), or \( \partial M \) is strictly pseudoconcave. Suppose in addition that \( \partial M \in C^3 \), \( \varphi \in C^3(\partial M) \), \( \psi \in C^2(\bar{M}) \) and the other assumptions of Theorem 1.1 hold. Then Dirichlet problem (1.1)-(1.2) admits a unique admissible solution \( u \in C^{2,\alpha}(\bar{M}) \) for some \( 0 < \alpha < 1 \). Moreover, the solution \( u \) satisfies (1.11).

**Theorem 1.5.** Let \( M \) be as in Theorem 1.4 but we assume \( \partial M \in C^{2,1} \). Suppose in addition that the other assumptions of Theorem 1.3 hold. Then the Dirichlet problem has a (weak) solution \( u \in C^{1,\alpha} \) (\( \forall 0 < \alpha < 1 \)) with \( \lambda(\mathcal{g}[u]) \in \bar{\Gamma} \) and \( \Delta u \in L^\infty(\bar{M}) \).

A somewhat remarkable fact to us is that, the regularity assumptions on boundary and boundary data can be further weakened under certain assumptions, which extends extensively a result of [84] to general settings.

The motivation is mainly based on the estimates which state that

- If \( \partial M \) is holomorphically flat and boundary value is furthermore a constant, then the constant in quantitative boundary estimate (2.4) below depends only on \( \partial M \) up to its second derivatives and other known data (see Theorem 1.3).
- If we furthermore assume \( M = X \times S \) and the boundary data \( \varphi \in C^2(\partial S) \), then the constant in (2.4) is bounded from above by a positive constant depending on \( |\varphi|_{C^2(\bar{S})} \), \( |\psi|_{C^1(\bar{M})} \), \( |u|_{C^2(\bar{M})} \), \( \partial S \) up to its second derivatives and other known data (see Theorem 1.4).

Besides, we can use a result due to Silvestre-Sirakov [69] to derive the \( C^{2,\alpha} \) boundary regularity with only assuming \( C^{2,\beta} \) boundary.
**Theorem 1.6.** Let $(M, J, \omega)$ be a compact Hermitian manifold with $C^{2,\beta}$ boundary which additionally satisfies that, for any sequence of smooth complex submanifolds $\{M_i\}$ (with the same complex dimension) whose boundaries $\partial M_i$ converge to $\partial M$ in the $C^{2,\beta}$ norm, there is $N \gg 1$ such that $\partial M_i$ is holomorphically flat for any $i \geq N$. Suppose in addition that (1.4), (1.5), (1.6), (1.7) and $\psi \in C^2(M)$. Then Dirichlet problem (1.1)-(1.2) with homogeneous boundary data $u|_{\partial M} = 0$ supposes a unique $C^{2,\alpha}$ admissible solution for some $0 < \alpha \leq \beta$, provided that either the Dirichlet problem has a $C^{2,\beta}$ admissible subsolution with $\frac{\partial}{\partial \nu} u|_{\partial M} \leq 0$ or $\frac{\partial}{\partial \nu} u|_{\partial M} \geq 0$. In particular, $u = 0$ if $\lambda(\tilde{\chi}) \in \Gamma$ and $\psi \leq f(\lambda(\tilde{\chi}))$.

**Theorem 1.7.** Let $(M, J, \omega)$ be as mentioned in Theorem 1.6 Suppose, in addition to (1.4), (1.5), (1.7), that $f \in C^\infty(\Gamma) \cap C(\bar{\Gamma})$ and $\psi \in C^{1,\lambda}(M)$ is a function with $\delta \psi, f = 0$. Suppose that the Dirichlet problem has a $C^{2,\beta}$ strictly admissible subsolution with $\frac{\partial}{\partial \nu} u|_{\partial M} \leq 0$ or $\frac{\partial}{\partial \nu} u|_{\partial M} \geq 0$. Then the Dirichlet problem with homogeneous boundary data admits a (weak) solution $u \in C^{1,a}(M), \forall 0 < \alpha < 1$, with $\lambda(g[u]) \in \bar{\Gamma}$ and $\Delta u \in L^\infty(M)$.

**Corollary 1.8.** Let $M$ be the complex manifold as mentioned in Theorem 1.6. Suppose, in addition to (1.4), (1.5) and $\lambda(\tilde{\chi}) \in \Gamma$, that $f$ is a homogeneous function of degree one with $f|_{\partial M} = 0$. Then $f(\lambda(g[u])) = 0$ with $u|_{\partial M} = 0$ supposes a weak solution $u \in C^{1,\alpha}(M) (\forall 0 < \alpha < 1)$, with $\lambda(g[u]) \in \Gamma$ and $\Delta u \in L^\infty(M)$.

The construction of subsolutions is a key ingredient to solve the Dirichlet problem according to the above theorems.

If one could construct a function $h$ with satisfying $h|_{\partial M} = 0$, $g[h] - \tilde{\chi} \geq 0$ and $\text{rank}(g[h] - \tilde{\chi}) \geq 1$, which is extremely hard to construct in general, then one may use it to construct subsolutions.

In this paper, we construct the subsolutions by considering the special case that $\text{rank}(g[h] - \tilde{\chi}) = 1$. The key ingredient is that if $\text{rank}(g[h] - \tilde{\chi}) = 1$ then it corresponds to second order linear elliptic operator. This naturally leads to an interesting case that the background space is a product $(M, J, \omega) = (X \times S, J, \omega)$ of a closed Hermitian manifold with a compact Riemann surface supposing boundary, which equips with the natural induced complex structure $J$ and Hermitian metric $\omega$ compatible with $J$.

Given boundary data $\varphi \in C^2(\partial M)$, we are able to construct (strictly) admissible subsolutions with $\frac{\partial}{\partial \nu} u|_{\partial M} < 0$, provided $\eta^{1,0} = \pi_2^* \eta_S^{1,0}$ and there is $w \in \mathfrak{F}(\varphi)$ such that

$$\lim_{t \to +\infty} f(\lambda(g[w] + t\pi_2^* \omega_S)) > \psi \text{ in } \bar{M}.$$  

Where $\pi_2: X \times S \to S$ is the nature projection, $\omega_S$ is Kähler form on $S$, $\eta_X^{1,0}$ and $\eta_S^{1,0}$ are respectively smooth $(1,0)$-forms on $X$ and $S$, and

$$\mathfrak{F}(\varphi) = \{ w \in C^2(\bar{M}) : w|_{\partial M} = \varphi, \lambda(g[w] + c\pi_2^* \omega_S) \in \Gamma \text{ in } \bar{M} \text{ for some } c > 0 \}.$$  

The subsolution is given by

$$u = w + N\pi_2^* h$$
for $N \gg 1$ ($\pi_2^* h = h \circ \pi_2$, still denoted by $h$ for simplicity), where $h$ is the solution to
\begin{equation}
(1.16) \quad \sqrt{-1} \partial \overline{\partial} h + \sqrt{-1} \partial h \wedge \eta_S^0 + \sqrt{-1} \eta_S^{1,0} \wedge \overline{\partial} h = \omega_S \text{ in } S, \quad h = 0 \text{ on } \partial S.
\end{equation}
In the local coordinate $z_n = x_n + \sqrt{-1} y_n$ of $S$, Dirichlet problem (1.16) reduces to
\begin{equation}
\Delta h + \frac{\eta_S}{g_S} \frac{\partial h}{\partial z_n} + \frac{\eta_S}{g_S} \frac{\partial h}{\partial \bar{z}_n} = 1 \text{ in } S, \quad h = 0 \text{ on } \partial S,
\end{equation}
where $\omega_S = \sqrt{-1} g_S dz_n \wedge d\bar{z}_n$, $\eta_S^{1,0} = \eta_S dz_n \wedge d\bar{z}_n$, and $\Delta = \frac{1}{g_S} \frac{\partial^2}{\partial z_n \partial \bar{z}_n}$ is the complex Laplacian operator with respect to $\omega_S$. In particular, if $\eta_S^{1,0} = 0$ then
\begin{equation}
(1.17) \quad \Delta h = 1 \text{ in } S, \quad h = 0 \text{ on } \partial S.
\end{equation}

According to the theory of elliptic equations, if $\partial S \in C^{2, \beta}$, Dirichlet problem (1.16) is uniquely solvable in the class of $C^{2, \beta}$ functions, and the maximum principle further implies $h|_{\partial S} < 0$, $\frac{\partial h}{\partial n}|_{\partial S} < 0$. Thus $g[u] = g[w] + N \pi_2^* \omega_S$, and $\frac{\partial g[u]}{\partial n} < 0$ if $N \gg 1$.

In contrast with the condition (1.6) of [70] for $J$-flow, cone condition in [28] for complex inverse $\sigma_k$ flow as well as the notion of $C$-subsolution, our condition (1.14) allows us to consider the asymptotic behavior along the only one direction $\pi_2^* \omega_S$. Condition (1.14) is always satisfied, if $\mathcal{F}(\varphi) \neq \emptyset$ (which is necessary for the solvability of Dirichlet problem within the framework of elliptic equations) and
\begin{equation}
(1.18) \quad \lim_{t \to +\infty} f(\lambda + te_i) > \sigma, \quad \text{for each } \lambda < \sup_{\Gamma} f, \quad \forall \lambda \in \Gamma, \quad \forall i = 1, \ldots, n.
\end{equation}

In the special case if $\varphi \in C^2(\partial S)$, $\eta_1^{1,0} = \pi_2^* \eta_S^{1,0}$ and $\lambda(\tilde{\chi} + c \pi_2^* \omega_S) \in \Gamma$ for some $c > 0$, then for each function $w \in C^2(S)$ with $w|_{\partial S} = \varphi$, $w$ always lies in $\mathcal{F}(\varphi)$, and moreover (1.14) can be derived from
\begin{equation}
(1.19) \quad \lim_{t \to +\infty} f(\lambda(\tilde{\chi} + t \pi_2^* \omega_S)) > \psi \text{ in } \bar{M}.
\end{equation}

From Theorem 5.1 below, such a condition guarantees the solvability in this special case when $\varphi \in C^2(\partial S)$.

Significantly, if $\omega = \pi_1^* \omega_X + \pi_2^* \omega_S$, $\tilde{\chi}$ splits into $\tilde{\chi} = \pi_1^* \tilde{\chi}_1 + \pi_2^* \tilde{\chi}_2$, where $\omega_X$ is the Kähler form on $X$, $\tilde{\chi}_1$ is a real (1,1)-form on $X$, $\tilde{\chi}_2$ is a real (1,1)-form on $S$, and $\pi_1: X \times S \to X$ denotes the nature projection, by Lemma 2.2 condition (1.19) then reduces to
\begin{equation}
(1.20) \quad \lim_{t \to +\infty} f(\lambda(\omega_X(\tilde{\chi}_1)) + t) > \psi \text{ in } \bar{M}, \quad \text{and } \lambda(\omega_X(\tilde{\chi}_1)) \in \Gamma_{\infty},
\end{equation}
where $\lambda(\omega_X(\tilde{\chi}_1))$ are the eigenvalues of $\tilde{\chi}_1$ with respect to $\omega_X$, as in Trudinger [74] $\Gamma_{\infty} = \{(\lambda_1, \ldots, \lambda_{n-1}) \in \mathbb{R}^{n-1} : (\lambda_1, \ldots, \lambda_{n-1}, c) \in \Gamma \text{ for some } c > 0\}$ denotes the projection of $\Gamma$ onto $\mathbb{R}^{n-1}$. This shows that, if $\tilde{\chi} = \pi_1^* \tilde{\chi}_1 + \pi_2^* \tilde{\chi}_2$, the solvability of Dirichlet problem is then heavily determined by $\tilde{\chi}_1$ rather than by $\tilde{\chi}_2$.

Together with Theorem 5.1 below, Theorems 1.6 and 1.7 and the construction of subsolutions immediately lead to
Theorem 1.9. Let \((M, J, \omega) = (X \times S, J, \omega)\) be as mentioned above. Let \(\partial S \in C^{2,\beta}\), \(\varphi \in C^{2,\beta}(\partial S)\), \(\eta^{1,0} = \pi_{2}^{*}\eta_{S}^{1,0}\), and \(f\) satisfy (1.4), (1.5) and (1.7). Suppose in addition that (1.14) holds for some \(w \in C^{2,\beta}(M) \cap \mathfrak{F}(\varphi)\). Then we have the following two conclusions:

- Equation (1.1) has a unique \(C^{2,\alpha}\) admissible solution with \(u|_{\partial M} = \pi_{2}^{*}\varphi = \varphi \circ \pi_{2}\) (still denoted by \(u|_{\partial M} = \varphi\) for convenience) for some \(0 < \alpha \leq \beta\), provided \(\psi \in C^{2}(M)\) and \(\inf_{M} \psi > \sup_{\partial M} f\).
- Suppose furthermore \(f \in C^{\infty}(\Gamma) \cap C(\bar{\Gamma})\), \(\psi \in C^{1,1}(\bar{M})\) and \(\inf_{M} \psi = \sup_{\partial M} f\). Then the Dirichlet problem has a weak solution \(u \in C^{1,\alpha}(\bar{M})\), \(\forall \alpha < 1\), with \(u|_{\partial M} = \varphi\), \(\lambda(g|u|) \in \bar{\Gamma}\) and \(\Delta u \in L^{\infty}(M)\).

If we assume \(\varphi \in C^{3}(\partial M)\) instead of \(\varphi \in C^{2,\beta}(\partial S)\), we also obtain

Theorem 1.10. Let \((M, J, \omega) = (X \times S, J, \omega)\), \(\partial S \in C^{3}\), be as mentioned above, we suppose the given data satisfies \(\varphi \in C^{3}(\partial M)\), \(\eta^{1,0} = \pi_{2}^{*}\eta_{S}^{1,0}\), \(\psi \in C^{2}(\bar{M})\). Suppose, in addition to (1.4), (1.5), (1.6), (1.7), that there is a \(w \in C^{2,1}(M) \cap \mathfrak{F}(\varphi)\) to satisfy (1.14). Then Dirichlet problem (1.1)-(1.2) admits a unique \(C^{2,\alpha}\) admissible solution for some \(0 < \alpha < 1\). In particular, the solution is smooth, if the given data \(\varphi, \psi, \partial S\) are all smooth.

Theorem 1.11. Let \((M, J, \omega) = (X \times S, J, \omega)\), \(\partial S \in C^{2,1}\), be as mentioned above. Assume \(\varphi \in C^{2,1}(\partial M)\), \(\psi \in C^{1,1}(M)\), \(\eta^{1,0} = \pi_{2}^{*}\eta_{S}^{1,0}\), \(f \in C^{\infty}(\Gamma) \cap C(\bar{\Gamma})\) and \(f\) satisfies (1.4), (1.5), (1.7) and \(\inf_{M} \psi = \sup_{\partial M} f\). Suppose in addition that (1.14) holds for \(w \in C^{2,1}(M) \cap \mathfrak{F}(\varphi)\). Then the Dirichlet problem for degenerate equation has a weak solution \(u \in C^{1,\alpha}(M)\), \(\forall \alpha < 1\), with \(\lambda(g|u|) \in \bar{\Gamma}\) and \(\Delta u \in L^{\infty}(M)\).

Applying each one of Theorems 1.3, 1.5 and 1.11 to Dirichlet problem for homogeneous complex Monge-Ampère equation on \(M = X \times A\), where \(A = S^{1} \times [0, 1]\) and \(X\) is a closed Kähler manifold, one immediately obtains Chen’s [14] result on the existence and regularity of weak solutions of geodesic equations in the space of Kähler metrics [28, 68, 60]. See for instance [11, 16, 27, 58, 65] for complement and the progress on understanding how the geodesics, homogeneous complex Monge-Ampère equation, are related the geometry of \(X\). Hopefully, our argument can be applied to some geometric partial differential equations arising from differential geometry.

Remark 1.12. The construction of subsolutions applies to certain fibered manifolds.

Remark 1.13. We emphasize the geometric quantities of \((M, \omega)\) (curvature \(R_{i j k l}\) and the torsion \(T_{ij}^{k}\)) keep bounded as approximating to \(\partial M\), and all derivatives of \(\bar{\chi}_{i j}\) and \(\eta^{1,0}\) have continues extensions to \(\bar{M}\), whenever \(M\) has less regularity boundary. Typical examples are as follows: \(M \subset M'\), \(\dim_{\mathbb{C}}M' = n\), \(\omega = \omega_{M'}|_{M}\) and the given data \(\bar{\chi}, \eta^{1,0}\) can be smoothly defined on \(M'\).

1.2. Some significant phenomena on regularity assumptions. When \(M = X \times S\) or \(\partial M\) is strictly pseudoconcave, for purpose of solving Dirichlet problem of
degenerate equations, we only need to assume \( \varphi \in C^{2,1} \) and \( \partial M \in C^{2,1} \) according to Theorem 1.5. Such regularity assumptions on the boundary and boundary data are impossible for homogeneous Monge-Ampère equation on certain bounded domains in \( \mathbb{R}^n \) as shown by some counterexamples in Caffarelli-Nirenberg-Spruck [12] who show that the \( C^{3,1} \)-regularity assumptions on the boundary and boundary data are optimal for the optimal \( C^{1,1} \) global regularity of the weak solution to homogeneous real Monge-Ampère equation on \( \Omega \). (For a strictly convex domain and the homogeneous boundary data \( \varphi = 0 \), Guan [46] proved that \( \partial \Omega \) can be weakened to be \( C^{2,1} \)). Such a new phenomenon follows from Theorem 4.2 which states that if the boundary is not holomorphically flat but more generally pseudoconcave the second order derivatives of solutions on the boundary are bounded by constants depending only on boundary data \( \varphi, \partial M \) up to their third order derivatives and other known data, but not on \( (\delta_{\psi,f})^{-1} \). Theorem 1.11 gives specific examples to support this new feature.

We find another significant phenomenon on regularity assumption on boundary the boundary data. More precisely, when \( M = X \times S \) and the boundary data only varies along \( \partial S \) (which is independent of \( X \)), the regularity of \( \partial M \) and \( \varphi \) can be weakened to be \( C^{2,\beta} \); while such \( C^{2,\beta} \) regularity assumptions on the boundary and boundary data are impossible even for Dirichlet problem of nondegenerate real Monge-Ampère equation on certain bounded domains \( \Omega \subset \mathbb{R}^2 \), as shown by Wang [80] the optimal regularity assumptions on the boundary and boundary data are both \( C^3 \)-smooth for such real Monge-Ampère equations. More precisely, Wang’s counterexamples implies that if \( \partial \Omega \) or \( \varphi \) is only \( C^{2,1} \) smooth, the solution to real Monge-Ampère equation on \( \Omega \) may fail to be \( C^2 \) smooth near the boundary. Furthermore, as shown in Caffarelli-Nirenberg-Spruck [12], the assumption of \( \partial M \in C^{2,\beta} \) is also impossible for Dirichlet problem of homogeneous Monge-Ampère equation on certain bounded domains in \( \mathbb{R}^n \). Theorem 1.9 and Corollary 1.8 show specific examples to support the surprising phenomenon. We also have new phenomenon on regularity assumption on boundary in Theorems 1.6 and 1.7 where the boundary data is constant.

The new features also indicate an interesting difference between the domain in \( \mathbb{R}^n \) (or in \( \mathbb{C}^n \)) and the curved complex manifolds with holomorphically flat or more generally pseudoconcave boundary. As we know, the domains \( \Omega \subset \mathbb{R}^n \) in their counterexamples of Caffarelli-Nirenberg-Spruck [12] and Wang [80] suppose strictly convex points at which every principal curvature of \( \partial \Omega \) is positive. We see that the existence of strictly convex points at the boundary affects regularity assumptions on the boundary and boundary data.

On the other hand, it seems that the regularity assumptions on boundary and boundary data in Theorem 1.9 cannot be directly to Riemannian manifolds of product \( M = X \times [0, 1] \), as \( \partial([0, 1]) = \{0\} \cup \{1\} \) (it is discrete) and \( \partial(X \times [0, 1]) \) is exactly \( X \times \{0\} \cup X \times \{1\} \) (it is smooth when \( X \) is smooth). This also shows another difference between the setting of real and complex variables. Certainly, in the setting of real variables, if \( M = X \times [0, 1] \) we can construct subsolutions and prove the corresponding result of Theorem 1.10 when the given data \( \psi, \varphi \) are smooth. As a contrast, for (real)
Monge–Ampère equation with less regular right-hand side, we are referred to the book [29] and references therein including [7, 8, 9, 23, 67, 79].

The rest of this paper is organized as follows. In Section 2 we sketch proof of the main results. In Section 3 we present some useful lemmas, notation and computation. In Section 4 we derive second order estimates including quantitative boundary estimates of Dirichlet problem. In particular, when \( \partial M \) is holomorphically flat, our quantitative boundary estimates allow us to use a blow-up argument. In Section 5 we show the significant phenomena on regularity assumptions. In Section 6 we study the Dirichlet problem when \( \partial M \) is general but not pseudoconcave. In particular, some direct proof of gradient estimate will be further discussed with assuming suitable conditions. In Section 7 we study fully nonlinear elliptic equations with right-hand sides depending on the unknown solutions. In Section 8 we also solve the Dirichlet problem for the Monge–Ampère equation for \((n-1)\)-plurisubharmonic functions associated to Gauduchon’s conjecture. In Appendix A we finally append the proof of Lemma 2.2, which is a key ingredient in the proof of Proposition 2.1 and so of quantitative boundary estimates.

I wish to thank Professors Bo Guan, Chunhui Qiu and Xi Zhang for their support and encouragement.

2. Sketch of proof of main results

2.1. Sketch of proof of Theorem 1.6. To complete the proof, we first approximate \( u \) by smooth functions if necessary, and then carefully use their level sets (near the boundary) to enclose complex submanifolds. Then we can approximate the original Dirichlet problem by Dirichlet problems, whose subsolutions are exactly the approximating functions, with constant boundary value condition on complex submanifolds.

In the proof we only need to consider the level sets of \( u \) or its approximating functions near the boundary. Without loss of generality we assume \( u \) is not a constant (otherwise, it is trivial when \( u = \) constant). In what follows, the level sets what we use in the proof lie in

\[
M_\delta := \{ z \in M : \sigma(z) < \delta \},
\]

where \( \sigma \) denotes the distance function to the boundary. The condition of \( \frac{\partial}{\partial \nu} u \big|_{\partial M} \neq 0 \) plays a formal role the same as the defining function, and is a key ingredient to produce the desired level sets. Intuitively speaking, \( \frac{\partial}{\partial \nu} u \big|_{\partial M} < 0 \) and \( \frac{\partial}{\partial \nu} u \big|_{\partial M} > 0 \) prevent \( u \) changing sign so that \( u < 0 \) and \( u > 0 \) near the boundary, respectively.

We first assume \( \frac{\partial}{\partial \nu} u \big|_{\partial M} < 0 \) or \( \frac{\partial}{\partial \nu} u \big|_{\partial M} > 0 \). For general \( u \in C^{2,\beta}(\bar{M}) \) the level sets of \( u \) are only \( C^{2,\beta} \) and thus one cannot apply Theorem 1.4 to submanifolds directly. Therefore, we need to approximate \( u \). Together with Sard’s theorem, by the diagonal method if necessary, we can approximate \( u \) by smooth functions \( \{u^{(k)}\} \) in \( C^{2,\beta}(\bar{M}) \) such that \( \partial M \) can be approximated, in the \( C^{2,\beta} \) norm, by suitable smooth level sets of \( u^{(k)} \), say \( W^k \), as \( k \to +\infty \), and then obtain smooth complex submanifolds, say
The gradient estimate is only used to derive the gradient estimate. The proof is based on two approaches: blow-up argument and maximum principle argument.

2.2.1. Blow-up argument. For purpose of applying the blow-up argument in [24, 72, 14] we need to establish the second order estimate of the form

$$\sup_M \Delta u \leq C(1 + \sup_M |\nabla u|^2).$$

When the background space is a closed Kähler manifold, such a second order estimate was obtained by Hou-Ma-Wu [53] for complex Hessian equation with $\eta^{1,0} = 0$. Recently, Hou-Ma-Wu’s result was extended extensively by Székelyhidi [72] to more general fully nonlinear elliptic equations on closed Hermitian manifolds under the assumption of the existence of $C^{2,\alpha}$ subsolutions, also by Tosatti-Weinkove [76, 77] and Zhang [86] for the Monge-Ampère equation for $(n-1)$-plurisubharmonic functions (without gradient terms) and complex Hessian equation on closed Kähler and Hermitian manifolds, respectively.

When the background space has boundary, i.e. $\partial M \neq \emptyset$, the proof of (2.2) is much more complicated. By treating with the two different types of complex derivatives due to the gradient terms in equation carefully, we prove in Theorem 4.9 that

$$\sup_M \Delta u \leq C(1 + \sup_M |\nabla u|^2 + \sup_{\partial M} |\Delta u|).$$

With the estimate above at hand, to achieve our goal, a specific problem that we have in mind is to derive the following quantitative boundary estimate

$$\sup_{\partial M} \Delta u \leq C(1 + \sup_M |\nabla u|^2).$$

This is done in Theorem 4.3. For the Dirichlet problem of complex Monge-Ampère equation with $\eta^{1,0} = 0$, this was obtained by Chen [14] on the above-mentioned Kähler manifold $X \times A$ ($A = S^1 \times [0,1]$), and by Phong-Strum [65] on compact...
Kähler manifolds with holomorphically flat boundary; while for Dirichlet problem of general fully nonlinear elliptic equations with \( \eta^{1,0} = 0 \) and with obeying (1.4), (1.5), (1.6) and (1.7), the estimate (2.4) was established in [84] when the background spaces are compact Hermitian manifolds with holomorphically flat boundary.

The proof is based on the following proposition.

**Proposition 2.1.** Let \((M, J, \omega)\) be a compact Hermitian manifold with pseudoconcave boundary. Suppose, in addition to (1.4), (1.5), (1.6), that for given \( \psi \in C^0(\bar{M}) \) and \( \varphi \in C^2(\partial M) \) there is a \( C^2 \)-admissible subsolution obeying (1.8). Let \( \nu \) be the unit inner normal vector along the boundary as mentioned above. We denote \( \xi_n = \frac{1}{\sqrt{2}}(\nu - \sqrt{-1}J\nu) \) and \( T^{1,0}_{\partial M} := T^{1,0}_{\bar{M}} \cap T^C_{\partial M} = \{ \xi \in T^{1,0}_{\bar{M}} : d\sigma(\xi) = 0 \} \), where \( \sigma \) is the distance function to the boundary as above. Let \( u \in C^3(M) \cap C^2(\bar{M}) \) be an admissible solution to Dirichlet problem (1.1)-(1.2). Fix \( x_0 \in \partial M \). Then for \( \xi_\alpha, \xi_\beta \in T^{1,0}_{\partial M, x_0} \) \((\alpha, \beta = 1, \ldots, n - 1)\) which satisfies \( g(\xi_\alpha, \xi_\beta) = \delta_{\alpha\beta} \) at \( x_0 \), we have

\[
g(\xi_\alpha, J\xi_\beta)(x_0) \leq C \left( 1 + \sum_{\alpha=1}^{n-1} |g(\xi_\alpha, J\xi_\alpha)(x_0)|^2 \right),
\]

where \( C \) is a uniformly positive constant depending only on \( |u|_{C^0(\bar{M})}, |u|_{C^2(\bar{M})}, \partial M \) up to its second order derivatives and other known data (but neither on \( \sup_{\bar{M}} |\nabla u| \) nor on \( (\delta_{\psi, f})^{-1} \)).

