Abstract

We consider the problem of online adaptive control of the linear quadratic regulator, where the true system parameters are unknown. We prove new upper and lower bounds demonstrating that the optimal regret scales as $\tilde{\Theta}(\sqrt{d_u d_x T})$, where $T$ is the number of time steps, $d_u$ is the dimension of the input space, and $d_x$ is the dimension of the system state. Notably, our lower bounds rule out the possibility of a poly$(\log T)$-regret algorithm, which has been conjectured due to the apparent strong convexity of the problem. Our upper bounds are attained by a simple variant of certainty equivalence control, where the learner selects control inputs according to the optimal controller for their estimate of the system while injecting exploratory random noise. While this approach was shown to achieve $\sqrt{T}$-regret by Mania et al. [2019], we show that if the learner continually refines their estimates of the system matrices, the method attains optimal dimension dependence as well.

Central to our upper and lower bounds is a new approach for controlling perturbations of Ricatti equations, which we call the self-bounding ODE method. The approach enables regret upper bounds which hold for any stabilizable instance, require no foreknowledge of the system except for a single stabilizing controller, and scale with natural control-theoretic quantities.

1 Introduction

Reinforcement learning has recently achieved great success in application domains including Atari [Mnih et al., 2015], Go [Silver et al., 2017], and robotics [Lillicrap et al., 2015]. All of these breakthroughs leverage data-driven methods for continuous control in large state spaces. Their success, along with challenges in deploying RL in the real world, has led to renewed interest on developing continuous control algorithms with improved reliability and sample efficiency. In particular, on the theoretical side, there has been a push to develop a non-asymptotic theory of data-driven continuous control, with an emphasis on understanding key algorithmic principles and fundamental limits.

In the non-asymptotic theory of reinforcement learning, much attention has been focused on the so-called “tabular” setting where states and actions are discrete, and the optimal rates for this setting are by now relatively well-understood [Jaksch et al., 2010, Dann and Brunskill, 2015, Azar et al., 2017]. Theoretical results for continuous control setting have been more elusive, with progress spread across various models [Kakade et al., 2003, Munos and Szepesvári, 2008, Jiang et al., 2017, Jin et al., 2019], but the linear-quadratic regulator (LQR) problem has recently emerged as a candidate for a standard benchmark for continuous control and RL. For tabular reinforcement learning problems, it is widely understood that careful exploration is essential for sample efficiency. Recently, however, it was has been shown that for the online variant of the LQR problem, relatively simple exploration strategies suffice obtain the best-known performance guarantees [Mania et al., 2019]. In this paper, we address a curious question raised by this work: Is sophisticated exploration helpful for LQR, is linear control truly substantially easier than the general reinforcement learning setting? More broadly, we aim to shed light on the question:

To what extent do sophisticated exploration strategies improve learning in online linear-quadratic control?
Is ε-Greedy Optimal for Online LQR? In the LQR problem, the system state $x_t$ evolves according to the dynamics

$$x_{t+1} = Ax_t + Bu_t + w_t, \quad \text{where} \quad x_1 = 0,$$

(1.1)

$u_t \in \mathbb{R}^{d_u}$ is the learner’s control input, $w_t \in \mathbb{R}^{d_x}$ is a noise process drawn as $w_t \overset{i.i.d.}{\sim} \mathcal{N}(0, I)$, and $A \in \mathbb{R}^{d_x \times d_x}$, $B \in \mathbb{R}^{d_x \times d_u}$ are unknown system matrices. Initially the learner has no knowledge of the system dynamics, and their goal is to repeatedly select control inputs and observing states over $T$ rounds so as to minimize their total cost $\sum_{t=1}^{T} c(x_t, u_t)$, where $c(x, u) = x^\top R_x x + u^\top R_u u$ is a known quadratic function. In the online variant of the LQR problem, we measure performance via regret to the optimal linear controller:

$$\text{Regret}_{A,B,T}[\pi] = \left[ \sum_{t=1}^{T} c(x_t, u_t) \right] - T \min_K \mathcal{J}_{A,B}[K],$$

(1.2)

where $K$ is a linear state feedback policy of the form $u_t = Kx_t$, and, letting $\mathbb{E}_{A,B,K}[\cdot]$ denote expectation under this policy, and where

$$\mathcal{J}_{A,B}[K] := \mathcal{J}_{A,B}[K] := \lim_{T \to \infty} \frac{1}{T} \mathbb{E}_{A,B,K} \left[ \sum_{t=1}^{T} c(x_t, u_t) \right],$$

is the average infinite-horizon cost of $K$, which is finite as long as $K$ is stabilizing in the sense that $\rho(A+BK) < 1$, where $\rho(\cdot)$ denotes the spectral radius.

This setting has enjoyed substantial development beginning with the work of Abbasi-Yadkori and Szepesvári [2011], and following a line of successive improvements [Dean et al., 2018, Faradonbeh et al., 2018a, Cohen et al., 2019, Mania et al., 2019], the best known algorithms for online LQR have regret scaling as $\sqrt{T}$.

In this paper we investigate a curious question that has emerged from this research: The role exploration in linear control. The first approach in this line of work, Abbasi-Yadkori and Szepesvári [2011], proposed a sophisticated though computationally inefficient strategy known as optimism under the face of uncertainty, upon which Cohen et al. [2019] improved to ensure optimal $\sqrt{T}$-regret and polynomial runtime. But another approach to enjoy this optimal bound due to Mania et al. [2019] employs a variant of the classical ε-greedy exploration strategy [Sutton and Barto, 2018] known in control literature as certainty equivalence: At each timestep, the learner computes the greedy policy for the current estimate of the system dynamics, then follows this policy, adding exploration noise proportional to $\epsilon$. While appealing in its simplicity, ε-greedy has severe drawbacks for reinforcement learning problems: For tabular RL, it leads to exponential blowup in the time horizon [Kearns et al., 2000], and for multi-armed bandits and variants such as bandit linear optimization and contextual bandits, it leads to suboptimal dependence on the time horizon $T$ [Langford and Zhang, 2007].

This begs the question: Can we improve beyond $\sqrt{T}$ regret for online LQR using more sophisticated exploration strategies? Or is exploration in LQR simply much easier than in general reinforcement learning settings? One natural hope would be to achieve logarithmic (i.e. poly(log $T$)) regret for this setting: Online LQR has strongly convex loss functions, and this is a sufficient condition for logarithmic regret in many simpler online learning and optimization problems [Vovk, 2001, Hazan et al., 2007, Rakhlin and Sridharan, 2014], as well as LQR with known dynamics but potentially changing costs [Agarwal et al., 2019b]. More subtly, Mania et al. [2019]’s $\sqrt{T}$ bound for online LQR appeals to strong controllability assumptions; it was not known if naive exploration attains this rate for arbitrary stabilizable problem instances, or if it necessarily leverages stronger assumptions to ensure its efficiency.

### 1.1 Contributions

We prove new upper and lower bounds which characterize the minimax optimal regret for online LQR as $\Theta(\sqrt{d_u d_x T})$. In addition to the horizon $T$, dimensions $d_x, d_u$, and logarithmic factors, our bounds depend

1. Non-identity covariances can be addressed by a change of basis.
2. For potentially asymmetric matrix $A \in \mathbb{R}^{d \times d}$, $\rho(A) := \max(|\lambda| \mid \lambda \text{ is an eigenvalue for } A)$.
only on \textit{operator} norms of transparent, control theoretic quantities, which do not hide additional dimension dependence. Our main lower bound is Theorem 1, which implies that no algorithm can improve upon $\sqrt{T}$ regret for online LQR, and so simple $\varepsilon$-greedy exploration is indeed \textit{rate-optimal}.

\textbf{Theorem 1 (informal).} For every sufficiently non-degenerate problem instance and every (potentially randomized) algorithm, there exists a nearby problem instance on which the algorithm must suffer regret at least $\Omega(\sqrt{d^2_d x^2 T})$.

Perhaps more surprisingly, our main upper bound shows that a simple variant of certainty equivalence is also \textit{dimension-optimal}, in that it asymptotically matches the $\sqrt{d^2_d x^2 T}$ lower bound of Theorem 1.

\textbf{Theorem 2 (informal).} Certainty equivalent control with continual $\varepsilon$-greedy exploration (Algorithm 1) has regret at most $\tilde{O}(\sqrt{d^2_d x^2 T} + d^2_d)$ for every stabilizable online LQR instance.

We stress that is the first analysis of \textit{any} algorithm to attain the optimal dimension dependence. In comparison, the result of Mania et al. [2019] guarantees $\sqrt{(d^2_d + d^2_u)^3}T$ regret \textit{and} imposes strong additional assumptions, and other approaches \textit{not} based on certainty equivalence suffer considerably larger dimension dependence [Cohen et al., 2019]. Together, Theorem 1 and Theorem 2 characterize the asymptotic minimax regret for online LQR, showing that there is little room for improvement over naive exploration.

\section{1.2 Our Approach}

Both our lower and upper bounds are facilitated by a new technique for establishing perturbation bounds for the Ricatti equations that characterize the optimal value function and controller for LQR. We call this technique the \textit{self-bounding ODE method}. The method sharpens existing perturbation bounds, weakens controllability and stability assumptions required by previous work [Dean et al., 2018, Faradonbeh et al., 2018a, Cohen et al., 2019, Mania et al., 2019], and yields an upper bound whose leading terms depend only on the horizon $T$, dimension parameters $d^2_d, d^2_u$, and certain control-theoretic parameters.

In more detail, if $(A, B)$ is stabilizable and $R_x, \bar{R}_u > 0$, there exists a unique positive semidefinite solution $P_\infty(A, B)$ for the \textit{discrete algebraic Ricatti equation} (or, DARE),

\begin{equation}
P = A^\top P A - A^\top P B (R_u + B^\top P B)^{-1} B^\top P A + R_x.
\end{equation}

The optimal infinite-horizon controller $K_\infty(A, B) := \arg \min_K J_{A,B,\infty}[K]$ is unique, and given by $K_\infty(A, B) := -(R_u + B^\top P_\infty(A, B) B)^{-1} B^\top P_\infty(A, B) A$, and the matrix $P_\infty(A, B)$ induces a positive quadratic form which can be interpreted as a value function for the LQR problem.

Both our upper and lower bounds make use of novel perturbation bounds to control the change in $P_\infty$ and $K_\infty$ when we move from a nominal instance $(A, B)$ to a nearby instance $(\hat{A}, \hat{B})$. For our upper bound, these are used to show that a good estimator for the nominal instance leads to a good controller, while for our lower bounds, they show that the converse is true. The self-bounding ODE method allows us to prove perturbation guarantees that depend only on the norm of the value function $\|P_\infty(A, B)\|_{op}$ for the nominal instance, which is a weaker assumption that subsumes these previous assumptions. The key observation underpinning the method is that the norm of the directional derivative of $\frac{d}{dt}P_\infty(A(t), B(t))$ at a point $t = u$ along a line $(A(t), B(t))$ is bounded in terms of the the magnitude of $\|P_\infty(A(u), B(u))\|$; we call this the \textit{self-bounding} property. From this equation, we show that bounding the norm of the derivatives reduces to solving a scalar ordinary differential equation, whose derivative saturates the scalar analogue of this self-bounding property. Notably, this technique \textit{does not} need the “strong controllability” assumption of Mania et al. [2019], and guarantees a data-verifiable “safe set” within which the perturbation bounds hold.\footnote{While other approaches do not require the strong assumptions of [Mania et al., 2019], they are either asymptotic in nature Faradonbeh et al. [2018b], or incur a highly suboptimal dimension dependence [Cohen et al., 2019].}

On the lower bound side, we begin with a nominal instance $(A, B)$ and consider a packing of alternative instances within a small neighborhood. We use a perturbation bound to show that any algorithm with low regret must identify the underlying instance, and from here deduce that any algorithm with low regret must deviate from the optimal controller. Balancing these tradeoffs leads to the $\sqrt{T}$ lower bound, and the
self-bounding ODE method ensures that the final lower bound depends only on properties \( \|P_s\|_{\text{op}}, \|B\|_{\text{op}}, \) and so on) for the nominal instance. At an intuitive level, the reason why the final bound scales as \( \sqrt{T} \) is that while the strong convexity and smoothness of the quadratic loss function lead to fast rates for estimation, any algorithm must deviate significantly from the optimal controller to ensure that covariates are well-conditioned.

Our upper bound refines the certainty equivalent control strategy proposed in Mania et al. [2019] by re-estimating the system parameters on a doubling epoch schedule to advantage of the endogenous excitation supplied by the \( w_e \)-sequence. A careful analysis of least squares estimations shows that the error on \( d_xd_u \) coordinates decays as \( O \left( 1/\sqrt{t} \right) \), and the remaining \( d_x^2 \) coordinates at fast rate of \( O \left( 1/t \right) \). The former implies yields the desired leader-order regret bound, and the latter contributes at most logarithmically. The novel perturbation analysis described above yields bounds in terms of natural control theoretic quantities, and obviates the need for additional assumptions or prior knowledge about the system.\(^4\)

### 1.3 Related work

Non-asymptotic guarantees for learning linear dynamical systems have been the subject of intense recent interest [Dean et al., 2017, Hazan et al., 2017, Tu and Recht, 2018, Hazan et al., 2018, Simchowitz et al., 2018, Sarkar and Rakhlin, 2019, Simchowitz et al., 2019, Mania et al., 2019, Sarkar et al., 2019]. The online LQR setting we study was introduced by Abbasi-Yadkori and Szepesvári [2011], which considers the problem of controlling an unknown linear system under stationary stochastic noise.\(^5\) They showed that an algorithm based on the optimism in the face of uncertainty (OFU) principle enjoys \( \sqrt{T} \), but their algorithm is computationally inefficient and their regret bound depends exponentially on dimension. The problem was revisited by Dean et al. [2018], who showed that an explicit explore-exploit scheme based \( \varepsilon \)-greedy exploration and certainty equivalence achieves \( T^{2/3} \) regret efficiently, and left the question of obtaining \( \sqrt{T} \) regret efficiently as an open problem. This issue was subsequently addressed by Faradonbeh et al. [2018a] and Mania et al. [2019], who showed that certainty equivalence obtains \( \sqrt{T} \) regret, and Cohen et al. [2019], who achieve \( \sqrt{T} \) regret using a semidefinite programming relaxation for the OFU scheme. The regret bounds in Faradonbeh et al. [2018a] do not specify dependence, and (for \( d_x \geq d_u \)), the dimension scaling of Cohen et al. [2019] can be as large as \( \sqrt{d_x^4T} \); Mania et al. [2019] incurs a dimension dependence of \( \sqrt{d_x^2T} \) (suboptimal when \( d_u \ll d_x \)), but at the expense of imposing a strong controllability assumption.

The question of whether regret for online LQR could be improved further (for example, to \( \log T \)) remained open, and was left as a conjecture by Faradonbeh et al. [2018b]. Our lower bounds resolve this conjecture by showing that \( \sqrt{T} \)-regret is optimal. Moreover, by refining the upper bounds of Mania et al. [2019], our results show that the asymptotically optimal regret is \( \Theta \left( \sqrt{d_x^2d_uT} \right) \), and that this achieved by certainty equivalence. Beyond attaining the optimal dimension dependence, our upper bounds also enjoy refined dependence on problem parameters, and do not require a-priori knowledge of these parameters.

Logarithmic regret bounds are ubiquitous in online learning and optimization problems with strongly convex loss functions [Vovk, 2001, Hazan et al., 2007, Rakhlin and Sridharan, 2014]. Agarwal et al. [2019b] demonstrate that for the problem of controlling an \( \text{known} \) linear dynamic system with adversarially chosen, strongly convex costs, logarithmic regret is also attainable. Our \( \sqrt{T} \) lower bound shows that the situation for the online LQR with an \( \text{unknown} \) system parallels that of bandit convex optimization, where Shamir [2013] showed that \( \sqrt{T} \) is optimal even for strongly convex quadratics. In spite of strong convexity of the losses, issues of partial observability prevent fast rates in both settings.

Our lower bound carefully exploits the online LQR problem structure to show that \( \sqrt{T} \) is optimal. To obtain optimal dimension dependence for the lower bound, we build on well-known lower bound technique for adaptive sensing based on Assouad’s lemma [Arias-Castro et al., 2012] (see also Assouad [1983], Yu [1997]).

Finally, a parallel line of research provides Bayesian and frequentist regret bounds for online LQR based on Thompson sampling [Ouyang et al., 2017, Abeille and Lazaric, 2017], with Abeille and Lazaric [2018] demonstrating \( \sqrt{T} \)-regret that Thompson sampling achieves \( \sqrt{T} \) regret for the scalar setting. Unfortunately,

---

\(^4\) We note that, without the doubling epoch schedule, we can obtain a near optimal rate of \( \sqrt{(d_x + d_u)d_xd_uT} \), slightly improving upon Mania et al. [2019] in dimension dependence, and also without the need for additional assumptions.

\(^5\) A more recent line of work studies a more general non-stochastic noise regime (see Agarwal et al. [2019a] et seq.), which we do not consider in this work.

\(^6\) The regret bound of Cohen et al. [2019] scales as \( (J\lambda^*, B^*)^5d_x^2\sqrt{T} \), typically, \( J\lambda^*, B^* \) scales linearly in \( d_x \).
Thompson sampling is not computationally efficient for the LQR.

1.4 Organization

Section 1.5 introduces basic notation and definitions. Section 2 introduces our main results: In Section 2.1 and Section 2.2 we state our main lower and upper bounds respectively and give an overview of the proof techniques, and in Section 2.3 we instantiate and compare these bounds for the simple special case of strongly stable systems. The remainder of the paper is devoted to proving these results. In Section 3 we introduce the self-bounding ODE method and show how it is used to prove key perturbation bounds used in our main results; additional details are given in Part I of the appendix. Detailed proofs for the lower and upper bound are given in Section 4 and Section 5, with additional proofs deferred to Appendix F and Appendix G. Finally, future directions and open problems are discussed in Section 6.

1.5 Preliminaries

Assumptions We restrict our attention stabilizable systems \((A, B)\) for which there exists a stabilizing controller \(K\). Note that this does not require that the system be controllable. We further assume that \(R_u = I\) and \(R_x \succeq I\). The first can be enforced by a change of basis in input space, and the second can be enforced by rescaling the state space, increasing the regret by at most a multiplicative factor of \(\min \{1, 1/\sigma_{\min}(R_x)\}\); similarly, a change of basis can extend the present results to noise arbitrary, known positive-definite covariance.

Algorithm Protocol and Regret Formally, the learner’s (potentially randomized) decision policy is modeled as a sequence of mappings \(\pi = (\pi_t)_{t=1}^T\), where each function \(\pi_t\) maps the history \((x_1, \ldots, x_t, u_1, \ldots, u_{t-1})\) and an internal random seed \(\xi\) to an output control signal \(u_t\). For a linear system evolving according to Eq. (1.1) and policy \(\pi\), we let \(\mathbb{P}_{A,B,\pi}\) and \(\mathbb{E}_{A,B,\pi}[\cdot]\) denote the probability and expectation with respect to the dynamics (1.1) and randomization of \(\pi\). For such a policy, we use the notation \(\text{Regret}_{A,B,T}[\pi]\) as in Eq. (1.2) for regret, which is a random variable with law \(\mathbb{P}_{A,B,\pi}[\cdot]\). We prove high-probability upper bounds on \(\text{Regret}_{A,B,T}[\pi]\), and prove lower bounds on the expected regret \(\mathbb{E}_{\text{Regret}_{A,B,T}[\pi]} := \mathbb{E}_{A,B,\pi}[\text{Regret}_{A,B,T}[\pi]]\).\(^7\)

Additional Notation For vectors \(x \in \mathbb{R}^d\), \(\|x\|\) denotes the \(\ell_2\) norm. For matrices \(X \in \mathbb{R}^{d_1 \times d_2}\), \(\|X\|_{\text{op}}\) denotes the spectral norm, and \(\|X\|_{\text{F}}\) the Frobenius norm. When \(d_1 \leq d_2\), \(\sigma_1(X), \ldots, \sigma_{d_1}(X)\) denote the singular values of \(X\), arranged in decreasing order. We say \(f \lesssim g\) to denote that \(f(x) \leq C g(x)\) for a universal constant \(C\), and \(f \lesssim g\) to denote informal inequality. We write \(f \approx g\) if \(g \lesssim f \lesssim g\).