When the boundary is supposed to be Levi flat, Proposition 2.1 was first proved by the author [84] \((\eta^{1,0} = 0)\), in which the following lemma proposed there is crucial.

**Lemma 2.2** ([84]). Let \( A \) be an \( n \times n \) Hermitian matrix

\[
\begin{pmatrix}
d_1 & \overline{a_1} \\
d_2 & \overline{a_2} & a_1 \\
& \ddots & \ddots \\
& & d_{n-1} & \overline{a}_{n-1} \\
& & & a_{n-1} & a
\end{pmatrix}
\]

with \( d_1, \ldots, d_{n-1}, a_1, \ldots, a_{n-1} \) fixed, and with \( a \) variable. Let \( \epsilon > 0 \) be a fixed positive constant. Suppose that the parameter \( a \) in \( A \) satisfies the quadratic growth condition

\[
a \geq \frac{2n-3}{\epsilon} \sum_{i=1}^{n-1} |a_i|^2 + (n-1) \sum_{i=1}^{n-1} |d_i| + \frac{(n-2)\epsilon}{2n-3}.
\]

Then the eigenvalues \( \lambda = (\lambda_1, \ldots, \lambda_n) \) of \( A \) (possibly with an order) behavior like

\[
|d_\alpha - \lambda_\alpha| < \epsilon, \quad \forall 1 \leq \alpha \leq n - 1,
\]

\[
0 \leq \lambda_n - a < (n-1)\epsilon.
\]

This lemma is in fact a quantitative version of Lemma 1.2 of Caffarelli-Nirenberg-Spruck [11] and plays a crucial role in the proof of quantitative boundary estimates.
Our argument of establishing quantitative boundary estimates proposes a unified approach to the regularity and solvability of a general class of fully nonlinear elliptic equations on compact Hermitian manifolds with \textit{holomorphically flat} boundary. Also, applying Proposition 2.1 we prove in Theorem 4.2 the quantitative boundary estimate

\begin{equation}
\sup_{\partial M} \Delta u \leq C (1 + \sup_M |\nabla u|^4),
\end{equation}

when the boundary is pseudoconcave. The quantitative boundary estimates (2.4) and (2.6) enable us to treat with Dirichlet problem for degenerate equations, additionally lead to significant phenomena as mentioned above.

Finally, we also prove in Section 8 the quantitative boundary estimates (2.4) and solve the Dirichlet problem for Monge-Ampère equation for \((n-1)\)-plurisubharmonic functions associated to Gauduchon’s conjecture. The key ingredient is also to set up Proposition 8.6 for equation (8.3), which is, however, much more complicated to prove in this context. We will briefly refer to the difficulty below. Fortunately, we discover that the direct product \((M, J, \omega) = (X \times S, J, \pi_1^* \omega_X + \pi_2^* \omega_S)\), with standard induced complex structure and with product metric, allows us to achieve our goal.

### 2.2.2. Maximum principle argument.

A primary obstruction to derive gradient estimate directly, without using second order estimate, is the terms due to holomorphic bisectional curvature tensor. In Theorem 6.10 we directly derive gradient estimate for equation (1.1) on Kähler manifolds with orthogonal bisectional curvature. To do this we divide such terms into two classes according to the directions: one of these two classes is controllable, while the other one arises from orthogonal bisectional curvature which is then controllable if orthogonal bisectional curvature is nonnegative. We explain in Remark 6.12 why we assume \((M, \omega)\) is a Kähler manifold.

By overcoming the difficulty without any assumption on orthogonal bisectional curvature but assuming condition (3), we show in Theorem 6.7 that gradient estimate directly. Condition (3) implies that for any fixed \(0 < \varepsilon \leq 1\) the function \(w\) satisfying (1.10) is a \(\mathcal{C}\)-subsolution of the rescaled equation

\begin{equation}
f(\frac{1}{3 - 2\varepsilon} \lambda(g[w])) = \psi.
\end{equation}

For the solutions satisfying \(g \geq 0\), we can use a \(\mathcal{C}\)-subsolution of the rescaled equation (2.7) to dominate the bad terms like \(\max_i F_i g_{ij} \) in (6.10). In particular, if \(f\) satisfies (1.18) then each \(C^2\)-admissible function is in fact a \(\mathcal{C}\)-subsolution of the rescaled equation. For the reason why we assume \(g \geq 0\), please refer to Remark 6.8.

**Remark 2.3.** This paper is part of series of papers that are devoted to investigating second order fully nonlinear elliptic equations on Hermitian manifolds. (See also other related and follow-up work [83, 84, 85]). As the present work neared completion, I learned of a preprint [78] by V. Tosatti and B. Weinkove which considers the complex Monge-Ampère equation with gradient term of the form (1.3) on closed Hermitian manifolds. I append some further discussion in this version, and as a result the present
paper was posted later. Comparing with previous version, this new version discusses
the Monge-Ampère equation for \((n - 1)\)-plurisubharmonic functions associated with
Gauduchon’s conjecture.

On the other hand, shortly after T. Collins and S. Picard posted their paper \[21\] to
arXiv.org, I learned that, without assuming the flatness of boundary, they also prove
\((2.4)\) for complex Hessian equations without gradient terms on complex manifolds.
Meanwhile, T. Collins also informed me that Lemma \[22\] (in a different form) was
also proved independently in \[22\] (see the Lemma 6.3 there). Indeed it was used in a
different way than our application. I want to thank T. Collins for informing me the
Lemma 6.3 in their work.

3. Preliminaries

We denote \(\Gamma^\sigma = \{\lambda \in \Gamma : f(\lambda) > \sigma\}\), \(\partial \Gamma^\sigma = \{\lambda \in \Gamma : f(\lambda) = \sigma\}\), and also denote
\(Df(\lambda) = (f_1(\lambda), \ldots, f_n(\lambda))\). Condition \((1.4)-(1.5)\) tell the level set \(\partial \Gamma^\sigma\) is convex and
\[(3.1)\]
\[f(\lambda) - f(\mu) \geq \sum_{i=1}^{n} f_i(\lambda)(\lambda_i - \mu_i), \text{ for } \lambda, \mu \in \Gamma.\]

Moreover, we have some stronger results.

**Lemma 3.1** (\[43\]). Suppose \(f\) satisfies \((1.4)\) and \((1.5)\). Let \(K\) be a compact subset
of \(\Gamma\) and \(\beta > 0\). There is a constant \(\varepsilon > 0\) such that, for any \(\mu \in K\) and \(\lambda \in \Gamma\), when
\(|\nu_\mu - \nu_\lambda| \geq \beta\),
\[(3.2)\]
\[\sum_{i=1}^{n} f_i(\lambda)(\mu_i - \lambda_i) \geq f(\mu) - f(\lambda) + \varepsilon(1 + \sum_{i=1}^{n} f_i(\lambda)),\]
where \(\nu_\lambda = Df(\lambda)/|Df(\lambda)|\) denotes the unit normal vector to the level surface \(\partial \Gamma^{F(\lambda)}\).

**Lemma 3.2** (\[72\]). Suppose there exists a \(C\)-subsolution \(u \in C^2(\bar{M})\). Then there
exist two positive constants \(R_0\) and \(\varepsilon\) with the property: If \(|\lambda| \geq R_0\), then either
\[(3.3)\]
\[F^{ij}(g_{ij} - g_{ij}) \geq \varepsilon F^{ij} g_{ij},\]
or
\[(3.4)\]
\[F^{ij} \geq \varepsilon(F^{pq} g_{pq}) g^{ij}.\]

Here \((g^{ij}) = (g_{ij})^{-1}\).

Lemmas \[3.1\] and \[3.2\] inspired by the work of Guan \[38, 39\], play important roles
in the proof of a priori estimates. From the original proof of Lemma 2.2 in \[43\], we
know that the constant \(\varepsilon\) in Lemma \[3.1\] depends only on \(\Lambda, \beta\) and other known data
(but not on \((\delta_{\psi,f})^{-1}\)). By the original proof of Proposition 5 of \[72\] the \(R_0\) and \(\varepsilon\)
in Lemma \[3.2\] depend only on \(\Lambda\) but not on \((\delta_{\psi,f})^{-1}\). Please refer to \[43, 72\] for the
detail.
Remark 3.3. In the proof of a priori estimates there are some bad constant terms without containing $\sum_{i=1}^{n} f_i(\lambda)$. Therefore, for purpose of applying Lemma 3.2 to control them, we need to assume

$$(3.5) \quad \sum_{i=1}^{n} f_i(\lambda) \geq \kappa(\sigma) > 0 \text{ in } \partial \Gamma^\sigma.$$ 

While for $f$ without satisfying (3.5) we can use Lemma 3.1 to derive estimates for Dirichlet problem (by setting $\mu = \lambda := \lambda(g[u]))$. On the other hand, for the equation with the right-hand side $\psi[u] = \psi(z,u), f(\mu) - f(\lambda) < 0$ may occur at some points as $f(\mu) - f(\lambda) \geq \psi[u] - \psi[u]$; in order to apply Lemma 3.1 in this case we assume

$$(3.6) \quad \liminf_{|\lambda| \to +\infty} \sum_{i=1}^{n} f_i(\lambda) = +\infty \text{ in } \Gamma,$$ 

so that one can control the bad term $f(\mu) - f(\lambda)$ in the right-hand side of (3.2). Condition (3.6) allows $f(\lambda) = (\sigma_k(\lambda))^\lambda$ with the cone

$$\Gamma_k = \{ \lambda \in \mathbb{R}^n : \sigma_i(\lambda) > 0 \text{ for each } 1 \leq i \leq k \},$$

while condition (3.5) is always satisfied if $f$ obeys (1.4), (1.5) and (1.7), see Part (b) of Lemma 9 of [72].

In this paper we prove the following lemma (Lemma 3.4) and then use it to give a different proof of Lemma 9 of [72]. Let us first sketch the proof: Let $\tilde{1} = (1, \cdots, 1) \in \mathbb{R}^n$. With (3.1) and the second statement, $f(\lambda + c_\sigma \tilde{1}) \geq f(c_\sigma \tilde{1}) + f_i(\lambda + c_\sigma \tilde{1}) \lambda_i > \sigma$, which yields $\Gamma + c_\sigma \tilde{1} \subset \Gamma^\sigma$, i.e. Part (a) of Lemma 9 in [72]. While the Part (b) holds for $\kappa = \frac{1}{1+c_\sigma}(f((1 + c_\sigma)\tilde{1}) - \sigma)$, according to (3.1) and $\sum_{i=1}^{n} f_i(\lambda) \lambda_i > 0$ in $\Gamma$.

Lemma 3.4. If $f$ satisfies (1.4) and (1.5), then the following three statements are equivalent each other.

- $f$ satisfies (1.7).
- $\sum_{i=1}^{n} f_i(\lambda) \mu_i > 0$ for any $\lambda, \mu \in \Gamma$. In particular $\sum_{i=1}^{n} f_i(\lambda) \lambda_i > 0$.
- For each $\epsilon > 0$ such that $\lambda - \epsilon \tilde{1} \in \Gamma$, $\sum_{i=1}^{n} f_i(\lambda) (\lambda_i - \epsilon) \geq 0$.

Proof. Condition (1.7) yields for any given $\lambda, \mu \in \Gamma$, there is $T \geq 1$ such that for each $t > T$, there holds $t \mu \in \Gamma^{J(\lambda)}$, which, together with the convexity of level sets, implies $Df(\mu) \cdot (t \mu - \lambda) > 0$. Thus, $Df(\lambda) \cdot \lambda > 0$ (if one takes $\mu = \lambda$) and $Df(\lambda) \cdot \mu > 0$.

Given a $\sigma < \sup_{\Gamma} f$. Let $a = 1 + c_\sigma$, where $c_\sigma$ is the positive constant given by

$$(3.7) \quad f(c_\sigma \tilde{1}) = \sigma.$$ 

For any $\lambda \in \Gamma$, one has $t \lambda - a \tilde{1} \in \Gamma$ for $t \gg 1$ (depending on $\lambda$ and $a$). By (3.1) and the third statement, $f(t \lambda) \geq f(a \tilde{1}) + f_i(t \lambda) (t \lambda_i - a) \geq f(a \tilde{1}) > \sigma$. □
Notation. Given a Hermitian matrix $A = (a_{ij})$, we write

$$F^{ij}(A) = \frac{\partial F}{\partial a_{ij}}(A), \quad F^{ij,kl}(A) = \frac{\partial^2 F}{\partial a_{ij} \partial a_{kl}}(A).$$

Throughout this paper, without specific clarification, we denote by $g = g[u]$ and $\tilde{g} = g[u]$ for the solution $u$ and subsolution $\tilde{u}$. And we also denote

$$F^\tilde{g} = F^{ij}(g_{ij}), \quad F^\tilde{g,kl} = F^{ij,kl}(g_{ij}).$$

In what follows one uses the derivatives with respect to the Chern connection $\nabla$ of $\omega$. In a local coordinate $(z_1, \ldots, z_n)$, we write $\partial_i = \frac{\partial}{\partial z_i}, \bar{\partial}_i = \frac{\partial}{\partial \bar{z}_i}, \nabla_i = \nabla \frac{\partial}{\partial z_i}$, $\nabla_i = \nabla \frac{\partial}{\partial \bar{z}_i}$. For a smooth function $v$

$$v_i := \partial_i v, \quad v_t := \partial_t v, \quad v_{ij} := \nabla_j \nabla_i v = \partial_i \bar{\partial}_j v, \quad v_{ij} := \nabla_j \nabla_i v = \partial_i \partial_j v - \Gamma^k_{ji} v_k,$$

$$v_{ijk} := \nabla_k v_{ij} = \partial_k v_{ij} - \Gamma^l_{ki} v_{lj}, \quad v_{ijk} := \nabla_i v_{jk} = \partial_i \partial_j v_k - \Gamma^q_{ij} v_{qk}, \ldots$$

where $\Gamma^l_{ij}$ are the Christoffel symbols which are defined by $\nabla_i \frac{\partial}{\partial z_j} = \Gamma^k_{ij} \frac{\partial}{\partial z_k}$. The curvature and torsion tensors are

$$T^k_{ij} = g^{kl} \left( \frac{\partial g_{ij}}{\partial z_k} - \frac{\partial g_{kj}}{\partial z_i} \right) \text{ and } R_{ijkl} = -\frac{\partial^2 g_{kl}}{\partial z_i \partial z_j} + g^{pq} \frac{\partial g_{qk}}{\partial z_i} \frac{\partial g_{pj}}{\partial z_j}.$$

For a real $(1, 1)$-form $\eta = \sqrt{-1} \eta_{ij} dz^i \wedge d\bar{z}^j$, we denote

$$\eta_{ijk} := \nabla_k \eta_{ij}, \quad \eta_{ijk} := \nabla_i \nabla_k \eta_{ij}.$$

Note that $\chi[u] = \sqrt{-1} \chi_{ij} dz^i \wedge d\bar{z}^j$ depends on both $\partial u$ and $\bar{\partial} u$. One shall use the notation as follows

$$\chi_{ijk} := \nabla_k \chi_{ij} = \nabla'_{k} \chi_{ij} + \chi_{ij,\zeta} u_{ak} + \chi_{ij,\bar{\zeta}} u_{\bar{a}k} = \chi_{ijk} + \chi_{ij,\zeta} u_{ak} + \chi_{ij,\bar{\zeta}} u_{\bar{a}k},$$

where $\chi_{ij,k} = \nabla_k \chi_{ij}$ and $\nabla_k \chi_{ij}$ denotes the partial covariant derivative of $\chi(z, \zeta, \bar{\zeta})$ when viewed as depending on $z \in M$ only, while the meanings of $\chi_{ij,\zeta}$ and $\chi_{ij,\bar{\zeta}}$ are explicit. By [13] we know that

$$\chi_{ij,\zeta} = \delta_{in} \bar{\eta}_j, \quad \chi_{ij,\bar{\zeta}} = \delta_{jn} \eta_i.$$

The above equality implies that the assumption (1.6) in [82] automatically holds for equation (1.1), and thus our results partially extends the results there. Moreover,

$$\chi_{ijk} = \chi_{ij,k} + \chi_{ij,\zeta} u_{ik} + \chi_{ij,\bar{\zeta}} u_{\bar{i}k},$$

$$\chi_{ij,kl} = \chi_{ij,kl} + \chi_{ij,\zeta} u_{ik} + \chi_{ij,\bar{\zeta}} u_{\bar{i}k} + \chi_{ij,k} u_{i\bar{l}} + \chi_{ij,k} u_{i\bar{l}} + \chi_{ij,\bar{\zeta}} u_{\bar{i}\bar{l}} + \chi_{ij,\bar{\zeta}} u_{\bar{i}\bar{l}}.$$
4. Second order estimates for Dirichlet problem on Hermitian manifolds with holomorphically flat or pseudoconcave boundary

In this section we derive the desired estimates up to second order for Dirichlet problem (1.1)-(1.2). Firstly, we present the following lemma:

**Lemma 4.1.** Let \( u \in C^3(M) \cap C^4(\overline{M}) \) be the admissible solution to equation (4.1)
\[
f(\lambda(g[u])) = \psi(z, u) \quad \text{in } M
\]
and \( \mathcal{L} \) be the linearized operator of the equation which is locally given by
\[
\mathcal{L}v = F^{ij}v_{ij} + F^{ij}\chi_{i,j,k}v_k + F^{ij}\chi_{i,j,k}v_k
\]
\[
= F^{ij}v_{ij} + F^{ij}v_i\bar{\eta}_j + F^{ij}\bar{\eta}_i
\]
for \( v \in C^2(M) \). Then, at the point where \( g_{ij} = \delta_{ij} \), one has the following identity
\[
\mathcal{L}(|\nabla u|^2) = F^{ij}(u_{ki}u_{kj} + u_{ik}u_{kj}) + F^{ij}R_{ijkl}u_ku_l - 2\Re\{F^{ij}T^{ik}u_ku_{ij}\}
\]
\[
+ 2\Re\{(\psi_{zk} - F^{ij}\chi_{ij,k})u_k\} + 2\psi_{u}|\nabla u|^2 + 2\Re\{F^{ij}T^{ik}\eta_{ij}u_ku_k\}.
\]

4.1. Quantitative boundary estimates. In this subsection, we continue previous work [84] and derive quantitative boundary estimates when the boundary of the background Hermitian manifold is holomorphically flat or more generally pseudoconcave. Thus we extend the result in [84].

**Theorem 4.2.** Suppose, in addition to \( \partial M \) is a \( C^3 \)-smooth pseudoconcave boundary, that \( \varphi \in C^3(\partial M) \), \( \psi \in C^1(M) \), (1.4), (1.5), (1.6) and (1.8) hold. Then for any admissible solution \( u \in C^3(M) \cap C^2(\overline{M}) \) to Dirichlet problem (1.1)-(1.2) we have
\[
\sup_{\partial M} \Delta u \leq C(1 + \sup_{\partial M} |\nabla u|^2)(1 + \sup_M |\nabla u|^4),
\]
where \( C \) is a uniformly positive constant \( C \) depending on \( \varphi_{C^3(\overline{M})} \), \( \psi_{C^1(M)} \), \( u_{C^2(\overline{M})} \), \( \psi_{C^1(M)} \), \( u_{C^2(\overline{M})} \), \( \partial M \) up to its second derivatives and other known data (but neither on \( \sup_M |\nabla u| \) nor on \( (\delta_{\psi,f})^{-1} \)).

**Theorem 4.3.** Suppose, in addition to \( \partial M \) is holomorphically flat, that the other assumptions in Theorem 4.2 hold. Then for any admissible solution \( u \in C^3(M) \cap C^2(\overline{M}) \) to Dirichlet problem (1.1)-(1.2), there is a uniformly positive constant \( C \) depending only on \( \varphi_{C^3(\overline{M})} \), \( \psi_{C^1(M)} \), \( u_{C^2(\overline{M})} \), \( \partial M \) up to its second derivatives and other known data (but neither on \( \sup_M |\nabla u| \) nor on \( (\delta_{\psi,f})^{-1} \)) such that
\[
\sup_{\partial M} \Delta u \leq C(1 + \sup_{\partial M} |\nabla u|^2)(1 + \sup_M |\nabla u|^2).
\]
Moreover, if the boundary data \( \varphi \) is exactly a constant then the \( C \) depends only on \( \varphi \) up to its second order derivatives, \( u_{C^2(\overline{M})} \), \( \psi_{C^1(M)} \), \( u_{C^2(\overline{M})} \) and other known data.

In particular, if \( M = X \times S \) and \( \varphi \in C^2(\partial S) \) then one has a more subtle result, i.e. \( C \) in (1.4) indeed depends on \( \varphi_{C^2(S)} \).
Theorem 4.4. Let $M = X \times S$, $\partial S \subset C^2$ and $\varphi \in C^2(\partial S)$, and we suppose (1.4), (1.5), (1.6) and (1.8) hold. Then (4.4) holds for $C$ depending only on $|\varphi|_{C^2(\bar{S})}$, $|\psi|_{C^1(M)}$, $\|k\|_{C^2(M)}$, $\partial S$ up to its second derivatives and other known data.

We should remark that the assumption of pseudoconcavity of boundary is only used to derive quantitative boundary estimates in Subsection 4.1. Moreover, part of the formulas and computations in Sections 4, 6.2 and 6 work when the equation has right-hand side $\psi[u] = \psi(z, u)$.

4.1.1. Tangential operators on the boundary. For a given point $x_0 \in \partial M$, we choose local coordinates

$$z = (z_1, \ldots, z_n), \ z_j = x_j + \sqrt{-1}y_j,$$

centered at $x_0$ in a neighborhood which we assume to be contained in $M_\delta$, such that $x_0 = \{z = 0\}$ and $\frac{\partial}{\partial x_n}$ is the interior normal direction to $\partial M$ at $x_0$. For convenience we set

$$t_{2k-1} = x_k, \ t_{2k} = y_k, \ 1 \le k \le n-1; \ t_{2n-1} = y_n, \ t_{2n} = x_n.$$

We assume further that $g_{ij}(0) = \delta_{ij}$ and $\{g_{\alpha\beta}(0)\}$ is diagonal for $(1 \le \alpha, \beta \le n-1)$.

Let $\rho$ be the distance function to the fixed point $x_0 \in \partial M$. Let’s denote

$$\Omega_\delta := \{z \in M : \rho(z) < \delta\}.$$

As in Subsection 2.1, $\sigma$ is the distance function to the boundary, and $M_\delta = \{z \in M : \sigma(z) < \delta\}$. Note that $|\nabla \sigma| = \frac{1}{2}$ on $\partial M$, $(\rho^2)_{ij}(0) = \delta_{ij}$. We know that $\{\frac{1}{2}g_{ij}\} \le \{(\rho^2)_{ij}\} \le 2\{g_{ij}\} \le 2\{\delta_{ij}\} \le 2\{\delta_{ij}\}$, $|\nabla \sigma| \ge \frac{1}{4}$ and $\sigma$ is $C^2$ in $\Omega_\delta$ for some small constant $\delta > 0$.

Now we derive the $C^0$-estimate, boundary $C^1$ estimates and the boundary estimates for pure tangential derivatives. Let $w \in C^2(M) \cap C^1(\bar{M})$ be a function satisfying

$$g^\beta \partial_\beta g_{ij}[w] = 0 \text{ in } M, w = \varphi \text{ on } \partial M. \quad (4.6)$$

The solvability of Dirichlet problem (4.6) can be found in [36]. Together with the boundary value condition, the maximum principle yields

$$u \le u \le w, \text{ in } M. \quad (4.7)$$

Since $u - \varphi = 0$ on $\partial M$, we can therefore write $u - \varphi = h\sigma$ in $\bar{M}_\delta$. On the boundary $h = (u - \varphi)_{\sigma_{xn}}$, we thus define the tangential operator on $\partial M$ for fixed $1 \le \alpha < 2n$,

$$\mathcal{T} = \nabla_{\sigma_{xn}} - \tilde{\eta} \nabla_{\sigma_{xn}}, \quad (4.8)$$

where $\tilde{\eta} = \frac{\sigma_{nx}}{\sigma_{xn}}$. One has $\mathcal{T}(u - \varphi) = 0 \text{ on } \partial M$. Furthermore, $\sigma_{xn}(0) = -1$,

$$(u - \varphi)_{\alpha\beta}(0) = -(u - \varphi)_{x_n}(0)\sigma_{\alpha\beta}(0) \text{ for } 1 \le \alpha, \beta \le n-1, \quad (4.9)$$

$$(u - \varphi)_{t_\alpha t_\beta}(0) = -(u - \varphi)_{x_n}(0)\sigma_{t_\alpha t_\beta}(0) \text{ for } 1 \le \alpha, \beta \le 2n-1. \quad (4.10)$$
We thus derive
\begin{equation}
\sup_M |u| + \sup_{\partial M} |\nabla u| \leq C, \tag{4.11}
\end{equation}
\begin{equation}
|u_{t_\alpha t_\beta}(0)| \leq \hat{C} \quad \text{for } 1 \leq \alpha, \beta \leq 2n - 1, \tag{4.12}
\end{equation}
where \( C \) in (4.11) is a uniform constant depending on \( w \) and \( \hat{C} \) in (4.12) is a positive constant depending on \(|\varphi|_{C^2(S)}\) and other known data under control.

Let's turn our attention to the setting of complex manifolds with holomorphically flat boundary. Given \( x_0 \in \partial M \), one can pick local holomorphic coordinates
\begin{equation}
(z_1, \cdots, z_n), \quad z_i = x_i + \sqrt{-1}y_i, \tag{4.13}
\end{equation}
centered at \( x_0 \) such that \( \partial M \) is locally of the form \( \mathfrak{Re}(z_n) = 0 \) and \( g_{ij}(x_0) = \delta_{ij} \).

Under the holomorphic coordinate (4.13), we can take
\begin{equation}
\mathcal{T} = D := \pm \frac{\partial}{\partial x_\alpha}, \pm \frac{\partial}{\partial y_\alpha}, \quad 1 \leq \alpha \leq n - 1. \tag{4.14}
\end{equation}
We then remove the term \( -\hat{\eta} \nabla_{\frac{\partial}{\partial x_n}} \) from \( \mathcal{T} \).

It is noteworthy that such local holomorphic coordinate system (4.13) is only needed in the proof of Proposition 4.7. In addition, when \( M = X \times S \) is a product of a closed Hermitian manifold \( X \) with a compact Riemann surface with boundary \( S \),
\[ \partial M = \pm \frac{\partial}{\partial x_\alpha}, \pm \frac{\partial}{\partial y_\alpha}, \text{ where } z' = (z_1, \cdots z_{n-1}) \text{ is local holomorphic coordinate of } X. \]

For simplicity we denote the tangential operator on \( \partial M \) by
\begin{equation}
\mathcal{T} = \nabla_{\frac{\partial}{\partial x_\alpha}} - \hat{\eta} \nabla_{\frac{\partial}{\partial x_n}}. \tag{4.15}
\end{equation}
Here \( \gamma = 0 \) (i.e. \( \mathcal{T} = \nabla_{\frac{\partial}{\partial x_\alpha}} = D \)) if \( \partial M \) is holomorphically flat, while for general boundary we take \( \gamma = 1 \).

4.1.2. Quantitative boundary estimates for tangential-normal derivatives. We derive quantitative boundary estimates for tangential-normal derivatives by using barrier functions. This type of construction of barrier functions at least goes back to [52, 44, 37]. We shall point out that the constants in the proof of quantitative boundary estimates, such as \( C, C_\Phi, C_1, C_1', C_2, A_1, A_2, A_3, \cdots \), etc, depend on neither \( |\nabla u| \) nor \((\delta_{\psi, f})^{-1}\).

By direct calculations, one derives \( u_{x_k t} = u_{t x_k} + T_{k l}^p u_p, \ u_{y_k t} = u_{t y_k} + \sqrt{-1}T_{k l}^p u_p \) and
\begin{equation}
\begin{aligned}
F^{ij} u_{x_k t_j} & = F^{ij} u_{t x_k} + g^{j m} F^{ij} R_{j k m} u_l - 2\Re(F^{ij} T_{ik}^l u_j), \\
F^{ij} u_{y_k t_j} & = F^{ij} u_{t y_k} + \sqrt{-1}g^{j m} F^{ij} R_{j k m} u_l + 2\Im(F^{ij} T_{ik}^l u_j).
\end{aligned} \tag{4.16}
\end{equation}
Hence, one has \( \mathcal{L}(\pm u_{t_\alpha}) \geq \pm(\psi_{t_\alpha} + \psi u_{t_\alpha}) - C(1 + |\nabla u|) \sum_{i=1}^n f_i - C \sum_{i=1}^n f_i |\lambda_i| \).

**Lemma 4.5.** Given \( x_0 \in \partial M \). Let \( u \) be a \( C^3 \) admissible solution to equation (4.1) with \( \psi_u \geq 0 \), and \( \Phi \) is defined as
\begin{equation}
\Phi = \pm \mathcal{T}(u - \varphi) + \gamma(u_{y_n} - \varphi_{y_n})^2 \quad \text{in } \Omega_\delta. \tag{4.17}
\end{equation}
Then there is a positive constant $C_{\Phi}$ depending on $|\varphi|_{C^2(M)}$, $|\chi|_{C^2(M)}$, $|\nabla'_{\psi}|_{C^0(M)}$ and other known data such that

$$
\mathcal{L}\Phi \geq - C_{\Phi}(1 + |\nabla u| + |\nabla u|^2) \sum_{i=1}^{n} f_i - C_{\Phi}(1 + |\nabla u|) \sum_{i=1}^{n} f_i |\lambda_i| - C_{\Phi}(1 + (\psi_u + \gamma)|\nabla u|)
$$

(4.18)

on $\Omega_{\delta}$ for some small positive constant $\delta$. Here $\nabla'_{\psi}$ denotes the partial covariant derivative of $\psi$ when viewed as depending on $z \in M$ only. In particular, if $\varphi \equiv \text{constant}$ then $C_{\Phi}$ depends on $|\chi|_{C^2(M)}$, $|\nabla'_{\psi}|_{C^0(M)}$ and other known data.

Furthermore, if $M = X \times S$ and $\varphi \in C^2(\partial S)$ then we have barrier function $\Phi = Du$, and then the constant $C_{\Phi}$ in (4.18) depends on $|\varphi|_{C^2(S)}$, $|\chi|_{C^2(M)}$, $|\nabla'_{\psi}|_{C^0(M)}$ and other known data. Where $D = \pm \frac{\partial}{\partial x_\alpha}, \pm \frac{\partial}{\partial y_\alpha}$ is as mentioned above.

**Proof.** By direct calculation, one obtains $F^{ij}\tilde{\eta}_{i}u_{x_{n_{j}}} = F^{ij}\tilde{\eta}_{i}(2u_{n_{j}} + \sqrt{-1}u_{y_{n_{j}}})$. Using Cauchy-Schwarz inequality $|2\Re(\sqrt{-1}F^{ij}\tilde{\eta}_{i}u_{y_{n_{j}}})| \leq F^{ij}u_{n_{j}}u_{y_{n_{j}}} + CF^{ij}g_{ij}$, we have

$$
\mathcal{L}(\pm Tu) \geq - C(1 + |\nabla u|) \sum_{i=1}^{n} f_i - C\psi_u|\nabla u| - C \sum_{i=1}^{n} f_i |\lambda_i| - \gamma F^{ij}u_{y_{n_{j}}}u_{y_{n_{j}}}.
$$

(4.19)

Here $\sum_{i=1}^{n} f_i = F^{ij}g_{ij}$. Applying (4.16), we obtain

$$
\mathcal{L}((u_{y_{n}} - \varphi_{y_{n}})^2) \geq F^{ij}u_{y_{n_{j}}}u_{y_{n_{j}}} - C\{(1 + |\nabla u|^2) \sum_{i=1}^{n} f_i - |\nabla u| \sum_{i=1}^{n} f_i |\lambda_i| - (1 + |\nabla u|)}
$$

here we use $\psi_u \geq 0$. Hence (4.18) holds. $\square$

To estimate the quantitative boundary estimates for mixed derivatives, we should employ barrier function of the form

$$
v = (\overline{u} - u) - t\sigma + N\sigma^2 \text{ in } \Omega_{\delta},
$$

(4.20)

where $t, N$ are positive constants to be determined.

Writing $b_1 = 1 + 2\sup_{\Omega_{\delta}} |\nabla u|^2 + 2\sup_{\Omega_{\delta}} |\nabla \varphi|^2$. In what follows we denote by $\overline{u} = u - \varphi$. Let $\delta > 0$ and $t > 0$ be sufficiently small such that $N\delta - t \leq 0$, $\sigma$ is $C^2$ in $\Omega_{\delta}$ and

$$
\frac{1}{4} \leq |\nabla \sigma| \leq 2, \quad |\mathcal{L}\sigma| \leq C_2 \sum_{i=1}^{n} f_i, \quad |\mathcal{L}\rho^2| \leq C_2 \sum_{i=1}^{n} f_i \text{ in } \Omega_{\delta}.
$$

(4.21)

In addition, we can choose $\delta$ and $t$ small enough such that

$$
\max\{|2N\delta - t|, t\} \leq \min\{\frac{\varepsilon}{2C_2}, \frac{\beta}{16\sqrt{n}C_2}\},
$$

(4.22)

where $\beta := \frac{1}{2} \min_{\partial M} \text{dist}(\nu_{\lambda}, \partial \Gamma_n)$, $\varepsilon$ is the constant corresponding to $\beta$ in Lemma 3.1 and $C_2$ is the constant in (4.21).
We construct the following barrier function as follows:

\begin{equation}
\widetilde{\Psi} = A_1 b_1^{(1+\gamma)/2} v - A_2 b_1^{(1+\gamma)/2} \rho^2 + b_1^{(\gamma-1)/2} \sum_{\tau<n} \tilde{u}_\tau^2 + A_3 \Phi \text{ on } \Omega_\delta.
\end{equation}

Since \( \widetilde{\Psi} \leq 0 \) on \( \Omega_\delta \) (if we set \( A_2 \gg A_3 \)) and \( \widetilde{\Psi}(x_0) = 0 \), we only need to prove \( \mathcal{L} \widetilde{\Psi} \geq 0 \) on \( \Omega_\delta \).

By a direct computation one has

\begin{equation}
\mathcal{L} v \geq F^{ij}(\varphi_{ij} - g_{ij}) - C_2 |2N\sigma - t| \sum_{i=1}^n f_i + 2NF^{ij}\sigma_i \sigma_j.
\end{equation}

By Lemma 6.2 in [38], \( F^{ij}\varphi_{ij} \geq \sum_{i=1}^n f_i(\lambda_\Delta) = \sum_{i=1}^n f_i\lambda_i \). Some straightforward computations yield

\[
\mathcal{L} \left( \sum_{\tau<n} |\tilde{u}_\tau|^2 \right) \geq \frac{1}{2} \sum_{\tau<n} F^{ij}\varphi_{ij} \tilde{u}_{ij} - C'_1 \sqrt{b_1} \sum_{i=1}^n f_i|\lambda_i| - C'_1 \sqrt{b_1} b_1 \sum_{i=1}^n f_i,
\]

where we use \( \psi_u \geq 0 \) and the elementary inequality \( |a - b|^2 \geq \frac{1}{2} |a|^2 - |b|^2 \). By Proposition 2.19 in [38], there is an index \( r \) so that \( \sum_{\tau<n} F^{ij}\varphi_{ij} \tilde{u}_{ij} \geq \frac{1}{4} \sum_{i \neq r} f_i\lambda_i^2 \). So,

\begin{equation}
\mathcal{L} \left( \sum_{\tau<n} |\tilde{u}_\tau|^2 \right) \geq \frac{1}{8} \sum_{i \neq r} f_i\lambda_i^2 - C'_1 \sqrt{b_1} \sum_{i=1}^n f_i|\lambda_i| - C'_1 \sqrt{b_1} b_1 \sum_{i=1}^n f_i - C'_1 \sqrt{b_1}.
\end{equation}

In particular, if \( M = X \times S \) and \( \varphi \in C^2(\partial S) \), then \( \tilde{u}_\tau = u_\tau \) for each \( 1 \leq \tau \leq n-1 \).

We finally obtain

\[
\mathcal{L} \tilde{\Psi} \geq A_1 b_1^{(1+\gamma)/2} \sum_{i=1}^n f_i(\lambda_i - \lambda_i) + \frac{b_1^{(\gamma-1)/2}}{8} \sum_{i \neq r} f_i\lambda_i^2 + 2A_1 Nb_1^{(1+\gamma)/2} F^{ij}\sigma_i \sigma_j
\]

(4.26)

\[
- (C'_1 + A_3 C_\Phi)b_1^{\gamma/2} \sum_{i=1}^n f_i|\lambda_i| - (C'_1 b_1^{\gamma/2} + A_3 C_\Phi(1 + (\psi_u + \gamma)\sqrt{b_1}))
\]

\[
- (C'_1 + A_2 C_2 + A_3 C_\Phi + A_1 C_2 |2N\sigma - t|) b_1^{(1+\gamma)/2} \sum_{i=1}^n f_i,
\]

**Proposition 4.6.** With the assumptions as in Theorem 4.2, then for any \( X \in T_{\partial M} \) with \( |X| = 1 \), for the admissible solution \( u \in C^3(M) \cap C^2(M) \) to the Dirichlet problem there is a uniformly positive constant \( C \) depending on \( |\varphi|_{C^3(M)} \), \( |u|_{C^2(M)} \), \( \sup_M |\nabla \psi| \) and other known data (but not on \( \sup_{\partial M} |\nabla u| \)) such that

\[
|\nabla^2 u(X, \nu)| \leq C(1 + \sup_{\partial M} |\nabla u|)(1 + \sup_M |\nabla u|^2),
\]

where \( \nabla^2 u \) denotes the real Hessian of \( u \), and as in Proposition 2.1, \( \nu \) is the unit inner normal vector along the boundary.
Proposition 4.7. With the assumptions as in Theorem 4.3, then for any $X \in T_{\partial M} \cap JT_{\partial M}$ with $|X| = 1$, the admissible solution $u \in C^3(M) \cap C^2(\bar{M})$ to the Dirichlet problem satisfies

\begin{equation}
(4.27) \quad |\nabla^2 u(X, \nu)| \leq C(1 + \sup_{\partial M} |\nabla u|)(1 + \sup_M |\nabla u|)
\end{equation}

where $C$ depends on $|\varphi|_{C^3(\bar{M})}, |\psi|_{C^1(\bar{M})}$ and $|u|_{C^2(\bar{M})}$ and other known data (but not on $\sup_M |\nabla u|$). Moreover, when the boundary data $\varphi$ is exactly a constant then the $C$ depends only on $\partial M$ up to its second derivatives, $|u|_{C^2(\bar{M})}, \sup_M |\nabla \psi|$ and other known data.

Proposition 4.8. With the assumptions as in Theorem 4.4, then there exists a positive constant depending on $|\varphi|_{C^2(S)}, |\psi|_{C^1(\bar{M})}, |u|_{C^2(\bar{M})} , \partial S$ up to its second derivatives and other known data such that (4.27) holds.

Proof of Propositions 4.6, 4.7 and 4.8. In these two propositions $\psi u = 0$. When $\lambda_r \geq 0$ where $r$ is the index as in (4.25), we can use the following inequality

\begin{equation}
(4.28) \quad \sum_{i=1}^{n} f_i |\lambda_i| = \sum_{i=1}^{n} f_i \lambda_i - 2 \sum_{\lambda_i < 0}^{\lambda_i < 0} f_i \lambda_i^2 \leq \frac{\epsilon}{16\sqrt{b_1}} \sum_{\lambda_i < 0} f_i \lambda_i^2 + (\sup_M |\lambda| + \frac{16\sqrt{b_1}}{\epsilon}) \sum_{i=1}^{n} f_i
\end{equation}

to control the bad term $\sum_{i=1}^{n} f_i |\lambda_i|$. The case $\lambda_r < 0$ is slightly harder than the formal case $\lambda_r \geq 0$. If $f$ further satisfies (1.7), as in [39], we have

\begin{equation}
\sum_{i=1}^{n} f_i |\lambda_i| = 2 \sum_{\lambda_i \geq 0} f_i \lambda_i - \sum_{\lambda_i < 0} f_i \lambda_i < 2 \sum_{\lambda_i \geq 0} f_i \lambda_i \leq \frac{\epsilon}{16\sqrt{b_1}} \sum_{\lambda_i \geq 0} f_i \lambda_i^2 + \frac{16\sqrt{b_1}}{\epsilon} \sum_{i=1}^{n} f_i
\end{equation}

according to Lemma 3.4. Then we can control $\sum_{i=1}^{n} f_i |\lambda_i|$ in this context. While for general functions without assuming (1.7), we use a trick used in new version of [39] to treat it:

\begin{equation}
(4.29) \quad \sum_{i=1}^{n} f_i |\lambda_i| \leq \frac{\epsilon}{16\sqrt{b_1}} \sum_{\lambda_i \geq 0} f_i \lambda_i^2 + (\sup_M |\lambda| + \frac{16\sqrt{b_1}}{\epsilon}) \sum_{i=1}^{n} f_i + \sum_{i=1}^{n} f_i (\lambda_i - \lambda_r).
\end{equation}

By (4.28) and (4.29) we thus obtain

\begin{equation}
(4.30) \quad \sum_{i=1}^{n} f_i |\lambda_i| \leq \frac{\epsilon}{16\sqrt{b_1}} \sum_{i \neq r} f_i \lambda_i^2 + (\sup_M |\lambda| + \frac{16\sqrt{b_1}}{\epsilon}) \sum_{i=1}^{n} f_i + \sum_{i=1}^{n} f_i (\lambda_i - \lambda_r).
\end{equation}
Taking $\epsilon$ as $\epsilon = \frac{1}{C_1 + A_3C_\Phi}$. By straightforward but careful computation, one gets

$$
\mathcal{L}\bar{\Psi} \geq \{A_1b_1^{(1+\gamma)} - (A_3C_\Phi + C_1')b_1^{\frac{3}{2}}\} \sum_{i=1}^{n} f_i(\bar{\lambda}_i - \lambda_i) + \frac{b_1^{(\gamma-1)}}{16} \sum_{i \neq p} f_i \lambda_i^2
$$

(4.31)

$$
+ 2A Nb_1^{(1+\gamma)} F^{\gamma} \sigma_i \sigma_j - \{C_1' + A_2C_2 + A_3C_\Phi + A_1C_2|2N\sigma - t| + 16(C_1' + A_3C_\Phi)^2 + \frac{1}{\sqrt{b_1}} \sup_{M} |\lambda|(C_1' + A_3C_\Phi)\}b_1^{(1+\gamma)} \sum_{i=1}^{n} f_i
$$

$$
- (C_1'b_1^{\frac{3}{2}} + A_3C_\Phi(1 + \gamma \sqrt{b_1})).
$$

**Case I:** If $|\nu_\lambda - \nu_\lambda| \geq \beta$, then by Lemma 3.1 we have

(4.32)

$$
\sum_{i=1}^{n} f_i(\bar{\lambda}_i - \lambda_i) \geq \varepsilon(1 + \sum_{i=1}^{n} f_i),
$$

where we take $\beta = \frac{1}{\min M \text{ dist}(\nu_\lambda, \partial \Gamma_n)}$ as above, $\varepsilon$ is the positive constant in Lemma 3.1. Note that (4.22) implies $A_1C_2|2N\sigma - t| \leq \frac{1}{2} A_1 \varepsilon$. Taking $A_1 \gg 1$ we can derive

$$
\mathcal{L}\bar{\Psi} \geq 0 \text{ on } \Omega_\delta.
$$

**Case II:** Suppose that $|\nu_\lambda - \nu_\lambda| < \beta$ and therefore $\nu_\lambda - \beta \bar{1} \in \Gamma_n$ and

(4.33)

$$
f_i \geq \frac{\beta}{\sqrt{n}} \sum_{j=1}^{n} f_j.
$$

As in [43] there exist two uniformly positive constants $c_0$ and $C_0$, such that

(4.34)

$$
\sum_{i \neq r} f_i \lambda_i^2 \geq c_0 |\lambda|^2 \sum_{i=1}^{n} f_i - C_0 \sum_{i=1}^{n} f_i.
$$

The original proof uses $\sum_{i=1}^{n} f_i(\bar{\lambda}_i - \lambda_i) \geq 0$. We can check that $c_0$ depends only on $\beta$ and $n$, and $C_0$ depends only on $\beta$, $n$, and $\sup_{M} |\lambda|$.

All the bad terms containing $\sum_{i=1}^{n} f_i$ in (4.31) can be controlled by the good term

(4.35)

$$
A_1Nb_1^{(1+\gamma)} F^{\beta} \sigma_i \sigma_j \geq \frac{A_1N\beta b_1^{(1+\gamma)}}{16\sqrt{n}} \sum_{i=1}^{n} f_i \text{ on } \Omega_\delta.
$$

On the other hand, the bad term $C_1'b_1^{\frac{3}{2}} + A_3C_\Phi(1 + \gamma \sqrt{b_1})$ can be dominated by (4.35) and

$$
\frac{c_0 b_1^{\frac{(\gamma-1)}{2}} |\lambda|^2}{32} \sum_{i=1}^{n} f_i + \frac{A_1N\beta b_1^{(1+\gamma)}}{32\sqrt{n}} \sum_{i=1}^{n} f_i \geq \frac{\sqrt{c_0 \beta A_1 N b_1^{\frac{3}{2}} |\lambda|}}{16\sqrt{n}} \sum_{i=1}^{n} f_i.
$$
Then $\mathcal{L}(\tilde{\Psi}) \geq 0$ on $\Omega_3$, if one chooses $A_1 N \gg 1$. Here we use

\begin{equation}
|\lambda| \sum_{i=1}^{n} f_i(\lambda) \geq b_0, \quad \text{if } |\lambda| \geq R_0;
\end{equation}

\begin{equation}
|\lambda| \sum_{i=1}^{n} f_i(\lambda) \geq b'_0, \quad \text{if } |\lambda| \leq R_0,
\end{equation}

where $R_0 = 1 + c_{\text{sup}_{\Omega_3} \psi}$, $b_0 = \frac{1}{2}(f(R_0 \bar{1}) - \text{sup}_{\bar{M}} \psi)$ and $b'_0 = \frac{1}{1+2R_0}(f((1+R_0) \bar{1}) - f(R_0 \bar{1}))$. Here $c_{\text{sup}_{\Omega_3} \psi}$ is the constant defined as in (3.7). The proof uses (3.1).

4.1.3. Proof of Proposition 2.1. The proof follows the outline of proof of Proposition 4.1 of [84]. Fix $x_0 \in \partial M$. In the proof we use the notation and local coordinate (4.5).

In what follows all the discussions will be given at $x_0$, and the Greek letters $\alpha, \beta$ range from 1 to $n - 1$.

For the local coordinate $z = (z_1, \cdots, z_n)$ given by (4.5), we assume further that $(g_{\alpha \bar{\beta}})$ is diagonal at $x_0$. Let’s denote

\[
A(R) = \begin{pmatrix}
g_{11} & g_{12} & \cdots & g_{1(n-1)} & g_{1n} 
g_{21} & g_{22} & \cdots & g_{2(n-1)} & g_{2n} \\
\vdots & \vdots & \ddots & \vdots & \vdots 
g_{(n-1)1} & g_{(n-1)2} & \cdots & g_{(n-1)(n-1)} & g_{(n-1)n} 
g_{n1} & g_{n2} & \cdots & g_{n(n-1)} & R
\end{pmatrix}
\]

and

\[
A(R) = \begin{pmatrix}
g_{11} & g_{12} & \cdots & g_{1(n-1)} & g_{1n} 
g_{21} & g_{22} & \cdots & g_{2(n-1)} & g_{2n} \\
\vdots & \vdots & \ddots & \vdots & \vdots 
g_{(n-1)1} & g_{(n-1)2} & \cdots & g_{(n-1)(n-1)} & g_{(n-1)n} 
g_{n1} & g_{n2} & \cdots & g_{n(n-1)} & R
\end{pmatrix}.
\]

It follows from the pseudoconcavity of $\partial M$ and the boundary value condition that

\begin{equation}
(g_{\alpha \bar{\beta}}) \geq (g_{\alpha \bar{\beta}}), \quad \text{and thus } A(R) \geq A(R).
\end{equation}

Firstly, as in proof of Proposition 4.1 of [84], we can apply Lemma 2.2 to show that there exist two uniformly positive constants $\varepsilon_0$, $R_0$ depending on $\mathfrak{g}$ and $f$, such that

\begin{equation}
(f(g_{11} - \varepsilon_0, \cdots, g_{(n-1)(n-1)} - \varepsilon_0, R_0) \geq \psi
\end{equation}

and $g_{11} - \varepsilon_0, \cdots, g_{(n-1)(n-1)} - \varepsilon_0, R_0) \in \Gamma$. Here (1.4), (1.5) (or more general the level sets of $f$ in $\Gamma$ are convex), openness of $\Gamma$ are also needed. The details of the proof can be found in [84].

Next, Lemma 2.2 together with (1.38) help us to establish the quantitative boundary estimates for double normal derivative.
Let’s pick $\epsilon = \frac{\delta}{128}$ in Lemma 2.2 and

$$R_c = \frac{128(2n-3)}{\varepsilon_0} \sum_{\alpha=1}^{n-1} |g_{\alpha\alpha}|^2 + \frac{(n-1)}{128(2n-3)} + R_0,$$

where $\varepsilon_0$ and $R_0$ are fixed constants so that (4.38) holds. It follows from Lemma 2.2 that the eigenvalues of $A(R_c)$ (possibly with an order) shall follow like

(4.39) \[ \lambda(A(R_c)) \in \left( \frac{\varepsilon_0}{128} \right) \bar{g}_{11}, \cdots, \bar{g}_{(n-1)(n-1)} - \frac{\varepsilon_0}{128}, R_c \right) + \Gamma_n \subset \Gamma. \]

Applying (1.4), (4.37), (4.38) and (4.39), one hence has

\[ F(A(R_c)) \geq F(A(R_c)) \geq f(\bar{g}_{11} - \frac{\varepsilon_0}{128}, \cdots, \bar{g}_{(n-1)(n-1)} - \frac{\varepsilon_0}{128}, R_c) \]

\[ > f(\bar{g}_{11} - \varepsilon_0, \cdots, \bar{g}_{(n-1)(n-1)} - \varepsilon_0, R_c) \geq \psi. \]

Therefore,

$$\bar{g}_{nn}(x_0) \leq R_c.$$  

We thus complete the proof of Proposition 2.1.

4.2. Global second order estimate. The primary obstruction to establishing second order estimate for solutions of fully nonlinear elliptic equations involving gradient terms in complex setting is the two different types of complex derivatives due to the gradient terms in equations. The following theorem gives global second order estimate for Dirichlet problem (1.1)-(1.2).

**Theorem 4.9.** Suppose, in addition to (1.4)-(1.6), that there is an admissible subsolution $u \in C^2(M)$ satisfying (1.8). Then for any admissible function $u \in C^4(M) \cap C^2(M)$ solving Dirichlet problem (1.1)-(1.2) with $\psi \in C^2(M)$, we have

(4.40) \[ \sup_M \Delta u \leq C(1 + \sup_M |\nabla u|^2 + \sup_M |\Delta u|), \]

where $C$ is a uniform positive constant $C$ depending only on $|u|_{C^0(M)}$, $|u|_{C^2(M)}$, $|\chi|_{C^2(M)}$, $\sup_M |\nabla \psi|$, $\inf_{x \in M} \inf_{\xi \in T^*_x M, |\xi|=1} \partial \bar{\psi}(\xi, \bar{\xi})$ and other known data (but not on $(\delta_{\psi, f})^{-1}$).

We first give computations when the equation has right-hand side $\psi[u] = \psi(z, u)$; therefore, by a slight modification of the proof below, one can derive in Section 7 such second order estimates for the admissible solutions for equation (1.1).

We use the method used by Székelyhidi [72] to treat the third order terms arising from nontrivial torsion. Denote the eigenvalues of the matrix $A = \{A_i\} = \{g^{ij}g_{j\bar{k}}\}$ by $(\lambda_1, \cdots, \lambda_n)$, where we suppose $\lambda_1 \geq \lambda_2 \cdots \geq \lambda_n$ at each point.

We want to apply the maximum principle to $H$,

(4.41) \[ H := \lambda_1 e^\phi, \]

where the test function $\phi$ is to be chosen later. Suppose $H$ achieves its maximum at an interior point $p_0 \in M$. Since the eigenvalues of $A$ need not be distinct at the point $p_0$, and so $\lambda_1(p_0) = \lambda_2(p_0)$ may occur, $H$ may only be continuous. To circumvent
this difficulty we use the perturbation argument used in \cite{72}. To do this, we choose a local coordinates \( z = (z_1, \ldots, z_n) \) around \( p_0 \), such that at \( p_0 \)

\[
g_{ij} = \delta_{ij}, \quad g_{ij} = \delta_{ij}\lambda_i \text{ and } F^{ij} = \delta_{ij}f_i.
\]

Let \( B \) be a diagonal matrix \( B_p^q \) with real entries satisfying \( B^1_1 = 0, B^n_n > 2B^2_2 \) and \( B^0_n < B^0_{n-1} \cdots < B^2_2 < 0 \) are small. Then we define the matrix \( \tilde{A} = A + B \) with the eigenvalues \( \tilde{\lambda} = (\lambda_1, \ldots, \lambda_n) \). At the origin, \( \tilde{\lambda}_1 = \lambda_1 = g_{11}, \tilde{\lambda}_i = \lambda_i + B^i_i \) if \( i \geq 2 \) and the eigenvalues of \( \tilde{A} \) define \( C \)-functions near the origin.