For “starred” systems \((A_*, B_* )\), we adopt the shorthand \(P_* := P_{\infty}(A_*, B_*)\), \(K_* := K_{\infty}(A_*, B_*)\) for the optimal controller, \(J_* := J_{A_*, B_*}[K_*]\) for optimal cost, and \(A_{cl,*} := A_* + B_* K_*\) for the optimal closed loop system. We define \(\Psi_* := \max\{1, \|A_*\|_{\text{op}}, \|B_*\|_{\text{op}}\}\). For systems \((A_0, B_0)\), we let \(B_{\text{op}}(\epsilon; A_0, B_0) = \{(A, B) \mid \|A - A_0\|_{\text{op}} \vee \|B - B_0\|_{\text{op}} \leq \epsilon\}\) denote the set of nearby systems in operator norm.

2 Main Results

We now state our main upper and lower bounds for online LQR and give a high-level overview of the proof techniques behind both results. At the end of the section, we instantiate and compare the two bounds for the simple special case of strongly stable systems.

Both our upper and lower bounds are motivated by the following question: Suppose that the learner is selecting near optimal control inputs \(u_t \approx K_t x_t\), where \(K_t = K_{\infty}(A_*, B_*)\) is the optimal controller for the system \((A_*, B_*)\). What information can she glean about the system?\(^7\)One might consider as a stronger benchmark described the expected loss of the optimal policy for fixed horizon \(T\). A fortiori, our lower bounds apply for this benchmark as well. In view of the proof of Lemma 4.3 in Appendix F.2, this benchmark differs from \(T J_{A,B}^{\star}\) by a constant factor which depends on \((A, B)\) but does not grow with \(T\).
2.1 Lower Bound

We provide a local minimax lower bound, which captures the difficulty of ensuring low regret on both a nominal instance \((A_*, B_*)\) and on the hardest nearby alternative. For a distance parameter \(\epsilon > 0\), we define the local minimax complexity at scale \(\epsilon\) as

\[
R_{A_*, B_*, T}(\epsilon) := \min_{\pi} \max_{A,B} \{ \mathbb{E} \text{Regret}_{A,B,T}[\pi] : \|A - A_*\|_F^2 \vee \|B - B_*\|_F^2 \leq \epsilon \}.
\]

Local minimax complexity captures the idea certain instances \((A_*, B_*)\) are more difficult than others, and allows us to provide lower bounds that scale only with control-theoretic parameters of the nominal instance. Of course, the local minimax lower bound immediately implies a lower bounds on the global minimax complexity as well.\(^8\)

**Intuition Behind the Lower Bound.** We show that if the learner plays near-optimally on every instance in the neighborhood of \((A_*, B_*)\), then there is a \(d_x d_u\)-dimensional subspace of system parameters that the learner must explore by deviating from \(K_*\) when the underlying instance is \((A_*, B_*)\). Even though the system parameters can be estimated at a fast rate, such deviations preclude logarithmic regret.

In more detail, if the learner plays near-optimally, she is not be able to distinguish between whether the instance she is interacting with is \((A_*, B_*)\), or another system of the form

\[
(A, B) = (A_* - \Delta, B_* + \Delta),
\]

for some perturbation \(\Delta \in \mathbb{R}^{d_x \times d_u}\). This is because all the observations \((x_t, u_t)\) generated by the optimal controller lie in the subspace \(\{(x, u) : u - K_* x = 0\}\), and likewise all observations generated by a near-optimal controller approximately lie in this subspace. Since the learner cannot distinguish between \((A_*, B_*)\) and \((A, B)\), she will also play \(u_t \approx K_* x_t\) on \((A, B)\). This leads to poor regret when the instance is \((A, B)\), since the optimal controller in this case has \(u_t = K_\infty(A, B)x_t\). This is made concrete by the next lemma, which shows to a first-order approximation that if \(\Delta\) is large, the distance between the optimal controller in this case has \(u_t \approx K_\infty(A, B)x_t\).

**Lemma 2.1.** Let \((A_*, B_*)\) be stabilizable. Then

\[
\frac{d}{dt} K_\infty(A_* - t\Delta K_*, B_* + t\Delta)\bigg|_{t=0} = -(R_u + B_\star^T P_\star B_\star)^{-1} : \Delta^T P_\star A_{cl,*},
\]

where we recall \(A_{cl,*} := A_* + B_* K_*\).

In particular, when the closed loop system \(A_{cl,*}\) is (approximately) well-conditioned, the optimal controllers for \((A_*, B_*)\) and for \((A, B)\) are \(\Omega(\|\Delta\|_F)\)-apart, and so the learner cannot satisfy both \(u_t \approx K_* x_t\) and \(u_t \approx K_\infty(A, B)x_t\) simultaneously. More precisely, for the learner to ensure \(\sum_t \|x_t - K_\infty(A, B)u_t\|_F^2 \leq d_x d_u \epsilon^2\) on every instance, she must deviate from optimal by at least \(\sum_{t=1}^T \|x_t - K_* u_t\|_F^2 \geq d_u T / \epsilon^2\) on the optimal instance; the \(d_u\) factor here comes from the necessity of exploring all control-input directions. Balancing these terms leads to the final \(\Omega(\sqrt{T d_u d_x^2})\) lower bound. The formal proof is given in Section 4.

**Theorem 1.** Let \(c_1, p > 0\) denote universal constants. For \(m \in [d_x]\), define \(\nu_m := \sigma_m(A_{cl,*})/\|R_u + B^\star^T P_\star B_\star\|_{op}\). Then if \(\nu_m > 0\), we have

\[
R_{A_*, B_*, T}(\epsilon T) \geq \sqrt{d_u^2 m T} \frac{1 \wedge \nu_m^2}{\|P_\star\|_{op}^2}, \text{ where } \epsilon T = \sqrt{d_u^2 m T},
\]

provided that \(T \geq c_1(\|P_\star\|_{op}^p (d_u m \vee \frac{d_u^2 4! b_{\star}}{m d_u^{-1}}) \vee d_x \log(1 + d_x \|P_\star\|_{op}))\).

Let us briefly discuss some key features of Theorem 1.

\(^8\)Some care must be taken in defining the global complexity, or it may well be infinite. One sufficient definition, which captures prior work, is to consider minimax regret over all instances subject to a global bound on \(\|P_\star\|, \|B_\star\|\), and so on.
• The only system-dependent parameters appearing in the lower bound are the operator norm bounds $\Psi_{B_*}$ and $\|P_\epsilon\|_{op}$ for the nominal instance. The latter parameter is finite whenever the system is stabilizable, and does not explicitly depend on the spectral radius or strong stability parameters.

• The lower bound takes $\epsilon_T \propto T^{-1/2}$, so the alternative instances under consideration converge to the nominal instance $(A_*, B_*)$ as $T \to \infty$.

• The theorem can be optimized for each instance by tuning the dimension parameter $m \in [d_x]$; the leading $\sqrt{d_x^2 m^2}$ term is increasing in $m$, while the parameter $\nu_m$ scales with $\sigma_m(A_{cl,*})$ and thus is decreasing in $m$. The simplest case is when $\sigma_m(A_{cl,*})$ is bounded away from 0 for $m \gtrsim d_x$; here we obtain the optimal $\sqrt{d_x^2 d_x^2 \tau_k}$ lower bound. In particular, if $d_x \leq d_x/2$, we can choose $m = \frac{1}{2}d_x$ to get $\sigma_m(A_{cl,*}) \geq \sigma_{\min}(A_*)$.

### 2.2 Upper Bound

While playing near-optimally prevents the learner from ruling out perturbations of the form Eq. (2.1), she can rule perturbations in orthogonal directions. Indeed, if $u_t \approx K_* x_t$, then $x_{t+1} \approx (A_* + B_* K_*) x_t + w_t$. As a result, the persistent noise process $w_t$ allows the learner to recover the closed loop dynamics matrix $A_{cl,*} = A_* + B_* K_*$ from Frobenius error $d_x \epsilon$ after just $T \gtrsim 1/\epsilon^2$ steps, regardless of whether she incorporates additional exploration [Simchowitz et al., 2018]. Hence, for perturbations perpendicular to those in Eq. (2.1), the problem closely resembles a setting where $\log T$ is achievable.

Our main algorithm, Algorithm 1, is an $\epsilon$-greedy scheme that takes advantage of this principle. The full pseudocode and analysis are deferred to Section 5, but we sketch the intuition here. The algorithm takes as input a stabilizing controller $K_0$ and proceeds in epochs $k$ of length $\tau_k = 2^k$. After an initial burn-in period ending with epoch $k_{\text{safe}}$, the algorithm can ensure the reliability of its synthesized controllers, and uses a (projected) least-squares estimate $(\hat{A}_k, \hat{B}_k)$ of $(A_*, B_*)$ to synthesize a controller $\hat{K}_k = K_\infty(\hat{A}_k, \hat{B}_k)$ known as the certainty equivalent controller. The learner then selects inputs by adding white Gaussian noise with variance $\sigma_k^2$: $u_t = \hat{K}_k x_t + \mathcal{N}(0, \sigma_k^2 I)$. We show that this scheme exploits the rapid estimation along directions orthogonal to those in Eq. (2.1), leading to optimal dimension dependence.

To begin, we show (Theorem 3) that the cost of the certainty-equivalent controller is bounded by the estimation error for $\hat{A}_k$ and $\hat{B}_k$:

$$ J_{A_*, B_*}[\hat{K}_k] - J_* \lesssim \text{poly}(\|P_\epsilon\|_{op}) \cdot (\|\hat{A}_k - A_*\|_F^2 + \|\hat{B}_k - B_*\|_F^2), $$

once $(\hat{A}_k, \hat{B}_k)$ are sufficiently accurate, as guaranteed by the burn-in period. Through a standard argument, we next show that the bulk of the algorithm’s regret scales as the sum of the suboptimality in the controller for a given epoch, plus the cost of the exploratory noise:

$$ \sum_{k = k_{\text{safe}}}^{\log_2 T} \tau_k \left( J_{A_*, B_*}[\hat{K}_k] - J_* \right) + d_u \tau_k \sigma_k^2 \lesssim \sum_{k = k_{\text{safe}}}^{\log_2 T} \tau_k \left( \|\hat{A}_k - A_*\|_F^2 + \|\hat{B}_k - B_*\|_F^2 \right) + d_u \tau_k \sigma_k^2. $$

Paralleling the lower bound, the analysis crucially relies on the exploratory noise to bound the error in the $d_x d_u$-dimensional subspace corresponding to Eq. (2.1), as the error in this subspace grows as $\frac{d_x^2 d_u}{\tau_k \sigma_k^2}$. However, for the directions parallel to those in Eq. (2.1), the estimation error is at most $d_x^2 / \tau_k$, and so the total regret is at most

$$ \text{Regret}_{A_*, B_*}[\text{Alg}] \lesssim \sum_{k = k_{\text{safe}}}^{\log_2 T} \tau_k \left( \frac{d_x^2}{\tau_k} + \frac{d_x d_u}{\tau_k \sigma_k^2} \right) + d_u \tau_k \sigma_k^2 \approx \frac{d_x^2 \log T}{\tau_k} + \frac{d_x d_u}{\sigma_k^2} + d_u \tau_k \sigma_k^2. $$

Trading off $\sigma_k^2 = \sqrt{d_x^2 / \tau_k}$ gives regret $d_x^2 \log T + \sum_{k=1}^{\log_2 T} \sqrt{d_x d_u} \tau_k \approx d_x^2 \log T + \sqrt{d_x d_u} T$. We emphasize that to ensure that the $d_x^2$ term in this bound scales only with $\log T$ due to rapid exploration perpendicular to Eq. (2.1), and it is crucial that the algorithm uses doubling epochs to take advantage of this. The full guarantee for Algorithm 1 is as follows.

7
Theorem 2. When Algorithm 1 is invoked with stabilizing controller $K_0$ and confidence parameter $\delta \in (0, 1/T)$, it guarantees that with probability at least $1 - \delta$,

$$
\text{Regret}_T[\text{Alg}; A_*, B_*] \lesssim \sqrt{\frac{d_u^2 d_x T \cdot \Psi_{B_*}^2 \|P_*\|_{op}^{11}}{\delta}} \log \frac{\|P_*\|_{op}}{\delta} + d^2 \cdot \mathcal{P}_0 \Psi_{B_*}^6 \|P_*\|_{op}^{11} (1 + \|K_0\|_{op}^2) \log \frac{d\Psi_{B_*} \mathcal{P}_0}{\delta} \log^2 \frac{1}{\delta},
$$

where $\mathcal{P}_0 := \mathcal{J}_{A_*, B_*}[K_0]/d_x$ is the normalized cost of $K_0$, and $d = d_x + d_u$.

Ignoring dependence on problem parameters, the upper bound of Theorem 2 scales asymptotically as $\sqrt{d_u^2 d_x T}$, matching our lower bound. Like the lower bound, the theorem depends on the instance $(A_*, B_*)$ only through the operator norm bounds $\Psi_{B_*}$ and $\|B_*\|_{op}$. Similar to previous work [Dean et al., 2018, Mania et al., 2019], the regret bound has additional dependence on the stabilizing controller $K_0$ through $\|K_0\|_{op}$ and $\mathcal{P}_0$, but these parameters only affect the lower-order terms.

### 2.3 Consequences for Strongly Stable Systems

To emphasize the dependence on dimension and time horizon in our results, we now present simplified findings for a special class of strongly stable systems.

**Definition 2.1** (Strongly Stable System [Cohen et al., 2018]). We say that $A_*$ is $(\gamma, \kappa)$-strongly stable if there exists a transform $T$ such that $\|T\|_{op} \cdot \|T^{-1}\|_{op} \leq \kappa$ and $\|TA_* T^{-1}\|_{op} \leq 1 - \gamma$. When $A_*$ is $(\gamma, \kappa)$-strongly stable, we define $\gamma_{\text{sta}} := \gamma/\kappa^2$.

For the simplified results in this section we make the following assumption.

**Assumption 1.** The nominal instance $(A_*, B_*)$ is such that $A_*$ is $(\gamma, \kappa)$-strongly stable and $\|B_*\|_{op} \leq 1$. Furthermore, $R_x = R_u = I$.

For strongly stable systems under Assumption 1, our main lower bound (Theorem 1) takes the following particularly simple form.

**Corollary 1** (Lower Bound for Strongly Stable Systems). Suppose that Assumption 1 holds, and that $d_u \leq \frac{1}{2} d_x$ and $\sigma_{\min}(A_*) > 0$. Then for any $T \geq (d_x d_u + d_x \log d_x) \log(1/\gamma_{\text{sta}} 1/\sigma_{\min}(A_*))$, we have

$$
\mathcal{R}_{A_*, B_*, T}(\varepsilon_T) \gtrsim \sqrt{d_u^2 d_x T} \cdot \sigma_{\min}(A_*)^2 \gamma_{\text{sta}}^2,
$$

where $\varepsilon_T := \sqrt{d_u^2 d_x T}$.

The upper bound from Theorem 2 takes on a similarly simple form, and is seen to be nearly matching.

**Corollary 2** (Upper Bound for Strongly Stable Systems). Suppose that Assumption 1 holds. Then Algorithm 1 with stabilizing controller $K_0 = 0$ and confidence parameter $\delta \in (0, 1/T)$, ensures that probability at least $1 - \delta$,

$$
\text{Regret}_T[\text{Alg}; A_*, B_*] \lesssim \sqrt{d_u^2 d_x T} \cdot \gamma_{\text{sta}}^{11} \log \frac{1}{\delta \gamma_{\text{sta}}} + (d_x + d_u)^2 \gamma_{\text{sta}}^{12} \log \frac{d}{\delta \gamma_{\text{sta}}} \log^2 \frac{1}{\delta}.
$$

We observe that the leading $\sqrt{d_u^2 d_x T}$ term in the upper and lower bounds differ only by factors polynomial in $\gamma_{\text{sta}}$, as well as a $\sigma_{\min}(A_*)$ factor incurred by the lower bound. The lower order term $(d_x + d_u)^2$ in the upper bound appears unavoidable, but we leave a complementary lower bound for future work.

Both corollaries hold because strong stability immediately implies a bound on $\|P_*\|_{op}$.

**Proof of Corollary 1 and Corollary 2.** First observe that under Assumption 1, $\Psi_{B_*} \leq 1$. Next, note that if $d_u < d_x/2$, then for $m = [d_x/2]$, $\sigma_m(A_*) = \sigma_m(A_* + B_* K_*) \geq \sigma_{m+d_u} (A_* + B_* K_*) \geq \sigma_{\min}(A_*)$. Thus gives $\nu_m \geq \sigma_{\min}(A_*)/(1 + \|P_*\|_{op})$. Finally, Lemma B.7 (stated and proved in Appendix B.3.1) gives $\|P_*\|_{op} \leq \gamma_{\text{sta}}^{-1}$. Plugging these three observations into Theorem 1 and Theorem 2 concludes the proof.}

The assumption $d_u \leq \frac{1}{2} d_x$ can be replaced with $d_u \leq \alpha d_x$ for any $\alpha < 1$, and can be removed entirely for special instances. See Corollary 7 in Appendix F.7 for more details.
3 Perturbation Bounds via the Self-Bounding ODE Method

Both Theorem 1 and Theorem 2 scale only with the natural system parameter \( \|P\|_\text{op} \), and avoid explicit dependence on the spectral radius or strong stability parameters found in prior work. This is achieved using the self-bounding ODE method, a new technique for deriving bounds on perturbations to the DARE solution \( P_\infty(A, B) \) and corresponding controller \( K_\infty(A, B) \) as the matrices \( A \) and \( B \) are varied. This method gives a general recipe for establishing perturbation bounds for solutions to implicit equations. It depends only on the norms of the system matrices and DARE solution \( P_\infty(A, B) \), and it applies to all stabilizable systems, even those that are not controllable.

In this section we give an overview of the self-bounding ODE method and use it to prove a simplified version of the main perturbation bound used in our main upper and lower bounds. To state the perturbation bound, we first define the following problem-dependent constants.

\[
C_\text{safe}(A, B) = 54\|P_\infty(A, B)\|_\text{est}^5, \quad \text{and} \quad C_\text{est}(A, B) = 142\|P_\infty(A, B)\|_\text{est}^8. \tag{3.1}
\]

The parameter \( C_\text{safe}(A, B) \) determines the radius of admissible perturbations, while the parameter \( C_\text{est}(A, B) \) determines the quality of the resulting perturbation. The main perturbation bound is as follows.

**Theorem 3.** Let \((A_*, B_*)\) be a stabilizable system. Given an alternate pair of matrices \((\hat{A}, \hat{B})\), for each \( \circ \in \{\text{op}, F\} \) define \( \epsilon_\circ := \max\{\|A - A_*\|_\circ, \|\hat{B} - B_*\|_\circ\} \). Then if \( \epsilon_\circ \leq 1/C_\text{safe}(A_*, B_*) \),

1. \( \|P_\infty(\hat{A}, \hat{B})\|_\circ \leq \|P_*\|_\circ \) and \( \|K_* - K_\infty(\hat{A}, \hat{B})\|_\circ \leq \frac{1}{\|P_*\|_\text{est}^3} \).

2. \( J_{A_*, B_*}[K_\infty(\hat{A}, \hat{B})] - J_{\hat{A}_*, \hat{B}_*}^* \leq C_\text{est}(A_*, B_*)\epsilon_\circ^2 \).

This theorem is a simplification of a stronger version, Theorem 5, stated and proven in Appendix B.1. In the remainder of this section, we sketch how to use the self-bounding ODE method to prove the following slightly more general version of the first bullet.

**Proposition 4.** Let \((A_*, B_*)\) be a stabilizable system, and \((\hat{A}, \hat{B})\), be an alternate pair of matrices. Then, if \( u := 8\|P_*\|_\text{est}^2 \leq 1 \), the pair \((\hat{A}, \hat{B})\) is stabilizable and the following bounds hold:

1. \( \|P_\infty(\hat{A}, \hat{B})\|_\circ \leq (1 - u)^{-1/2}\|P_*\|_\circ \).

2. For each \( \circ \in \{\text{op}, F\} \), \( \|K_\infty(\hat{A}, \hat{B}) - K_*\|_\circ \leq 7(1 - u)^{-7/4}\|P_*\|_\text{est}^{7/2} \epsilon_\circ \).

To begin proving the proposition, set \( \Delta_A := \hat{A} - A_* \) and \( \Delta_B := \hat{B} - B_* \). We consider a linear curve between the two instances, parameterized by \( t \in [0, 1] \):

\[
(A(t), B(t)) = (A_* + t\Delta_A, B_* + t\Delta_B). \tag{3.2}
\]

At each point \( t \) for which \((A(t), B(t))\) is stabilizable, the DARE has a unique solution, which allows us to define associated optimal cost matrices, controllers, and closed-loop dynamics matrices:

\[
P(t) := P_\infty(A(t), B(t)), \quad K(t) := K_\infty(A(t), B(t)), \quad \text{and} \quad A_{cl}(t) := A(t) + B(t)K(t). \tag{3.3}
\]

Our strategy will be to show that \( P(t) \) and \( K(t) \) are in fact smooth curves, and then obtain uniform bounds on \( \|P'(t)\|_\circ \) and \( \|K'(t)\|_\circ \) over the interval \([0, 1]\), yielding perturbation bounds via the mean value theorem. As a starting point, we express the derivatives of the DARE in terms of Lyapunov equations.

**Definition 3.1** (Discrete Lyapunov Equation). Let \( X, Y \in \mathbb{R}^{d_x \times d_x} \) with \( Y = Y^\top \) and \( \rho(X) < 1 \). We let \( T_X[P] := X^\top PX - X \), and let \( \text{dlyap}(X, Y) \) denote the unique PSD solution \( T_X[P] = Y \). We let \( \text{dlyap}[X] := \text{dlyap}(X, I) \).

The following lemma (proven in Appendix C.2) serves as the basis for our computations, and also establishes the requisite smoothness required to take derivatives.
Lemma 3.1 (Derivative and Smoothness of the DARE). Let \((A(t), B(t))\) be an analytic curve, and define \(\Delta_{A_0}(t) := A'(t) + B'(t)K_\infty(A(t), B(t))\). Then for any \(t\) such that \((A(t), B(t))\) is stabilizable, the functions \(P(u)\) and \(K(u)\) are analytic in a neighborhood around \(t\), and we have

\[
P'(u) = d\text{yap}(A_{cl}(u), Q_1(u)), \quad \text{where } Q_1(u) := A_{cl}(u)^T P(u) \Delta_{A_0}(u) + \Delta_{A_0}(u)^T P(u) A_{cl}(u).
\]

Lemma 3.1 expresses \(P(t)\) as the solution to an ordinary differential equation. While the lemma guarantees local existence of the derivatives, it is not clear that the entire curve \((A(t), B(t))\), \(t \in [0, 1]\) is stabilizable. However, since ODEs are locally guaranteed to have solutions, we should only expect trouble when the corresponding ODE becomes ill-defined, i.e. if \(P'(t)\) escapes to infinity. We circumvent this issue by observing that \(P'(t)\) satisfies the following self-bounding property.

Lemma 3.2 (Bound on First Derivatives). Let \((A(t), B(t))\) be an analytic curve. Then, for all \(t\) at which \((A(t), B(t))\) is stabilizable, we have

\[
\|P'(t)\|_\infty \leq 4 \|P(t)\|^{3/2} \epsilon_0, \quad \text{and} \quad \|K'(t)\|_\infty \leq 7 \|P(t)\|^{7/2} \epsilon_0.
\]

The bound on \(P'(t)\) above follows readily from the expression for \(P'(t)\) derived in Lemma 3.1, and the bound on \(K'(t)\) uses that \(K\) is an explicit, analytic function of \(P\); see Appendix C.2 for a full proof. Intuitively, the self-bounding property states that if \(P\) does not escape to infinity, then \(P'(t)\) cannot escape either.

Since the rate of growth for \(P(t)\) is in turn bounded by \(P'(t)\), this suggests that there is an interval for \(t\) on which \(P\) and \(P'\) self-regulate one another, ensuring a well-behaved solution. We proceed to make this intuition formal.

3.1 Norm Bounds for Self-Bounding ODEs

Informally, the self-bounding ODE method argues that if a vector-valued ODE \(y(t)\) satisfies a self-bounding property of the form \(\|y'(t)\| \leq g(\|y(t)\|)\) wherever it is defined, then the ODE can be compared to a scalar ODE \(z'(t) \approx g(z(t))\) with initial condition \(z(0) \approx \|y(0)\|\). Specifically, its admits a solution \(y(t)\) which is well-defined on an interval roughly as large as that of \(z(t)\). We develop the method in a general setting where \(y(t)\) (when defined) is the zero of a sufficiently regular function.

Definition 3.2 (Valid Implicit Function). A function \(F(\cdot, \cdot) : \mathbb{R}^m \times \mathbb{R}^d \to \mathbb{R}^d\) is a called a valid implicit function with domain \(\mathcal{U} \subseteq \mathbb{R}^d\) if \(F\) is continuously differentiable, and if for any continuously differentiable curve \(x(t)\) and any \(t \in [0, 1]\), either (a) \(F(x(t), y) = 0\) has no solution \(y \in \mathcal{U}\), or (b) it has a unique solution \(y(t) \in \mathcal{U}\), and there exists an open interval around \(t\) and a continuously differentiable curve \(y(u)\) defined on this interval for which \(F(x(u), y(u)) = 0\).

This setting captures as a special case the characterization of \(P(t)\) from Lemma 3.1. As a consequence of the lemma, we may take \(F = \mathcal{F}_{\text{DARE}}\), where, identifying \(\mathbb{S}^d_{\text{cl}}\) as a \((d^2/2 + 1)\)-dimensional Euclidean space, \(\mathcal{F}_{\text{DARE}} : (\mathbb{R}^{d^2} \times \mathbb{R}^{d \times d_{\text{cl}}} \times \mathbb{S}^d_{\text{cl}}) \to \mathbb{S}^d_{\text{cl}}\) is the function whose zero-solution defines the DARE:

\[
\mathcal{F}_{\text{DARE}}((A, B), P) := A^T PA - P - A^T PB(R_u + B^T PB)^{-1}B^T PA + R_x.
\]

Then \(\mathcal{F}_{\text{DARE}}\) is a valid implicit function with unique solutions in the set of positive-definite matrices \(\mathcal{U} := \mathbb{S}^d_{++}\). To proceed, we introduce our self-bounding condition.

Definition 3.3 (Self-bounding). Let \(g : \mathbb{R} \to \mathbb{R}_{\geq 0}\) be non-negative and non-decreasing, let \(F\) be a valid implicit function with domain \(\mathcal{U}\), and let \(\|\cdot\|\) be a norm. For a continuously differentiable curve \(x(t)\) defined on \([0, 1]\), we say that \(F\) is \((g, \|\cdot\|)\)-self bounded on \(x(t)\) if \(F(x(0), y) = 0\) has a solution \(y \in \mathcal{U}\) and

\[
\|y'(t)\| \leq g(\|y(t)\|) \quad \text{for all } t \in [0, 1]\]

for which \(F(x(t), y)\) has a solution \(y \in \mathcal{U}\).

We call the tuple \((F, \mathcal{U}, g, \|\cdot\|, x(\cdot))\) an self-bounding tuple.

Lemma 3.2 shows that \(\mathcal{F}_{\text{DARE}}\) is \((g, \|\cdot\|_{\text{op}})\)-self bounding on the curve the \((A(t), B(t))\) with \(g(z) = cz^3\) for \(c \propto \epsilon_{\text{op}}\). For functions \(g(z)\) with this form we have the following general bound on \(\|y(t)\|\).
Corollary 3. Let \((F, \mathcal{U}, g, \|\|, x(\cdot))\) be a self-bounding tuple, where \(g(z) = cz^p\) for \(c > 0\) and \(p > 1\). Then, if \(\alpha := c(p - 1)\|y(0)\|^{p-1} < 1\), there exists a unique continuously differentiable function \(y(t) \in \mathcal{U}\) defined on \([0, 1]\) which satisfies \(F(x(t), y(t)) = 0\), and this solution satisfies
\[
\forall t \in [0, 1], \quad \|y(t)\| \leq (1 - \alpha)^{-1/(p-1)}\|y(0)\|, \quad \text{and} \quad \|y'(t)\| \leq c(1 - \alpha)^{-p/(p-1)}\|y(0)\|^p.
\]

Corollary 3 is a consequence of a similar result for general functions \(g\) (Theorem 13), which is stated in Appendix D. The condition on the parameter \(\alpha\) directly arises from the requirement that the scalar ODE \(w'(u) = cw(u)^3\) has a solution on \([0, 1]\).

**Finishing the Proof of Proposition 4** To close out this section, we use Corollary 3 to conclude the proof of Proposition 4.

**Proof of Proposition 4.** Lemma 3.2 states that for any \(t \in [0, 1]\) for which \((A(t), B(t))\) is stabilizable (i.e., \(\mathcal{F}_{\text{DARE}}([A(t), B(t)], \cdot)\) has a solution), we have the bound
\[
\|P'(t)\|_{\text{op}} \leq 4\|P(t)\|_{\text{op}}^3.
\]

Applying Corollary 3 with \(p = 2\) and \(c = 4\|P\|_{\text{op}}\), we see that if \(\alpha := 8\|P\|_{\text{op}}^2 < 1\), then \(P(t)\) is continuously differentiable on the interval \([0, 1]\) and
\[
\forall t \in [0, 1], \quad \|P(t)\|_{\text{op}} \leq \|P\|_{\text{op}} / \sqrt{1 - \alpha}.
\]

By Lemma 3.2, \(K(t)\) is well defined as well, and satisfies
\[
\max_{t \in [0, 1]} \|K'(t)\|_0 \leq 7e_0 \max_{t \in [0, 1]} \|P(t)\|_{\text{op}}^7/2 \leq (1 - \alpha)^{-7/4}\|P\|_{\text{op}}.
\]

The desired bound on \(\|K_\infty(A_\star, B_\star) - K_\infty(\hat{A}, \hat{B})\|_0\) follows from the mean value theorem. \(\square\)

4 Proof of Lower Bound (Theorem 1)

We now prove the main lower bound, Theorem 1. The proof follows the plan outlined in Section 2: We construct a packing of alternative instances, show that low regret on a given instance implies low estimation error, and then deduce from an information-theoretic argument that this implies high regret an alternative instance. All omitted proofs for intermediate lemmas are given in Appendix F. Recall throughout that we assume \(\sigma_w^2 = 1\).

4.1 Alternative Instances and Packing Construction

We construct a packing of instances of alternate instances \((A_c, B_c)\) which take the form \((A_\star + K_\star \Delta_c, B_\star + \Delta_c)\). To obtain the correct dimension dependence, it is essential that the packing is sufficiently large; a single alternative instance will not suffice. Our goal is to make the packing as large as possible while ensuring that if one can recover the optimal controller for a given instance, they can also should be able to recover the perturbation \(\Delta_c\).

Let \(n = d_w\), and let \(m \leq d_x\) be the free parameter from the theorem statement. We construct a collection of instances indexed by sign vectors \(e \in \{-1, 1\}^{[n] \times [m]}\). Let \(w_1, \ldots, w_n\) denote an eigenbasis basis of \((R_n + B_r^T P_c B_r)^{-1}\), and \(v_1, \ldots, v_m\) denote the first \(m\) right-singular vectors of \(A_{ci}, P_c\). Then for each \(e \in \{-1, 1\}^{[n] \times [m]}\), the corresponding instances is
\[
(A_c, B_c) := (A_\star - \Delta_c K_\star, B_\star + \Delta_c), \quad \text{where} \quad \Delta_c = \epsilon_{\text{pack}} \sum_{i=1}^{n} \sum_{j=1}^{m} e_{i,j} w_i v_j^\top.
\]

It will be convenient to adopt the shorthand \(K_c := K_\infty(A_c, B_c), P_c = P_\infty(A_c, B_c)\) and \(J_c = J_{A_c, B_c}\), and \(\Psi_c = \max\{1, \|A_c\|_{\text{op}}, \|B_c\|_{\text{op}}\}\). The following lemma—proven in Appendix F.1—gathers a number of bounds
We now demonstrate that if one can achieve low regret on every instance, then one can estimate the infinite-err(Uniform Correctness) Assumption 3 Assumption 2 well through least squares whenever K-Err

The following lemma, proven in Appendix F.2, shows that regret is lower bounded by K-Err

4.2 Low Regret Implies Estimation for Controller

Let us define an intermediate term which captures which captures the extent to which the control inputs

We now define an intermediate term which captures which captures the extent to which the control inputs

Henceforth, we take ε_{pack} sufficiently small so as to satisfy the conditions of Lemma 4.1.

Assumption 2 (Small ε_{pack}). ε_{pack}^2 \leq \frac{1}{mn} (p_1(\|P_1\|_\infty)^{-1} \wedge \frac{1}{20} p_2(\|P_1\|_\infty)^{-1}).

4.2 Low Regret Implies Estimation for Controller

We now demonstrate that if one can achieve low regret on every instance, then one can estimate the infinite-horizon optimal controller K_c. Suppressing dependence on T, we introduce the shorthand ERegret_ε[π] := ERegret_{A_c,B_c,T}[π]. Going forward, we restrict ourselves to algorithms whose regret is sufficiently small on every packing instance; the trivial case where this is not satisfied is handled at the end of the proof.

Assumption 3 (Uniform Correctness). For all instances (A_e,B_e), the algorithm π ensures that ERegret_ε[π] \leq \frac{1}{6d_e\|P_1\|_\infty}\|b\|_\infty^2 - \gamma_{err}, where \gamma_{err} := 6\|P_1\|_\infty^3\|b\|_\infty^2.

We now define an intermediate term which captures which captures the extent to which the control inputs under instance e deviate from those prescribed by the optimal infinite horizon controller K_c on the first T/2 rounds:

K-Err_ε[π] := E_{A_e,B_e,π}\left[\frac{T/2}{t=1} ||u_t - K_c x_t||^2\right].

The following lemma, proven in Appendix F.2, shows that regret is lower bounded by K-Err_ε[π], and hence any algorithm with low regret under this instance must play controls close to K_c x_t.

Lemma 4.3. There is a universal constant c_{err} > 0 such that if Assumptions 2 and 3 hold and T \geq c_{err}\|P_1\|_\infty^2\|b\|_\infty^4, then

ERegret_ε[π] \geq \frac{1}{2} K-Err_ε[π] - \gamma_{err}.

In light of Lemma 4.3, the remainder of the proof will focus on lower bounding the deviation K-Err_ε. As a first step, the next lemma—proven in Appendix F.3—shows that the optimal controller can be estimated well through least squares whenever K-Err_ε is small. More concretely, we consider a least squares estimator which fits a controller using the first half of the algorithm’s trajectory. The estimator returns

\[ \hat{K}_{LS} := \arg\min_K \sum_{t=1}^{T/2} ||u_t - K x_t||^2, \]  \tag{4.2} \]

when \( \sum_{t=1}^{T/2} x_t x_t^\top \geq c_{min} T \cdot I \), and returns \( \hat{K}_{LS} = 0 \) otherwise.
Lemma 4.4. If \( T \geq c_0 d_x \log(1 + d_x \|P_e\|_{op}) \) and Assumptions 2 and 3 hold, and if \( c_{min} \) is chosen to be an appropriate numerical constant, then the least squares estimator Equation (4.2) guarantees

\[
K_{e,e}[\pi] \geq c_{LS} T \cdot E_{A_e,B_e,\pi} \left( \|\hat{K}_{LS} - K_e\|_F^2 \right) - 1,
\]

where \( c_0 \) and \( c_{LS} \) are universal constants.

Henceforth we take \( T \) large enough such that Lemma 4.3 and Lemma 4.4 apply.

Assumption 4. We have that \( T \geq c_0 d_x \log(1 + d_x \|P_e\|_{op}) \lor c_{err} \|P_e\|_{op}^2 \Psi_4^2 \).

4.3 Information-Theoretic Lower Bound for Estimation

We have established that low regret under the instance \((A_e, B_e)\) requires a small deviation from \(K_e\) in the sense that \(K_{e,e}[\pi]\) is small, and have shown in turn that any algorithm with low regret yields an estimator for the optimal controller \(K_e\) (Lemma 4.4). We now provide necessary condition for estimating the optimal controller, which will lead to the final tradeoff between regret on the nominal instance and the alternative instance. This condition is stated in terms of a quantity related to \(K_{e,e}[\pi]\):

\[
K_{e,e}[\pi] := E_{A_e,B_e,\pi} \left[ \sum_{t=1}^{T/2} \|u_t - K_e x_t\|^2 \right].
\]

Both \(K_{e,e}[\pi]\) and \(K_{e,e}[\pi]\) concern the behavior of the algorithm under instance \((A_e, B_e)\), but former measures deviation from \(K_e\) ("exploration error") while the latter measures deviation from the optimal controller \(K_e\). The next lemma, proven in Appendix F.4, is an information-theoretic lower bound that shows that any algorithm that can recover the index vector \(e\) in Hamming distance on every instance must have \(K_{e,e}[\pi]\) is large on some instances. The lemma concerns the case where the alternative instance index \(e\) is drawn uniformly from the hypercube. Let \(E_e\) denote expectation \(e \sim \{ -1, 1 \}^{[n \times m]}\), and \(d_{ham}(e, e')\) denotes the Hamming distance.

Lemma 4.5. Let \(\hat{e}\) be any estimator depending only on \((x_1, \ldots, x_{T/2})\) and \((u_1, \ldots, u_{T/2})\).

Then either

\[
E_e K_{e,e}[\pi] \geq \frac{n}{4 \epsilon_{pack}^2}, \quad \text{or} \quad E_e E_{A_e,B_e,\pi} \left[ d_{ham}(e, \hat{e}) \right] \geq \frac{nm}{4}.
\]

To apply this result to the least squares estimator \(\hat{K}_{LS}\), we prove the following lemma (Appendix F.5), which shows that any estimator \(\hat{K}\) with low Frobenius error relative to \(K_e\) can be used to recover \(e\) in Hamming distance.

Lemma 4.6. Let \(\hat{e}_{i,j}(\hat{K}) := \text{sign} (w_i^T (\hat{K} - K_e) v_j)\), and define \(\nu_k := \|\hat{K} u + B_e^* P_e B_e\|_{op} / \sigma_k (A_{cl,e})\). Then under Assumption 2,

\[
d_{ham}(\hat{e}_{i,j}(\hat{K}), e_{i,j}) \leq \frac{2 \|\hat{K} - K_e\|_F}{\nu_k^2 \epsilon_{pack}^2} + \frac{1}{20} nm.
\]

Combining Lemmas 4.4, 4.5, and 4.6, we arrive at a dichotomy: either the average exploration error \(K_{e,e}[\pi]\) is large, or the regret proxy \(K_{e,e}[\pi]\) is large:

Corollary 4. Let \(e \sim \{ -1, 1 \}^{[n \times m]}\). Then if Assumptions 2, 3, and 4 hold,

\[
\text{either} \quad E_e K_{e,e}[\pi] \geq \frac{n}{4 \epsilon_{pack}^2}, \quad \text{or} \quad E_e K_{e,e}[\pi] \geq \frac{c_{LS}}{10} T nm \nu_k^2 \epsilon_{pack}^2 - \gamma_0.
\]

Proof: Let \(\hat{e} = \hat{e}(\hat{K}_{LS})\), where \(\hat{e}\) is the estimator from Lemma 4.6, and \(\hat{K}_{LS}\) from Lemma 4.4. Since this estimator only depends on \(x_1, \ldots, x_{T/2}\) and \(u_1, \ldots, u_{T/2}\), we see that if (sufficient exploration) fails, then by Lemma 4.5, we have \(E_e E_{A_e,B_e,\pi} \left[ d_{ham}(\hat{e}, e) \right] \geq \frac{nm}{4} = \frac{nm}{5} + \frac{nm}{20}\). Thus, by Lemma 4.6, we have \(E_e \|\hat{K} - K_e\|_F^2 \geq \frac{nm}{5}\), yielding \(E_e E_{A_e,B_e,\pi} \|\hat{K} - K_e\|_F^2 \geq \frac{1}{10} nm \nu_k^2 \epsilon_{pack}^2\). The bound now follows from Lemma 4.4.

\(\square\)
4.4 Completing the Proof

To conclude the proof, we show (Appendix F.6) that $E_K - E_e \approx E_K - E_e$, so that the final bound follows by setting $\epsilon^2_{\text{pack}} \approx \sqrt{1/mT}$.

Lemma 4.7. Under Assumptions 2 and 3, we have $E_K - E_e [\pi] \leq 2E_K - E_e [\pi] + 4nmT\|P\|_{\text{op}}^4 \epsilon_{\text{pack}}^2$.