Notice \( \tilde{H} = \tilde{\lambda}_1 e^\phi \) also achieves its maximum at the same point \( p_0 \) (we may assume \( \lambda_1(p_0) = \tilde{\lambda}_1(p_0) > 1 \)).

In what follows, the computations will be given at the origin \( p_0 \). By maximum principle one has

\[
\tilde{\lambda}_{1,i} + \lambda_1\phi_i = 0, \quad \tilde{\lambda}_{1,ii} + \lambda_1\phi_i = 0,
\]

(4.42)

\[
\frac{\tilde{\lambda}_{1,ii}}{\lambda_1} - \frac{|\tilde{\lambda}_{1,i}|^2}{\lambda_1^2} + \phi_{ii} \leq 0.
\]

By straightforward calculations, one obtains

(4.43)

\[
\tilde{\lambda}_{1,ii} = g_{11k} + (B^1_1)_i.
\]

As in \cite{72}, one obtains

(4.44)

\[
\tilde{\lambda}_{1,kk} \geq 2g_{11k} + \frac{1}{2(n + 1)\lambda_1} \sum_{p > 1} (|g_{jk}|^2 + |g_{jk}|^2) - C.
\]

It follows from (5.13) that

\[
\chi_{1kk} = \chi_{1,kk} + \chi_{1,\zeta_i}R_{kk\zeta_i}u_i + 2g_{kkk}\Re (\chi_{1,k\zeta_i}\delta_{ik} - \chi_{1,\zeta_i}T_{kk}^k) + 2\Re (\chi_{1,\zeta_i}u_{ik}\chi_{1,k\zeta_i}) + 2\Re (\chi_{1,\zeta_i}\chi_{kk\zeta_i}u_{ki} + \chi_{1,\zeta_i}\chi_{kk\zeta_i}u_{ik}).
\]

(4.45)

Differentiating the equation (1.1) twice (using covariant derivative), we obtain

\[
F^{kk}g_{kk} = \psi_{z_1} + \psi_u u_t,
\]

\[
F^{kk}g_{kk} = \psi_{z_1} + 2\Re (\psi_{z_{11}}u_{1}) + \psi_u u_{11} + \psi_u u_{1}^2 - F^{ij,lm}g_{ij}g_{ml},
\]

we then have

\[
F^{ii}g_{i1} = -F^{ij,lm}g_{ij}g_{ml} - 2\Re (F^{ii}\chi_{1,\zeta_i}g_{11}) + 2\Re (F^{ii}\tilde{T}_{1i}u_{j1}) + 2\Re (F^{ii}\chi_{1,\zeta_i}u_{1}) + \psi_{z_1} + 2\Re (\psi_{z_{11}}u_{1}) + \psi_u u_{11} + \psi_u u_{1}^2 - Cg_{11} \sum F^{ii},
\]
here we use the structure of $\chi$ in (1.3) and also the following standard formula

$$u_{i\bar{j}k} - u_{k\bar{j}i} = T_{i\bar{k}j}^lu_{\bar{t}j},$$

$$u_{i\bar{a}i} - u_{i\bar{a}i} = R_{i\bar{a}p_{\bar{1}}} - R_{i\bar{a}p_{\bar{2}}} + 2\Re \{ \bar{T}_{\bar{i}1}^1u_{\bar{t}j1} \} + T_{i\bar{t}1}^1u_{\bar{t}p_{\bar{q}}}.$$ 

Let’s set

$$\phi = \Phi(|\nabla u|^2) + \Psi(u - \bar{u}),$$

where $\Phi(t) = -\frac{1}{2} \log(1 - \frac{t}{2K})$ is used by Hou-Ma-Wu [53],

$$K = 1 + \sup_{M}(|\nabla u|^2 + |\nabla (u - \bar{u})|^2),$$

and $\Psi : [\inf_M (u - \bar{u}), +\infty) \to \mathbb{R}$ is given by

$$\Psi(x) = \frac{C_*}{(1 + x - \inf_M (u - \bar{u}))^N},$$

where $C_* \geq 1$ and $N \in \mathbb{N}$ are constants to be chosen later. Here $\Psi(x)$ was used in [52]. We get

$$\Phi'' = 2\Phi'^2, \quad (4K)^{-1} < \Phi' < (2K)^{-1} \text{ for } t \in [0, \sup_{M} |\nabla u|^2]$$

$$L \phi = \Phi' L(|\nabla u|^2) + \Psi' L(u - \bar{u}) + \Phi'' F_{\bar{a}i}(|\nabla u|^2_i)|^2 + \Psi'' F_{\bar{a}i}((u - \bar{u})_i|^2.$$ 

Together with Lemma 4.1 one has a differential inequality

$$0 \geq \frac{1}{2} \Phi' F_{\bar{a}i}(|u_{ki}|^2 + |u_{ki}|^2) + 2\Phi' \{ \Re \{ \psi_{z_k}u_k \} + \psi_u |\nabla u|^2 \}

+ \Psi' L(u - \bar{u}) + \Phi'' F_{\bar{a}i}(|\nabla u|_i|^2 + \Psi'' F_{\bar{a}i}((u - \bar{u})_i|^2

+ 2\Re \{ F_{\bar{a}i}\bar{T}_{\bar{i}1}^1 \frac{\lambda_{\bar{1}1}}{\lambda_{11}} - \frac{\bar{F}_{\bar{a}i}m_{\bar{1}1}}{g_{11}1^1} - F_{\bar{a}i}^2 \frac{\lambda_{\bar{1}1}^2}{\lambda_{11}^2}

+ \frac{\psi_u u_{\bar{1}1} + 2\Re \{ \psi_u u_{\bar{1}1} + \psi_u u_{\bar{1}1} + \psi_u u_{\bar{1}1} \}^2}}{g_{11}} - C \sum F_{\bar{a}i}. ($$}

Note that in this computation $\tilde{\lambda}_1$ denotes the largest eigenvalue of the perturbed endomorphism $\tilde{A} = A + B$. At the origin $p_0$ where we carry out the computation, $\tilde{\lambda}_1$ coincides the largest eigenvalue of $A$. However, at nearby points, it is a small perturbation. We would take $B \to 0$, and obtain the above differential inequality (4.46) as well. It only holds in a viscosity sense because the largest eigenvalue of $A$ may not be $C^2$ at the origin $p_0$, if some eigenvalues coincide.

**Case I:** Assume that $\delta \lambda_1 \geq -\lambda_u (0 < \delta \ll \frac{1}{2})$. Set

$$I = \{ i : F_{\bar{a}i} > \delta^{-1} F_{11} \}, \text{ and } J = \{ i : F_{\bar{a}i} \leq \delta^{-1} F_{11} \}.$$
Clearly $1 \in J$ and identity (4.42) implies that for any fixed index $i$
\[ -F^{\tilde{\alpha}}(\tilde{\lambda}_{1,i})^2 \geq -2\Psi^2 F^{\tilde{\alpha}}((u - \bar{u})_i)^2 - 2\Phi^2 F^{\tilde{\alpha}}(|\nabla u|^2)_i^2 \]
\[ = -2\Psi^2 F^{\tilde{\alpha}}((u - \bar{u})_i)^2 - \Phi'' F^{\tilde{\alpha}}(|\nabla u|^2)_i^2. \]

The assumption $\delta \lambda_1 \geq -\lambda_n$ implies that $\frac{1 - \delta}{\lambda_i - \lambda_i} \geq \frac{1 - \Psi}{\lambda_1}$. Then
\[ -\frac{1}{\mathcal{g}_{11}} F^{\tilde{\alpha}}(\mathcal{g}_{11}^2 - |\tilde{\lambda}_{1,i}|^2 ) \geq \sum_{i \in I} \frac{F^{\tilde{\alpha}} - F^{\tilde{11}}}{\lambda_1 - \lambda_i} |\mathcal{g}_{11}|^2 |\tilde{\lambda}_{1,i}|^2 - F^{\tilde{\alpha}}|\tilde{\lambda}_{1,i}|^2 \]
\[ \geq (1 - \delta)^2 \frac{\sum_{i \in I} F^{\tilde{\alpha}}(\mathcal{g}_{11})^2 - |\tilde{\lambda}_{1,i}|^2 }{\mathcal{g}_{11}^2} \]
\[ - 4\delta \Psi^2 \sum_{i \in I} F^{\tilde{\alpha}}((u - \bar{u})_i)^2 \]
\[ - 2\Psi^2 \delta^{-1} F^{\tilde{11}}K - \Phi'' F^{\tilde{\alpha}}(|\nabla u|^2)_i^2. \]

The estimates for the lower bound of the differences $|\mathcal{g}_{11}|^2 - |\mathcal{g}_{11}|^2$ for $i \in I$ are crucial. A straightforward computation gives
\[ \mathcal{g}_{11} = \tilde{\lambda}_{1,i} + \tau_i - \chi_{11,i,\alpha} u_{\alpha i} + \chi_{11,i,\alpha} u_{\alpha 1} \]
\[ = \tilde{\lambda}_{1,i} + \tau_i - \chi_{11,i,\alpha} u_{1i} + \chi_{11,i,\alpha} u_{11}. \]

where $\tau_i = \chi_{11,i,\alpha} u_{\alpha 1} - \chi_{11,i,\alpha} u_{\alpha 1} + \chi_{11,i,\alpha} u_{\alpha 1} + T^{1}_{1} u_{11} + (B^{1}_{1})_i$. Here, (3.11) is crucial. Combining it with (4.3) one has
\[ F^{\tilde{\alpha}}(\mathcal{g}_{11}^2 - |\tilde{\lambda}_{1,i}|^2 ) \geq - CF^{\tilde{\alpha}}(\mathcal{g}_{11}^2 (1 + |u_{11}|) \]
\[ \geq - \frac{C}{\sqrt{K}} F^{\tilde{\alpha}}(|u_k| + |u_{ki}|) \]
\[ \geq - \frac{C}{\mathcal{g}_{11} \sqrt{2K}} F^{\tilde{\alpha}}|u_k|^2 - C|\Psi'| F^{\tilde{\alpha}}((u - \bar{u})_i)^2. \]

We now choose small $\delta$ such that $4\delta \Psi^2 < \frac{1}{2} \Psi''$. It follows from (4.42), (4.36), (4.47), (4.48) and an elementary inequality $\frac{1}{2} \Psi'' F^{kk}((u - \bar{u})_k)^2 - C|\Psi'| F^{kk}((u - \bar{u})_k) \geq -\frac{C^2 \Psi''}{2} \sum F^{\tilde{\alpha}}$ that
\[ 0 \geq \frac{1}{16K} F^{kk}(|u_{ik}|^2 + |u_{ik}|^2) + \Psi' C(u - \bar{u}) - 2\Psi^2 \delta^{-1} F^{\tilde{11}}K \]
\[ + 2\Phi'(\mathcal{R}(\psi_{z_k} u_k) + \psi_u |\nabla u|^2) - \left( \frac{C^2 \Psi''}{\Psi''} + C \right) \sum F^{\tilde{\alpha}} \]
\[ + \frac{\psi_{z_k} \xi_{i} + 2\mathcal{R}(\psi_{z_k} u_{ik}) + \psi_u u_{i1} + \psi u_{ik}|u_{1}|^2}{\mathcal{g}_{11}}. \]
Case II: We assume that $\delta \lambda_1 < -\lambda_1$ with the constants $C_*, N$ and $\delta$ fixed as in the previous case. Then $|\lambda_i| \leq \frac{1}{\delta}|\lambda_n|$ for all $i$. Moreover

$$- \sum F^{\tilde{i}} \bar{|\lambda_{1,i}|^2} \geq - 2 \Psi'^2 \sum F^{\tilde{i}} |(u - \bar{u})_i|^2 - 2 \Psi'^2 \sum F^{\tilde{i}} |(\nabla u)^2_i|^2.$$ Combining it with (4.42) and (4.46), one derives that

$$0 \geq \frac{1}{16K} F^{\tilde{i}} (|u_{ki}|^2 + |u_{ki}|^2) + (\Psi'' - 2 \Psi'^2) F^{\tilde{i}} |(u - \bar{u})_i|^2$$

$$+ 2 \Phi'(\Re \{\psi_{zk} u_k\} + \psi_u |\nabla u|^2) - C |\Psi'| F^{\tilde{i}} |(u - \bar{u})_i|$$

$$+ \psi_{z_1 \bar{z}_1} + 2 \Re \{\psi_{z_1 u_1} + \psi_u u_{11} + \psi_u u_{11}^2\}$$

$$\geq 0 \quad \text{for all} \quad \bar{g}_{11} \geq \frac{\delta}{32nK} |\bar{g}_{11}|^2 \sum F^{\tilde{i}} + (\Psi'' - 2 \Psi'^2) F^{\tilde{i}} |(u - \bar{u})_i|^2$$

(4.50)

Note that $F^{\bar{g}_{11}} \geq \frac{1}{n} \sum F^{\tilde{i}}$ and $|u_{\bar{g}_{11}}| = |u_{\bar{g}_{11}}|^2 - |\chi_{\bar{g}_{11}}|^2 \geq \frac{\delta^2}{2} |\bar{g}_{11}|^2 - C_2 (1 + |\nabla u|^2)$, one has

$$0 \geq \frac{\delta^2}{32nK} |\bar{g}_{11}|^2 \sum F^{\tilde{i}} + (\Psi'' - 2 \Psi'^2) F^{\tilde{i}} |(u - \bar{u})_i|^2$$

$$+ 2 \Phi'(\Re \{\psi_{zk} u_k\} + \psi_u |\nabla u|^2) - C (1 + |\Psi| \sqrt{K}) \sum F^{\tilde{i}}$$

$$+ \psi_{z_1 \bar{z}_1} + 2 \Re \{\psi_{z_1 u_1} + \psi_u u_{11} + \psi_u u_{11}^2\}.$$

Proof of Theorem 4.9. In this theorem $\psi_u \equiv 0$. Suppose now that $\bar{g}_{11} \gg 1 + \sup_M |\nabla u|^2$ (otherwise we are done).

In case I, we assume $\delta \lambda_1 \geq -\lambda_n \left(0 < \delta \ll \frac{1}{2}\right)$, and then have (4.49). In the proof we use Lemma 3.1. In the first subcase one assumes

$$L(u - \bar{u}) \geq \varepsilon (1 + \sum F^{\tilde{i}}).$$

(4.51)

Moreover, based on (4.49), we choose $C_* \gg 1$ and $N \gg 1$ such that $\frac{C_0 |\psi_u|}{\bar{g}_{11}} \leq \frac{\varepsilon}{2}$ and

$$-\frac{\varepsilon}{2} \Psi' \geq \frac{\varepsilon C_* N}{2(1 + \sup_M (u - \bar{u})_i - \inf_M (u - \bar{u})_i)^{N+1}} \gg 1.$$ Thus one derives

$$\bar{g}_{11} \leq CK.$$

In the other subcase, we can assume $f_i \geq \frac{\delta}{\sqrt{n}} \sum_{j=1}^n f_j$ for each $i$. Note that

$$|u_{\bar{g}_{11}}|^2 = |\bar{g}_{11} - \chi_{\bar{g}_{11}}|^2 \geq \frac{1}{2} |\bar{g}_{11}|^2 - C(1 + |\nabla u|^2).$$

Combining it with (4.49) and (4.39), we derive that

$$\bar{g}_{11} \leq CK.$$

RIRONG YUAN
In case II we assume that $\delta \lambda_1 < -\lambda_n$ with the constants $C_*, N$ and $\delta$ fixed as in the previous case. By (4.50) we have

$$g_{II} \leq CK.$$ 

Here we use condition (4.36) again.

We complete the proof. □

Following the outline of proof of Theorem 4.9, with admissible subsolutions replaced by the existence of $C^r$-subsolutions, we can apply Lemma 3.2 in place of Lemma 3.1 to prove that the second order estimate of the form (4.52) holds for any admissible solution to equation (1.1).

**Theorem 4.10.** Let $(M, \omega)$ be a compact Hermitian manifold possibly with boundary, and $\psi \in C^2(M)$. Suppose, in addition to (1.4) - (1.6) and (3.5), that there exists a $C^r$-subsolution $u \in C^2(M)$ satisfying (1.9). Then for any admissible solution $u \in C^3(M) \cap C^2(\bar{M})$ of equation (1.1), we have

$$\sup_M \Delta u \leq C(1 + \sup_M |\nabla u|^2 + \sup_{\partial M} |\Delta u|),$$

where $C$ is a uniform positive constant $C$ depending only on $|u|_{C^0(M)}, |u|_{C^2(\bar{M})}, |\chi|_{C^2(\bar{M})}, |\psi|_{C^2(\bar{M})}$ and other known data.

Based on Theorem 4.10 as in [72], we can derive $C^0$-estimate and gradient estimate for equation (1.1) on closed Hermitian manifolds. Together with Evans-Krylov theorem, one then slightly extends Székelhidi’s $C^{2,\alpha}$-estimates for fully nonlinear elliptic equations with $\eta^{1,0} = 0$ in [72] and also partially extends a result in [82]. See also [20, 24, 71, 76, 77, 86] for $C^{2,\alpha}$-estimates for some special equations. Please refer to Lemma 6.10 and Remark 6.11 for the direct proof of gradient estimate when $(M, \omega)$ is a Kähler manifold with nonnegative orthogonal bisectional curvature.

**Proposition 4.11.** Let $(M, \omega)$ be a closed Hermitian manifold, and $\psi$ be a smooth function. Suppose (1.4), (1.5), (1.6), (1.7) and (1.9) hold. Then for any admissible solution $u \in C^4(M)$ of equation (1.1) with $\sup_M u = 0$, we have $C^{2,\alpha}$-estimates $|u|_{C^{2,\alpha}(M)} \leq C$ for $0 < \alpha < 1$, where $C$ depends on $\alpha$, $|\psi|_{C^2(M)}$, $|\chi|_{C^2(M)}$, $|\Gamma|_{C^2(M)}$ and other known data. Moreover, if $(M, \omega)$ is a closed Kähler manifold with nonnegative orthogonal bisectional curvature, then (1.7) can be replaced by (3.5).

Applying Proposition 4.11 one has

**Proposition 4.12.** Let $(M, \omega)$ be a closed Hermitian manifold of complex dimension $n \geq 2$, $\phi \in C^\infty(M)$, $2 \leq k \leq n$. Then there is a unique real valued smooth function $u \in C^\infty(M)$ with $\lambda(g[u]) \in \Gamma_k$ and $\sup_M u = 0$, and a unique constant $b$ such that

$$(g[u])^k \wedge \omega^{n-k} = e^{\phi + b} \omega^n, \text{ in } M.$$
Remark 4.13. Proposition [4.12] for complex Monge-Ampère equation involving gradient term of the form \([\eta^{1,0}]\) was also proved by Tosatti-Weinkove [78] independently. Moreover, they also observe in Remark 1.2 of their paper that if \(\eta^{1,0}\) is holomorphic then \(\omega + \sqrt{-1}(\partial u + \bar{\partial} u)\) can be rewritten as \(\omega + \partial \zeta + \bar{\partial} \zeta\), where \(\zeta = -\sqrt{-1}(u\eta^{1,0} + \partial u)\). So the equation potentially applies to the deformation of forms in Aeppli cohomology class.

5. Discussion on significant phenomena on regularity assumptions

5.0.1. Proof of Theorem [1.7]. In the proof we only need to consider the level sets of \(u\) or its approximating functions near the boundary. Without loss of generality we assume \(u\) is not a constant (otherwise, it is trivial if \(u = \text{constant}\)). In what follows, the level sets we use in the proof are all near the boundary \(M_0\) for some \(0 < \delta \ll 1\), here \(M_0\) is defined in (2.1).

Suppose \(\frac{\partial u}{\partial \nu}\big|_{\partial M} \neq 0\). Without loss of generality, we assume \(\frac{\partial u}{\partial \nu}\big|_{\partial M} < 0\). Then \(u < 0\), \(\nabla u \neq 0\) in \(M_0\) for some \(\delta_0 > 0\). We first choose a sequence of smooth approximating functions \(\{u^{(k)}\}\) such that \(u^{(k)} \to u\) in \(C^{2,\beta}(M)\) as \(k\) tends to infinity.

Then \(\frac{\partial u^{(k)}}{\partial \nu}\big|_{\partial M} \neq 0\) for \(k \gg 1\). Next, for any \(k \gg 1\), by the diagonal method and Sard’s theorem if necessary, we carefully choose \(\{\alpha_k\}\) satisfying \(\alpha_k \to 0\) as \(k \to +\infty\) and a sequence of level sets of \(u^{(k)}\), say \(\{u^{(k)} = -\alpha_k\}\), and use them to enclose smooth complex submanifolds with the same complex dimension, say \(M^{(k)}\), such that \(\cup M^{(k)} = M\) and \(\partial M^{(k)}\) converge to \(\partial M\) in the norm of \(C^{2,\beta}\). Moreover, we can choose \(\{\beta_k\}\) \((\beta_k > 0)\) with \(\beta_k \to 0\) as \(k \to +\infty\), such that

\[
F(g[u^{(k)}]) \geq \psi - \beta_k \text{ in } M.
\]

Furthermore, \(u^{(k)}\) are admissible functions for sufficiently large \(k\), as \(\Gamma\) is open.

According to Theorem [1.1] we have a unique smooth admissible function \(u^{(k)} \in C^\infty(M^{(k)})\) to solve

\[
F(g[u^{(k)}]) = \psi - \beta_k \text{ in } M^{(k)}, \quad u^{(k)} = -\alpha_k \text{ on } \partial M^{(k)}.
\]

Moreover, Theorems [4.3] and [4.9] imply

\[
\sup_{M^{(k)}} \Delta u^{(k)} \leq C_k (1 + \sup_{\partial M^{(k)}} |\nabla u^{(k)}|^2)(1 + \sup_{M^{(k)}} |\nabla u^{(k)}|^2)
\]

holds for \(C_k\) depending on \(|\psi|_{C^2(M^{(k)})}, |u^{(k)}|_{C^2(M^{(k)})}, |u^{(k)}|_{C^0(M^{(k)})}, \partial M^{(k)}\) up to its second order derivatives and other known data.

If we could prove there is a uniform constant \(C\) depending not on \(k\), such that

\[
|u^{(k)}|_{C^0(M^{(k)})} + \sup_{\partial M^{(k)}} |\nabla u^{(k)}| \leq C,
\]

together with the construction of approximating Dirichlet problems, (5.3) then holds for a uniformly constant \(C'\) which is independent of \(k\). Thus we have \(|u|_{C^2(M^{(k)})} \leq C\) depending not on \(k\) (here we use blow up argument to derive gradient estimate).
Thus the equations are all uniformly elliptic, and as in [40] we can directly prove the bound of real Hessians of solutions.

Finally, we are able to apply Silvestre-Sirakov’s [69] result to derive \( C^{2,\alpha'} \) estimates on the boundary, while the convergence of \( \partial M^{(k)} \) in the norm \( C^{2,\beta} \) allows us to take a limit (\( \alpha' \) can be uniformly chosen).

Let \( w^{(k)} \) be the solution of
\[
\Delta w^{(k)} + g^{ij} w_i^{(k)} \eta_j + g^{ik} \eta_i w_j^{(k)} + g^{ij} \tilde{\chi}^{ij} = 0 \text{ in } M^{(k)}, \quad w^{(k)} = -\alpha_k \text{ on } \partial M^{(k)}.
\]
By maximum principle and the boundary value condition \( \underline{u}^{(k)} = u^{(k)} = w^{(k)} = -\alpha_k \) on \( \partial M^{(k)} \) we have
\[
\underline{u}^{(k)} \leq u^{(k)} \leq w^{(k)} \text{ in } M^{(k)}, \quad \text{and } \frac{\partial u^{(k)}}{\partial \nu} \leq \frac{\partial u^{(k)}}{\partial \nu} \leq \frac{\partial w^{(k)}}{\partial \nu} \text{ on } \partial M^{(k)}.
\]
By the regularity theory of elliptic equations we have
\[
\sup_{M^{(k)}} w^{(k)} + \sup_{\partial M^{(k)}} \frac{\partial u^{(k)}}{\partial \nu} \leq C.
\]
We thus complete the proof of (5.4), and then obtain \( C^{2,\alpha}\text{-admissible} \) solution of
\[
F(g[\hat{u}]) = \psi \text{ in } M, \quad u = 0 \text{ on } \partial M.
\]
If \( \frac{\partial g[u]}{\partial \nu}|_{\partial M} \geq 0 \) or \( \frac{\partial g[u]}{\partial \nu}|_{\partial M} \leq 0 \), we can apply a \( C^{2,\beta} \) function extended by the distance function to boundary to make perturbation for \( u \) to construct a sequence of approximating problems on \( M \) with homogeneous boundary data. We then continue the perturbation process as previous case.

5.0.2. The significant phenomena on \( M = X \times S \). First of all, an observation claims that, when \( M = X \times S \) the solutions of equation (1.1) with different boundary data can be expressed each other if the boundary values only differ by a function varying only on \( S \). More precisely,

**Theorem 5.1.** Let \( (M, J, \omega) = (X \times S, J, \omega) \), \( \eta^{1,0} = \pi_2^* \eta_S^{1,0} \) be as in Theorem 1.9, we assume \( \hat{u} \) is the solution to \( F(g[\hat{u}]) = \psi \) with boundary data \( \hat{u}|_{\partial M} = \hat{\varphi} \). Suppose \( \hat{\varphi} = \tilde{\varphi} + \varphi \) for some \( \varphi \in C^{2,\beta}(\partial S) \). Then \( \hat{u} = \hat{\varphi} + \varphi \) coincides with the solution of
\[
F(g[\hat{u}]) = \psi \text{ in } M, \quad \hat{u} = \hat{\varphi} \text{ on } \partial M,
\]
where \( \varphi \) solves
\[
\sqrt{-1} \partial_S \bar{\psi} + \sqrt{-1} \partial_S \bar{\varphi} + \sqrt{-1} \eta_{S}^{1,0} \wedge \bar{\varphi} = 0 \text{ in } S, \quad \varphi = \varphi \text{ on } \partial S.
\]

**Proof.** \( g[u] = g[\hat{u}] + \pi_2^* (\sqrt{-1} \partial_S \bar{\psi} + \sqrt{-1} \partial_S \bar{\varphi} + \sqrt{-1} \eta_{S}^{1,0} \wedge \bar{\psi}) = g[\bar{u}] \).