Combining Lemma 4.7 with Corollary 4, we have

$$\max_e K - E_e [\pi] \geq \frac{m}{8\epsilon_{\text{pack}}^2} - 2nmT\|P\|_{\text{op}}^4 \epsilon_{\text{pack}}^2 \wedge C_{\text{LS}} Tn\epsilon_{\text{pack}}^2\epsilon_{\text{pack}}^2.$$ 

Setting $\epsilon_{\text{pack}} = \frac{1}{32\|P\|_{\text{op}}^2 \sqrt{mT}}$ and substituting in $n = d_u$, we find that as long as $T$ is large enough such that Assumptions 2-4 hold,

$$\max_e K - E_e [\pi] \geq d_u \sqrt{mT}/\|P\|_{\text{op}}^2 \wedge \sqrt{d_u^2 mT r_m^2}/\|P\|_{\text{op}}^2 - 1$$

$$\geq (1 \wedge r_m^2)mT/\|P\|_{\text{op}}^2 - 1.$$ 

Thus, by Lemma 4.4, we have that for a sufficiently small numerical constant $C_{\text{lb}}$ (which we choose to have value at most 1 l.o.g.),

$$\max_e \mathbb{E} \text{Regret}_e [\pi] \geq 2C_{\text{lb}} \left( (1 \wedge r_m^2) \sqrt{d_u^2 mT} - \frac{1}{2} - \gamma_{\text{err}} \geq 2C_{\text{lb}} \left( (1 \wedge r_m^2) \sqrt{d_u^2 mT} \right) - 7d_x \|P\|_{\text{op}}^3 \Psi^2. \right)$$ 

It follows that once

$$T \geq c_1 \left( \frac{\|P\|_{\text{op}}^2 (nm \sqrt{d_u^2 mT} \vee \frac{d_u^2 \Psi^4 (1 \vee r_m^2)}{nn^2}) \vee d_x \log (1 + d_x \|P\|_{\text{op}}) \right),$$

where $c_1$ and $p$ sufficiently numerical constants, then Assumption 2 and 4 are indeed satisfied, so we have

$$\max_e \mathbb{E} \text{Regret}_e [\pi] \geq C_{\text{lb}} \left( (1 \wedge r_m^2) \sqrt{d_u^2 mT} \right) := \mathcal{R}.$$ 

We now justify Assumption 3. Suppose the assumption fails, i.e. for some instance $e$ the algorithm has $\text{Regret}_e [\pi] \geq \frac{T}{K} - \gamma_{\text{err}}$. Then since $C_{\text{lb}} \leq 1$ and $\|P\|_{\text{op}} \geq 1$, we see that if $\sqrt{T} \geq 12\Psi d_x \sqrt{nn^2}$, then $\text{Regret}_e [\pi] \geq 2\mathcal{R} - \gamma_{\text{err}} \geq \mathcal{R}$. By taking $c_1$ sufficiently large, we see that whenever Equation (4.4) holds, we have $\text{Regret}_e [\pi] \geq 2\mathcal{R} - \gamma_{\text{err}} \geq \mathcal{R}$ as desired.

To conclude, we verify that the construction is consistent with the scale parameter $\epsilon_T$ from the theorem statement:

$$\|A_e - A_s\|_F^2 \vee \|B_e - B_s\|_F^2 \leq nme_{\text{pack}}^2 \|P\|_{\text{op}} \leq n \sqrt{m/T} \leq \epsilon_T,$$

where (i) follows by Lemma 4.1, and (ii) follows by plugging in our choice for $\epsilon_{\text{pack}}$. 

5 Algorithm and Proof of Upper Bound (Theorem 2)

We now formally describe our main algorithm, Algorithm 1, and prove that it attains the upper bound in Theorem 2. The algorithm is a variant of certainty equivalent control with continual $\varepsilon$-greedy exploration. In line with previous work [Dean et al., 2018, Cohen et al., 2019, Mania et al., 2019], the algorithm takes as input a controller $K_0$ that is guaranteed to stabilize the system but otherwise may be arbitrarily suboptimal relative to $K_s$. The algorithm proceeds in epochs of doubling length. At the beginning of epoch $k$, the algorithm uses an ordinary least squares subroutine (Algorithm 2) to form an estimate $(\hat{A}_k, \hat{B}_k)$ for the system dynamics using data collected in the previous epoch. The algorithm then performs a check whether
We begin the proof by showing that the initial estimation phase (in which the algorithm uses the stabilizing controller) ensures that various regularity conditions hold for the epochs \( k \geq k_{\text{safe}} \) (in which the algorithm uses the certainty-equivalent controller). Such controllers have

\[
J(k) \leq \| P_{\infty}(K; A, B) \|_{\text{op}},
\]

for the perturbation bounds developed in Theorem 3 take effect; such closeness guarantees that the optimal controller for \( (\hat{A}_k, \hat{B}_k) \) stabilizes the system and has low regret. If the test fails, the algorithm falls back on the stabilizing controller \( K_0 \) for the remainder of the epoch, adding exploratory noise with constant scale. Otherwise, if the test succeeds, the algorithm forms the certainty equivalent controller \( \hat{K}_k := K_{\infty}(\hat{A}_k, \hat{B}_k) \) and plays this for the remainder of the epoch, adding exploratory noise whose scale is carefully chosen to balance exploration and exploitation.

**Preliminaries** Before beginning the proof, let us first give some additional definitions and notation. We adopt the shorthand \( \bar{d} := d_x + d_u \) and define \( k_{\text{fin}} = \lceil \log_2 T \rceil \). For every controllers \( K \) for which \( (A + BK) \) is stable, we define \( P_{\infty}(K; A, B) := \text{dlyap}(A + BK, R_x + K^T R_u K) \). It is a standard fact (see e.g. Lemma B.6) that such controllers have \( J_{A, B}[K] = \text{tr}(P_{\infty}(K; A, B)) \).

We make will make heavy use of the following system parameters for the controllers used within Algorithm 1:

\[
P_k := P_{\infty}(\hat{K}_k; A_*, B_*), \quad \mathcal{P}_0 := \frac{J_0}{\bar{d}}, \quad \| P_{\infty}(K_0; A_*, B_*) \|_{\text{op}},
\]

\[
J_k := J_{A_*, B_*}[\hat{K}_k], \quad J_0 := J_{A_*, B_*}[K_0],
\]

\[
A_{\text{cl}, k} := A_* + B_* \hat{K}_k, \quad A_{\text{cl}, 0} := A_* + B_* K_0.
\]

**5.1 Proof**

We begin the proof by showing that the initial estimation phase (in which the algorithm uses the stabilizing controller \( K_0 \)) ensures that various regularity conditions hold for the epochs \( k \geq k_{\text{safe}} \) (in which the algorithm uses the certainty-equivalent controller). One such regularity condition bounds the \( \mathcal{H}_{\infty} \)-norm, which describes the worst-case response of a system to perturbations.

**Definition 5.1** \( \mathcal{H}_{\infty} \) norm. For any stable \( \hat{A} \in \mathbb{R}^{d_x^2} \) (e.g. \( A + BK_{\infty}(A, B) \)), we define \( \| \hat{A} \|_{\mathcal{H}_{\infty}} := \sup_{z \in \mathbb{C}, |z| = 1} \| (zI - \hat{A})^{-1} \|_{\text{op}} \).

The following is proved in Appendix G.1.

---

Lemma 5.1 (Correctness of Perturbations). On the event

\[ \mathcal{E}_{\text{safe}} := \left\{ \left\| \begin{bmatrix} \hat{A}_{k_{\text{safe}}} - A_* & B_{k_{\text{safe}}} - B_* \end{bmatrix} \right\|_{\text{op}}^2 \leq \text{Conf}_{k_{\text{safe}}} \right\}, \]

the following bounds hold for all \( k \geq k_{\text{safe}} \):

1. \( \mathcal{J}_k - \mathcal{J}_* \leq C_{\text{est}}(A_*, B_*) \left( \| \hat{A} - A_* \|_F^2 + \| \hat{B} - B_* \|_F^2 \right) \lesssim \| P_* \|_{\text{op}}^8 \left( \| \hat{A} - A_* \|_F^2 + \| \hat{B} - B_* \|_F^2 \right) \).
2. \( \mathcal{J}_k \lesssim \mathcal{J}_* \), and \( \| P_k \|_{\text{op}} \lesssim \| P_* \|_{\text{op}} \).
3. \( \| \hat{K}_k \|_{\text{op}}^2 \leq \frac{21}{MT} \| P_* \|_{\text{op}} \).
4. \( \| A_{\text{cl},k} \|_{\infty} \lesssim \| A_{\text{cl},*} \|_{\infty} \lesssim \| P_* \|_{\text{op}}^{3/2} \).
5. \( A_{\text{cl},k} \text{dlyap}[A_{\text{cl},*}] A_{\text{cl},k} \preceq \left( 1 - \frac{1}{4} \| \text{dlyap}[A_{\text{cl},*}] \|_{\text{op}}^4 \right) \), where \( I \preceq \text{dlyap}[A_{\text{cl},*}] \preceq P_* \), where we recall the shorthand \( \text{dlyap}[A_{\text{cl},*}] = \text{dlyap}(A_{\text{cl},*}, I) \).
6. \( \sigma_{\text{in}}^2 \simeq \sqrt{T} \| P_* \|_{\text{op}}^{3/2} \| \Psi_{B_*} \| \sqrt{\log \frac{\| P_* \|_{\text{op}}}{\delta}} \).

We will verify at the end of the proof that \( \mathcal{E}_{\text{safe}} \) indeed holds with high probability. We remark that Part 5 of the above lemma places the role of “sequential strong stability” in Cohen et al. [2019, Definition 2]. By \( \text{dlyap}[A_{\text{cl},*}] \) as a common Lyapunov function, we refining the complications involved in applying sequential strong stability.

Building on this result, we provide (Appendix G.2) a decomposition of the algorithm’s regret which holds conditioned on \( \mathcal{E}_{\text{safe}} \).

Lemma 5.2 (Regret Decomposition on Safe Rounds). There is an event \( \mathcal{E}_{\text{reg}} \) which holds with probability at least \( 1 - \frac{6}{8} \) such that, on \( \mathcal{E}_{\text{reg}} \cap \mathcal{E}_{\text{safe}} \), following bound holds

\[
\sum_{t=\tau_{k_{\text{safe}}}^k}^T (x_t^\top R_x x_t + u_t^\top R_u u_t - \mathcal{J}_*) \lesssim \sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} \tau_k (\mathcal{J}_k - \mathcal{J}_*) + \log T \max_{k \leq \log T} \| x_{r_k} \|_2^2 \\
+ \sqrt{T} \left( d_{\text{in}} \sigma_{\text{in}}^2 \| P_* \|_{\text{op}}^2 + \sqrt{d \log(1/\delta)} \| P_* \|_{\text{op}}^4 \right) \\
+ \log^2 \frac{1}{\delta} \left( 1 + \sqrt{d_{\text{in}} \sigma_{\text{in}}^2} \right) \| P_* \|_{\text{op}}^4.
\]  

(5.1)

Let us unpack the terms that arise in Equation (5.1). The term \( \sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} \tau_k (\mathcal{J}_k - \mathcal{J}_*) \) captures the suboptimality of the controllers \( \hat{K}_k \) selected at each epoch. We bound this term by using that, in light of Lemma 5.2 we have, \( \mathcal{J}_k - \mathcal{J}_* \propto \| \hat{A}_k - A_* \|_F^2 + \| \hat{B}_k - B_* \|_F^2 \). The next term, \( \log T \max_{k \leq \log T} \| x_{r_k} \|_2^2 \), is of lower order, and roughly captures the penalty for switching controllers at each epoch. The term proportional to \( \sqrt{T} \) captures both the penalty for injecting exploratory noise into the system (which incurs a dependence on \( d_{\text{in}} \)), as well as random fluctuations in the cost coming from the underlying noise process. Finally, the term on the last line of the display is also of lower order (poly(\( \log T \))). To proceed, we show that the norms \( \| x_{r_k} \| \) appearing in the second term are well-behaved.

Lemma 5.3. There is an event \( \mathcal{E}_{\text{bound}} \) which holds with probability \( 1 - \frac{6}{8} \) such that, conditioned on \( \mathcal{E}_{\text{safe}} \cap \mathcal{E}_{\text{bound}} \),

\[ \| x_{r_k} \| \lesssim \sqrt{T} \| \Psi_{B_*} \|_{\text{op}} \log(1/\delta) \| P_* \|_{\text{op}}^{3/2}, \quad \forall k \geq k_{\text{safe}}. \]

This bound is quite crude but is sufficient for our purposes. We give a concise proof (Appendix G.3) using that in light of Lemma 5.1, \( \text{dlyap}[A_{\text{cl},*}] \) acts as a Lyapunov function for all the systems \( A_{\text{cl},k} \) conditioned on \( \mathcal{E}_{\text{safe}} \).

To bound the error terms \( \mathcal{J}_k - \mathcal{J}_* \) appearing in Equation (5.1) we prove (Appendix G.4) the following bound, which ensures the correctness of the estimators \( \{ \hat{A}_k, \hat{B}_k \} \) once \( k \geq k_{\text{safe}} \).
Algorithm 2: OLS($k$)

1. **Input:** Examples $x_{tk-1}, \ldots, x_t, u_{tk-1}, \ldots, u_{t-1}$.
2. **Return** $(\hat{A}_k, \hat{B}_k, A_k)$, where

$$
[\hat{A}_k \quad \hat{B}_k] \leftarrow \left( \sum_{t=\tau_{k-1}}^{\tau_k-1} x_{t+1} x_t^T \right)^\dagger \Lambda_k^\dagger, \text{ and } A_k \leftarrow \sum_{t=\tau_{k-1}}^{\tau_k-1} x_{t+1} (x_t, u_t)^T.
$$

Algorithm 3: SafeRoundInit($\hat{A}, \hat{B}, \text{Conf}, \delta$)

1. **Input:** Stabilizable pair $(\hat{A}, \hat{B}, \text{Conf}, \delta)$.
2. **Return** $E_{\text{safe}} := E_{\text{conf}}(\hat{A}, \hat{B})$ and $\sigma_{in}^2 := \sqrt{d_k \|P_\infty(\hat{A}, \hat{B})\|_{op}^2 \max \{1, \|\hat{B}\|_{op}\} \sqrt{\log \frac{\|P_{\text{safe}}(\hat{A}, \hat{B})\|_{op}}{\delta}}}$.

**Lemma 5.4.** Define $\tau_k := \frac{d \left( \|P_0\|_{op} + \|P_k\|_{op} \right)}{c_{\text{ini}} \sqrt{T} \log \|P_k\|_{op}} \log \frac{d \|P_k\|_{op}}{\delta}$. There is an event $E_{\text{safe}}$ which holds with probability $1 - \delta/(8T)$ such that conditioned on $E_{\text{safe}}$, we have

$$
\|\hat{A}_k - A_*\|_F^2 + \|\hat{B}_k - B_*\|_F^2 \lesssim \frac{d d_k}{c_{\text{ini}} \sqrt{T}} \|P_k\|_{op} \log \frac{\|P_k\|_{op}}{\delta} + \frac{d_k^2}{\tau_k} \|P_k\|_{op} \log^2 \frac{1}{\delta} \quad \forall k : \tau_k \geq c_{\text{ini}},
$$

where $c > 0$ is a universal constant.

We now put all of these pieces together to prove the final regret bound. Henceforth, we condition on the event $E_{\text{safe}} \cap E_{\text{bound}} \cap E_{\text{reg}} \cap E_{\text{stabil}}$. To begin, consider the sum of errors $J_k - J_*$ in Equation (5.1). We apply Lemma G.2 followed by the bound on $J_k \lesssim J_*$ from Lemma 5.1, which yields

$$
\frac{1}{k_{fs}} \sum_{k=k_{fs}}^{k_{fs}} \tau_k (J_k - J_*) + \log T \max_{k \leq \log T} \|x_{rk}\|^2
$$

where the last line uses that $\delta \leq 1/T$ to combine the lower-order terms in the line preceding it. Next, using the bound $J_k - J_* \lesssim \|P_k\|_{op}^2 \left( \|A_* - \hat{A}_k\|_F^2 + \|B_* - \hat{B}_k\|_F^2 \right)$ from Lemma 5.1 followed by the error bound in Lemma 5.4, we have

$$
\sum_{k > \tau_{ks}} \tau_k (J_k - J_*) \lesssim \|P_k\|_{op}^2 \sum_{k > \tau_{ks}} \frac{d_k d_{x} \sqrt{T}}{c_{\text{ini}} \sqrt{T}} \|P_k\|_{op} \log \frac{\|P_k\|_{op}}{\delta} + \frac{d_k^2}{\tau_k} \|P_k\|_{op} \log^2 \frac{1}{\delta},
$$

where again we use $\log T \lesssim \log(1/\delta)$. Combining the computations so far shows that

$$
\sum_{k = k_{fs}}^{k_{fs}} \tau_k (J_k - J_*) + \log T \max_{k \leq \log T} \|x_{rk}\|^2 \leq \frac{d_k d_{x} \sqrt{T}}{c_{\text{ini}} \sqrt{T}} \|P_k\|_{op} \log \frac{\|P_k\|_{op}}{\delta} + d_k \|P_k\|_{op} \tau_{ks} \log \frac{1}{\delta}.
$$

17
Hence, on $E_{\text{safe}} \cap E_{\text{bound}} \cap E_{\text{reg}} \cap E_{\text{ls}}$, the regret in the episodes $k \geq k_{\text{safe}}$ decomposes into a component scaling with $\sqrt{T}$ and a component scaling with $\log T$:

$$
\sum_{t=\tau_{\text{safe}}}^{T} \left( x_t^T R_x x_t + u_t^T R_u u_t - J_t \right)
\lesssim \sqrt{T} \left( d_u \sigma_{\text{in}}^2 \psi_{B_2} \| P_* \|_{\text{op}} + \sqrt{d \log(1/\delta)} \| P_* \|_{\text{op}}^4 + \frac{d_u d_x}{\sigma_{\text{in}}^2} \| P_* \|_{\text{op}}^{10} \log \frac{\| P_* \|_{\text{op}}}{\delta} \right) \sqrt{\text{T-component}}
+ (1 + \sqrt{d \sigma_{\text{in}}^2 \psi_{B_2}^2 \| P_* \|_{\text{op}}^4 \log^2 \frac{1}{\delta}} + d_x r_{ls} \log \frac{1}{\delta}. \) \tag{poly(log T)-component}
$$

Using that $\sigma_{\text{in}}^2 \approx \sqrt{d x \| P_* \|_{\text{op}}^{9/2} \psi_{B_2} \sqrt{\log \frac{\| P_* \|_{\text{op}}}{\delta}}$ (Lemma 5.1) and recalling that $d = d_x + d_u$, we upper bound these terms as

$$
(\sqrt{T}\text{-component}) \lesssim \sqrt{T d_u^2 d_x \psi_{B_2}^2 \| P_* \|_{\text{op}}^{10} \log \frac{\| P_* \|_{\text{op}}}{\delta}}$$
$$
(\text{poly}(\log T)\text{-component}) \lesssim d_x r_{ls} \log \frac{1}{\delta}.
$$

We conclude that conditioned on $E_{\text{safe}} \cap E_{\text{bound}} \cap E_{\text{reg}} \cap E_{\text{ls}}$,

$$
\sum_{t=\tau_{\text{safe}}}^{T} \left( x_t^T R_x x_t + u_t^T R_u u_t - J_t \right) \lesssim \sqrt{T d_u^2 d_x \psi_{B_2}^2 \| P_* \|_{\text{op}}^{10} \log \frac{\| P_* \|_{\text{op}}}{\delta}} + d_x r_{ls} \log \frac{1}{\delta}. \tag{5.2}
$$

To finish the proof, we (a) verify that $E_{\text{safe}}$ indeed holds with high probability, and (b) bound the regret contribution of the initial rounds (proof given in Appendix G.5).

**Lemma 5.5.** The event $E_{\text{safe}}$ holds with probability $1 - \frac{\delta}{2}$, and the following event $E_{\text{reg}, \text{init}}$ holds with probability $1 - \frac{\delta}{8}$:

$$
\sum_{t=1}^{\tau_{\text{safe}} - 1} x_{t,0}^T R_x x_{t,0} + u_{t,0}^T R_u u_{t,0} \lesssim \mathcal{P}_0 d^2 \psi_{B_2}^2 \| P_* \|_{\text{op}}^{10} (1 + \| K_0 \|_{\text{op}}^2) \log \frac{d \psi_{B_2} \mathcal{P}_0}{\delta} \log \frac{1}{\delta}.
$$

Thus, $E_{\text{safe}} \cap E_{\text{bound}} \cap E_{\text{reg}} \cap E_{\text{ls}}, E_{\text{reg}, \text{init}}$ holds with total probability at least $1 - \delta$, and conditioned on this event Lemma 5.5 and Equation (5.2) imply

$$
\text{Regret}_T[\text{Alg}; A_*, B_*] = \sum_{t=1}^{T} \left( x_t^T R_x x_t + u_t^T R_u u_t - J_t \right)
\lesssim \sqrt{T d_u^2 d_x \psi_{B_2}^2 \| P_* \|_{\text{op}}^{10} \log \frac{\| P_* \|_{\text{op}}}{\delta}}
+ \mathcal{P}_0 d^2 \psi_{B_2}^2 \| P_* \|_{\text{op}}^{10} (1 + \| K_0 \|_{\text{op}}^2) \log \frac{d \psi_{B_2} \mathcal{P}_0}{\delta} \log \frac{1}{\delta} + d_x r_{ls} \log \frac{1}{\delta}.
$$

Recalling that $r_{ls} := d \left( \| P_* \|_{\text{op}}^3 \mathcal{P}_0 + \| P_* \|_{\text{op}}^{11} \psi_{B_2} \right) \log \frac{d \| P_* \|_{\text{op}}}{\delta}$, that $\mathcal{P}_0, \| P_* \|_{\text{op}} \psi_{B_2} \geq 1$, and that $d \| P_* \|_{\text{op}} \leq d J_* \leq d J_0 = d^2 \mathcal{P}_0$, we move to a simplified upper bound:

$$
\text{Regret}_T[\text{Alg}; A_*, B_*] \lesssim \sqrt{T d_u^2 d_x \psi_{B_2}^2 \| P_* \|_{\text{op}}^{10} \log \frac{\| P_* \|_{\text{op}}}{\delta}}
+ d^2 \mathcal{P}_0 d^2 \psi_{B_2}^2 \| P_* \|_{\text{op}}^{10} (1 + \| K_0 \|_{\text{op}}^2) \log \frac{d \psi_{B_2} \mathcal{P}_0}{\delta} \log \frac{1}{\delta}.
$$

Since the square of $d \psi_{B_2}$ inside the logarithm contributes only a constant factor, we may remove it in the final bound. This concludes the proof.

\qed
6 Conclusion

We have established that the asymptotically optimal regret for the online LQR problem is $\tilde{\Theta}(\sqrt{d_u^2 d_x T})$, and that this rate is attained by $\varepsilon$-greedy exploration. We are hopeful that the our new analysis techniques, especially our perturbation bounds, will find broader use within the non-asymptotic theory of control and beyond. Going forward our work raises a number of interesting conceptual questions. Are there broader classes of “easy” reinforcement learning problems beyond LQR for which naive exploration attains optimal sample complexity, or is LQR a fluke? Conversely, is there a more demanding (eg, robust) version of the LQR problem for which more sophisticated exploration techniques such as robust synthesis [Dean et al., 2018] or optimism in the face of uncertainty [Abbasi-Yadkori and Szepesvári, 2011, Cohen et al., 2019] are required to attain optimal regret? On the purely technical side, recall that while our upper and lower bound match in terms of $d_u$, $d_x$, and $T$, they differ in their polynomial dependence on $\|P^*\|_{op}$. Does closing this gap require new algorithmic techniques, or will a better analysis suffice?

A Organization and Notation

A.1 Organization of the Appendices

This section of the appendix addresses organization and summarizes notation. The remainder of the appendix is divided into two parts.

Part I establishes the main technical tools used throughout the upper and lower bounds. Appendix B describes and proves our main perturbation bounds, deferring additional proof details to Appendix C. Appendix D proves guarantees for the Self-Bounding ODE method, summarized in Corollary 3, as well as a slightly more general statement for generic self-bounding relations, Theorem 13. This part of the appendix concludes with Appendix E.1, which describes a set of tools for analyzing ordinary least squares estimation, which we use in the proofs of both our upper and lower bounds.

Part II provides omitted details from the proofs of our main results. Specifically, Appendix F proves the constituent lemmas for the lower bound from Section 4, and Appendix G does the same for the proof of the upper bound given in Section 5.

B Main Perturbation Bounds

Preliminaries Throughout, we shall use extensively the dlyap operator, which we recall here.

Definition 3.1 (Discrete Lyapunov Equation). Let $X, Y \in \mathbb{R}^{d_x \times d_x}$ with $Y = Y^\top$ and $\rho(X) < 1$. We let $\mathcal{T}_X[P] := X^\top PX - X$, and let dlyap($X, Y$) denote the unique PSD solution $\mathcal{T}_X[P] = Y$. We let dlyap($X$) := dlyap($X, I$).

We shall need to describe the “$P$”-matrix analogue of the functional $J$.

Definition B.1. Suppose that $(A_\star + B_\star K)$ is stable. We define $P_\infty(K; A_\star, B_\star) := \text{dlyap}(A_\star + B_\star K, R_\star + K^\top R_\star K)$.

It is a standard fact (see e.g. Lemma B.6) that $J_{A_\star, B_\star}[K] = \text{tr}(P_\infty(K; A_\star, B_\star))$ whenever $A_\star + B_\star K$ is stable. We also recall the definition of the $\mathcal{H}_\infty$-norm:

Definition 5.1 ($\mathcal{H}_\infty$ norm). For any stable $\hat{A} \in \mathbb{R}^{d_x}$ (e.g. $A + BK_\infty(A, B)$), we define $\|\hat{A}\|_{\mathcal{H}_\infty} := \sup_{x \in \mathbb{C} \mid |x|=1} \|(zI - \hat{A})^{-1}\|_{\text{op}}$.

Organization of Appendix B The remainder of this appendix is organized as follows. Appendix B.1 states our main perturbation upper bounds, and provides proofs in terms of various supporting propositions. Appendix B.2 walks the reader through the relevant computations of various derivatives. Appendix B.3 states numerous technical tools which we use in the proofs of our main perturbation bounds, and finally Appendix B.4 proves the supporting propositions leveraged in Appendix B.1. Many supporting proofs are deferred to Appendix C.

B.1 Main Results

B.1.1 Main Perturbation Upper Bound

Recall $C_{\text{safe}}(A_\star, B_\star) = 54\|P_\star\|_{\text{op}}^5$ and $C_{\text{est}}(A_\star, B_\star) = 142\|P_\star\|_{\text{op}}^8$. We state a strengthening of our main perturbation bound from the main text (Theorem 3) here.

Theorem 5. Let $(A_\star, B_\star)$ be a stabilizable system. Given an alternate pair of matrices $(\hat{A}, \hat{B})$, for each $\circ \in \{\text{op}, F\}$ define $\epsilon_\circ := \max\{\|\hat{A} - A_\star\|_\circ, \|\hat{B} - B_\star\|_\circ\}$. Then if $\epsilon_\circ \leq 1/C_{\text{safe}}(A_\star, B_\star)$,

1. $\|P_\infty(\hat{A}, \hat{B})\|_{\text{op}} \leq 1.0835\|P_\star\|_{\text{op}}$ and $\|B_\star(K_\star - K_\infty(\hat{A}, \hat{B}))\|_2 < \frac{1}{5\|P_\star\|_{\text{op}}^2}$.

2. $\mathcal{J}_{A_\star, B_\star}(K_\infty(\hat{A}, \hat{B})) - \mathcal{J}_{A_\star, B_\star}^* \leq C_{\text{est}}(A_\star, B_\star)\epsilon_\circ^2$.

3. $\|P_\infty(K_\infty(\hat{A}, \hat{B}); A_\star, B_\star) - P_\star\|_{\text{op}} \leq C_{\text{est}}(A_\star, B_\star)\epsilon_\circ^2$.

4. Moreover, $P_\infty(K_\infty(\hat{A}, \hat{B}); A_\star, B_\star) \leq (21/20)P_\star$.

Proof. Throughout, we use $P_\star \succeq I$ (see Lemma 4.2). This theorem requires two constituent results. First, we have a perturbation bound for $P_\infty$ and $K_\infty$, which refines Proposition 4, and is proven in Section B.4.1:

Proposition 6. Let $(A_\star, B_\star)$ be a stabilizable system, and define the DARE solution $P_\star := P_\infty(A_\star, B_\star)$ and controller $K_\star = K_\infty(A_\star, B_\star)$. Given an alternate pair of matrices $(\hat{A}, \hat{B})$, define for norms $\circ \in \{\text{op}, F\}$ the
error \( \epsilon \) := max\{\|A_\ast - \hat{A}\|_\infty, \|B_\ast - \hat{B}\|_\infty\}. Then, if \( \alpha := 8\|P_\ast\|^2_{\text{op}} \epsilon_{\text{op}} < 1 \), the pair \((\hat{A}, \hat{B})\) is stabilizable, and

\[
\|P_\infty(\hat{A}, \hat{B})\|_{\text{op}} \leq (1 - \alpha)^{-1/2}\|P_\ast\|_{\text{op}},
\]
\[
\|R_u^{1/2}(K_\infty(\hat{A}, \hat{B}) - K_\ast)\|_\infty \leq 7(1 - \alpha)^{-7/4}\|P_\ast\|_{\text{op}}^{7/2} \epsilon_{\text{op}},
\]
\[
\|B_\ast(K_\infty(\hat{A}, \hat{B}) - K_\ast)\|_\infty \leq 8(1 - \alpha)^{-7/4}\|P_\ast\|_{\text{op}}^{7/2} \epsilon_{\text{op}}.
\]

In addition, if \( \epsilon_{\text{op}} \leq 32\|P_\ast\|^3_{\text{op}} \), then

\[
\|P_\ast^{1/2}B(K_\infty(\hat{A}, \hat{B}) - K_\ast)\|_\infty \leq 9(1 - \alpha)^{-7/4}\|P_\ast\|_{\text{op}}^{7/2} \epsilon_{\text{op}}.
\]

Next, we have a perturbation bound for the \( J \)-functional as the controller \( K \) is varied. The proof is deferred to Section B.4.2.

**Proposition 7.** Fix any controller \( K \) satisfying \( \|B_\ast(K - K_\ast)\|_2 \leq 1/5\|P_\ast\|_{\text{op}}^{3/2} \). Then,

\[
J_{A_\ast, B_\ast}(K) - J_{A_\ast, B_\ast} \leq \|P_\ast\|_{\text{op}} \max\{\|K - K_\ast\|_F^2, \|P_\ast^{1/2}B_\ast(K - K_\ast)\|_F^2\},
\]
\[
\|P_\infty(K; A_\ast, B_\ast) - P_\infty(A_\ast, B_\ast)\|_{\text{op}} \leq \|P_\ast\|_{\text{op}} \max\{\|K - K_\ast\|_{\text{op}}^2, \|P_\ast^{1/2}B_\ast(K - K_\ast)\|_{\text{op}}^2\}.
\]

Now, observe that \( \epsilon_{\text{op}} \leq 1/54\|P_\ast\|_{\text{op}}^{5/2} < 1/8\|P_\ast\|_{\text{op}}^{2} \) and \( \alpha = 8\|P_\ast\|_{\text{op}}^{2} \epsilon_{\text{op}} \), Proposition 6 gives that

\[
\|P_\infty(\hat{A}, \hat{B})\|_{\text{op}} \leq \|P_\ast\|_{\text{op}} / \sqrt{1 - 8/54} \leq 1.0835\|P_\ast\|_{\text{op}},
\]

and that

\[
5\|P_\ast\|_{\text{op}}^{3/2} \cdot \|B_\ast(K_\infty(\hat{A}, \hat{B}) - K_\ast)\|_{\text{op}} \leq 8(1 - \alpha)^{-7/4}\|P_\ast\|_{\text{op}}^{7/2} \epsilon_{\text{op}}
\]
\[
\leq 40(1 - \alpha)^{-7/4}\|P_\ast\|_{\text{op}}^{5} \epsilon_{\text{op}}
\]
\[
\leq 40/54 \cdot (1 - 8/54)^{-7/4} < 1.
\]

Hence, for such \( \epsilon_{\text{op}} \), we find from Proposition 7 followed by Proposition C.3.1 that

\[
J_{A_\ast, B_\ast}(K) - J_{A_\ast, B_\ast} \leq \|P_\ast\|_{\text{op}} \max\{\|R_u^{1/2}(K - K_\ast)\|_F^2, \|P_\ast^{1/2}B_\ast(K - K_\ast)\|_F^2\}
\]
\[
\leq 81\|P_\ast\|_{\text{op}}^8 (1 - \alpha)^{-7/2} \epsilon_{\text{op}}^2
\]
\[
\leq 142\|P_\ast\|_{\text{op}}^8 \epsilon_{\text{op}}^2,
\]

and similarly, using \( \|P_\ast\|_{\text{op}} \geq 1 \),

\[
\|P_\infty(K; A_\ast, B_\ast) - P_\infty(A_\ast, B_\ast)\|_{\text{op}} \leq 142\|P_\ast\|_{\text{op}}^8 \epsilon_{\text{op}}^2 \leq 1/20,
\]

yielding \( P_\infty(K; A_\ast, B_\ast) \leq (1 + 1/20)P_\ast \) as \( P_\ast \geq I \).

\[\square\]

### B.1.2 Perturbation of \( H_\infty \) Norm and Lyapunov Functions

Next, we establish perturbation bounds on the \( H_\infty \) norm of the closed loop system, and show that all perturbed closed loop systems share a common Lyapunov function:

**Theorem 8.** Let \( A_\ast, B_\ast \) be stabilizable, and let \((\hat{A}, \hat{B})\) satisfy the conditions of Theorem 5, with \( R_\infty \geq I \) and \( R_u = I \). Define \( A_{\text{cl}, \ast} := A_\ast + B_\ast K_\ast \), and given \((\hat{A}, \hat{B}) \in B_{\text{op}}(\epsilon_\ast, A_\ast, B_\ast)\), define and \( A_{\text{cl}, \hat{z}} := A_\ast + B_\ast K_\infty(\hat{A}, \hat{B}) \). Then,

1. \( I \leq \text{dlyap}[A_{\text{cl}, \ast}] \leq P_\ast \).

2. \( \|A_{\text{cl}, \hat{z}}\|_{H_\infty} \leq 2\|A_{\text{cl}, \ast}\|_{H_\infty} \leq 4\|\text{dlyap}[A_{\text{cl}, \ast}]\|_{\text{op}}^{3/2} \leq 4\|P_\ast\|_{\text{op}}^{3/2} \).
3. $A_{c1, \hat{A}}^T \cdot \text{dlyap}[A_{c1, *}] \cdot A_{c1, \hat{A}} \preceq (1 - \frac{1}{2} \| \text{dlyap}[A_{c1, *}] \|_{\text{op}}^{-1}) \cdot \text{dlyap}[A_{c1, *}] \leq (1 - \frac{1}{2} \| P_* \|_{\text{op}}^{-1}) \cdot \text{dlyap}[A_{c1, *}]$.

**Proof of Part 1.** We can directly verify $\| \text{dlyap}[A_{c1, *}] \| \geq I$ from the definition, and $\| \text{dlyap}[A_{c1, *}] \| \leq P_*$ by Lemma B.5.

**Proof of Part 2.** We use a general-purpose perturbation bound for the $\| H_\infty \|$ norm:

**Proposition 9 (H_\infty Bounds).** Fix $u \in (0, 1)$, and matrices $A_{\text{safe}}, \epsilon_1 \in \mathbb{R}^{d \times d}$ with $A_{\text{safe}}$ stable. Then if $\| A_1 - A_{\text{safe}} \| \leq \frac{\epsilon_1}{\| A_{\text{safe}} \|_H}$, $\| A_1 \|_H \leq \frac{1 - \epsilon_1}{\| A_{\text{safe}} \|_H}$.

From Part 1 of Theorem 5,

$$\| A_{c1, *}, A_{\hat{A}, \hat{B}} \|_{\text{op}} \leq \| B_\ast(K_\infty(A_\ast, B_\ast) - K_\infty(A_{\hat{A}, \hat{B}})) \|_{\text{op}} \leq \frac{1}{5\| P_* \|_{\text{op}}^{3/2}}.$$ (B.1)

By Lemma B.11 followed by Lemma B.5, we have that

$$\| A_{c1, *}, A_{\hat{A}, \hat{B}} \|_{\text{H}_\infty} \leq 2\| \text{dlyap}[A_{c1, *}] \|_{\text{op}}^{3/2} \leq 2\| P_* \|_{\text{op}}^{3/2}.$$ Therefore, since $P_* \geq 1$, we have

$$\| A_{c1, *} \|_{\text{H}_\infty} \leq \frac{1}{\| A_{c1, *} \|_{\text{H}_\infty}} \leq \frac{1}{2\| A_{c1, *} \|_{\text{H}_\infty}}.$$ Propostion 9 then implies that $\| A_{c1, *}, A_{\hat{A}, \hat{B}} \|_{\text{H}_\infty} \leq \frac{2\| A_{c1, *} \|_{\text{op}}^{3/2}}{4\| P_* \|_{\text{op}}^{3/2}}$. Moreover, by Lemma B.11, we can upper bound this in term by $4\| \text{dlyap}[A_{c1, *}] \|_{\text{op}}^{3/2} \leq 4\| P_* \|_{\text{op}}^{3/2}$.

**Proof of Part 3.** Here, we use a perturbation bound which we prove from first principles, without the self-bounding ODE method.

**Proposition 10.** Suppose that $A$ is a stable matrix, and suppose that $\hat{A}$ satisfies

$$\| \hat{A} - A \|_{\text{op}} \leq \frac{1}{4} \min \left\{ \frac{1}{\| \text{dlyap}[A] \|_{\text{op}} \| A \|_{\text{op}}} \right\}.$$ Then, $\hat{A}^T \text{dlyap}[A] \hat{A} \preceq (1 - \frac{1}{2} \| \text{dlyap}[A] \|_{\text{op}}^{-1}) \cdot \text{dlyap}[A]$.

By Lemma B.8, we have $\| A_{c1, *}, A_{\hat{A}, \hat{B}} \|_{\text{op}} \leq \| P_* \|_{\text{op}}^{1/2}$. Since $\| \text{dlyap}[A_{c1, *}] \|_{\text{op}} \leq \| P_* \|_{\text{op}}$, combining with Eq. B.1 gives

$$\| A_{c1, *}, A_{\hat{A}, \hat{B}} \|_{\text{op}} \leq \frac{1}{5\| P_* \|_{\text{op}}^{3/2}} \leq \| B_\ast(K_\infty(A_\ast, B_\ast) - K_\infty(A_{\hat{A}, \hat{B}}))\|_{\text{op}}.$$ Similarly, we have $\| A_{c1, *}, A_{\hat{A}, \hat{B}} \|_{\text{op}} \leq \frac{1}{\| \text{dlyap}[A_{c1, *}] \|_{\text{op}}}$, which means that, in particular, $A_{c1, *}, A_{\hat{A}, \hat{B}}$ satisfy the conditions for $A, \hat{A}$ in Proposition 10. This means that $A_{c1, *}, A_{\hat{A}, \hat{B}} \preceq (1 - \frac{1}{2} \| \text{dlyap}[A_{c1, *}] \|_{\text{op}}^{-1}) \cdot \text{dlyap}[A_{c1, *}, A_{\hat{A}, \hat{B}}]$. The last inequality follows from Part 1. □

**B.1.3 Continuity of the Safe Set**

We show that the size of the so-called “safe” set is continuous in nearby instances:

**Theorem 11.** Let $(A_0, B_0)$ be a stabilizable system. Then, for any pair of systems $(\hat{A}, \hat{B}), (A_\ast, B_\ast) \in \mathcal{B}_\text{op}(C_{\text{safe}}(A_0, B_0), \frac{3}{2} C_{\text{safe}}(A_0, B_0), A_{\text{safe}}, B_{\text{safe}})$ is stabilizable, and satisfies $\max\{\| A_\ast - \hat{A} \|_{\text{op}}, \| \hat{B} - B_\ast \|_{\text{op}} \} \leq 1/C_{\text{safe}}(A_\ast, B_\ast)$. Moreover, $\| P_\infty(A_\ast, B_\ast) \|_{\text{op}} \leq 1.0835\| P_\infty(A_0, B_0) \|_{\text{op}}$.