**Corollary 5.2.** Let \( \bar{u}, \hat{u} \) are respectively admissible solutions of
\[
F(g[\bar{u}]) = \psi \text{ in } M, \quad \bar{u} = \bar{\varphi} \text{ on } \partial M, \quad F(g[\hat{u}]) = \psi \text{ in } M, \quad \hat{u} = \hat{\varphi} \text{ on } \partial M,
\]
and \( \hat{\varphi} - \bar{\varphi} = \varphi \) for some \( \varphi \in C^{2,\beta}(\partial S) \). Then \( \hat{\varphi} = \bar{\varphi} + \varphi \), where \( \varphi \) solves (5.9).
Proof of Theorem 1.9. Here we give two proofs.

First proof: By Theorem 5.1 we only need to consider the special case when the boundary data $\varphi = 0$. As above Dirichlet problem (5.8) admits admissible subsolutions $u = Nh$ for large $N$, where $h$ is the solution to (1.16). Theorems 1.6 and 5.1 together with the construction of subsolution, immediately yield Theorem 1.9.

Besides, we construct the approximating Dirichlet problems precisely as in the following, and also give another constructive proof by only using $h$ and maximum principle but without using the regularity theory of elliptic equations.

Note that $h$ is a function on $S$ with $\frac{\partial h}{\partial \nu}|_{\partial S} < 0$. Similarly, there is a sequence of smooth approximating functions $\{h^{(k)}\}$ on $S$ such that $h^{(k)} \to h$ in $C^{2,\beta}(S)$, and

$$\frac{1}{2}\omega_S \leq \sqrt{-1}\partial_S\bar{\partial_S}h^{(k)} + \sqrt{-1}\partial_Sh^{(k)} \wedge \eta_S^{1,0} + \sqrt{-1} \eta_S^{1,0} \wedge \bar{\partial_S}h^{(k)}$$

(where here we use (1.16)), moreover, we also get a sequence of level sets of $h^{(k)}$, say $\{h^{(k)} = -\frac{\alpha}{N}\}$ and use it to enclose a smooth complex submanifold of complex dimension one, say $S^{(k)}$, such that $\cup S^{(k)} = S$ and $\partial S^{(k)}$ converge to $\partial S$ in the norm of $C^{2,\beta}$.

Let us denote $M^{(k)} = X \times S^{(k)}$, and $u^{(k)} = Nh^{(k)}$. Then $u^{(k)}$ satisfies (5.11), $u^{(k)}|_{\partial M^{(k)}} = -\alpha_k$ and

$$(5.10) \quad \frac{N}{2} \tr_\omega(\pi_2^*\omega_S) \leq \Delta u^{(k)} + g^{ij}(u^{(k)})\eta_{ij} + g^{ij}\eta_i(u^{(k)}j)$$

in $M^{(k)}$.

In other words, Dirichlet problem (5.2) has an admissible subsolution $u^{(k)}$. To derive (5.10) we use the fact that $J$ is the induced complex structure.

Let $u^{(k)}$ be the solution to (5.2). We only need to prove (5.11). Let $N \geq k^{-1}\sup_M \tr_\omega \bar{\chi}$, where $\kappa_1 = \inf_M \frac{1}{2} \tr_\omega(\pi_2^*\omega_S)$. Applying comparison principle to (5.5) and (5.10),

$$w^{(k)} \leq -u^{(k)} - 2\alpha_k$$

in $M^{(k)}$, and

$$\frac{\partial w^{(k)}}{\partial \nu} \leq -\frac{\partial u^{(k)}}{\partial \nu}$$

on $\partial M^{(k)}$,

which is exactly (5.7). Here we don’t use the regularity theory of elliptic equations. Therefore, we get the $C^{2,\alpha'}$ admissible solution $u$ to (5.8).

Since the boundary values of approximating Dirichlet problems (5.2) are all constants, the advantage of this proof is that one may improve H"older exponent $\alpha'$ for $C^{2,\alpha'}$ boundary estimates which is derived from a result of Silvestre-Sirakov [69].

Second proof: The second proof is based on Theorem 1.14 and so the boundary data of approximating Dirichlet problems need not be constant. It is straightforward by using standard approximation.

Let $v$ be the solution to (5.9). The subsolution is given by $u = v + Nh$ for $N \gg 1$. The conditions of $\eta^{1,0} = \pi_2^*\eta_S^{1,0}$ and $\lambda(\bar{\chi} + c\pi_2^*\omega_S) \in \Gamma$ for some $c > 0$ yield $u$ is admissible for large $N$.

Let $S^{(k)} \subset S$ be smooth domains which approximate $S$ in the $C^{2,\beta}$ norm ($\partial S^{(k)} \to \partial S$ in $C^{2,\beta}$ norm). We also approximate $u$ by smooth functions $u^{(k)}$ and then obtain
a sequence of approximating Dirichlet problems
\begin{equation}
F(\mathbf{g}[u^{(k)}]) = \psi - \beta_k \text{ in } X \times S^{(k)}, \ u^{(k)} = u^{(k)} \text{ on } X \times \partial S^{(k)},
\end{equation}
with admissible subsolution \( u^{(k)} \) (\( \beta_k \to 0, \beta_k > 0 \)). Thus there is a unique smoothly admissible solution \( u^{(k)} \in C^\infty(X \times S^{(k)}) \) for each \( k \gg 1 \).

We need only to prove (5.4). Let \( w^{(k)} \) be the solution to
\[ \Delta w^{(k)} + g^{i\bar{j}} w_i^{(k)} \eta_j + g^{i\bar{j}} \eta_i w_j^{(k)} + g^{i\bar{j}} \tilde{\eta}_{i\bar{j}} = 0 \text{ in } X \times S^{(k)}, \ w^{(k)} = u^{(k)} \text{ on } X \times \partial S^{(k)}. \]
Thus one has (5.6) and (5.7) by using standard regularity theory of elliptic equations.

Proof of Theorem 1.10. We prove it by using standard method of approximation. Let’s choose a sequence of smooth Riemann surfaces/domains \( S_k \subset S \) such that \( \bigcup_k S_k = S \), and \( \partial S_k \to \partial S \) in \( C^{2,1} \)-norm as \( k \to +\infty \). Also, we denote \( M_k = X \times S_k \).

Let’s consider a family of approximating problems
\begin{equation}
F(\mathbf{g}[u^{(k)}]) = \psi \text{ in } M_k, \ u^{(k)} |_{\partial M_k} = w |_{\partial M_k}.
\end{equation}
The condition (1.14) allows us applying the solution of \( \Delta s h^{(k)} = 1 \) in \( S_k, \ h^{(k)} |_{\partial S_k} = 0 \) to construct the admissible subsolutions \( u^{(k)} \) to Dirichlet problem (5.12). Then (5.12) has a unique admissible solutions \( u^{(k)} \) according to Theorem 1.4. Similarly, the standard regularity theory of elliptic equations gives (5.6) and (5.7).

This completes the proof. \[ \square \]

Remark 5.3. The proof of Theorem 1.6 is based on approximation method. The approximating Dirichlet problems are constructed as follows: one first approximates \( u \) by smooth functions in the norm of \( C^{2,\beta} \), and then uses the level sets of smooth approximating functions to enclose submanifolds/domains.

Remark 5.4. The weak solutions for degenerate equations in Theorem 1.9 may achieve shape \( C^{2,\beta} \)-regularity in some context:
\[ f |_{\partial T} = 0, \ \omega = \pi^*_X \omega_X + \pi^*_S \omega_S, \ \tilde{\chi} = \pi^*_X \tilde{\omega}_X + \pi^*_S \tilde{\omega}_S, \ \eta^{1,0} = \pi^*_S \eta^{1,0}_S. \]
More precisely, the line \( \{1, \cdots, 1, t : t \in \mathbb{R}\} \) must intersect with \( \partial T \) at a unique point \((1, \cdots, 1, \mu_n)\). Let \( h' \) be the solution to
\[ \chi_2 + \sqrt{-1} \partial_s \bar{s} h' + \sqrt{-1} \partial_s h' \wedge \eta^{1,0}_S + \sqrt{-1} \bar{s} h' = \mu_n \omega_S \text{ in } S, \ h' = 0 \text{ on } \partial S. \]
Then \( \lambda(\mathbf{g}[u]) = (1, \cdots, 1, \mu_n) \) on \( M \) for \( u = h' \). And thus it is the weak solution of
\[ f(\lambda(\mathbf{g}[u])) = 0 \text{ in } M, \ u = 0 \text{ on } \partial M, \]
which has optimal \( C^{2,\beta} \)-regularity. In particular, \( u = -h \) (here \( h \) solves (1.16)) solves homogeneous complex Monge-Ampère equation
\[ \left( \omega + \sqrt{-1} \partial \bar{\partial} u + \sqrt{-1} \partial u \wedge \eta^{1,0} + \sqrt{-1} \bar{s} \eta^{1,0} \wedge \bar{s} u \right)^n = 0 \text{ in } M, \ u = 0 \text{ on } \partial M. \]
6. Dirichlet problem on complex manifolds with general boundary

6.1. The solvability and uniqueness of weak solution to Dirichlet problem. Assuming either (2) or (3) in Theorem 1.1 holds, we can directly derive the gradient estimate which relaxes the restriction to the shape of boundary. The proof of estimates will be given below. We then have

Theorem 6.1. Let $\partial M \in C^4$, $\varphi \in C^4(\partial M)$, $\psi \in C^2(\overline{M})$ and we assume (1.4), (1.5), (1.6) and there is an admissible subsolution $u \in C^{3,1}(\overline{M})$. Suppose one of (2) and (3) in Theorem 1.1 holds. Then there is a unique $C^{3,\alpha}$, $\forall 0 < \alpha < 1$ admissible function to solve Dirichlet problem (1.1)-(1.2). Moreover, if the given data $\partial M$, $\varphi$, $\psi$ are all smooth, then the solution is also smooth.

We also solve the Dirichlet problem for degenerate equations.

Theorem 6.2. Suppose, in addition to $f \in C^\infty(\Gamma) \cap C(\overline{\Gamma})$, (1.4), (1.5), $\psi \in C^1(\overline{M})$, and $\delta \varphi = 0$, that $\varphi \in C^{3,1}$, $\partial M$ is $C^{3,1}$ pseudoconcave boundary, and there is a strictly admissible subsolution $u \in C^{3,1}(\overline{M})$. Suppose one of (2) and (3) in Theorem 1.1 holds. Then Dirichlet problem (1.1)-(1.2) has a weak solution $u \in C^{1,\alpha}(\overline{M})$, $\forall 0 < \alpha < 1$, with $u|_{\partial M} = \varphi$, $\lambda(g[u]) \in \Gamma$ and $\Delta u \in L^\infty(\overline{M})$.

Following [14] we define

Definition 6.3. A continuous function $u \in C(\overline{M})$ is a weak $C^0$-solution to degenerate equation (1.1) (inf $\psi = \sup \partial \Gamma f$) with boundary data $\varphi$ if the following is true: For any $\epsilon > 0$, there is a $C^2$-admissible function $\tilde{u}$ such that $\|u - \tilde{u}\| < \epsilon$, where $\tilde{u}$ solves

$$F(g(\tilde{u})) = \varphi + \rho \epsilon \text{ in } M, \quad \tilde{u} = \varphi \text{ on } \partial M.$$ 

Here $\rho \epsilon$ is a function satisfying $0 < \rho \epsilon < C(\epsilon)$, and $C(\epsilon) \to 0^+$ as $\epsilon \to 0^+$.

Theorem 6.4. Suppose $u^1$ and $u^2$ are two $C^0$-weak solutions to the degenerate equation (1.1) with boundary data $\varphi^1$ and $\varphi^2$, respectively. Then $\sup_M \|u^1 - u^2\| \leq \sup_{\partial M} |\varphi^1 - \varphi^2|$.

The proof is based on comparison principle, which is almost parallel to that of Theorem 4 in [14]. We thus omit it here.

Corollary 6.5. The weak $C^0$-solution to Dirichlet problem (1.1)-(1.2) for degenerate equation is unique provided the boundary data is fixed.

Clearly, the weak solutions we obtain in this paper by using continuity method are weak $C^0$-solutions to corresponding Dirichlet problem in the sense of Definition 6.3.

As a corollary, we prove the constant rank in Theorem 1 of Li [59] is indeed $n$ when the boundary data is $\varphi = 0$.

Corollary 6.6. Let $\Omega \subset C^n$ be a smooth bounded strictly pseudoconvex domain, $\phi$ be a smooth plurisubharmonic function. If the solution to

$$\sigma_k(u_{i\overline{j}}) = e^{-\phi} \text{ in } \Omega, \quad u|_{\partial \Omega} = 0,$$

(6.1)
is plurisubharmonic, Then $u$ is a strictly plurisubharmonic function in $\Omega$. Moreover, $\sqrt{-1} \partial \bar{\partial} u|_{\partial \Omega} > 0$.

**Proof.** If the rank as claimed by Li’s constant rank theorem is $\leq n - 1$, then $u$ is a weak $C^0$-solution to homogeneous complex Monge-Ampère equation with homogeneous boundary data. We observe that $u \equiv 0$ is clearly a weak $C^0$-solution to $\det(u_{i\bar{j}}) = 0$ with homogeneous boundary data and with rank($u_{i\bar{j}}$) $\equiv 0 < k$. We thus have two different weak $C^0$-solutions, which contradict to Corollary 6.5.$^\Box$

### 6.2. The direct proof of gradient estimate.

In this subsection we prove gradient estimate directly with assuming (2) or (3). Let’s consider the quantity $\epsilon \phi |\nabla u|^2$, where

$$\phi = Ae^\delta, \quad \hat{\eta} = B[u - u - \inf_M(u - u)],$$

and $A$ and $B$ are both two positive constants to be determined.

Suppose that $\epsilon \phi |\nabla u|^2$ achieves its maximum at an interior point $p \in M$. We can further assume $|\nabla u|^2(p) \geq 1$ (otherwise we are done). We choose local holomorphic coordinates $z = (z^1, \ldots, z^n)$ around $p$ such that at $p$

$$g_{i\bar{j}} = \delta_{ij}, \quad g_{i\bar{j}} = \lambda_i \delta_{ij}, \quad F^{i\bar{j}} = \delta_{ij} f_i,$$

\[
\begin{align*}
\left\{ \begin{array}{l}
\frac{(|\nabla u|^2)_i}{|\nabla u|^2} + \phi_i = 0, \\
\frac{(|\nabla u|^2)_{\bar{i}}}{|\nabla u|^2} + \phi_{\bar{i}} = 0, \\
\frac{(|\nabla u|^2)_{i\bar{i}}}{|\nabla u|^2} - (\frac{|\nabla u|^2}{|\nabla u|^2})_i^2 + \phi_{i\bar{i}} \leq 0.
\end{array} \right.
\end{align*}
\]

At $p$ we then obtain

$$\mathcal{L}(|\nabla u|^2 + \phi) \leq 0.$$  

In what follows the computations are done at $p$. We have by (6.3) and (6.4)

\[
\begin{align*}
\mathcal{L}(|\nabla u|^2) &\geq F^{i\bar{k}} |u_{ki}|^2 + F^{i\bar{k}} |u_{ik}|^2 - 2\Re(F^{i\bar{k}} u_{ki} T_{i\bar{l}}^k u_l) - 2|\nabla' \psi| |\nabla u| \\
&- C|\nabla u| \sum F^{i\bar{k}} + F^{i\bar{k}} R_{i\bar{kl}} u_{ki} u_{l\bar{k}} + 2\Re \{F^{i\bar{j}} \chi_{ij,\bar{\alpha} \bar{\beta}} T_{k\alpha}^i u_{l\bar{k}} u_{\bar{l}\bar{k}} \} \\
&- 2\Re[F^{i\bar{i}} (\eta_{i\bar{k} u_i} + u_i \eta_{k,i}) u_{\bar{k}}] + 2\psi_u |\nabla u|^2, \\
F^{i\bar{i}}(|\nabla u|^2)_i^2 &\leq \epsilon \phi^2 |\nabla u|^4 F^{i\bar{i}} |\nabla \hat{\eta}|^2 + (1 - \epsilon) F^{i\bar{i}} |u_{ki} u_{k\bar{i}}|^2 \\
&- 2(1 - \epsilon) |\nabla u|^2 F^{i\bar{i}} \Re(u_{ki} u_{k\bar{i}} \phi_i),
\end{align*}
\]
where $0 \leq \epsilon < 1$, which are used to deal with $\mathcal{L}(\log |\nabla u|^2)$ precisely as follows:

$$
\mathcal{L}(\log |\nabla u|^2) \geq \frac{1}{|\nabla u|^2} F^{\bar{i}i} u_{i\bar{k}}^2 - \frac{2}{|\nabla u|^2} \Re(F^{\bar{i}i} u_{k\bar{i}} T_{k\bar{i}}^i u_i) + 2 \psi u
- 2|\nabla' \psi| + \frac{2}{|\nabla u|^2} \Re\{F^{\bar{ij}} \chi_{j\bar{k},i\alpha} T_{k\alpha}^l u_i u_k\}
- \frac{2}{|\nabla u|^2} \Re(F^{\bar{i}i}(u_i \eta_{i,k} + u_i \eta_{k,i}) u_k) + \frac{1}{|\nabla u|^2} F^{\bar{i}i} R_{i\bar{k}i\bar{k}i} u_k u_k
+ \frac{2(1 - \epsilon)}{|\nabla u|^2} F^{\bar{i}i} \Re(u_k u_{i\bar{k}} \phi_i) - \epsilon \phi^2 F^{\bar{i}i} |\hat{\eta}|^2.
$$

(6.7)

6.2.1. A direct proof of gradient estimate for solutions, part I. We derive directly gradient estimate given (1.10) and $g \geq 0$.

Firstly, the condition $\sum_{i=1}^{n} f_i \lambda_i \geq 0$ together with (3.1) implies that there is a uniformly positive constant $\kappa_0$ such that $\sum_{i=1}^{n} f_i \geq \kappa_0$. Next, we will describe a property of the level hypersurface $\partial \Gamma^\alpha$. By the concavity and monotonicity of $f$, we know that if the level hypersurface $\partial \Gamma^\alpha$ is nonempty then it is smooth and convex. For $\lambda \in \partial \Gamma^\alpha$, let $t_\lambda(\lambda) = \frac{\sum_{i=1}^{n} f_i \lambda_i}{\sum_{i=1}^{n} f_i (\lambda)}$. The convexity of the level hyperplane yields

$$
t_\lambda(\lambda) \leq c_\alpha \lambda \in \partial \Gamma^\alpha,
$$

where $c_\alpha$ is the positive constant defined as in (3.7). In particular $f_i \lambda_i \leq c_\alpha \sum_{j=1}^{n} f_j$ for each $1 \leq i \leq n$.

When (1.10) holds it was considered in [33]. In this paper, we consider the critical case that the equality in (1.10) may occur. To deal with this critical case we need some new observation.

Suppose (1.10) holds. Then for any fixed $0 < \epsilon < 1$, $w$ obeying (1.10) is a $\mathcal{C}$-subsolution of the rescaled equation (2.7). We take in (6.2) $u = w$.

A straightforward computation shows

$$
\phi_i = \phi \hat{\eta}, \ \phi_{\bar{i}\bar{j}} = \phi(|\hat{\eta}|^2 + \hat{\eta}_{i\bar{j}}) \text{ and } \mathcal{L} \phi = \phi \mathcal{L} \hat{\eta} + \phi F^{\bar{i}i} |\hat{\eta}|^2.
$$

(6.9)

It follows from (6.3), (6.7) and (6.9) that

$$
0 \geq \mathcal{L} \hat{\eta} + \frac{1}{2\phi |\nabla u|^2} F^{\bar{i}i} u_{i\bar{k}}^2 + (1 - \epsilon \phi) F^{\bar{i}i} |\hat{\eta}|^2 - \frac{C}{\phi} \sum_{i} F^{\bar{i}i}
+ \frac{2}{\phi} \left( \psi u - \frac{|\nabla' \psi|}{|\nabla u|} \right) + \frac{2(1 - \epsilon)}{\phi |\nabla u|^2} \Re(F^{\bar{i}i} u_k u_{i\bar{k}} \phi_i).
$$

Using Cauchy-Schwarz inequality, (6.6) and (6.9), one obtains

$$
2\phi^{-1} \Re(u_k u_{i\bar{k}} \phi_i) \geq 2\Re(g_{\bar{i}\bar{j}} u_i \hat{\eta}) - \frac{1}{8} |\nabla u|^2 |\hat{\eta}|^2 - C(1 + |\nabla u|^2 |\hat{\eta}|)
\geq 2B \Re(g_{\bar{i}\bar{j}} u_i u_j) - 2B g_{\bar{i}\bar{j}} |u_i|^2 - \frac{1}{2} |\nabla u|^2 |\hat{\eta}|^2 - C' |\nabla u|^2.
$$
Choosing $0 < \epsilon < 1$ small enough such that $\epsilon \sup_M \phi \leq \frac{1}{4}$, we finally have

$$0 \geq \mathcal{L}\hat{\eta} + \frac{1}{2\phi|\nabla u|^2}F^{\hat{u}}|u_{\hat{\kappa}}|^2 + \frac{2}{\phi}(\psi_u - \frac{\nabla'\psi}{|\nabla u|}) - C(1 + \frac{1}{\phi})\sum_i F^{\hat{u}}$$

(6.10)

$$+ \frac{1}{4}F^{\hat{u}}|\hat{\eta}_{\hat{\kappa}}|^2 + \frac{2B(1-\epsilon)}{|\nabla u|^2}\Re(F^{\hat{u}}g_{\hat{u}}u_{\hat{\kappa}}) - 2B(1-\epsilon)\max_i F^{\hat{u}}g_{\hat{u}}.$$

**Theorem 6.7.** Let $(M, \omega)$ be a compact Hermitian manifold (possibly with $C^2$ boundary), and $\psi \in C^4(M)$ be a smooth function. In addition to (1.4), (1.5), (1.6), we suppose (3) in Theorem 7.1 holds. Then for any admissible solution $u \in C^3(M) \cap C^4(M)$ of equation (1.1), there is a uniformly positive constant $C$ depending on $|u|_{C^0(M)}$, $|\chi|_{C^1(M)}$, $|\varrho u|_{C^2(M)}$, $|\psi|_{C^4(M)}$ and other known data under control so that

$$\sup_M |\nabla u| \leq C(1 + \sup_{\partial M} |\nabla u|).$$

(6.11)

Moreover, the constant $C$ is independent of $(\delta_{\psi,1})^{-1}$.

**Proof.** In this theorem $\psi_u = 0$ and $\Lambda$ denotes $\lambda(\varrho(\bar{w}))$ for $\bar{w}$ obeying (1.10). As above, we suppose that $e^\phi|\nabla u|^2$ achieves its maximum at an interior point $p \in M$. It follows from (6.8) and $g \geq 0$ that if there is a positive constant $\bar{\psi}$ such that $f_i \geq \bar{\psi}\sum_{j=1}^n f_j$ for each $i$, then $\lambda_i \leq \bar{\psi}^{-1}C_{\sup_M} \psi$ and so

$$|\varrho| \leq n\bar{\psi}^{-1}C_{\sup_M} \psi.$$

(6.12)

The second case of Lemma 3.2 goes to (6.12). We know that there are two uniformly positive constants $R_1$ and $\bar{\psi}$ such that if $|\varrho| \geq R_1$ then

$$\sum_{i=1}^n f_i(\lambda)(\frac{1}{3 - 2\epsilon}\lambda_i - \lambda_i) \geq \bar{\psi}\sum_{i=1}^n f_i(\lambda).$$

(6.13)

More precisely, if there exists a $C$-subsolution of the rescaled equation (2.7) we know that (6.13) holds according to Lemma 3.2 and (6.12). This observation leads to using the $C$-subsolution for the rescaled equation to prove gradient estimate.

If $|\varrho| < R_1$ then we have the bound of $|\nabla u|$ by the interpolation inequality, see [36]. (On the other hand, when $|\varrho| < R_1$ the equation is a uniformly elliptic equation, and so the proof of the bound of $|\nabla u|$ is trivial).

From now on, we assume $|\varrho| \geq R_1$. Lemma 6.2 in [11] implies

$$\mathcal{L}\hat{\eta} = B\mathcal{L}(u - u) = BF^{\hat{u}}(g_{\hat{u}} - g_{\hat{u}}) \geq B\sum_{i=1}^n f_i(\lambda_i - \lambda_i)$$

which can be used to dominate the bad term $2B\max_i f_i \lambda_i$ in (6.10). More explicitly, (6.13) and the assumption $g \geq 0$ immediately yield

$$\mathcal{L} \hat{\eta} - 2B(1-\epsilon)\max_i F^{\hat{u}}g_{\hat{u}} \geq B\sum_{i=1}^n f_i(\lambda_i - (3 - 2\epsilon)\lambda_i) \geq (3 - 2\epsilon)B\bar{\psi}\sum_{i=1}^n f_i.$$
By choosing $A \gg 1$ and $B \gg 1$ we derive $|\nabla u| \leq C$. Here we use (6.8) and $g \geq 0$ to control $\frac{2B(1-\epsilon)}{|\nabla u|^2} \Re(\bar{g}^i u_i u_k)$, and also use $\sum f_i \geq \kappa_0$ to control the bad term $\frac{2|\nabla \psi|}{\bar{g}|\nabla u|}$.

Remark 6.8. With $\tilde{\varphi}$ replaced by $g[u]$, we can assume the $C$-subsolution of the rescaled equation is $\underline{u} = 1$. The proof does work for the equation satisfying

$$f_j\lambda_j \leq \varphi(\lambda) \sum_{i=1}^{n} f_i\lambda_i \text{ in } \Gamma^\varphi = \Gamma^\lambda$$

for each $j$,

where $\varphi: \Gamma \to \mathbb{R}^+$ is a positive continuous function with $\lim \sup_{|\lambda| \to +\infty} \varphi(\lambda) = \varphi_0 > 0$, and $\Gamma^\varphi = \{ \lambda \in \Gamma: \inf_M \psi \leq f(\lambda) \leq \sup_M \psi \}$. More precisely, gradient estimate for equation (6.8) holds, provided that there exists $\underline{u} \in C^3(\Omega) \cap C^{2,1}(\Omega)$ such that

$$\lim_{t \to +\infty} f\left(\frac{1}{1 + 2\varphi_0}(\lambda(\varphi[u] + te_i))\right) > \psi \text{ in } \Omega, \text{ for each } i.$$ 

If $f$ further satisfies $\sum_{i=1}^{n} f_i(\frac{\lambda}{\varphi})\lambda_i > 0$, then (6.15) can be replaced by

$$\lim_{t \to +\infty} f\left(\frac{1}{1 + 2\varphi_0}(\lambda(\varphi[u] + te_i))\right) \geq \psi, \text{ in } \Omega, \forall i,$$

since $\underline{u}$ is a $C$-subsolution of $f\left(\frac{1}{1 + 2\varphi_0 - \epsilon}(\lambda)\right) = \psi$ for $0 < \epsilon \ll 1$ with using these two conditions. In particular, if $g \geq 0$ then we can choose $\varphi = 1$.