**Proof.** Let $\epsilon_0 := \max\{\| A_0 - \hat{A} \|_{\text{op}}, \| B_0 - B_\ast \|_{\text{op}} \} \leq 1/C_{\text{safe}}(A_0, B_0)$. Applying Theorem 5 Part 1 with $(\hat{A}, \hat{B}) \leftarrow (A_\ast, B_\ast)$ and $(A_\ast, B_\ast) \leftarrow (A_0, B_0)$, we have $\| P_\infty(A_\ast, B_\ast) \|_{\text{op}} \leq 1.0835\| P_\infty(A_0, B_0) \|_{\text{op}}$. Hence, $C_{\text{safe}}(A_\ast, B_\ast) \leq 1.5C_{\text{safe}}(A_0, B_0)$. Hence $(\hat{A}, \hat{B}), (A_\ast, B_\ast) \in \mathcal{B}_\text{op}(C_{\text{safe}}(A_\ast, B_\ast), \frac{3}{2} C_{\text{safe}}(A_\ast, B_\ast), A_{\text{safe}}, B_{\text{safe}})$, which means by triangle inequality that $\max\{\| \hat{B} - \hat{A} \|_{\text{op}}, \| \hat{B} - B_\ast \|_{\text{op}} \} \leq 1/C_{\text{safe}}(A_\ast, B_\ast)$. □
B.1.4 Quality of First-Order Taylor Approximation

We bound the error of the first-order Taylor expression in the following theorem:

**Theorem 12.** There exists universal constants \( c, p > 0 \) such that the following holds. Let \( (A_*, B_*) \) be stabilizable, and let \( \epsilon_o := \max\{\|\Delta - A_*\|_\circ, \|\Delta - B_*\|_\circ\} \), and suppose that \( \epsilon_{op} \leq 1/C_{safe}(A_*, B_*) \) and \( R_\Delta \geq I \), \( R_u = I \). Let

\[
K' := \frac{d}{dt} K_\infty(A_* + t(A_* - \hat{A}), B_* + t(B_* - \hat{B})).
\]

Then, \( \|K_\infty(\hat{A}, \hat{B}) - (K_* + K')\|_\circ \leq c\|P_*\|_\circ^{p} \epsilon_{op}^{2} \epsilon_o^{2} \).

**Proof.** Consider the curve \( K(t) = K_\infty(A(t), B(t)) \) for \( A(t) = (1 - t)A_* + t\hat{A} \) and \( B(t) = (1 - t)B_* + t\hat{B} \). By Theorem 5, the curve \( A(t), B(t) \) for \( t \in [0, 1] \) consists of all stabilizable matrices with \( \|P_\infty(A(t), B(t))\|_\circ \leq \|P_*\|_\circ \). By Lemma 3.1, the curve \( K(t) \) is analytic on \([0, 1]\). Moreover, from Lemma B.3 below, we have \( \|K''(t)\|_\circ \leq c_0\|P(t)\|_\circ^{p} \epsilon_{op}^{2} \epsilon_o^{2} \leq c\|P_*\|_\circ^{p} \epsilon_{op}^{2} \epsilon_o^{2} \) for universal constants \( c_0, p \). The bound now follows by Taylor’s theorem.

\[\square\]

B.2 Key Derivative Computations

In the following computations, let \( \Delta_A = \hat{A} - A_* \) and \( \Delta_B = \hat{B} - B_* \). We recall \( \epsilon_o := \max\{\|\Delta_A\|_\circ, \|\Delta_B\|_\circ\} \).

We consider derivatives allow curves \( (A(t), B(t)) = (A_* + t\Delta_A, B_* + t\Delta_B) \), and associated functions \( P(t) := P_\infty(A(t), B(t)) \) and \( K_\infty(A(t), B(t)) \) defined at stabilizes \( A(t), B(t) \). All proofs are given in Section C.2.

We begin by recalling the derivative computation from the main text, which also establishes local smoothness of \( K(t) \) and \( P(t) \):

**Lemma 3.1** (Derivative and Smoothness of the DARE). Let \( (A(t), B(t)) \) be an analytic curve, and define \( \Delta_{A(t)} := A'(t) + B(t)K_\infty(A(t), B(t)) \). Then for any \( t \) such that \( (A(t), B(t)) \) is stabilizable, the functions \( P(u) \) and \( K(u) \) are analytic in a neighborhood around \( t \), and we have

\[
P'(u) = d\text{lyap}(A_{cl}(u), Q_1(u)), \quad \text{where} \quad Q_1(u) := A_{cl}(u)^\top P(u)\Delta_{A_{cl}}(u) + \Delta_{A_{cl}}(u)^\top P(u)A_{cl}(u).
\]

Note that the above lemma allows for general analytic curves \( (A(t), B(t)) \). For our purposes, we restrict to linear curves given a above. For \( K' \), we have the following computation

**Lemma B.1** (Computation of \( K' \)). The first derivative of the optimal controller can be expressed as

\[
K' = -(R_u + B^\top PB)^{-1} (\Delta_B^\top PA_{cl} + B^\top P(\Delta_{A_{cl}}) + B^\top P'A_{cl}).
\]

Of importance to our lower bound is the setting where the perturbations are of the form \( \Delta_A \triangleq (\Delta K_*, \Delta) \). In this case, the expression for the derivative of \( K \) simplifies considerably: we recall the following from the main text

**Lemma 2.1.** Let \( (A_*, B_*) \) be stabilizable. Then

\[
\frac{d}{dt} K_\infty(A_* - t\Delta K_*, B_* + t\Delta)|_{t=0} = -(R_u + B_*^\top P_* B_*)^{-1} \cdot \Delta^\top P_* A_{cl,*},
\]

where we recall \( A_{cl,*} := A_* + B_* K_* \).

**Proof.** Observe that for the perturbation in question, \( \Delta_{A_{cl}}(0) = \Delta K_* - \Delta K(0) = \Delta K_* - \Delta K_* = 0 \). By Lemma 3.1 and the fact that \( d\text{lyap}(X, 0) = 0 \), we have that \( P'(0) = 0 \). Thus, the term \( B^\top P(\Delta_{A_{cl}}) + B^\top P'A_{cl} \) in Eq. (C.2) is 0 at \( t = 0 \). The result follows.

\[\square\]
B.2.1 Bounds on the Derivatives

Here, we state bounds on the various derivatives. Recall \( \epsilon_o := \max\{\|\Delta_A\|_o, \|\Delta_B\|_o\} \). These bounds are established in Sections C.3.1 and C.3.2, respectively.

Lemma 3.2 (Bound on First Derivatives). Let \((A(t), B(t))\) be an analytic curve. Then, for all \(t\) at which \((A(t), B(t))\) is stabilizable, we have

\[
\|P'(t)\|_o \leq 4\|P(t)\|^3_{\text{op}} \epsilon_o, \quad \text{and} \quad \|K'(t)\|_o \leq 7\|P(t)\|^7/2_{\text{op}} \epsilon_o.
\]

In fact, it will be more useful to prove the following related bound:

Lemma B.2. \[ \|R_{1/2}^{\infty}K'\|_o \lor \|P^{1/2}BK'\|_o \lor \|BK''\|_o \leq 7\|P\|^{7/2}_{\text{op}} \epsilon_o. \]

For our lower bounds, we shall also use a second-order derivative bound

Lemma B.3 (Bound on \(K''\)). If \( \epsilon_o = \max\{\|A_\star - \hat{A}\|_o, \|B_\star - \hat{B}\|_o\} \) and \( K(t) = K_\infty(A(t), B(t)) \) for \( A(t) = (1-t)A_\star + t\hat{A} \) and \( B(t) = (1-t)B_\star + t\hat{B} \), that at any \(t\) at which \((A(t), B(t))\) is stabilizable,

\[
\|K''(t)\|_o \leq \text{poly}(\|P(t)\|_{\text{op}})\epsilon_{\text{op}}\epsilon_o.
\]

B.3 Main Control Theory Tools

B.3.1 Properties of the \texttt{dlyap} Operator

We begin by describing relevant facts about \texttt{dlyap} operator. The first is standard (see e.g. [Bof et al., 2018, Boyd, 2008]), and gives a closed-form expression for the function.

Lemma B.4. Let \(Y = Y^\top\) and \(\rho(X) < 1\). Then \(T_X(Y) := X^\top YX - Y\) is an invertible map from \(\mathbb{S}^{d_X} \to \mathbb{S}^{d_X}\), and

\[
dlyap(X,Y) = T_X^{-1}(Y) = \sum_{k=0}^{\infty} (X^\top)^k Y X^k.
\]  

Next, we show that \texttt{dlyapis} order-preserving in the following sense:

Lemma B.5 (Elementary \texttt{dlyap} bounds). The following bounds hold

1. If \(Y \preceq Z\) and \(A_{\text{safe}}\) is stable, then \(\text{dlyap}(A_{\text{safe}},X) \preceq \text{dlyap}(A_{\text{safe}},Y)\).
2. \(Y \succeq 0\) and \(A_{\text{safe}}\) is stable, \(\text{dlyap}(A_{\text{safe}},Y) \succeq Y\).
3. Suppose \(R_X \succeq I\), and let \(A + BK\) is stable. Then,

\[
\pm \text{dlyap}(A + BK, Y) \preceq \text{dlyap}(A + BK, I)\|Y\|_{\text{op}} \preceq \|Y\|_{\text{op}} \cdot P_\infty[K; A, B].
\]

4. When \(R_X \succeq I\), \(\text{dlyap}[A + BK] \preceq P_\infty[K; A, B]\), and \(I \preceq \text{dlyap}[A + BK_\infty(A, B)] \preceq P_\infty(A, B)\).
5. If \(A_{\text{safe}}\) is stable, \(\|\text{dlyap}[A_{\text{safe}}]\|_{\text{op}} = \|\text{dlyap}[A_{\text{safe}}^\top]\|_{\text{op}}\).

Next, we give a standard identity which relates the cost functions \(J\) to the \texttt{dlyap} operator.

Lemma B.6 (PSD bounds on \(P\)). Let \((A_\star, B_\star)\) be a stabilizable system, and let \(A_\star + B_\star K\) be stable. Set \(K_\star = K_\infty(A_\star, B_\star)\). Then,

\[
P_\infty[K_\star; A_\star, B_\star] \succeq P_\infty(A_\star, B_\star) = P_\infty(K_\star; A_\star, B_\star).
\]

Moreover, we have \(J_{A_\star, B_\star, A, B_\star}^*[K] = \text{tr}(P_\infty[K; A, B])\), and in particular, \(J_{A_\star, B_\star}^*[K_\star] = \text{tr}(P_\infty(A_\star, B_\star))\).

As a consequence, if \(R_X \succeq I\), then \(J_{A_\star, B_\star}^*[K] \geq J_{A_\star, B_\star}^*[K_\star] \geq d_X\) by Lemma B.5 part 4.
The following is a consequence of the above lemmas, and is useful for deriving interpolable corollaries of our main results:

**Lemma B.7.** Suppose that \( R_x = I \). If \( A_* \) is \((\gamma, \kappa)\)-strongly stable, then \( \| P_* \|_{op} \leq \gamma^{-1}_s \) and \( \frac{\kappa}{\gamma^s} J_{A_*, B_*} [0] \leq \gamma^{-1}_s \). More generally, if \((A_* + B_* K)\) is \((\gamma, \kappa)\)-strongly stable, then \( \| P_* \|_{op} \leq \gamma^{-1}_s (1 + \| K \|_{op}^2) \).

**Proof of Lemma B.7.** By considering the controller \( K = 0 \), Lemma B.6 implies \( P_* \leq \text{dlyap}(A_*, R_x) \) and \( J_{A_*, B_*} [0] = \text{tr} (\text{dlyap}(A_*, R_x)) \leq \frac{\| \text{dlyap}(A_*, R_x) \|_{op}}{\gamma_x} \). If \( R_x = I \), and we can bound

\[
\| \text{dlyap}(A_*, I) \|_{op} \leq \sum_{t \geq 0} \| A^t \|_{op}^2.
\]

If there exists a transform \( T \) with \( \sigma_{\text{max}}(T) / \sigma_{\text{min}}(T) \) \( \leq \kappa \) such that \( \| T \mathbf{A}_* T^{-1} \|_{op} \leq 1 - \gamma \), then \( \| A^t \|_{op} \leq \kappa^t \gamma^{-1} \). Hence, \( \| P_* \|_{op} \leq \| \text{dlyap}(A_*, I) \|_{op} \leq \kappa^2 \sum_{t \geq 0} \gamma^2 \leq \frac{\kappa^2}{1 - (1 - \gamma)^2} \leq \frac{\kappa^2}{1 - (1 - \kappa/\gamma)^2} = \kappa^2 \gamma^{-1} \). More generally, we have that \( P_* \leq \text{dlyap}(A_* + B_* K, R_x + K^\top R_u K) \) for \( R_x, R_u = I, R_x + K^\top R_u K \leq (1 + \| K \|_{op}^2) I \), and the bound follows by invoking Lemma B.5.

\( \square \)

### B.3.2 Helpful Norm Bounds

**Lemma B.8 (Helpful norm bounds).** Let \((A_*, B_*)\) be given, with \( P_* = P_\infty (A_*, B_*) \), \( K_* = K_\infty (A_*, B_*) \), and \( A_{cl.*} = A_* + B_* K_* \). If \( R_x \geq I \), \( R_u = I \), then the following bounds hold:

1. \( P_* \geq I \), so that \( \| P_*^{-1} \|_2 \leq 1 \), and \( \| P_* \|_{op} \geq 1 \).
2. \( \| K_* \|_{op} \leq \| P_* \|_{op} \) and \( \| A_{cl.*} \|_{op} \leq \| P_* \|_{op} \).
3. More generally, if \((A_* + B_* K)\) is stable, \( K^\top K \leq P_\infty (K; A_*, B_*) = \text{dlyap}(A_* + B_* K, R_x + K^\top R_u K) \).

### B.3.3 Bounds on \( P_\infty (K; A_*, B_*) \) and \( J_{A_*, B_*} [K] \):

We now state a variant of a result due to Fazel et al. [2018], which bounds the effect of perturbations on \( P_\infty (K; A_*, B_*) = P_\infty (A_*, B_*) \).

**Lemma B.9 (Generalization of Lemma 12 of Fazel et al. [2018]).** Let \( K \) be an arbitrary static controller which stabilizes \( A_*, B_* \). Then,

\[
P_\infty (K; A_*, B_*) - P_\infty (A_*, B_*) = \text{dlyap}(A_* + B_* K, (K - K_*)^\top (R_u + B_*^\top P_* B_*) (K - K_*)).
\]

As a consequence of Lemma B.9 and B.5, we have the following corollary:

**Corollary 5.** Let \( K \) be any arbitrary static controller which stabilizes \( A_*, B_* \), and suppose \( R_u = I \). Define the adjoint\(^{10}\) as \( \Sigma_{A_*, B_*} [K] := \text{dlyap}(A_* + B_* K, I) \) covariance matrix. Then,

\[
J_{A_*, B_*} [K] - J_{A_*, B_*} \leq \| \Sigma_{A_*, B_*} [K] \|_{op} \max \{ \| R_{u, 1/2} (K - K_*) \|_{op}, \| P_*^{1/2} B (K - K_*) \|_{op} \},
\]

\[
\| P_\infty (K; A_*, B_*) - P_\infty (A_*, B_*) \|_{op} \leq \| \Sigma_{A_*, B_*} [K] \|_{op} \max \{ \| R_{u, 1/2} (K - K_*) \|_{op}, \| P_*^{1/2} B (K - K_*) \|_{op} \}.
\]

### B.3.4 Linear Lyapunov Theory

We now state a classical result in Lyapunov theory (see, e.g. Boyd [2008]). Recall the notation \( \text{dlyap}(A) := \text{dlyap}(A, I) \).

**Lemma B.10.** For any \( x \in \mathbb{R}^d \) and stable \( A \), we have \( \text{dlyap}(A) \geq I \) and

\[
A^\top \text{dlyap}(A) A \leq (1 - \| \text{dlyap}(A) \|_{op}^{-1}) \cdot \text{dlyap}(A).
\]

\(^{10}\) Note that the canonical state covariance matrix \( \Sigma_{A_*, B_*} [K] \) is given by \( \text{dlyap}((A_* + B_* K)^\top, I) \). By Lemma B.6, we have that \( \| \Sigma_{A_*, B_*} [K] \|_{op} = \| \Sigma_{A_*, B_*} [K] \|_{op} \)}
Lemma B.11. For any stable $A$, $\|A\|_{\infty} \leq 2\|\text{dlyap}(A)\|_{op}^{3/2}$. More generally, suppose that $P \geq I$ is a matrix satisfying $(Ax)^T\text{dlyap}(A)(Ax) \leq (1-\rho)x^TPx$. Then,

$$\|A\|_{\infty} \leq \sum_{t \geq 0} \|A^t\|_2 \leq 2\sqrt{\frac{\rho}{\rho'}}.$$ 

B.4 Proofs for Supporting Perturbation Upper Bounds

B.4.1 Proof of Proposition 6

The proof is analogous to that of Proposition 4, except we also apply the derivative bound on $R_u^{1/2}K'(t)$ from Lemma B.2. That bound also gives

$$\|R_u^{1/2}K'(t)\|_o \leq 7\|P(t)\|_{op}^{7/2}\epsilon_o$$

$$\|B_*K'(t)\|_o = \epsilon_o\|K'(t)\|_o + \|B(t)K'(t)\|_o \leq (1 + \epsilon_o)7\|P(t)\|_{op}^{7/2}\epsilon_o \leq 8\|P(t)\|_{op}^{7/2}\epsilon_o,$$

so that the desired bound follows by the mean value theorem.

Moreover, we have

$$\|P_*^{1/2}B_*K'(t)\|_o \leq \|P_*^{1/2}P(t)^{-1/2}\|_{op}\|PB_*K'(t)\|_o \leq \|P_*^{1/2}P(t)^{-1/2}\|_{op}8\|P(t)\|_{op}^{7/2}\epsilon_o,$$

which translates to a bound of

$$\|P_*^{1/2}B(K_\infty(\hat{A}, \hat{B}) - K_*\|_o \leq \max_{t \in [0,1]} \|P_*^{1/2}P(t)^{-1/2}\|_{op} \leq 7\|P(t)\|_{op}^{7/2}\epsilon_o.$$ 

Finally, by the mean value theorem, we can bound for $\epsilon_o \leq 1/32\|P_*\|_{op}^{3}$ and $\alpha = 8\epsilon_o\|P_*\|_{op}^{2} \leq 1/4$,

$$\|P(t) - P_*\|_{op} \leq 4 \max_{t \in [0,1]} \|P(t)\|_{op}^{3}\epsilon_o \leq 4\|P_*\|_{op}^{3}(1-\alpha)^{-3/2} \leq \frac{1}{8}(4/3)^{3/2}.$$ 

Since $P(t) \geq I$, then, this implies that for $t \in [0,1]$,

$$P(t) \geq (1 - \frac{1}{8}(4/3)^{3/2})P_*,$$

yielding $\|P_*^{1/2}P(t)^{-1/2}\|_{op} \leq \sqrt{(1 - \frac{1}{8}(4/3)^{3/2})} \leq 9/8$. Hence, for this $\epsilon_o$, we have

$$\|P_*^{1/2}B_*K_\infty(\hat{A}, \hat{B}) - K_*\|_o \leq 9\|P(t)\|_{op}^{7/2}\epsilon_o.$$ 

B.4.2 Proof of Proposition 7

Since the final bound we derive does not depend on the control basis, we may assume without loss of generality that $R_u = I$. Recall the steady state covariance matrix $\Sigma_{A_*,B_*}[K_*] := \text{dlyap}(A_* + B_*K,I)$. We shall prove the following lemma:

Lemma B.12. Suppose that $\|B_*(K - K_*)\|_2 \leq 1/5\|\Sigma_{A_*,B_*}[K_*]\|_{op}^{3/2}$, then $\|\Sigma_{A_*,B_*}[K]\|_2 \leq 2\|\Sigma_{A_*,B_*}[K_*]\|_2$.