We provide a unified and straightforward approach to the direct proof of gradient estimate for $\omega$-plurisubharmonic solutions of complex Monge-Ampère equation [5, 48, 40, 50] and complex Hessian equation [87], as (1.18) allows a class of functions $f = (\sigma_k)^{\frac{1}{k}}$ corresponding to the cone $\Gamma_k$. Condition (1.18) is also satisfied by $\log P_k(\lambda) = \sum_{1 \leq i_1 < \cdots < i_k \leq n} \log(\lambda_{i_1} + \cdots + \lambda_{i_k})$ with the cone $P_k := \{ \lambda \in \mathbb{R}^n : \lambda_{i_1} + \cdots + \lambda_{i_k} > 0 \text{ for any } 1 \leq i_1 < \cdots < i_k \leq n \}$. The function $\log P_{n-1}$ has received attention, as Gauduchon’s conjecture reduces to solve Monge-Ampère equation for $(n-1)$-plurisubharmonic functions $\log P_{n-1}(\lambda(\bar{\chi} + \sqrt{-1}\bar{\partial}u + W(\partial u, \bar{\partial}u))) = \psi$ on closed Hermitian manifolds, where $W(\partial u, \bar{\partial}u)$ is a certain real $(1,1)$-form which depends linearly on $\partial u$ and $\bar{\partial}u$ (see also equation (8.3) below). Please refer to Section 8 for the discussion.

By an observation in Remark 6.8, we can give a direct proof of gradient estimate for Monge-Ampère equation for $(n-1)$ plurisubharmonic functions associated to Gauduchon’s conjecture under a stronger assumption: $\lambda(\bar{\chi} + \sqrt{-1}\bar{\partial}u + W(\partial u, \bar{\partial}u)) \in P_{n-2} = \{ \lambda \in \mathbb{R}^n : \lambda_{i_1} + \cdots + \lambda_{i_{n-2}} \geq 0, i_1 < \cdots < i_{n-2} \}$. Similarly, the argument works for the solutions with $\lambda \in P_{k-1}$ of the equations generated by $\log P_k$, in which we can check that (6.14) holds with $\varphi = \frac{\lambda}{n}$ if

$$\lambda(\bar{\chi} + \sqrt{-1}\bar{\partial}u + W(\partial u, \bar{\partial}u)) \in P_{k-1}.$$
We shall stress that our argument relaxes the restriction to \(W(\partial u, \overline{\partial} u)\) and works for more general real \((1, 1)\)-forms depending linearly on \(\partial u\) and \(\overline{\partial} u\).

**Proposition 6.9.** Let \(\psi \in C^1(\hat{M})\) and \(u \in C^3(\hat{M}) \cap C^1(\hat{M})\) be a solution of 
\[
\log P_k(\lambda(\hat{\chi} + \sqrt{-1}\partial\overline{\partial} u + W(\partial u, \overline{\partial} u))) = \psi, \quad 2 \leq k \leq n - 1.
\]
In addition, we assume \(W(\partial u, \overline{\partial} u)\) is a real \((1, 1)\)-form depending linearly on \(\partial u\) and \(\overline{\partial} u\). Then the gradient estimate \((6.11)\) holds for a uniformly positive constant \(C\), provided that \((6.17)\) holds.

6.2.2. A direct proof of gradient estimate for solutions, part II. Suppose \((M, \omega)\) is a compact Kähler manifold (possibly with boundary) with nonnegative orthogonal bisectional curvature, which tells

\[
\sum_{k,l} F^{i\bar{i}} R_{i\bar{i}k\bar{l}} u_k u_{\bar{l}} = \sum_{k \neq \bar{l}, l \neq \bar{i}} F^{i\bar{i}} R_{i\bar{i}k\bar{l}} u_k u_{\bar{l}} + F^{i\bar{i}} R_{i\bar{i}i\bar{i}} |u_i|^2
\]

\[
+ \sum_{k \neq \bar{i}} F^{i\bar{i}} R_{i\bar{i}k\bar{i}} u_k u_{\bar{i}} + \sum_{l \neq \bar{i}} F^{i\bar{i}} R_{i\bar{i}i\bar{i}} u_i u_{\bar{i}} 
\]

\[
\geq - C |\nabla u| (F^{i\bar{i}} |u_i|^2 + \sum F^{i\bar{i}}).
\]

Combining these inequalities with \((6.1)\) (by setting \(\epsilon = 0\)) and \(\psi_u \geq 0\), one has

\[
\mathcal{L}(\log |\nabla u|^2) \geq \frac{1}{|\nabla u|^2} F^{i\bar{i}} |u_{i\bar{i}}|^2 - \frac{2 |\nabla' \psi|}{|\nabla u|} + 2 \psi_u + \frac{1}{|\nabla u|^2} F^{i\bar{i}} R_{i\bar{i}k\bar{k}} u_k u_{\bar{k}}
\]

\[
- \frac{2}{|\nabla u|^2} \text{Re}[F^{i\bar{i}}(u_i \eta_{\bar{k}, k} + u_{\bar{k}} \eta_{k, i}) u_k] + \frac{2}{|\nabla u|^2} \text{Re}(F^{i\bar{i}} u_{i\bar{k}} u_{\bar{i}k} \phi_{\bar{i}})
\]

\[
\geq 1 |\nabla u|^2 F^{i\bar{i}} |u_{i\bar{i}}|^2 - \frac{C}{|\nabla u|} (1 + \sum F^{i\bar{i}}) - \frac{C}{|\nabla u|} F^{i\bar{i}} |u_i|^2
\]

\[
- \phi(\frac{4}{|\nabla u|^2} F^{i\bar{i}} |u_{i\bar{k}}|^2 + \frac{1}{4} F^{i\bar{i}} |\eta_{\bar{k}}|^2).
\]

Here we also use

\[
|2 \text{Re}[F^{i\bar{i}}(u_i \eta_{\bar{k}, k} + u_{\bar{k}} \eta_{k, i}) u_k]| \leq C |\nabla u|(F^{i\bar{i}} |u_i|^2 + \sum F^{i\bar{i}}),
\]

\[
\frac{2}{|\nabla u|^2} \text{Re}(F^{i\bar{i}} u_{i\bar{k}} u_{\bar{i}k} \phi_{\bar{i}}) \geq - \phi(\frac{4}{|\nabla u|^2} F^{i\bar{i}} |u_{i\bar{k}}|^2 + \frac{1}{4} F^{i\bar{i}} |\eta_{\bar{k}}|^2).
\]

We assume \(\psi_u \geq 0\) so that \((6.20)\) below can be applied to the equations considered in Section 7.

Assume \(|\nabla u|\) is large sufficiently. Then one has

\[
0 \geq \mathcal{L} \hat{\eta} + \frac{1}{2} F^{i\bar{i}} |\hat{\eta}_{\bar{i}}|^2 + \frac{1}{4 \phi |\nabla u|^2} F^{i\bar{i}} \hat{g}_{i\bar{i}}^2 - \frac{C}{\phi |\nabla u|} (1 + \sum F^{i\bar{i}}).
\]

Here we assume \(B \gg 1\), and \(A\) is small enough such that \(\phi \leq \frac{1}{8}\). Therefore, we extend a result in [83] and obtain
**Theorem 6.10.** Let \((M, \omega)\) be a compact Kähler manifold admitting nonnegative orthogonal bisectional curvature with \(C^2\) boundary. Let \(\psi \in C^1(M)\). Assume (1.4), (1.5), (1.6) and (1.8) hold. Then for any admissible solution \(u \in C^3(M) \cap C^1(M)\) of Dirichlet problem (1.1)-(1.2) we have

\[
\sup_M |\nabla u| \leq C (1 + \sup_{\partial M} |\nabla u|),
\]

where \(C\) is a positive constant depending on \(|u|_{C^0(M)}, |\psi|_{C^1(M)}\) and other known data under control (but not on \((\delta \psi, f)^{-1}\)).

**Proof.** The proof is based on (6.20). In this theorem \(\psi u = 0\). By using Lemma 3.1 we can derive the direct gradient estimate. When \(|\nu_\lambda - \nu_\lambda| \geq \beta\) we have (4.32), and thus \(|\nabla u| \leq C\). On the other hand, if \(|\nu_\lambda - \nu_\lambda| < \beta\), then one has (4.33). Fix \(A, B\) as we chosen above. Note that the concavity of equation (1.1) implies that \(\mathcal{L}(u - u) \geq 0\) (since \(\psi\) is independent of \(u\)). We can assume \(|\nabla u| \geq 2|\nabla u|\) (otherwise we are done). Then \(|\nabla \tilde{\eta}|^2 \geq \frac{B^2}{\phi} |\nabla u|^2\). By Cauchy-Schwarz inequality,

\[
\frac{\beta}{8\sqrt{n}} |\nabla \eta|^2 \sum_{i=1}^n f_i + \frac{\beta |\lambda|^2}{8n \phi |\nabla u|^2} \sum_{i=1}^n f_i \geq \frac{\beta B}{8\sqrt{n \sup_M \phi}} |\lambda| \sum_{i=1}^n f_i.
\]

If \(|\lambda| \geq R_0\), by using (4.36) then \(|\lambda| \sum f_i \geq b_0\), and thus we derive

\[
|\nabla u| \leq C.
\]

When \(|\lambda| < R_0\) the bound of \(|\nabla u|\) can be also derived by the interpolation inequality. \(\square\)

**Remark 6.11.** With (1.8) replaced by a \(C\)-subsolution, and we assume (3.5) and the other assumptions Theorem 6.10 hold. Then the gradient estimate holds for any admissible solution \(u \in C^3(M) \cap C^1(M)\) of equation (1.1). The proof is similar, while the slight difference is that in the proof we apply Lemma 3.2 and use (4.3) and \(\frac{1}{2} |\nabla \hat{\eta}|^2\) in (6.20) to control the bad term \(\mathcal{L}(u) \geq B(f(\lambda(g)) - \psi)\) when (3.4) holds.

**Remark 6.12.** The term \(-2\Re(F^2 u_k\bar{k} \sum T^k_i u_i)\) in (6.5) vanishes on a Kähler manifold which plays a formal role the same as the term due to holomorphic bisectional curvature tensor (when \(\Gamma = \Gamma_n\) it can be extended to Hermitian setting). This is the reason why we assume \((M, \omega)\) is a Kähler manifold.

### 6.3. Boundary estimates for second order estimates on general boundary.

To complete the proof we need to derive directly the boundary estimates for Dirichlet problem on compact complex manifolds with general boundary.

**Theorem 6.13.** In addition to (1.4), (1.5), (1.6) and (1.8), we suppose \(\partial M \in C^4, \varphi \in C^4(\partial M)\) and \(\psi \in C^1(M)\). Then for any admissible solution \(u \in C^3(M) \cap C^2(M)\) to Dirichlet problem (1.1)-(1.2), one has

\[
\sup_{\partial M} |\Delta u| \leq C,
\]
where $C$ is a uniformly positive constant depending on $|\varphi|_{C^4(M)}$, $|\psi|_{C^1(M)}$, $|u|_{C^1(M)}$ and $|u|_{C^2(M)}$ and other known data.

Proof. In complex setting Guan-Li [40], Guan-Sun [45] and the author [83] respectively proved Theorem 6.13 for complex Monge-Ampère equation and complex inverse $\sigma_k$ equations and certain fully nonlinear elliptic equations on compact Hermitian manifolds.

For completeness we give a proof of boundary estimates for Dirichlet problem (1.1)-(1.2) with gradient terms. Our proof is inspired by the proof of boundary estimates for fully nonlinear elliptic equations on Riemannian manifolds [38], and use an idea used in [74] who studied Hessian equations on bounded domains of $\mathbb{R}^n$. To do it we only need to prove there are two uniformly positive constants $c_0$, $\tilde{R}_1$ such that for $R \geq \tilde{R}_0$, $(\lambda'[g_{\alpha\beta}(x_0)], R) \in \Gamma$ and

$$f(\lambda'[g_{\alpha\beta}[u](x_0)], R) \geq \psi(x_0) + c_0. \tag{6.21}$$

Suppose we have found such $c_0$ and $\tilde{R}_0$. Then by Lemma 2.2 one could find $\tilde{R}_1$ such that if $g_{\alpha\beta} \geq \tilde{R}_1$ then

$$f(\lambda[\{g_{\alpha\beta}(x_0)\}]) \geq f(\lambda'[\{g_{\alpha\beta}(x_0)\}], g_{\alpha\beta}(x_0)) - \frac{c_0}{2}, \tag{6.22}$$

which gives the desired bound $g_{\alpha\beta}(x_0) \leq \max\{\tilde{R}_0, \tilde{R}_1\}$. Given $R > 0$ and a $(n-1) \times (n-1)$ Hermitian matrix $\{r_{\alpha\beta}\}$ with $(\lambda'[r_{\alpha\beta}(x_0)], R) \in \Gamma$, one defines

$$\tilde{F}[r_{\alpha\beta}] := f(\lambda'[r_{\alpha\beta}], R).$$

Let $c_R = \inf_{\partial M}(\tilde{F}[g_{\alpha\beta}] - F(\{g_{\alpha\beta}\}))$ and $m_R = \inf_{\partial M}(\tilde{F}[g_{\alpha\beta}] - \psi)$, where $\lambda'[g_{\alpha\beta}] = (\lambda_1', \ldots, \lambda_{n-1}')$ are the eigenvalues of the $(n-1) \times (n-1)$ matrix $\{g_{\alpha\beta}\}$ $(1 \leq \alpha, \beta \leq n-1)$. It is easy to see that if $R$ is large such that $(\lambda'[g_{\alpha\beta}(x_0)], R) \in \Gamma, (\lambda'[g_{\alpha\beta}(x_0)], R) \in \Gamma$, then $c_R$ and $m_R$ are both increase in $R$. By (1.4)-(1.6) and Lemma 2.2 there exists a uniformly positive constant $\tilde{R}_0$ depending only on $f$ and $A$, such that $c_{\tilde{R}_0} > 0$. The monotonic property of $c_R$ implies $c_R \geq c_{\tilde{R}_0} > 0$ for $R \geq \tilde{R}_0$.

We wish to show $m_R > 0$ for large $R$. If there is a uniformly positive constant $R$ such that $c_R > 0$ and $m_R \geq \frac{1}{2} c_R$, then there is nothing to prove. Therefore, we now assume $m_R < \frac{1}{2} c_R$ for any large $R$. Suppose $m_R$ is achieved at a point $p_0 \in \partial M$. As in (4.5), we choose the local coordinates centered at $p_0$ ($z = 0$). Our calculations below are done in $\Omega_\delta = \{z \in M : \rho(z) < \delta\}$.

Let $\tau_1, \ldots, \tau_{n-1}$ be a local frame of vector fields in $T^1.0 M$ around $p_0$ such that $g(\tau_\alpha, \tau_\beta) = \delta_{\alpha\beta}$ for $\alpha, \beta < n$ and $\tau_\beta = \frac{\partial}{\partial z_\beta}$ at $p_0$. Following [45] one extends $\tau_1, \ldots, \tau_{n-1}$ by their parallel transports along geodesics normal to $\partial M$ so that they are smoothly defined in a neighborhood $\Omega_\delta$ of $p_0$. Set $\tilde{F}^{(1)}_{\alpha\beta} = \frac{\partial \tilde{F}}{\partial r_{\alpha\beta}}[g_{\gamma\delta}(0)]$ and

$$\tilde{u}_{\alpha\beta} = u_{\tau_\alpha \tau_\beta}, \quad \tilde{g}_{\alpha\beta} = u_{\tau_\alpha r_\beta} + \tilde{x}(\tau_\alpha, \tau_\beta) + u_{\tau_\alpha} \tau_\beta + \eta_{\tau_\alpha} u_{\tau_\beta} \text{ for } \alpha, \beta < n.$$
In what follows, the Greek letters range from 1 to \( n - 1 \). By the concavity of \( \bar{F} \), for any symmetric matrix \( \{ r_{\alpha \beta} \} \) with \( (\lambda'[r_{\alpha \beta}(0)], R) \in \Gamma \),
\[
\bar{F}^\alpha_\beta(r_{\alpha \beta} - g_{\alpha \beta}(0)) \geq \bar{F}[r_{\alpha \beta}] - \bar{F}[g_{\alpha \beta}(0)].
\]
In particular, we have
\[
(6.23) \quad \bar{F}^\alpha_\beta g_{\alpha \beta} - \psi - \bar{F}^\alpha_\beta g_{\alpha \beta}(0) + \psi(0) \geq \bar{F}[g_{\alpha \beta}] - \psi - m_R \geq 0 \text{ on } \partial M.
\]
The boundary value condition implies that
\[
(6.24) \quad \bar{u}_{\alpha \beta} = \bar{\varphi}_{\alpha \beta} + (u - \varphi)\nu \bar{\sigma}_{\alpha \beta} \text{ on } \partial M \cap \bar{\Omega}_\delta,
\]
where \( \nu = \sum_{k=1}^{2n} \nu^k \frac{\partial}{\partial x_k} \) is the interior unit normal vector field to \( \partial M \). We know that \( |\nu^k| \leq C\rho \) and \( |(u - \varphi)t_k| \leq C\rho \) for \( k < 2n \), \( \nu^{2n}(0) = 1 \) on \( \partial M \cap \bar{\Omega}_\delta \) since \( \nu^k(0) = 0 \) for \( k \leq 2n - 1 \) and \( u = \varphi \) on \( \partial M \) (see also [45]).

Inequality (6.23) and identity (6.24) lead to constructing the barrier function
\[
\bar{\Phi} = -\bar{\eta}(u - \varphi)_{x_n} - \bar{F}^\alpha_\beta \bar{g}_{\alpha \beta}(0) - \psi + \psi(0) + \bar{F}^\alpha_\beta \left[ \bar{\varphi}_{\alpha \beta} + \bar{\chi}_{\alpha \beta} + \eta_{\alpha \beta} \varphi_{\alpha \beta} + \varphi_{\alpha \beta} \eta_{\alpha \beta} \right]
\]
\[
= -\bar{\eta}(u - \varphi)_{x_n} + Q,
\]
where \( \bar{\eta} = -\nu^{2n} \bar{F}^\alpha_\beta (\bar{\sigma}_{\alpha \beta} + \sigma_{\alpha \eta_{\alpha \beta}} + \eta_{\alpha \eta_{\alpha \beta}}) \). Moreover,
\[
\bar{\Phi} \geq -\sum_{k < 2n} \nu^k (u - \varphi)_{t_k} \bar{F}^\alpha_\beta \bar{\sigma}_{\alpha \beta} \geq -C_A \rho^2 \text{ on } \partial M \cap \bar{\Omega}_\delta,
\]
here we use (6.23) and [45]. It is similar to (4.9), at \( p_0 \) \((z = 0)\) we have
\[
(6.25) \quad g_{\alpha \beta}(0) - \bar{g}_{\alpha \beta}(0) = -(u - \bar{u})_{x_n}(0) (\sigma_{\alpha \beta}(0) + \sigma_{\alpha}(0) \eta_{\beta}(0) + \eta_{\alpha}(0) \sigma_{\beta}(0)).
\]
Hence
\[
(6.26) \quad (u - \bar{u})_{x_n} \bar{F}^\alpha_\beta (\bar{\sigma}_{\alpha \beta} + \sigma_{\alpha} \eta_{\beta} + \eta_{\alpha} \sigma_{\beta}) = \bar{F}^\alpha_\beta (\bar{g}_{\alpha \beta} - g_{\alpha \beta})
\]
\[
\geq \bar{F}[\bar{g}_{\alpha \beta}] - \bar{F}[g_{\alpha \beta}],
\]
\[
\geq c_R - m_R \geq \frac{c_R}{2}, \text{ at } p_0.
\]
Together with (6.26) and maximum principle, one gets \((u - \bar{u})_{x_n}(0) > 0\) and
\[
\bar{\eta}(0) \geq \frac{c_R}{2(u - \bar{u})_{x_n}(0)} \geq \frac{c_R}{2 \sup_{\partial M} |\nabla (u - \bar{u})|}.
\]
We now may assume \( \bar{\eta} \geq \frac{c_R}{4 \sup_{\partial M} |\nabla (u - \bar{u})|} \) near \( p_0 \). As in proof of (4.19) one derives
\[
\mathcal{L} \bar{\Phi} \leq C (1 + \sum_{i=1}^{n} f_i + \sum_{i=1}^{n} f_i |\lambda_i|) + F_{ij} u_{y_n} u_{y_n}.
\]
Set $\Psi = B_1 v - B_2 \rho^2 + B_3 \sum_{\tau < n} |(u - \varphi_\tau)|^2$. We can take $B_1 \gg B_2 \gg B_3 \gg 1$ and $N \gg 1$, so that $\tilde{\Phi} - \Psi - (u_{y_n} - \varphi_{y_n})^2 \geq 0$ on $\partial \Omega_\delta$ and
\[
\mathcal{L}(\tilde{\Phi} - \Psi - (u_{y_n} - \varphi_{y_n})^2) \leq 0 \text{ in } \Omega_\delta.
\]
Hence $\tilde{\Phi} - \Psi - (u_{y_n} - \varphi_{y_n})^2 \geq 0$ in $\Omega_\delta$. Combining it with $\tilde{\phi}^n - \Psi - (u_{y_n} - \varphi_{y_n})^2 \geq 0$ on $\partial \Omega_\delta$ and $\mathcal{L}(\tilde{\Phi} - \Psi - (u_{y_n} - \varphi_{y_n})^2) \leq 0$ in $\Omega_\delta$, one obtains $g_{nn}(\phi^n)^2 \geq 0$ in $\Omega_\delta$. Combining it with Lemma 2.2 one knows that, for $R$ large under control,
\[
m_R = f(\lambda'[\{g_{\alpha\beta}(0)\}], R) - \psi(0) > 0.
\]
Hence (6.21) holds. We thus get the upper bound of $g_{nn}(x_0)$ and complete the proof.

7. The equations with right-hand side depending on unknown solutions

7.0.1. The Dirichlet problem. In this subsection we solve the Dirichlet problem
\[
f(\lambda(g)) = \psi(z, u) =: \psi[u] \text{ in } M, \quad u = \varphi \text{ on } \partial M,
\]
where $\psi_u \geq 0$ and $\bar{\chi}$ is a smooth real $(1,1)$-form with $\lambda(\bar{\chi}) \in \Gamma$. The non-degenerate assumption is
\[
\inf_{z \in M} \psi(z, t) > \sup_{\partial \Gamma} f \text{ for any fixed } -\infty < t < +\infty.
\]
As in the discussion above we shall use Lemma 3.1 or 3.2 to derive the desired estimates. We need assuming (3.6) to use Lemma 3.1. According to Székelyhidi’s insight, we then slightly modify the notion of a $C$-subsolution so that one can apply Lemma 3.2. That is, for the unknown admissible solution $u$, there is a function $\bar{u} \in C^2(M)$ such that
\[
\lim_{t \to +\infty} f(\lambda(g([u])) + te_i) > \psi[u] \text{ in } \bar{M} \text{ for each } i.
\]
This condition is very hard to verify, since the right-hand side depends on the unknown solution $u$. Fortunately, we can apply it to study equations obeying both (1.18) and
\[
\psi[w] < \sup_{\Gamma} f,
\]
where $w$ is the supersolution constructed in (4.6), since any admissible function must satisfy (7.3) if both (1.18) and (7.4) hold. (Here one uses $\psi[w] \geq \psi[u]$ which follows from $\psi_u \geq 0$ and $w \geq u$). On the other hand, condition (3.3) is also needed for applying Lemma 3.2 thanks to Remark 3.3 while (3.5) can be derived by combining (3.6) with (4.36). Therefore, to apply Lemma 3.1 or 3.2 we assume for simplicity
\[
\text{either conditions (1.18), (7.4) hold, or condition (3.6) holds.}
\]
Theorem 7.1. Let \( \partial M \in C^\infty \), \( \psi(z,t) \in C^\infty(M \times \mathbb{R}) \). Suppose, in addition to (1.4), (1.5), (3.5), (7.2) and (7.5), that there is an admissible function \( u \in C^{3,1}(M) \) with
\[
(7.6) \quad f(\lambda [u]) \geq \psi[u] \text{ in } M, \ u = \varphi \text{ on } \partial M.
\]
Then Dirichlet problem (7.1) is uniquely solvable in class of smooth admissible functions, provided that either (1), (2), \( \Gamma = \Gamma_n \) holds. Moreover, one can assume the subsolution is only \( C^{2,1} \) if \( \partial M \) is pseudoconcave.

If we suppose \( M = X \times S \), \( \eta^1,0 = \eta_S^1,0 \) and (1.18) hold, then we can construct the subsolution satisfying (7.6) with using the solution to (1.16).

The proof of Theorem 7.1 is based on the following estimates. In the proof of estimates, we assume the admissible subsolution is only \( C^2 \).

Proposition 7.2. Suppose (1.4), (1.5), (3.5), (7.2) and (7.5) hold. Then the second order estimate (4.52) holds for any admissible solution \( u \in C^4(M) \) of equation (4.1), provided that there is an admissible function \( u \in C^2(M) \). Moreover, when \( \psi[u] = \psi(u) \) then condition (3.5) can be removed, provided that either \( \psi > 0 \), or both \( \psi_u > 0 \) and \( \psi_{uu} \geq 0 \) hold.

Proposition 7.3. Suppose, in addition to (1.4), (1.5), (3.5), (7.2), (7.5) and (7.6), that the other assumptions of Theorem 4.2 (respectively, Theorem 4.3) hold. Then the estimates in Proposition 4.6 (respectively, Proposition 4.7) hold for the admissible solution to Dirichlet problem (7.1).