Note that a similar result was given by Lemma 16 [Fazel et al., 2018]; we give our proof using the self-bounding ODE to demonstrate the generality of its scope, and to avoid dependence on system matrices. Noting that $\|\Sigma_{A_*,B_*}[K_*]\|_2 \leq \|P_*\|_{op}$ as verified above, it is enough that $\|B_*(K - K_*)\|_2 \leq 1/5\|P_*\|_{op}$ to ensure that $\|\Sigma_{A_*,B_*}[K]\|_2 \leq 2P_*$. When this holds, we have by Corollary 5, we have (assuming $R_u = I$)

$$\mathcal{J}_{A_*,B_*}[K] - \mathcal{J}_{A_*,B_*} \leq \|\Sigma_{A_*,B_*}[K]\|_{op} \max\{\|R_u^{1/2}(K - K_*)\|_F^2, \|P_*^{1/2}B_*(K - K_*)\|_F^2\} \leq \|P_*\|_{op} \max\{\|R_u^{1/2}(K - K_*)\|_F^2, \|P_*^{1/2}B_*(K - K_*)\|_F^2\},$$

$$\|P_\infty(K; A_*, B_*) - P_*\|_{op} \leq \|P_*\|_{op} \max\{\|R_u(K - K_*)\|_{op}^2, \|P_*^{1/2}B_*(K - K_*)\|_{op}^2\},$$

as needed.
Proof of Lemma B.12. We shall now use the self-bounding machinery developed above to bound $\Sigma_{A_*,B_*}[K]$. Introduce the straight curve $\tilde{K}(t) := K_* + t\Delta_K$, where $\Delta_K = K - K_*$, and where the $\tilde{\cdot}$ is to avoid confusion with the curve $K(t) = K_\infty(A(t), B(t))$. Let $\Sigma(t) = \text{dlyap}(A_*, B_*, \tilde{K}(t), I)$, so that $\Sigma(0) = \Sigma_{A_*,B_*}[K_\text{safe}]$ and $\Sigma(1) = \Sigma_{A_*,B_*}[K]$. By the definition of dlyap, we have that at all $t$ for which $K(t)$ stabilizes $A_*, B_*$,
$$
\Sigma(t) = (A_* + B_* \tilde{K}(t))^\top \Sigma(t)(A_* + B_* \tilde{K}(t)) + I.
$$
We shall now prove that $\Sigma(t)$ satisfies a self-bounding relation analogous to Proposition 4:

Claim B.13. For all $t \in [0, 1]$ for which $\Sigma(t)$ is defined, $\|\Sigma'(t)\|_{\text{op}} \leq 2\|\Sigma(t)\|^{5/2}B_*\Delta_K\|_{\text{op}}$.

Proof. Taking a derivative with respect to $\Sigma$, we have
$$
\Sigma'(t) = (A_* + B_* \tilde{K}(t))^\top \Sigma'(t)(A_* + B_* \tilde{K}(t)) + Q_{\Sigma}(t),
$$
where $Q_{\Sigma}(t) = (B_* \Delta_K)^\top \Sigma(t)(A_* + B_* \tilde{K}(t)) + (A_* + B_* \tilde{K}(t))^\top \Sigma(t)B_*\Delta_K$. Thus, we can render
$$
\Sigma'(t) = \text{dlyap}(A_*, B_* \tilde{K}(t), Q_{\Sigma}(t)).
$$
By an argument analogous to Lemma B.5, we have $\pm \Sigma'(t) \leq \|Q_{\Sigma}(t)\|\text{dlyap}(A_*, B_* \tilde{K}(t), I) = \|Q_{\Sigma}(t)\|\Sigma(t)$, yielding the self-bounding relation
$$
\|\Sigma'(t)\|_{\text{op}} \leq \|Q_{\Sigma}(t)\|_{\text{op}}\|\Sigma(t)\|_{\text{op}}.
$$
Moreover, we can bound for $t \in [0, 1]$
$$
\|Q_{\Sigma}(t)\|_{\text{op}} \leq 2\|\Sigma(t)\|_{\text{op}}\|B_*\Delta_K\|_{\text{op}}\|A_* + B_* \tilde{K}(t)\|_{\text{op}}
\leq 2\|\Sigma(t)\|^{3/2}_{\text{op}}\|B_*\Delta_K\|_{\text{op}},
$$
where we use that $\|A_* + B_* \tilde{K}(t)\|^2_{\text{op}} \leq \|\text{dlyap}(A_*, B_* \tilde{K}(t), I)\|_{\text{op}} = \|\Sigma(t)\|_{\text{op}}$. \qed

We check explicitly that $\Sigma(t)$ corresponds to the solution of a valid implicit function with domain $\mathcal{U} := \{\Sigma_{\text{adj}} : \Sigma_{\text{adj}} > 0\}$ (using the more general second condition that ensures that $t \mapsto \Sigma(t)$ is a continuously differentiable function, which follows from the form of dlyap). Applying Corollary 3 with $p = 5/2$ and $c = 2\|B_*\Delta_K\|_{\text{op}}$, this yields that if $\alpha = (p - 1)c\|\Sigma(0)\|^{3/2}_{\text{op}} = 3\|\Sigma(0)\|^{3/2}_{\text{op}}\|B_*\Delta_K\|_{\text{op}} < 1$, then $\|\Sigma(1)\|_{\text{op}} \leq (1 - u)^{-2/3}\|\Sigma(0)\|_{\text{op}}$. In particular, if $\|B_*\Delta_K\|_{\text{op}} \leq 1/5\|\Sigma(0)\|^{3/2}_{\text{op}}$, then we can show $\|\Sigma(1)\|_{\text{op}} \leq 2\|\Sigma(0)\|_{\text{op}}$. \qed

B.4.3 Proof of Proposition 9

Introduce the curve $A(t) = A_{\text{safe}} + t\Delta_A$, where $\Delta_A = A_1 - A_{\text{safe}}$, define $Y_z(t) := (zI - A(t))^{-1}$. Then, $\|A(t)\|_{\mathcal{H}_\infty} = \sup_{z \in \mathbb{T}} \|Y_z(t)\|_2$. Let us now use the self-bounding method to bound $\|Y_z(t)\|$. We can observe that
$$
Y_z'(t) = (zI - A(t))^{-1}\Delta_A(zI - A(t))^{-1},
$$
so that $\|Y_z'(t)\|_2 \leq \|Y_z(t)\|_2^2\|\Delta_A\|$. Since $Y_z(t)$ corresponds to the zeros of the valid implicit function $F^z(A,Y) = Y \cdot (zI - A(t)) - I$, Theorem 13 implies that, if $\|\Delta_A\| \leq \|A_{\text{safe}}\|_{\mathcal{H}_\infty} = \min_{z \in \mathbb{T}} \frac{\|A_{\text{safe}}\|_{\mathcal{H}_\infty}}{\|Y_z(0)\|_2}$, then we have $\|Y_z(1)\| \leq \frac{1}{1 - \alpha}\|Y_z(0)\|$ for all $z \in \mathbb{T}$. Hence,
$$
\|A_1\|_{\mathcal{H}_\infty} = \max_{z \in \mathbb{T}} \|Y_z(1)\| \leq \max_{z \in \mathbb{T}} \|Y_z(0)\| = \frac{1}{1 - \alpha}\|A_{\text{safe}}\|_{\mathcal{H}_\infty},
$$
as needed. \qed
We then have
\[(Ax)^\top \text{dlyap}[A](Ax) \leq (Ax)^\top \text{dlyap}[A](Ax) + x^\top (\tilde{A} - A)^\top \text{dlyap}[A]Ax + x^\top (\tilde{A} - A)^\top \text{dlyap}[A](\tilde{A} - A)x\]
\[\leq (1 - \|\text{dlyap}[A]\|_{\text{op}}^{-1}) \cdot x^\top \text{dlyap}[A]x + \|x\|^2_2 \left(\|\tilde{A} - A\|_{\text{op}} \|\text{dlyap}[A]\|_{\text{op}} + \|\tilde{A} - A\|^2_{\text{op}} \|\text{dlyap}[A]\|_{\text{op}}\right)\]
\[\leq (1 - \|\text{dlyap}[A]\|_{\text{op}}^{-1} + \left(\|\tilde{A} - A\|_{\text{op}} \|\text{dlyap}[A]\|_{\text{op}} + \|\tilde{A} - A\|^2_{\text{op}} \|\text{dlyap}[A]\|_{\text{op}}\right)) \cdot x^\top \text{dlyap}[A]x,
\]
where we used that \(\text{dlyap}[A] \geq I\). In particular, if
\[\|\tilde{A} - A\|_{\text{op}} \leq \frac{1}{4} \min\{\|A\|_{\text{op}} \|\text{dlyap}[A]\|_{\text{op}}^{-1}, \|\text{dlyap}[A]\|_{\text{op}}^{-1/2}\},\]
then, the above is at most, \((1 - \frac{1}{4}\|\text{dlyap}[A]\|_{\text{op}}^{-1}) \cdot x^\top \text{dlyap}[A]x.\]
\[\square\]

C Supporting Proofs for Appendix B

C.1 Proofs for Main Technical Tools (Section B.3):

We begin with the following lemma, which follows from a standard computation.

C.1.1 Proof of Lemma B.5

Proof. Let \(\rho(A_0) < 1\), and so from (B.3) we have that for any \(Z\) with \(Y \preceq Z\) that
\[
\text{dlyap}(A_0, Y) = \sum_{k=0}^{\infty} (A_0^k)^\top Y A_0^k \preceq \sum_{k=0}^{\infty} (A_0^k)^\top Z (A_0^k).
\]
Second, if \(Y \succeq 0\), \(\sum_{k=0}^{\infty} (A_0^k)^\top Y (A_0^k)\text{dlyap}(A_0, Y) \succeq Y\).

The third statement is a direct consequence of the first. Moreover, since \(I \preceq R_x \preceq R_x + K^\top R_u K\), taking \(Z = \|Y\|(R_x + K^\top R_u K)\) yields the fourth inequality.

For the last statement, let \(\|x\|_2 = 1\). Then, we have
\[
x^\top \text{dlyap}[A_0]x = \sum_{k=0}^{\infty} x^\top (A_0^k)^\top (A_0^k)x = \sum_{k=0}^{\infty} \text{tr}(A_0^k xx^\top (A_0^k)^\top)
\[= \text{dlyap}(A_0, xx^\top)
\[\preceq \|xx^\top\|_{\text{op}} \|\text{dlyap}(A + BK, I)\|_{\text{op}} I = \|\text{dlyap}(A + BK, I)\|_{\text{op}} I.
\]
\[\square\]

C.1.2 Proof of Lemma B.6

We begin with the following lemma, whose proof is a straightforward computation.

Lemma C.1. Let \(A_\ast, B_\ast\) be stabilizable. For a controller \(K\) such that \(A_\ast + B_\ast K\) is stable, we define the value function
\[
V^K(x) := \sum_{t=0}^{\infty} c(x_t^{K,x}, K x_t^{K,x}), \quad \text{where } x_0^{K,x} = x, \quad \text{and } x_t^{K,x} = (A_\ast + B_\ast K)x_{t-1}^{K,x}.
\]

We then have \(x_t^{K,x} = (A_\ast + B_\ast K)^t x\), \(\sum_{t=0}^{\infty} (x_t^{K,x})^\top Y x_t^{K,x} = \text{dlyap}(A_\ast + B_\ast K, Y)\), and in particular,
\[
V^K(x) = x^\top \text{dlyap}(A_\ast + B_\ast K, R_x + K^\top R_u K)x = x^\top P_\infty(K)x,
\]
We now prove Lemma B.6:

**Proof.** Introduce the shorthand $P_\ast = P_\infty(A_\ast, B_\ast)$, $P_\infty(K) = P_\infty(K; A_\ast, B_\ast)$, and in particular, $V^K_\infty(x) = x^\top P_\infty(x)$. It is well known that $x^\top P_\infty x = V^K_\infty(x)$ and that $V^K_\infty(x) = \inf_K V^K(x) \leq V^K(x)$ [Bertsekas, 2005]. Hence, $P_\infty(K) \succeq P_\infty$. Finally, observe that by using that $A + BK$ is stable, we have

$$J_{A, B}[L] = \lim_{t \to \infty} \frac{1}{t} \sum_{i=1}^{t} E_{A, B, K}[x_i^\top R_x x_i + u_i^\top R_u u_i]$$

$$= \lim_{t \to \infty} \frac{1}{t} \sum_{i=1}^{t} (A + BK) (A + BK)^\top (x_i - x_{i-1})^\top (x_i - x_{i-1})$$

$$= \left( \sum_{s=0}^{\infty} (A + BK)^\top (x_s + K^\top R_u K)(A + BK)^\top \right)$$

$$= \text{tr}(P_\infty(K))$$

The identity for $P_\infty$ is the special case where $K = K_\infty$. \hfill \Box

### C.1.3 Proof of Lemma B.8

**Proof.** We address each bound in succession.

1. $\sigma_{\min}(P_\ast) \geq 1$ by Lemma B.5.

2. We have that

$$P_\infty = \text{dlyap}(A_\ast + B_\ast K_\ast, R_x + K_\ast^\top R_u K_\ast) \succeq R_x + K_\ast^\top R_u K_\ast \succeq K_\ast^\top K_\ast,$$

since $R_u \succeq I$ and $R_x \succeq I$. Moreover, we have that

$$P_\infty = \text{dlyap}(A_\ast + B_\ast K_\ast, R_x + K_\ast^\top R_u K_\ast) = \sum_{t=0}^{\infty} ((A_\ast + B_\ast K_\ast)^\top)^t (R_x + K_\ast^\top R_u K_\ast) (A_\ast + B_\ast K_\ast)^t$$

$$\geq \sum_{t=0}^{\infty} ((A_\ast + B_\ast K_\ast)^\top)^t (A_\ast + B_\ast K_\ast)^t$$

$$\geq (A_\ast + B_\ast K_\ast)^\top (A_\ast + B_\ast K_\ast).$$

\hfill \Box

### C.1.4 Proof of Lemma B.9

**Proof.** The first inequality is precisely Lemmas 12 in Fazel et al. [2018]. In light of Lemma C.1, it suffices to show that

$$V^K(x) - V^K_\ast(x) = x^\top \text{dlyap}(A_\ast + BK_\ast, (K - K_\ast)^\top (R_u + B_\ast^\top P_\ast B_\ast)(K - K_\ast))$$

Lemma 10 in Fazel et al. [2018] implies (noting $E_{K_\ast} = 0$ for $E_K$ defined therein) that

$$V^K(x) - V^K_\ast(x) = \sum_{t=0}^{\infty} (x^\top K_\ast x)^{t}(K - K_\ast)^\top (R_u + B_\ast^\top P_\ast B_\ast)(K - K_\ast) x^\top K_\ast x$$

$$= \text{dlyap}(A_\ast + B_\ast K, (K - K_\ast)^\top (R_u + B_\ast^\top P_\ast B_\ast)(K - K_\ast)),$$

where the second inequality uses Lemmas 12 in Fazel et al. [2018]. \hfill \Box
C.1.5 Proof of Lemma B.11

Let us prove the more general claim.

\[ \|A\|_{\infty} \leq \sum_{t=0}^{\infty} \|A^t\|_{\text{op}} = \sum_{t=0}^{\infty} \sqrt{||(A^t)^\top(A^t)||_{\text{op}}} \]

\[ \leq \sum_{t=0}^{\infty} \frac{1}{\sigma_{\min}(\text{dlyap}[A])} ||(A^t)^\top P(A^t)||_{\text{op}} \]

\[ \leq \sum_{t=0}^{\infty} \frac{1}{\sigma_{\min}(P)} \sqrt{(1-\rho)^t ||P||_{\text{op}}} \]

\[ \leq ||P||_{\text{op}}^{1/2} \sum_{t=0}^{\infty} \sqrt{1-\rho}^t \quad \text{since } P \geq I \]

\[ = ||P||_{\text{op}}^{1/2} \frac{1}{1-\sqrt{1-\rho}} \]

\[ \leq ||P||_{\text{op}}^{1/2} \frac{1 + \sqrt{1-\rho}}{1 - (1 - \rho)} \]

\[ \leq 2 \|P\|_{\text{op}}^{1/2} / \rho. \]

C.2 Derivative Computations

C.2.1 Proof of Lemma 3.1

Recall the function

\[ \mathcal{F}_{\text{DARE}}(\{A, B\}, P) = A^\top PA - P - A^\top PB(R_u + B^\top PB)^{-1}B^\top PA + R_x. \]

Let us compute the differentiable of this map. To keep notation, let us supress the dependence of the A, B arguments on t. We have that

\[ \mathcal{D}\mathcal{F}_{\text{DARE}}[dP, dt]_{A(t), B(t), P} = \mathcal{D}(A^\top PA) - DP + \mathcal{D}(A^\top PB) \cdot (R_u + B^\top PB)^{-1}B^\top PA \]

\[ - (A^\top PB)(R_u + B^\top PB)^{-1} \cdot (B^\top PA)D \]

\[ - (A^\top PB) \cdot \mathcal{D}((R_u + B^\top PB)^{-1}) \cdot B^\top PA \]

\[ = \mathcal{D}(A^\top PA) + \mathcal{D}(A^\top PB) \cdot K + K^\top \cdot \mathcal{D}(B^\top PA) \]

\[ - (A^\top PB) \cdot \mathcal{D}((R_u + B^\top PB)^{-1}) \cdot B^\top PA, \]

where for compactness, we substituted in the formula

\[ K = K(t, P) = -(R_u + B(t)^\top PB(t))^{-1}B(t)^\top PA(t). \quad (C.1) \]

Recall that for a symmetric matrix, we have \((X^{-1})' = -X^{-1}X^{-1}\). Thus, substituting in the definition of K, we can write the last term in the expression above as

\[ - (A^\top PB) \cdot \mathcal{D}((R_u + B^\top PB))'B^\top PA \]

\[ = (A^\top PB)(R_u + B^\top PB)^{-1}(R_u + B^\top PB)\mathcal{D}(R_u + B^\top PB)^{-1}B^\top PA \]

\[ = K^\top \mathcal{D}(R_u + B^\top PB)K. \]

Hence, gathering terms, we have

\[ \mathcal{D}\mathcal{F}_{\text{DARE}}[dP, dt]_{A(t), B(t), P} = \mathcal{D}(A^\top PA) - DP + \mathcal{D}(A^\top PB)K + K^\top \cdot \mathcal{D}(B^\top PA) + K^\top \mathcal{D}(R_u + B^\top PB)K. \]
Let us now adopt shorthand $(\cdot)' := \frac{d}{dt}(\cdot)$. Expanding the derivatives using the product rule, we then have

$$\mathcal{DF}_{\text{DARE}}[dP, dt]_{A(t), B(t), P} = A^TDPA - D(P) + A^TDBK + K^TB^TDA + K^TB^TP \cdot BK$$
$$+ A^TPA + A^TPA' + A^TPBK + (BK)^TPA'$$
$$+ A^TP(B'K) + (B'K)^TPA + (B'K)^TPBK + (BK)^TP(B'K).$$

Grouping terms, this is equal to

$$\mathcal{DF}_{\text{DARE}}[dP, dt]_{A(t), B(t), P} = (A + BK)^TdP(A + BK) - dP_{A(t), B(t), P}$$
$$+ A'^TPA + (A + BK)^TPA_{A(t), B(t), P}$$
$$+ (B'K)^TP(A + BK) + (A + BK)^TP(B'K)_{A(t), B(t), P}$$
$$= (A + BK)^T \cdot dP \cdot (A + BK) - dP_{A(t), B(t), P}$$
$$+ (A'(t) + B'(t)K)^TP(A(t) + B(t)K) + (A(t) + B(t)K)P(A'(t) + B'(t)K)$$

$$= \mathcal{T}_{A(t) + B(t)K}[dP] + Q(t, P)dt.$$ 

In particular, if $\mathcal{F}_{\text{DARE}}([A(t), B(t)], P) = 0$, then for $K(t, p)$ as in Eq. (C.1), the matrix $A(t) + B(t)K(t, P)$ is stable. Hence, $\mathcal{T}_{A(t) + B(t)K(t, P)}[\cdot]$ is invertible on $\mathbb{S}_d^+$. Moreover, since the second term has no-explicit depending on $dP$, we find that $(dP, dt) \rightarrow \mathcal{DF}_{\text{DARE}}[dP, dt]_{A(t), B(t), P}$ is full-rank, with zero solution

$$dP = \mathcal{T}^{-1}_{A(t) + B(t)K(t, P)}[Q_1(t, P)dt] = \text{dlyap}(A(t) + B(t)K(t, P), Q_1(t, P)).$$

By the implicit function theorem, this implies that if $\mathcal{F}_{\text{DARE}}([A(t), B(t)], P) = 0$, then there exists a neighborhood around $t$ on which the function $u \mapsto P(u)$ is analytic (recall $\mathcal{F}_{\text{DARE}}$ is analytic), and $\mathcal{F}_{\text{DARE}}([A(u), B(u)], P(u)) = 0$ on this neighborhood. By the above display then, we have $P'(u) = \text{dlyap}(A(u) + B(u)K(u), Q_1(u))$, where $Q_1(u) \leftarrow Q_1(u, P(u))$ and $K(t) \leftarrow K(u, P(u))$ are specializations of the above to the curve $u \mapsto P(u)$.

\[\square\]

### C.2.2 Computation of $K'$ (Lemma B.1)

Throughout, we suppress dependence on $t$, and the computations are understood to hold only at those $t$ for which $(A(t), B(t))$ is stabilizable.