As above, (1.34) is important for proof of boundary estimates when (3.4) holds, while the original proof of (1.34) uses \( \sum_{i=1}^{n} f_i(\lambda_i - \lambda) \geq 0 \). When \( \sum_{i=1}^{n} f_i(\lambda_i - \lambda) \geq 0 \), we can prove the corresponding estimates word by word. However, if \( \psi_u \geq 0 \), then \( \sum_{i=1}^{n} f_i(\lambda_i - \lambda_i) < 0 \) and \( \mathcal{L}(u - u) < 0 \) may occur at some points, as
\[
(7.7) \quad \sum_{i=1}^{n} f_i(\lambda_i - \lambda_i) \geq f(\lambda) - f(\lambda) \geq \psi[u] - \psi[u].
\]

In what follows the proof is done at the point where \( \sum_{i=1}^{n} f_i(\lambda_i - \lambda_i) < 0 \). By Lemma 3.2 or 3.1, one has
\[
(7.8) \quad f_i(\lambda) \geq \varepsilon'' \sum_{j=1}^{n} f_j(\lambda) \text{ for each } i, \text{ for some } \varepsilon'' > 0.
\]
Next, we give a proof of (4.34) (possibly with different constants \( c_0, C_0 \)) without using \( \sum_{i=1}^{n} f_i(\lambda_i - \lambda_i) \geq 0 \) but with using (3.5). If \( \lambda_r \leq 0 \) then \( \sum_{i \neq r} \lambda_i > |\lambda_r| \) and \( \lambda^2 \leq (n-1) \sum_{i \neq r} \lambda_i^2 \). So \( \sum_{i \neq r} \lambda_i^2 \geq \frac{1}{n} |\lambda|^2 \) and (4.34) holds for \( c_0 = \frac{\varepsilon''}{n} \) and \( C_0 = 0 \). Here \( \varepsilon'' \) is the constant in (7.8). If \( \lambda_r > 0 \),
\[
f_r^2 \lambda_r^2 \leq 4(\psi[u] - \psi[u])^2 + 2 \sup_M |\Delta|^2 \left( \sum_{i=1}^{n} f_i \right)^2 + 2(n-1) \sum_{i \neq r} f_i^2 \lambda_i^2,
\]
here we use (7.7) and Cauchy-Schwarz inequality, thereby
\[
\sum_{i \neq r} f_i \lambda_i^2 \geq \frac{\varepsilon n^2}{2n-1} |\lambda|^2 \sum_{i=1}^n f_i - \frac{2 \sup_M |\lambda|^2}{2n-1} \sum_{i=1}^n f_i - \frac{4(\psi[u] - \psi[w])^2}{(2n-1) \sum_{i=1}^n f_i},
\]
and (4.34) holds by using (3.5).

**Proof of Proposition 7.3.** We need to use (7.1) to deal with \( \sum_{i=1}^n f_i |\lambda_i| \), and obtain
\[
\sum_{i=1}^n f_i |\lambda_i| \leq \frac{\epsilon}{16\sqrt{b_1}} \sum_{i \neq r} f_i \lambda_i^2 + (\sup_M |\lambda| + \frac{16\sqrt{b_1}}{\epsilon}) \sum_{i=1}^n f_i + \psi[u] - \psi[w].
\]

The proof is almost same as in Propositions 4.6 and 4.7. Combining with (3.5), (4.34), (7.8), (7.7) and (4.34) holds by using (3.5).

Here we set \( \epsilon = \frac{1}{C_1 + A_3 C_\Phi} \) in (7.9), \( 0 < \delta \ll 1 \), \( 0 < t \ll 1 \) and \( N \gg 1 \) so that \( |2N\sigma - t| \ll 1 \) and \( N\delta - t \leq 0 \).

Together with Proposition 2.1, we obtain the quantitative boundary estimates.

**Theorem 7.4.** With the same assumptions of Proposition 7.3, the corresponding quantitative boundary estimates in Theorem 4.2 and 4.3 hold.

**Remark 7.5.** In the real variable setting, assuming \( \chi[u] = A + \nabla u \otimes \eta + \eta \otimes \nabla u \), where \( A \) is a smoothly symmetric \((0,2)\) tensor, and \( \eta \) is a smooth \((0,1)\) tensor, we can apply Lemma 2.2 to extend the corresponding part of Theorems 4.1, 4.3 and 7.1 to Dirichlet problem on compact Riemannian manifolds \((M, g)\) with concave boundary whose second fundamental form is nonpositive.

For general \( C^4 \) smooth boundary one can derive the boundary estimates as follows:

**Theorem 7.6.** Suppose, in addition to (1.1), (1.3), (3.3), (7.2), (7.5) and (7.6), that \( \partial M \in C^4 \) and \( \psi(z, t) \) is a \( C^1 \) function in \( \bar{M} \times \mathbb{R} \). Then for any admissible solution \( u \in C^4(\bar{M}) \cap C^2(\overline{\bar{M}}) \) to Dirichlet problem (7.1), there exists a uniformly positive constant \( C \) depending on \( |\varphi|_{C^4(\bar{M})}, |u|_{C^1(\bar{M})} \) and \( |u|_{C^2(\bar{M})} \) and other known data such that \( \sup_{\partial M} \Delta u \leq C \).
Theorem 7.7. Let \((M,\omega)\) be a compact Kähler manifold admitting nonnegative orthogonal bisectional curvature (possibly with smooth boundary). Suppose, in addition to \((1.4), (1.5), (7.2), (3.5)\) and \((7.5)\), that there is an admissible function \(u \in C^2(M) \cap C^{1,1}(M)\). We also assume \(\psi(z,t)\) is a smooth function. Then for any admissible solution \(u \in C^3(M) \cap C^1(\overline{M})\) of equation \((4.1)\) we have
\[
\sup_M |\nabla u| \leq C(1 + \sup_{\partial M} |\nabla u|),
\]
where \(C\) is a positive constant depending on \(|u|_{C^0(M)}, \sup_M |\nabla' z \psi|\) and other known data under control.

Proof. Using \((6.20), (7.8)\) and \((7.7)\) one has
\[
0 \geq -B(\psi[u] - \psi[u]) + \frac{B^2}{2} |\nabla(u - u)|^2 \sum F^i \overline{F}^i - \frac{C}{\phi|\nabla u|}(1 + \sum F^i \overline{F}^i).
\]
Together with \((3.5)\), the above formula implies \(|\nabla u|\) has a bound. \(\square\)

For the equation satisfying \((1.18)\), it is not difficult to see that if
\[
(7.11) \sup_{z \in M} \psi(z,t) < \sup_{\Gamma} f(\lambda(\chi(z))) < \lim_{t \to +\infty} \psi(z,t), \forall z \in M,
\]
then every \(C^2\) admissible function \(w\) is a desired \(C\)-subsolution for the rescaled equation \(f(\frac{1}{3}\lambda(g[w]))) = \psi[u]\), i.e.
\[
\lim_{t \to +\infty} f(\frac{1}{3}\lambda(g[w]) + te_i) > \psi[u] \text{ in } \overline{M} \text{ for each } i,
\]
and thus \((6.13)\) holds. We also prove

Theorem 7.8. Let \((M,\omega)\) be a compact Hermitian manifold (possibly with smooth boundary) supposing an admissible function \(u \in C^2(M)\). Let \(u \in C^3(M) \cap C^1(\overline{M})\) be an admissible solution with \(g \geq 0\) of equation \((4.1)\) with a smooth function \(\psi(z,t)\) in \(\overline{M} \times \mathbb{R}\). Suppose in addition that \((1.4), (1.5), (1.18), (7.2)\) and \((7.4)\) hold. Then there is a uniformly positive constant \(C\) depending on \(|u|_{C^0(M)}, |\chi|_{C^1(M)}, |u|_{C^2(M)}, \sup_M |\nabla' z \psi|, \inf_M \psi_t\) and other known data under control such that
\[
\sup_M |\nabla u| \leq C(1 + \sup_{\partial M} |\nabla u|).
\]

7.0.2. The estimates up to second order on closed Hermitian manifolds. Let’s turn our attention to the equation \((4.1)\) on closed Hermitian manifolds, in which we further assume \(\lambda(\chi) \in \Gamma\). If
\[
(7.12) \lim_{t \to +\infty} \psi(z,t) < f(\lambda(\chi(z))) < \lim_{t \to +\infty} \psi(z,t), \forall z \in M,
\]
then we can obtain \(C^0\) estimate by applying maximum principle. Similarly, replacing \((7.4)\) by \((7.11)\), we know any \(C^2\) admissible function \(u\), for instance \(u = 1\), satisfies \((7.3)\) when \((1.18)\) holds. Then we can derive the second order estimate \((4.52)\) for equation \((4.1)\), and thus
Proposition 7.9. Let $(M, \omega)$ be a closed Hermitian manifold, $\psi[u] = \psi(z, u)$ be a smooth function. Assume \((1.4), (1.5), (1.7), (1.18), (7.2), (7.11)\) and \((7.12)\) hold. Then for any admissible solution $u \in C^4(M)$ of equation \((4.1)\), one has
$$|u|_{C^{2,\alpha}(M)} \leq C$$
for $0 < \alpha < 1$, where $C$ is a uniformly positive constant.

8. The Dirichlet problem of the Monge-Ampère equation for $(n-1)$-plurisubharmonic functions

Gauduchon [34] proved every closed Hermitian manifold $(M, \omega)$ of complex dimension $n \geq 2$ admits a unique (up to rescaling) Gauduchon metric ($\omega$ is called Gauduchon if $\partial \overline{\partial} (\omega^{n-1}) = 0$) which is conformal to the original Hermitian metric, and furthermore conjectured in [35] that the Calabi-Yau theorem in the counterpart of Gauduchon metrics is also true.

In the case of complex dimension two, Gauduchon’s conjecture was proved by Cherrier [17] via solving a standard complex Monge-Ampère equation. In the case when $\omega$ is astheno-Kähler (i.e. $\partial \overline{\partial} (\omega^{n-2}) = 0$) introduced in [55], the Gauduchon metric, say $\Omega_u$, with prescribed volume form (may allow a dilation since the nontrivial torsion tensor) can be obtained by using the solution of the Monge-Ampère equation for $(n-1)$-plurisubharmonic functions in the sense of Harvey-Lawson [51],

\begin{align*}
\Omega_u^n &= e^\phi \omega^n \text{ in } M \\
\omega_u^{n-1} &= \omega_0^{n-1} + \sqrt{-1} \partial \overline{\partial} u \wedge \omega^{n-2} > 0 \text{ in } M,
\end{align*}

with $\omega_u^{n-1} = \omega_0^{n-1} + \sqrt{-1} \partial \overline{\partial} u \wedge \omega^{n-2} > 0$, here $\omega_0$ is a Gauduchon metric on $M$.

For more general background Gauduchon metric $\omega$, one can seek $\Omega_u$ by solving equation \((8.1)\) with the following property

\begin{align*}
\Omega_u^{n-1} &= \omega_0^{n-1} + \partial \gamma + \overline{\partial} \gamma, \text{ where } \gamma = \frac{\sqrt{-1}}{2} \partial u \wedge \omega^{n-2}.
\end{align*}

(8.1)

(8.2)

\begin{align*}
\left( \tilde{\chi} + \frac{1}{n-1} (\Delta u) \omega - \sqrt{-1} \partial \overline{\partial} u + Z \right)^n &= e^{(n-1)\phi} \omega^n \text{ in } M \\
\text{where } \tilde{\chi}_{ij} &= \left( \frac{1}{(n-1)!} \ast (\omega_0^{n-1}) \right)_{ij}, \ Z_{ij} &= Z_{ij}(\partial u, \overline{\partial} u) = \left( \frac{1}{(n-1)!} \ast \Re (\sqrt{-1} \partial u \wedge \overline{\partial} (\omega^{n-1})) \right)_{ij}, \text{ here } \ast \text{ is the Hodge } \ast \text{-operator associated with } \omega \text{ (see [66, 77]). }
\end{align*}

Then it can be reduced to solve the following equation

\begin{align*}
\log P_{n-1}(\lambda(\theta[u])) &= \psi \text{ in } M, \\
\omega_0^{n-1} + \sqrt{-1} \partial \overline{\partial} u \wedge \omega^{n-2} + \Re (\sqrt{-1} \partial u \wedge \overline{\partial} (\omega^{n-1})) > 0 \text{ in } M,
\end{align*}

\((8.3), (8.4)\)
where \( P_{n-1}(\lambda) = \prod_{i=1}^{n}(\lambda_1 + \cdots + \lambda_i + \cdots + \lambda_n) \). \( g_{ij} = u_{ij} + \chi_{ij} + W_{ij}(\partial u, \bar{\partial} u) \), \( \psi = (n-1)\phi + n \log(n-1) \), here \( \chi_{ij} = (\text{tr}_{\omega} \chi)g_{ij} - (n-1)\bar{\chi}_{ij} \), \( W_{ij} = (\text{tr}_{\omega} \chi)g_{ij} - (n-1)\bar{Z}_{ij} \). Locally,

\[
Z_{ij} = \frac{1}{2(n-1)} \left( g^{pq}T^l_{qj}\bar{g}j_{up} + g^{pq}T^k_{pk}g_{ij}u_q - g^{kl}g_{ij}T^q_{ik}u_l - T^i_{ij}u_i - T^k_{ik}u_j \right),
\]

see also [73].

We see that condition (8.4) is rather natural from the viewpoint of geometric meaning of the equation. One can verify that condition (8.1) implies, at each point in \( M \),

\[
\lambda(\mathbf{g}[u]) \in P_{n-1} = \left\{ \lambda \in \mathbb{R}^n : \lambda_1 + \cdots + \lambda_i + \cdots + \lambda_n > 0 \text{ for each } i \right\}
\]

(or equivalently \( \bar{\lambda} + \frac{1}{n-1}(\Delta u)\omega - \sqrt{-1}\partial\bar{\partial} u + Z > 0 \)), and allows one to seek the solutions of (8.3) or equivalently (8.2) within the framework of elliptic equations, since \( f = \log P_{n-1} \) satisfies (1.4), (1.5) and (1.7) in the convex symmetric cone \( P_{n-1} \).

In [77] Tosatti-Weinkove proved Gauduchon’s conjecture when \( M \) admits an astheno-Kähler metric, and further showed that the Gauduchon conjecture for general case can be reduced to show the second order estimate of form (2.2), i.e. \( \sup_M \Delta u \leq C(1 + |\nabla u|^2) \), for the solution \( u \) to (8.3) with \( \sup_M u = 0 \) and \( \lambda(\mathbf{g}[u]) \in P_{n-1} \).

It is however much more complicated for general cases, since the equation (8.3) (or equivalently (8.2)) involves gradient terms. Recently, by carefully dealing with the special structures of \( W(\partial u, \bar{\partial} u) \) and \( \log P_{n-1} \) (see also Step 3 of proof of Theorem 8.12 below for the crucial ingredients), Székelyhidi-Tosatti-Weinkove [73] derived (2.2) (see Theorem 8.1 below) and then completely proved Gauduchon’s conjecture. See also [41] for related work. Also, we are referred to [18, 19, 63, 64, 73] for the progress on Fu-Yau equation [32, 33] and Form-type Calabi-Yau equation [30, 31].

**Theorem 8.1.** Let \( \psi \in C^2(M) \), and we assume \( u \in C^4(M) \) is the solution to (8.3) with \( \sup_M u = 0 \) and \( \lambda(\mathbf{g}[u]) \in P_{n-1} \), then one has the second order estimate (2.2).

We remark here that one can check that the constant \( C \) in (2.2) depends on \( \sup_M \psi, \sup_M |\nabla \psi|, \inf_M \inf_{\xi \in T_x \partial M} \partial \bar{\partial} \psi(\xi, \bar{\xi}) \) and other known data (but not on \( \inf_M \psi \)).

This section is devoted to investigating the Dirichlet problem of equation (8.3)

\[
\log P_{n-1}(\lambda(\mathbf{g}[u])) = \psi \text{ in } M, \ u = \varphi \text{ on } \partial M
\]

when \( M = X \times S \) is a product of a closed Hermitian manifold \((X, \omega_X)\) of complex dimension \( n-1 \) with a compact Riemann surface \((S, \omega_S)\) admitting boundary \( \partial S \), where \( \omega = \pi_X^* \omega_X + \pi_S^* \omega_S \) denotes the Kähler form of \( M \). Here \( \omega_X = \sqrt{-1}g_{\alpha\beta}dz^\alpha \wedge d\bar{z}^\beta \), \( \omega_S = \sqrt{-1}g_{nm}dz^n \wedge d\bar{z}^n \). Locally,

\[
\omega = \sqrt{-1}g_{\alpha\bar{\beta}}dz^\alpha \wedge d\bar{z}^\beta + \sqrt{-1}g_{nm}dz^n \wedge d\bar{z}^n.
\]

When \( W(\partial u, \bar{\partial} u) = 0 \), the regularity and solvability of Dirichlet problem (8.5) is covered by the results in [84] as a special case, while it is very hard if \( W(\partial u, \bar{\partial} u) \neq 0 \).
Throughout this section, without specific clarification, we denote $M = X \times S$, and \( \omega = \pi_1^* \omega_X + \pi_2^* \omega_S \). One can verify that if \( \omega_X \) is Gauduchon (respectively, balanced) then so is \( \omega \), since
\[
\omega^{n-1} = \pi_1^* \omega_X^{n-1} + (n-1)\pi_1^* \omega_X^{n-2} \wedge \pi_2^* \omega_S,
\]
\[
d(\omega^{n-1}) = (n-1)\pi_1^* d(\omega_X^{n-2}) \wedge \pi_2^* \omega_S, \quad \partial_S(\omega^{n-1}) = (n-1)\pi_1^* \partial_S(\omega_X^{n-2}) \wedge \pi_2^* \omega_S.
\]
Here one uses \( \omega_S^2 = 0, d\omega_S = 0 \) and \( d(\omega_X^{n-1}) = 0 \) (notice \( \dim_C X = n - 1 \)).

In this section we prove

**Theorem 8.2.** Suppose the given data \( \partial S, \psi \) and \( \varphi \) are all smooth. Suppose in addition that there is a \( C^{2,1} \)-admissible subsolution \( u \in C^{2,1}(\bar{M}) \) satisfying
\[
(8.6) \quad \log P_{\eta-1}(\lambda(g|u|)) \geq \psi \text{ in } M, \; u = \varphi \text{ on } \partial M,
\]
and
\[
(8.7) \quad \omega_0^{n-1} + \sqrt{-1} \partial \bar{\partial} u \wedge \omega^{n-2} + \Re(\sqrt{-1} \partial \bar{\partial} u \wedge \partial(\omega^{n-2})) > 0 \text{ in } \bar{M}.
\]

Then there is a unique smooth function satisfying (8.6) to solve (8.5). Moreover, the solution obeys \( \Delta u \leq C \), where \( C \) depends on \( \sup_M |\nabla \psi|, \inf_{\xi \in M} \inf_{\xi \in \mathcal{T}_1(M) \mathcal{M}} \partial_S \psi(\xi, \bar{\xi}), |u|_{C^{2,1}(\bar{M})}, |\varphi|_{C^2(\bar{M})}, \partial M \) up to its second derivatives and other known data.

In the case when \( W(\partial u, \bar{\partial}u) = 0 \), as above, we can use the function \( h \) solving (1.17) to construct the subsolution, provided \( \bar{\mathcal{S}}(\varphi) \neq \emptyset \), which is necessary for the solvability of the Dirichlet problem within the framework of elliptic equations. Here
\[
\bar{\mathcal{S}}(\varphi) = \{ v \in C^{2,1}(\bar{M}) : v|_{\partial M} = \varphi, \; \lambda(g|v|) \in \mathcal{P}_{n-1} \text{ in } \bar{M} \}.
\]

In our case when \( W(\partial u, \bar{\partial}u) \neq 0 \), the obstruction to construct subsolution by using \( h \) is that \( W_{\alpha \beta}(\partial h, \bar{\partial} h) \) does not vanish generally for \( 1 \leq \alpha \leq n - 1 \). Applying Lemma 8.7 we see \( W_{\alpha \beta}(\partial h, \bar{\partial} h) = 0 \) is derived from
\[
(8.8) \quad \sum_{\beta=1}^{n-1} T_{\alpha \beta}^\beta = 0 \text{ for each } 1 \leq \alpha \leq n - 1,
\]
i.e. the torsion \((1,0)\)-form of \( \omega_X \) vanishes, which is satisfied if and only if \( \omega_X \) is a balanced metric on \( X \) (see [62]). More precisely, in the case when \( \omega_X \) is balanced, the subsolution is given by \( \underline{u} = v + Ah, \; A \gg 1 \), where \( v \in \bar{\mathcal{S}}(\varphi) \) and \( h \) is the solution to (1.17).

**Corollary 8.3.** Suppose the given data \( \partial S, \psi \) and \( \varphi \) are all smooth. Then Dirichlet problem (8.5) is uniquely solvable in the class of smooth functions satisfying (8.4), provided that \( \bar{\mathcal{S}}(\varphi) \neq \emptyset \) and \( \omega_X \) is furthermore balanced.
Similarly, we have a somewhat interesting fact that, when the boundary has less regularity \( \partial S \in C^{2,\beta} (0 < \beta < 1) \), with only assuming \( u \in C^{2,\beta}(\bar{M}) \), we can use Silvestre-Sirakov’s [69] boundary \( C^{2,\alpha'} \) estimate and our estimates (Propositions 8.6 and 8.8) to study the equation with constant boundary data.

**Theorem 8.4.** Suppose the given data \( \partial S \in C^{2,\beta} (0 < \beta < 1) \), \( \phi = 0 \) and \( \psi \in C^2(\bar{M}) \) satisfies \( \psi \leq \log P_{n-1}(\lambda(\chi)) \), then Dirichlet problem (8.5) admits a unique \( C^{2,\alpha} \) function satisfying (8.4) for some \( 0 < \alpha < \beta \).

Theorems 8.2 and 8.4, in a sense, give Gauduchon metric with prescribed volume form when \( M = X \times S \).

We also study degenerate equation and prove

**Theorem 8.5.** Suppose the given data \( \partial S \in C^{2,\beta} (0 < \beta < 1) \). Then

\[
\left( \tilde{\chi} + \frac{1}{n-1}(\Delta u)\omega - \sqrt{-1}i\partial\bar{\partial}u + Z \right)^n = 0
\]

admits a weak \( C^{1,\alpha} (\forall 0 < \alpha < 1) \) solution \( u \) with \( u|_{\partial M} = 0 \), \( \Delta u \in L^\infty(\bar{M}) \) and \( \omega_0^{n-1} + \sqrt{-1}i\partial\bar{\partial}u \wedge \omega^{n-2} + 2\text{Re}(\sqrt{-1}i\partial\bar{\partial}(\omega^{n-2})) \geq 0 \) in \( \bar{M} \).

In particular, if \( \omega_0 = \omega \) (thus \( \tilde{\chi} = \omega \)), then the weak solution is exactly \( u = -(n-1)h \), where \( h \) is the solution to (1.17), and thus has the sharp \( C^{2,\beta} \)-regularity.

If \( \omega_X \) is both astheno-Kähler and Gauduchon, i.e. \( \partial\bar{\partial}(\omega_X^{n-3}) = \partial\bar{\partial}(\omega_X^{n-2}) = 0 \) (notice \( \dim\mathbb{C}X = n-1 \)), then so is \( \omega \) (i.e. \( \partial\bar{\partial}(\omega^{n-2}) = \partial\bar{\partial}(\omega^{n-1}) = 0 \)). Such closed non-Kähler manifolds, which further endow with balanced metrics \( \omega_{X,0} \), were constructed in [77]. Then the proof of Theorem 8.1 can also be used to derive (2.2) for Form-type Calabi-Yau equation on such manifolds as stated in [73], since it is reduced to the Form type Calabi-Yau equation

\[
\Xi^{n-1} = \omega_0^{n-1} + \sqrt{-1}i\partial\bar{\partial}u \wedge \omega^{n-2} + 2\text{Re}(\sqrt{-1}i\partial\bar{\partial}(\omega^{n-2}))
\]

where \( \omega_0 \) is balanced. It is worthy to note that our results in this section also hold for the Form-type Calabi-Yau equation on such manifolds, since the proof of Propositions 8.6 and 8.8 below also work in this context. As above we can construct subsolutions if \( \omega_X \) is further balanced, however, a balanced metric on a closed complex manifold cannot be astheno-Kähler unless it is Kähler (see [61]). The results can be further extended to general equations in Theorems 8.12, 8.13 and 8.14 below.

8.1. **Proof of main estimates.** We can construct supersolution which together with maximum principle yields (1.11), i.e. \( \sup_{\bar{M}} |u| + \sup_{\partial M} |\nabla u| \leq C \).

The main difficulty to solve equation (8.3) as well as its Dirichlet problem (8.3) is to derive gradient estimate. In Proposition 6.9 above we give a direct proof of gradient estimate for equation (8.3) with a stronger assumption \( \lambda \in \mathcal{P}_{n-2} \). However, such an assumption does not preserve along the whole continuity path generally, and cannot apply to the Gauduchon’s conjecture.
Theorem 8.1 essentially shows admissible solutions to Dirichlet problem (8.5) obey (2.3), i.e.

$$\sup_M \Delta u \leq C(1 + \sup_M |\nabla u|^2 + \sup_{\partial M} |\Delta u|).$$

In this section, as above we also set up the quantitative boundary estimate (2.4), i.e.

$$\sup_{\partial M} \Delta u \leq C(1 + \sup_M |\nabla u|^2).$$

Such a quantitative boundary estimate immediately follows from (4.11), Propositions 8.6 and 8.8. With (2.4) at hand, we can use the blow-up argument as in [14, 76, 77, 73] to derive the desired gradient estimate.

We remark furthermore that, in the proof of estimates, $W(\partial u, \overline{\partial u})$ has the special structure as above, while the assumption that $\omega_0$ and $\omega$ are both Gauduchon metrics is not needed. Furthermore, we choose the local coordinate $(z_1, \cdots, z_{n-1})$ around $p_s$ of $X$ and the local coordinate $z_n$ around $p_s$ of $S$. In Proposition 8.6 the local coordinate around $p_0 = (p_x, p_s)$ is $(z_1, \cdots, z_{n-1}, z_n)$.

**Proposition 8.6.** Let $\partial S \in C^2$ and $u$ be the $C^2$ solution of (8.5) with $\lambda(g[u]) \in P_{n-1}$. Suppose there is $u \in C^2(M)$ obeying (8.6) and $\lambda(g[u]) \in P_{n-1}$. As above $(z_1, \cdots, z_{n-1}, z_n)$ is a local coordinate of $M$ around $p_0 \in \partial M$ with $g_{ij}(p_0) = \delta_{ij}$, then

$$(8.9) \quad g_{n\bar{n}}(p_0) \leq C(1 + \sum_{\alpha=1}^{n-1} |g_{\alpha \bar{n}}(p_0)|^2),$$

where $C$ is a uniformly positive constant depending only on $|u|_{C^0(M)}$, $|u|_{C^2(M)}$, $\partial M$ up to its second order derivatives and other known data (but neither on $\inf_M \psi$ nor on $\sup_M |\nabla u|$).

This proposition follows the spirit of Proposition 2.1. However, the proof is much more complicated, as (4.37) does not hold generally when we consider equation (8.3).

We discover that the product structure $M = X \times S$ endowed with the standard metric $\omega = \pi_1^* \omega_X + \pi_2^* \omega_S$ allows us to show Lemma 8.7 and then to prove (8.11) as well as Proposition 8.6 (Indeed we only use such a product structure near the boundary).

**Lemma 8.7.** The torsion $T^k_{nl} = 0$, $T^u_{kl} = 0$ for each $1 \leq k, l \leq n$, and

$$Z_{ij} = \frac{1}{2(n-1)} \sum_{\alpha, \beta, \tau=1}^{n-1} g^{\alpha \beta} \left( (\overline{T^\tau_{\beta i}} g_{ij} - g_{i\tau} \overline{T^\tau_{\beta j}}) u_\alpha + (T^\tau_{\alpha i} g_{ij} - g_{\tau j} T^\tau_{\alpha i}) u_\beta \right)$$

$$(8.10) \quad - \frac{1}{2(n-1)} \sum_{\tau=1}^{n-1} \left( T^\tau_{ji} u_i + T^\tau_{ir} u_j \right).$$

In particular, if $\omega_X$ is balanced, then

$$Z_{ij} = - \frac{1}{2(n-1)} \sum_{\alpha, \beta, \tau=1}^{n-1} g^{\alpha \beta} \left( g_{i\tau} \overline{T^\tau_{\beta j}} u_\alpha + g_{\tau j} T^\tau_{\alpha i} u_\beta \right).$$
Proof. We only need to prove $T^k_{nl} = 0$ for all $1 \leq k, l \leq n$, while (8.10) automatically follows.

The torsion satisfies $T^k_{nm} = 0$. By using $g_{\alpha\beta} = g_{n\bar{n}} = 0$, $\partial g_{\bar{n}\bar{n}} \partial z_n = 0$ for each $1 \leq \alpha, \beta, l \leq n - 1$, one has

$$T^k_{nl} = g^{kj}(\frac{\partial g_{nj}}{\partial z_l} - \frac{\partial g_{lj}}{\partial z_n}) = 0.$$

For $1 \leq k, l \leq n - 1$,

$$T^n_{kl} = g^{nj}(\frac{\partial g_{kj}}{\partial z_l} - \frac{\partial g_{lj}}{\partial z_n}) = g^{n\bar{n}}(\frac{\partial g_{\bar{n}j}}{\partial z_l} - \frac{\partial g_{\bar{n}j}}{\partial z_n}) = 0.$$

Proof of Proposition 8.6. In the proof, the Greek letters, such as $\alpha, \beta, \gamma, \tau, \eta$, range from 1 to $n - 1$.

The proof is done at $p_0 = (p_x, p_s) \in \partial M$. Follow the outline of proof of Proposition 2.1 we only need to prove

(8.11)

$$g_{\alpha\bar{\alpha}} = g_{\bar{\alpha}\bar{\alpha}}, \text{ at } p_0.$$

Identity (8.11) is obvious for the standard equation on $X \times S$ with $g[u] = \chi + \sqrt{-1} \partial \bar{\partial} u$ as shown in [84], while it is rather difficult to verify when $g[u]$ depends on $\partial u$ and $\bar{\partial} u$.

The boundary value condition implies

(8.12)

$$u_\alpha = u_{\bar{\alpha}}, \ u_{\alpha\bar{\beta}} = u_{\bar{\alpha}\bar{\beta}}.$$

The remaining goal is to verify $Z_{\alpha\bar{\beta}} = Z_{\bar{\alpha}\bar{\beta}}$ and $Z_{n\bar{n}} = Z_{\bar{n}n}$. By (8.10), (8.12), one has

$$Z_{n\bar{n}} = \frac{1}{2(n-1)}(g^{\alpha\bar{\beta}}T^\tau_{\beta\gamma}g_{\alpha\gamma}u_\alpha + g^{\alpha\bar{\beta}}T^\tau_{\alpha\gamma}g_{\bar{n}\gamma}u_{\bar{\beta}}) = \frac{1}{2(n-1)}(g^{\alpha\bar{\beta}}T^\tau_{\beta\gamma}g_{\alpha\gamma}u_\alpha + g^{\alpha\bar{\beta}}T^\tau_{\alpha\gamma}g_{\bar{n}\gamma}u_{\bar{\beta}}) = Z_{n\bar{n}},$$

$$Z_{\alpha\bar{\beta}} = \frac{1}{2(n-1)}(g^{\gamma\bar{\tau}}(T_{\gamma\tau\rho}g_{\alpha\beta} - g_{\alpha\rho}T_{\gamma\tau\beta})u_\gamma + g^{\gamma\bar{\tau}}(T_{\gamma\tau\rho}g_{\alpha\beta} - g_{\alpha\rho}T_{\gamma\tau\beta})u_{\bar{\gamma}} - T_{\alpha\rho\beta}u_\rho - T_{\alpha\rho\beta}u_{\bar{\rho}}) = \frac{1}{2(n-1)}(g^{\gamma\bar{\tau}}(T_{\gamma\tau\rho}g_{\alpha\beta} - g_{\alpha\rho}T_{\gamma\tau\beta})u_\gamma + g^{\gamma\bar{\tau}}(T_{\gamma\tau\rho}g_{\alpha\beta} - g_{\alpha\rho}T_{\gamma\tau\beta})u_{\bar{\gamma}} - T_{\alpha\rho\beta}u_\rho - T_{\alpha\rho\beta}u_{\bar{\rho}}) = Z_{\alpha\bar{\beta}}.$$

Thus

$$\text{tr}_{\alpha} Z = g^{\alpha\bar{\beta}}Z_{\alpha\bar{\beta}} + g^{n\bar{n}}Z_{n\bar{n}} = g^{\alpha\bar{\beta}}Z_{\alpha\bar{\beta}} + g^{n\bar{n}}Z_{n\bar{n}} = \text{tr}_{\alpha} Z,$$

and we achieve (8.11).

Proposition 8.8. Let $u \in C^3(M) \cap C^2(\bar{M})$ be the function satisfying $\lambda(g[u]) \in P_{n-1}$ to solve (8.5), and we assume there is a $C^2$ subsolution satisfying $\lambda(g[u]) \in P_{n-1}$ and (8.6). Then there is a uniformly positive constant $C$ depending only on $|\varphi|_{C^3(M)}$.
\[ \sup_M |\nabla \psi|, \psi \in C^2(M), \partial M \text{ up to its second derivatives and other known data (but neither on } \sup_M |\nabla u| \text{ nor on } \inf_M \psi) \text{ such that} \]
\[
(8.13) \quad \sup_M |g_{\alpha\beta}| \leq C(1 + \sup_M |\nabla u|)(1 + \sup_M |\nabla u|), 1 \leq \alpha \leq n - 1.
\]

Moreover, if the boundary data \( \varphi \in C^2(\partial S) \) then the \( C \) depends only on \( \partial M \) up to its second order derivatives, \( |\varphi|_{C^2(S)} \), \( \sup_M |\nabla \psi| \) and \( |\psi|_{C^2(M)} \) and other known data.

Notice that in the proof of Proposition 4.8 we only use the fact that \( \chi(\partial u, \bar{\partial} u) \) depends linearly on \( \partial u \) and \( \bar{\partial} u \) but without using the special linear dependence of \( \partial u \) and \( \bar{\partial} u \) in \( \chi(\partial u, \bar{\partial} u) \). The proof of Proposition 8.8 is hence almost the same as that of Proposition 4.8 which goes through word by word. So we omit the proof.

Similarly, one can check that Theorem 8.1, Propositions 8.6 and 8.8 hold when the right-hand side depends on unknown solutions, \( \psi[u] = \psi(z, u) \), and satisfies \( \psi_u \geq 0 \).

**Theorem 8.9.** Suppose, in addition to \( \partial S \), \( \varphi \) and \( \psi(z, t) \) are all smooth, that \( \psi_t \geq 0 \) and there is a subsolution \( \underline{u} \in C^{2,1}(M) \) with \( \lambda(g[\underline{u}]) \in P_{n-1} \) and

\[ \log P_{n-1}(\lambda(g[\underline{u}])) \geq \psi[\underline{u}] \text{ in } M, \underline{u} = \varphi \text{ on } \partial M. \]

Then there is a unique smooth function satisfying (8.4) to solve

\[ \log P_{n-1}(\lambda(g[u])) = \psi[u] \text{ in } M, \; u = \varphi \text{ on } \partial M. \]

Moreover, such a subsolution then can be constructed by using the solution to (1.17), provided that \( \tilde{\mathcal{S}}(\varphi) \neq \emptyset \), and \( \omega_X \) is a balanced metric.

**Corollary 8.10.** Suppose, in addition to \( \partial S \) and \( \psi \) are both smooth, that \( \varphi \) is a smooth function with \( \lambda(g[\varphi]) \in P_{n-1} \). Then for each constant \( \mu \geq \sup_M |\varphi + \psi - \log P_{n-1}(\lambda(\varphi))| \), the equation \( P_{n-1}(\lambda(g[u])) = e^{u+\psi-\mu} \) with the boundary value condition \( u|_{\partial M} = \varphi \) has a unique smooth solution satisfying (8.4).

### 8.2. The Dirichlet problem for general equations

We claim that our results still hold for more general equations

\[ f(\lambda(U[u])) = \psi \text{ in } M, \]

in which \( U[u] = \chi + (\Delta u)\omega - \sqrt{-1}i\partial \bar{\partial} u + g Z(\partial u, \bar{\partial} u), \) and \( f \) is the function as above which is defined on \( \Gamma \) and satisfies fundamental structures (1.4), (1.5), (1.6) and (1.7).

Also, the corresponding results for degenerate equations are obtained. We omit them.

**Remark 8.11.** Let \( g[u] = \sqrt{-1}i\partial \bar{\partial} u + \frac{1}{n-1}(tr_\omega \chi)\omega - \chi + \frac{g}{n-1} W(\partial u, \bar{\partial} u), \) and we furthermore denote

\[ (8.15) \quad \lambda(g[u]) = (\lambda_1, \ldots, \lambda_n) \quad \text{and} \quad \lambda(U[u]) = (\mu_1, \ldots, \mu_n), \]

then \( \mu_i = \lambda_1 + \cdots + \hat{\lambda}_i + \cdots + \lambda_n. \)
Let \( P' : \Gamma \rightarrow P'(\Gamma) =: \tilde{\Gamma} \) be a map given by
\[
(8.16) \quad (\mu_1, \ldots, \mu_n) \rightarrow (\lambda_1, \ldots, \lambda_n) = (\mu_1, \ldots, \mu_n)Q^{-1},
\]
where \( Q = (q_{ij}) \) and \( q_{ij} = 1 - \delta_{ij} \) (\( Q \) is symmetric). Here \( Q^{-1} \) is well defined, since the eigenvalues of \( Q \) are \((n - 1, -1, \ldots, -1)\), and \( \det Q = (-1)^{n-1}(n - 1) \neq 0 \). Thus, \( \tilde{\Gamma} \) is also an open symmetric convex cone of \( \mathbb{R}^n \).

Let's define \( \tilde{f} : \tilde{\Gamma} \rightarrow \mathbb{R} \) by
\[
(8.17) \quad f(\mu) = \tilde{f}(\lambda)
\]
and thus we can rewrite (8.14) as
\[
(8.18) \quad \tilde{f}(\lambda(g[u])) = f(\lambda(U[u])).
\]
In particular, for equation (8.3),
\[
f(\mu) = \sum_{i=1}^{n} \log \mu_i, \quad \tilde{f}(\lambda) = \log P_{n-1}(\lambda) = \sum_{i=1}^{n} \log(\lambda_1 + \cdots + \lambda_i + \cdots + \lambda_n).
\]

Let's verify that \( \tilde{f} \) also satisfies (1.4), (1.5) and (1.7) in \( \tilde{\Gamma} \). The condition (1.7) is clear. Straightforward computation yields
\[
\frac{\partial \tilde{f}}{\partial \lambda_i} = \sum_{k} (1 - \delta_{ki}) \frac{\partial f}{\partial \mu_k} > 0, \quad \frac{\partial^2 \tilde{f}}{\partial \mu_k \partial \mu_i} = \sum_{k,l} (1 - \delta_{kl})(1 - \delta_{lj}) \frac{\partial^2 f}{\partial \mu_k \partial \mu_l},
\]
i.e. \( \left( \frac{\partial^2 \tilde{f}}{\partial \mu_k \partial \mu_i} \right) = Q \left( \frac{\partial^2 f}{\partial \mu_k \partial \mu_i} \right) Q \). Thus \( \tilde{f} \) satisfies (1.4) and (1.5) in \( \tilde{\Gamma} \).

Here we only state the result for non-degenerate case, while the corresponding results for degenerate equations (i.e. \( f \in C^\infty(\Gamma) \cap C(\bar{\Gamma}) \), \( \inf_M \psi = \sup_{\partial \Gamma} f \)) can be derived from it. When \( \varrho = 0 \) it is covered by the results in [84] as a special case.

**Theorem 8.12.** Let \( \psi, \varrho \in C^\infty(\bar{M}), \varphi \in C^\infty(\partial M), \chi \) be a real smooth (1,1)-form on \( M \), and we further assume \( Z \) has the same structure as above. Let’s denote
\[
\mathcal{F}(\varphi) = \{ v \in C^2(\bar{M}) : \lambda(U[v]) \in \Gamma, \ v|_{\partial M} = \varphi \}.
\]
Suppose there is a subsolution \( u \in \mathcal{F}(\varphi) \cap C^{2,1}(\bar{M}) \) satisfying \( f(\lambda(U[u])) \geq \psi \) in \( M \). Then there is a unique smooth function in \( \mathcal{F}(\varphi) \) to solve (8.14).

Moreover, if \( \varrho = 0 \) or \( \omega_X \) is balanced, then we can construct such subsolutions, provided there is \( v \in \mathcal{F}(\varphi) \cap C^{2,1}(\bar{M}) \) such that
\[
(8.19) \quad \lim_{t \to +\infty} f(\lambda(U[v] + t\pi_2^*\omega_S)) > \psi \text{ in } \bar{M}.
\]

**Proof.** The linearized operator \( \tilde{L} \) of equation (8.14) is given by
\[
\tilde{L}v = C^{ij} v_{ij} + \varrho F^{ij} Z_{ij,\zeta_k} v_k + \varrho F^{ij} Z_{ij,\zeta_k} v_k,
\]
where \( F^{ij} = \frac{\partial F}{\partial g^{ij}}, \ C^{ij} = \sum_{k,l=1}^{n} (F^{kl} g_{kl}) g^{ij} - F^{ij}, \) and \( U_{ij} = \chi_{ij} + \Delta u g_{ij} - u_{ij} + \varrho Z_{ij}. \)
The $C^0$-estimate and boundary gradient estimate are also obtained by using sub-
solution, supersolution and comparison principle.

We follow the notation in Remark 8.11 and sketch the proof below. The proof is
based on three steps.

Step 1: The identity (8.11) is clearly holds, and then so does (8.9) of Proposition 8.6,
which gives (8.5).

Step 2: We follow the outline of proof of Proposition 4.8 to show the admissible
solution for equation (8.14) also satisfies (8.13). In the proof we use the linear dependence
of $\partial u, \partial u$ in $W(\partial u, \partial u)$.

Step 3: The global second order estimate (2.3) for equation (8.14) essentially follows
from the outline of proof in [73].

Let’s first recall two crucial ingredients in their proof of Theorem 8.1 for equation
(8.3): One is about the special structure of $Z$, and the other one is about the coefficient
matrix $(G_{ij})$ of $\tilde{L}$, whose eigenvalues are $(\frac{\partial f}{\partial \lambda_1}, \cdots, \frac{\partial f}{\partial \lambda_n})$. More precisely,

- $Z$ satisfies the assumption in Page 187 of [73].
- If $\lambda_1 \geq \cdots \geq \lambda_n$, then $\frac{\partial f}{\partial \lambda_i} = \sum_{j \neq i} \frac{1}{\mu_j} \geq \frac{1}{\mu_1} \geq \frac{1}{n(n-1)} \sum_{k=1}^n \frac{\partial f}{\partial \lambda_k}$ for each $i \geq 2$.

For equation (8.14), as in [73], $\rho Z$ clearly satisfies the assumption in Page 187 of [73].
On the other hand, if $\lambda_1 \geq \cdots \geq \lambda_n$, then $\frac{\partial f}{\partial \lambda_i} = \sum_{j \neq i} \frac{\partial f}{\partial \mu_j} \geq \frac{1}{n(n-1)} \sum_{k=1}^n \frac{\partial f}{\partial \lambda_k}$
for each $i \geq 2$. The same argument as the proof of Theorem 8.1 then derives (2.3).

Consequently, the previous three steps immediately set up (2.2), and then give the
gradient estimate.

Theorem 8.13. Suppose furthermore $(X, \omega_X)$ is a closed balanced manifold, and the
given data satisfies $\psi \in C^2(\bar{M}), \varphi \in C^{2, \beta}(\bar{M}), \partial S \in C^{2, \beta}, \varphi \in C^{2, \beta}(\partial S)$ for some
$0 < \beta < 1$. Then equation (8.14) has a unique $C^{2, \alpha}$ solution in $F(\varphi)$, for some
$0 < \alpha \leq \beta$, provided that there is $v \in F(\varphi) \cap C^{2, \beta}(\bar{M})$ satisfying (8.19).

Theorem 8.14. Suppose furthermore $(X, \omega_X)$ is a closed balanced manifold, and the
given data satisfies $\psi \in C^2(\bar{M}), \varphi \in C^3(\bar{M}), \partial S \in C^3, \varphi \in C^3(\partial M)$. Then equation
(8.14) has a unique $C^{2, \alpha}$ solution in $F(\varphi)$, for some $0 < \alpha < 1$, provided that there
is $v \in F(\varphi) \cap C^3(M)$ satisfying (8.19).

Appendix A. Proof of Lemma 2.2

In this appendix we present the proof of Lemma 2.2 for convenience and completeness.

We start with $n = 2$. In this case, we can verify that if $a \geq \frac{|a_1|^2}{\epsilon} + d_1$ then
$$0 \leq d_1 - \lambda_1 = \lambda_2 - a < \epsilon.$$
eigenvalues concentrate near certain diagonal elements and the number of eigenvalues near the corresponding diagonal elements is stable, which enables us to count the eigenvalues near the diagonal elements via a deformation argument. It is an essential ingredient in proof of Lemma 2.2 for general $n$.

Lemma A.1 ([84]). Let $A$ be a Hermitian $n$ by $n$ matrix defined as in Lemma 2.2 with $d_1, \ldots, d_{n-1}, a_1, \ldots, a_{n-1}$ fixed, and with $a$ variable. Denote $\lambda = (\lambda_1, \ldots, \lambda_n)$ by the the eigenvalues of $A$ with the order $\lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_n$. Fix a positive constant $\epsilon$. Suppose that the parameter $a$ in the matrix $A$ satisfies the quadratic growth condition

(A.1) \[ a \geq \frac{1}{\epsilon} \sum_{i=1}^{n-1} |a_i|^2 + \sum_{i=1}^{n-1} [d_i + (n-2)|d_i|] + (n-2)\epsilon. \]

Then for any $\lambda_\alpha$ ($1 \leq \alpha \leq n - 1$) there exists an $d_{i_\alpha}$ with $1 \leq i_\alpha \leq n - 1$ such that

(A.2) \[ |\lambda_\alpha - d_{i_\alpha}| < \epsilon, \]

(A.3) \[ 0 \leq \lambda_n - a < (n-1)\epsilon + \sum_{\alpha=1}^{n-1} (d_\alpha - d_{i_\alpha}). \]

Proof. Without loss of generality, we assume $\sum_{i=1}^{n-1} |a_i|^2 > 0$ and $n \geq 3$ (otherwise we are done, since $A$ is diagonal or $n = 2$). It is well known that, for a Hermitian matrix, every diagonal element is less than or equals to the largest eigenvalue. In particular,

(A.4) \[ \lambda_n \geq a. \]

We only need to prove (A.2), since (A.3) is a consequence of (A.2), (A.4) and

(A.5) \[ \sum_{i=1}^{n} \lambda_i = \text{tr}(A) = \sum_{\alpha=1}^{n-1} d_\alpha + a. \]

Let’s denote $I = \{1, 2, \ldots, n - 1\}$. We divide the index set $I$ into two subsets by

$B = \{\alpha \in I : |\lambda_\alpha - d_i| \geq \epsilon, \forall i \in I\}$

and $G = I \setminus B = \{\alpha \in I : \text{There exists an } i \in I \text{ such that } |\lambda_\alpha - d_i| < \epsilon\}$. To complete the proof we only need to prove $G = I$ or equivalently $B = \emptyset$. It is easy to see that for any $\alpha \in G$, one has

(A.6) \[ |\lambda_\alpha| < \sum_{i=1}^{n-1} |d_i| + \epsilon. \]

Fix $\alpha \in B$, we are going to give the estimate for $\lambda_\alpha$. The eigenvalue $\lambda_\alpha$ satisfies

(A.7) \[ (\lambda_\alpha - a) \prod_{i=1}^{n-1} (\lambda_\alpha - d_i) = \sum_{i=1}^{n-1} (|a_i|^2 \prod_{j \neq i} (\lambda_\alpha - d_j)). \]
By the definition of $B$, for $\alpha \in B$, one then has $|\lambda_\alpha - d_i| \geq \epsilon$ for any $i \in I$. Therefore

\begin{equation}
|\lambda_\alpha - a| \leq \sum_{i=1}^{n-1} \frac{|a_i|^2}{|\lambda_\alpha - a_i|} \leq \frac{1}{\epsilon} \sum_{i=1}^{n-1} |a_i|^2, \text{ if } \alpha \in B.
\end{equation}

Hence, for $\alpha \in B$, we obtain

\begin{equation}
\lambda_\alpha \geq a - \frac{1}{\epsilon} \sum_{i=1}^{n-1} |a_i|^2.
\end{equation}

For a set $S$, we denote $|S|$ the cardinality of $S$. We shall use proof by contradiction to prove $B = \emptyset$. Assume $B \neq \emptyset$. Then $|B| \geq 1$, and so $|G| = n - 1 - |B| \leq n - 2$.

We compute the trace of the matrix $A$ as follows:

$$
\text{tr}(A) = \lambda_n + \sum_{\alpha \in B} \lambda_\alpha + \sum_{\alpha \in G} \lambda_\alpha
$$

\begin{equation}
> \lambda_n + |B| (a - \frac{1}{\epsilon} \sum_{i=1}^{n-1} |a_i|^2) - |G| (\sum_{i=1}^{n-1} |d_i| + \epsilon)
\end{equation}

\begin{equation}
\geq 2a - \frac{1}{\epsilon} \sum_{i=1}^{n-1} |a_i|^2 - (n - 2)(\sum_{i=1}^{n-1} |d_i| + \epsilon)
\end{equation}

$$
\geq \sum_{i=1}^{n-1} d_i + a = \text{tr}(A),
$$

where we use (A.1), (A.4), (A.6) and (A.9). This is a contradiction.

We now prove $B = \emptyset$. Therefore, $G = I$ and the proof is complete. \qed

**Proof of Lemma 2.2.** The proof is based on Lemma A.1 and a deformation argument. Without loss of generality, we assume $n \geq 3$ and $\sum_{i=1}^{n-1} |a_i|^2 > 0$. Fix $d_1, \ldots, d_{n-1}, a_1, \ldots, a_{n-1}$, and we let $a$ be variable. Denote $\lambda_1(a), \ldots, \lambda_n(a)$ by the eigenvalues of $A$. Clearly, the eigenvalues $\lambda_i(a)$ can be viewed as continuous functions of $a$. For simplicity, we write $\lambda_i = \lambda_i(a)$. Without loss of generality, we may assume

$$
d_1 \leq d_2 \leq \cdots \leq d_{n-1} \text{ and } \lambda_1 \leq \lambda_2 \leq \cdots \lambda_{n-1} \leq \lambda_n.
$$

Fix $\epsilon > 0$. Let $I'_\alpha = (d_\alpha - \frac{\epsilon}{2n-3}, d_\alpha + \frac{\epsilon}{2n-3})$ and $P'_0 = \frac{2n-3}{\epsilon} \sum_{i=1}^{n-1} |a_i|^2 + (n - 1) \sum_{i=1}^{n-1} |d_i| + \frac{(n-2)\epsilon}{2n-3}$.

In what follows we assume $a \geq P'_0$ (i.e. (2.5) holds). The connected components of $\bigcup_{\alpha=1}^{n-1} I'_\alpha$ are as in the following:

$$
J_1 = \bigcup_{\alpha=1}^{j_1} I'_\alpha, J_2 = \bigcup_{\alpha=j_1+1}^{j_2} I'_\alpha, \ldots, J_i = \bigcup_{\alpha=j_{i-1}+1}^{j_i} I'_\alpha, \ldots, J_m = \bigcup_{\alpha=j_{m-1}+1}^{n-1} I'_\alpha,
$$

(here we denote $j_0 = 0$ and $j_m = n - 1$). Moreover, $J_i \cap J_k = \emptyset$, for $1 \leq i < k \leq m$. 

Let $\widetilde{\text{Card}}_k : [P'_0, +\infty) \to \mathbb{N}$ be the function that counts the eigenvalues which lie in $J_k$. (When the eigenvalues are not distinct, the function $\widetilde{\text{Card}}_k$ denotes the summation of all the multiplicities of distinct eigenvalues which lie in $J_k$.) This function measures the number of the eigenvalues which lie in $J_k$.

The crucial ingredient is that Lemma A.1 yields the continuity of $\widetilde{\text{Card}}_i(a)$ for $a \geq P'_0$. More explicitly, by using Lemma A.1 we conclude that if $a$ satisfies the quadratic growth condition (2.5) then

(A.11)

$$\lambda_\alpha \in \bigcup_{i=1}^{n-1} I'_i = \bigcup_{i=1}^m J_i \text{ for each } 1 \leq \alpha < n, \text{ and } \lambda_n \in \mathbb{R} \setminus \left( \bigcup_{k=1}^{n-1} \overline{I'_k} \right) = \mathbb{R} \setminus \left( \bigcup_{i=1}^m \overline{J_i} \right).$$

Hence, $\widetilde{\text{Card}}_i(a)$ is a continuous function of the variable $a$. So it is a constant. Together with the line of the proof Lemma 1.2 of Caffarelli-Nirenberg-Spruck [11] in the setting of Hermitian matrices we see that $\widetilde{\text{Card}}_i(a) = j_i - j_{i-1}$ for sufficiently large $a$. The constant of $\widetilde{\text{Card}}_i$ therefore follows that

$$\widetilde{\text{Card}}_i(a) = j_i - j_{i-1}.$$ 

We thus know that the $(j_i - j_{i-1})$ eigenvalues $\lambda_{j_{i-1}+1}, \lambda_{j_{i-1}+2}, \ldots, \lambda_{j_i}$ lie in the connected component $J_i$. Thus, for any $j_{i-1} + 1 \leq \gamma \leq j_i$, we have $I'_\gamma \subset J_i$ and $\lambda_\gamma$ lies in the connected component $J_i$. Therefore,

$$|\lambda_\gamma - d_\gamma| < \frac{(2(j_i - j_{i-1}) - 1)\epsilon}{2n - 3} \leq \epsilon.$$

Here we also use the fact that $d_\gamma$ is midpoint of $I'_\gamma$ and every $J_i \subset \mathbb{R}$ is an open subset.

Roughly speaking, for each fixed index $1 \leq i \leq n - 1$, if the eigenvalue $\lambda_i(P'_0)$ lies in $J_\alpha$ for some $\alpha$, then Lemma A.1 implies that, for any $a > P'_0$, the corresponding eigenvalue $\lambda_i(a)$ lies in the same interval $J_\alpha$. Adapting the outline of proof the Lemma 1.2 of [11] to our context, we get the asymptotic behavior as $a$ goes to infinity. \hfill \Box