**Proof.** Note that we can take derivatives freely by Lemma 3.1. Invoking the product rule and the identity $((X^{-1})' = -X^{-1}X'X^{-1})$,

$$K' = (Ru + B^TPB)^{-1} \cdot (Ru + B^TPB)' \cdot (Ru + B^TPB)^{-1}B^TPA - (Ru + B^TPB)^{-1} \cdot (B^TPA)'$$
$$= -(Ru + B^TPB)^{-1}Ru + B^TPB)' \cdot K - (Ru + B^TPB)^{-1}(B^TPA)'$$
$$= -(Ru + B^TPB)^{-1}((Ru + B^TPB)'K + K(B^TPA)',$$

We simplify the expression inside the parentheses as

$$(Ru + B^TPB)'K + K(B^TPA)' = B^TP(A + BK) + B^TP(A' + B'K) + B^TP'(A + BK)$$
$$= B^TPA_{cl} + B^TP(A_{cl}) + B^TP'A_{cl}.$$ 

Since $B' = \Delta_B$, this yields the result.

\[\square\]
C.2.3 Computation of \( P'' \)

Again, suppress dependence on \( t \). We compute \( P'' \), which Lemma 3.1 ensures exists whenever \( (A(t), B(t)) \) is stabilizable.

**Lemma C.2** (Computation of \( P'' \)). The second derivative of the optimal cost matrix has the form

\[
P'' = \text{dlyap}(A_{cl}, Q_2),
\]

where \( Q_2 := A_{cl}^T P' A_{cl} + A_{cl}^T P' A_{cl}' + Q_1' \) is a symmetric matrix defined in terms of

\[
Q_1' := A_{cl}^T P(\Delta_{A_{cl}}) + A_{cl}^T P\Delta_{A_{cl}} + A_{cl}^T P(\Delta_{A_{cl}})' + (\Delta_{A_{cl}})'^T P A_{cl} + \Delta_{A_{cl}}^T P A_{cl} + \Delta_{A_{cl}}^T P A_{cl}'.
\]

**Proof.** Applying the product rule to the expression for \( P' \) from Lemma 3.1, we have

\[
P'' = A_{cl}^T P'' A_{cl} + A_{cl}^T P' A_{cl} + A_{cl}^T P' A_{cl}'
\]

\[
+ A_{cl}^T P \Delta_{A_{cl}} + A_{cl}^T P' \Delta_{A_{cl}} + A_{cl}^T P(\Delta_{A_{cl}})' + (\Delta_{A_{cl}})'^T P A_{cl} + \Delta_{A_{cl}}^T P A_{cl} + \Delta_{A_{cl}}^T P A_{cl}'.
\]

where \( Q_2 := A_{cl}^T P' A_{cl} + A_{cl}^T P' A_{cl} + A_{cl}^T P \Delta_{A_{cl}} + A_{cl}^T P' \Delta_{A_{cl}} + A_{cl}^T P(\Delta_{A_{cl}})' + (\Delta_{A_{cl}})'^T P A_{cl} + \Delta_{A_{cl}}^T P A_{cl} + \Delta_{A_{cl}}^T P A_{cl}'. \) We conclude by observing that \( (\Delta_{A_{cl}})' = (A' + B' K + B' K') = B' K' \), since \( A \) and \( B \) are linear in \( t \).

\[ \square \]

C.3 Norm Bounds for Derivatives

C.3.1 Norm bounds for First Derivatives

In this section, we work through obtaining concrete bounds on the derivatives of \( P(t), K(t) \) using the expressions derived in the previous section. As above, we assume that \( R_u \geq I \) and \( R_x \geq I \). We state some more bounds that will be of use to see:

**Lemma C.3** (Norm-Bounds for Derivative Quantities). Let \( (A_*, B_*) \) be given, with \( P_* = P_\infty(A_*, B_*) \), \( K_* = K_\infty(A_*, B_*) \), and \( A_{cl} = A_* + B_* K_* \). If \( R_u, R_x \geq I \), then the following bounds hold:

1. Let \( R_0 := R_u + B_2^T P B_* \). Then for any \( X,Y \in \{B_*, P_*^{1/2} B_*, R_*^{1/2} I\}, \|XR_0^{-1}Y^T\|_o \leq 1. \)

2. For \( o \in \{\text{op}, \text{F}\} \), we have \( \|\Delta_{A_{cl}}\|_o \leq 2\|P\|_{\text{op}}\epsilon_o. \)

**Proof.** First, we have that \( \|XR_0^{-1}Y^T\|_o \leq \|XR_0^{-1/2}\|_o\|YR_0^{-1/2}\|_o \leq \sqrt{\|XR_0^{-1}X^T\|_o\|YR_0^{-1}Y^T\|_o}. \) Since \( R_u, R \geq I \), we can verify that \( XX^T, YY^T \leq R_0 \), which means that \( \|XR_0^{-1}X^T\|_o, \|YR_0^{-1}Y^T\|_o \leq 1. \)

Second, for \( \|\cdot\|_o \) denoting either the operator or Frobenius norm, we bound \( \|\Delta_{A_{cl}}\|_o = \|\Delta_A + \Delta_B B\|_o \leq \|\Delta_A\|_o + \|\Delta_B\|_o\|K\|_o = \epsilon_o(1 + \|K\|_o) \leq 2\sqrt{\|P\|_{\text{op}}\epsilon_o}. \)

\[ \square \]

C.3.2 Proof of Lemma 3.2 and Lemma B.2

Recall that \( P' = \text{dlyap}(A_{cl}, Q_1) \), where \( Q_1 := A_{cl}^T P(\Delta_{A_{cl}}) + (\Delta_{A_{cl}})'^T P A_{cl} \). Hence, using Lemma B.5 with \( R_x \geq I \), followed by Lemmas B.8 and C.3, we can bound

\[
\|P'\|_o = \|\text{dlyap}(A_{cl}, Q_1)\|_o
\]

\[
\leq \|P\|_{\text{op}}\|Q_1\|_o \leq 2\|P\|_{\text{op}}\|A_{cl}\|_o\|\Delta_{A_{cl}}\|_o
\]

\[
\leq 2\|P\|_{\text{op}}^2 \cdot \|P\|_{\text{op}}^{1/2} \cdot 2\|P\|_{\text{op}}^{1/2}\epsilon_o = 4\|P\|_{\text{op}}^3.
\]

Next, recall from Lemma B.1 that we have the identity

\[
K' = -R_0^{-1}(\Delta_B^T PA_{cl} + B^T P(\Delta_{A_{cl}}) + B^T P'A_{cl}),
\]
where $R_0 := R_u + B^T PB$. Next bound each of the three terms that arise. Again using $\|R_0^{-1}\|_{op} \leq 1$ and $\|A_{cl}\|_{op} \leq \|P\|_{op}^2$ (Lemma B.8), we have

$$\|R_0^{-1} \Delta_B PA_{cl} \|_o \leq \|P\|_{op}^{3/2} \epsilon_o.$$  

Next, since $\|R_0^{-1} B^T P^{1/2} \|_{op} \leq 1$ (Lemma C.3), we have

$$\| (R_u + B^T PB)^{-1} (B^T P(\Delta_{A_{cl}}) + B^T P' A_{cl}) \|_o \leq \|P\|_{op}^{1/2} \|\Delta_{A_{cl}}\|_{op} + \|P^{1/2}\|_{op} \|P'\|_{op} \|A_{cl}\|_{op} \leq 2\|P\|_{op} \epsilon_o + \|P^{-1/2}\|_{op} \|P'\|_{op} \|P\|_{op}^{1/2} \leq 2\|P\|_{op} \epsilon_o + 4\|P\|_{op}^{7/2} \epsilon_o.$$  

where the second to last line uses Lemma B.8, and the last line uses $\|P^{-1/2}\|_{op} \leq 1$, as well as $\|P'\|_{op} \leq \|P\|_{op}^3$. Putting the bounds together, we have $\|K'\|_o \leq 7\|P\|_{op}^{7/2} \epsilon_o$.

We also restate and prove an analogous bound that pre-conditions $K'(t)$ by appropriate matrices.

**Lemma B.2.** $\|R_u^{1/2} K'\|_o \vee \|P^{1/2} BK'\|_o \vee \|BK'\|_o \leq 7\|P\|_{op}^{7/2} \epsilon_o$.

**Proof.** The bound is analogous to the bound on $K'$ from Lemma 3.2, but now uses right multiplication of $R_0^{-1}$ which addresses left-multiplication by $B, P^{1/2} B, R_u^{1/2}$.

### C.3.3 Norm Bounds for Second Derivatives

Next, we turn to bounding $P''$ and $K''$. We shall need some intermediate lemmas. Let us bound the intermediate term $A'_{cl}$

**Lemma C.4.** It holds that $\max\{\|\Delta_{A_{cl}}\|_o, \|A'_{cl}\|_o\} \leq 9\|P\|_{op}^{7/2} \epsilon_o$, and $\|\Delta'_{A_{cl}}\|_o \leq \epsilon_o \|P\|_{op}^{7/2} \epsilon_o$.

**Proof.** $A'_{cl} = \Delta_{A_{cl}} + BK'$. From Lemma C.3, $\|\Delta_{A_{cl}}\|_o \leq 2\|P\|_{op} \epsilon_o$. Moreover, from Lemma B.2, $\|BK'\|_o \leq 7\|P\|_{op}^{7/2} \epsilon_o$. Thus, $\|A'_{cl}\|_o \leq 9\|P\|_{op}^{7/2} \epsilon_o$. The second bound uses $\Delta'_{A_{cl}} = \Delta_B K'$, and the same bound on $\|K'\|_o$.

Next, we bound the norm of $P''$.

**Lemma C.5.** We have the bound $\|P''\|_o \leq \text{poly}(\|P\|_{op} \epsilon_o)$.

**Proof.** Recall that $P'' = \text{dlyap}(A_{cl}, Q_2)$, where

$$Q_2 = A_{cl}^T P'A_{cl} + A_{cl}^T P' A_{cl}^T + A_{cl}^T P(\Delta_{A_{cl}}) + A_{cl}^T P' \Delta_{A_{cl}} + A_{cl}^T P(B'K') + (B'K')^T PA_{cl} + \Delta_{A_{cl}}^T P' A_{cl} + \Delta_{A_{cl}}^T P A_{cl}^T .$$

Hence, $\|P''\|_{op} \leq \|P\|_{op} \|Q_2\|_{op}$. We upper bound the norm of $Q_2$ by

$$\|Q_2\|_o \leq 2(\|A'_{cl}\|_o \|P\|_{op} \|A_{cl}\|_{op} + \|A'_{cl}\|_o \|\Delta_{A_{cl}}\|_{op} \|P\|_{op} + \|B'\|_o \|K'\|_{op} \|PA_{cl}\|_{op} + \|A_{cl}\|_{op} \|P'\|_{op} \|\Delta_{A_{cl}}\|_o) .$$

Using Lemma B.8 and Lemma 3.2, one can show that

$$\|P''\|_o \leq \text{poly}(\|P\|_{op} \epsilon_o) .$$

**Proof of Lemma B.3.** From Lemma B.1, we have that

$$K' = -(R_u + B^T PB)^{-1} (\Delta_B^T PA_{cl} + B^T P(\Delta_{A_{cl}}) + B^T P' A_{cl}) .$$  

(2.2)
Then, we begin by stating Theorem 13, which provides a generic guarantee for self-bounding ODES (recall Definition 3.3):

**Theorem 13.** Let \((F, U, g, \| \cdot \|, \langle \cdot , \cdot \rangle)\) be a self-bounding tuple. Suppose that for some \(\eta > 0\), \(h(\cdot)\) satisfies \(h(z) \geq g(z) + \eta\) for all \(z \geq \|y(0)\|\), and that the scalar ODE

\[
w(0) = \|y(0)\| + \eta, \quad w'(t) = h(w(t))
\]

has a continuously differentiable solution on \([0, 1]\). Then, there exists a unique continuously differentiable function \(y(t) \in U\) defined on \([0, 1]\) which satisfies \(F(x(t), y(t)) = 0\), and this solution satisfies \(\|y(t)\| \leq w(t) \leq w(1), \quad \|y'(t)\| \leq g(w(t)) \leq g(w(1))\) for all \(t \in [0, 1]\).

We shall prove the above theorem, and then derive Corollary 3 as a consequence. We begin the proof of this theorem with a simple scalar comparison inequality:

**Lemma D.1 (Scalar Comparison Inequalities for Curves).** Suppose that \(x(t), w(t)\) are continuously differentiable curves defined on \([0, u]\). Suppose further that, for a function \(f(\cdot, \cdot), x'(t) = f(x(t), t),\) and that \(w'(t) = g(x(t))\). In addition, suppose

1. \(w(0) > x(0)\)
2. \(g(\cdot) \geq 0\)
3. For \(t \in [0, u]\) such that \(x(t) \geq w(0), g(x(t)) > f(x(t), t)\).

Then, \(x(t) < w(t)\) for \(t \in [0, u]\).

**Proof.** Define \(\delta(t) = w(t) - x(t)\). Since \(\delta(0) > 0\), there exists an \(s > 0\) such that \(\delta(t)\) for \(t \in [0, s]\). Choose the maximal such \(s := \sup \{ t : \delta(t') \geq 0, \forall t' < t \} \), and suppose for the sake of contradiction that \(s < u\). Then, by continuity, \(\delta(s) = 0\), and therefore \(\delta'(s) = g(w(s)) - f(x(s), s) = g(x(s)) - f(x(s), s)\), since \(x(s) = w(u)\) for \(\delta(s) = 0\).

Next, note that since \(g(\cdot) \geq 0\), \(w(t)\) is non-decreasing on \([0, u]\), and thus \(w(s) \geq w(0)\) for all \(s \in [0, u]\). Since \(x(s) = w(s)\) at \(s\), we have \(x(s) \geq w(0)\) as well. Thus, \(\delta'(s) = g(x(s)) - f(x(s), s) > 0\), by the assumption of the lemma. Hence, for an \(\epsilon > 0\) sufficiently small, \(\delta(s - \epsilon) < \delta(s) = 0\). This contradicts the fact that of \(\delta(t') = 0\) for all \(t' < s\).
Next, we extend the above scalar comparison inequality to a comparison inequality between scale ODEs, and vector ODES:

**Lemma D.2 (Norm Comparison for Vector ODE).** Let $\| \cdot \|$ denote an arbitrary norm. Suppose that $v(t) \in \mathbb{R}^d$ is a continuously differentiable curve defined on $[0, u)$ such that $\|v'(t)\| \leq g(\|v(t)\|)$ for a non-decreasing function $g$. Fix $\eta > 0$, and let $h(z)$ denote a function such that $h(z) \geq \max\{0, g(z) + \eta\}$ for all $z \geq \|v(0)\|$. Then, if the ODE

$$w(0) = \|v(0)\| + \eta, \quad w'(t) = h(w(t))$$

has a continuously differentiable solution defined on $[0, u)$, then $\|v(t)\| \leq w(t)$ for all $t \in [0, u)$.

**Proof of Lemma D.2.** The main challenge is that $\| v \|$ may be non-smooth. We circumvent this with a Gaussian approximation. Let $c_Z := E_{Z\sim N(0,1)}(\|Z\|)$, and for every $\eta > 0$, and define $\Psi_\eta(v) := E_{Z\sim N(0,1)}(\|v + \frac{\eta}{2c_Z}Z\|)$. Defining $c_Z := E_{Z\sim N(0,1)}(\|Z\|)$, Moreover, we can see that $0 \leq \|v\| \leq \Psi_\eta(v) \leq \|v\| + \eta/2 < \|v\| + \eta$ by Jensen’s inequality and the triangle inequality. Consider the curve $x(t)$

$$x(t) = \Psi_\eta(v(t)), t \in [0, u),$$

Note then that the curve satisfies

$$x(0) = \Psi_\eta(v(0)), \quad \text{and} \quad x'(t) = f(t, x(t)) = \frac{d}{dt}(\Psi_\eta(v(t))),$$

where $f(t, x(t))$ does not depend implicitly on $x(t)$, but only on $t$ through the function $t \mapsto v(t)$.

Now, let $g$ be a monotone function satisfying $\|v'(t)\| \leq g(\|v(t)\|)$, and let $h$ be the assumed function satisfying $h(z) \geq g(z) + \eta$ for all $z \geq \|v(0)\| + \eta$. We define the associated ODE

$$w(0) = \|v(0)\| + \eta, \quad w'(t) = h(w(t)),$$

which we assume is also defined on $[0, u)$. We would like to show that $w(t) > x(t)$ for $t \in [0, u)$. To this end, we would like to verify the conditions of Lemma D.1. First, we have $w(0) = \|v(0)\| + \eta > \Psi_\eta(v(0)) = x(0)$, by above application of the triangle inequality.

For the second condition, we have

$$f(t, x(t)) := \frac{d}{dt}(\Psi_\eta(v(t))) = \frac{d}{dt}E_{Z\sim N(0,1)} \left[ \left\| v + \frac{\eta}{2c_Z}Z \right\| \right]$$

$$\leq E_{Z\sim N(0,1)} \left[ \left\| v' + \frac{\eta}{2c_Z}Z \right\| \right]$$

$$= \Psi_\eta(v'(t)) < \|v'(t)\| + \eta$$

$$\leq g(\|v(t)\|) + \eta \quad \text{(since $g$ satisfies $\|v'(t)\| \leq g(\|v(t)\|)$}$$

$$\leq g(\Psi_\eta(v(t))) + \eta \quad \text{(since $g$ is monotone)}$$

$$= g(x(t)) + \eta.$$ 

Now, if $h(z) \geq g(z) + \eta$ for any $z \geq w(0)$, then, we see that, for any $t \in [0, u)$ such that $x(t) \geq w(0)$, we have $f(t, x(t)) \leq h(x(t))$. Lemma D.1 therefore implies that $x(t) \leq w(t)$ for $t \in [0, u)$. But $x(t) = \Psi_\eta(v(t)) \geq \|v(t)\|$. 

Let us now prove the general guarantee for self-bounding functions:

**Proof of Theorem 13.** Observe that by the valid-function assumption and the assumption that $F(x(0), y(0))$ has a solution, there exists some interval $[0, u)$ on which a solution $y(t)$ to $F(x(t), y(t)) = 0$ exists. Let $u$ denote the maximal value of $u \leq 2$ for which this holds.

First, let us bound $\|y(t)\|$ for $t \in I := [0, u) \cap [0, 1]$. By assumption, there is a function $h(z) \geq g(z) + \eta$, where $g(z)$ is non-negative and non-decreasing, such that the scalar ODE $w'(t) = h(w(t))$ has a solution on
which is well defined and continuous for $\eta$ the condition in (D.1) the above display holds for all $In particular, if $c < 1$ then $s$ which is well defined and continuous for $s \in [0, u)$, since $y'(s)$ is continuously differentiable on this interval. Moreover, $\|y'(t)\| \leq g(y(t)) \leq g(w(t)) \leq g(w(1))$ on $[0, u)$ since $y(t) \leq w(t) \leq w(1)$. Therefore, $y'(t)$ is uniformly bound on $[0, u)$, so that $y(u) = \lim_{s \to u} y(s)$ is well-defined at $u$, and in fact continuous on $[0, u]$.

Since $\tilde{y}(s)$ is continuous on $[0, u)$, and since $F(\cdot, \cdot)$ and $x(s)$ are continuous, $\lim_{s \to u} F(x(s), \tilde{y}(s)) = F(x(u), \tilde{y}(u))$. But by the fundamental theorem of Calculus, we see that $\tilde{y}(s) = y(s)$ for $s \in [0, u)$, so that $F(x(u), \tilde{y}(s)) = F(A(s), B(s), y(s)) = 0$ for $s \in [0, u)$. Thus, $\lim_{s \to u} F(A(s), B(s), \tilde{y}(s)) = 0$, and hence $F(x(u), \tilde{y}(u)) = 0$. This shows that $F(x(u), \cdot) = 0$ has a solution, as needed.

We now prove the corollary for the specific function form $g(z) = cz^p$.

**Proof of Corollary 3.** Fix $\eta > 0$ to be selected later. By assumption, we have

$$\|y'(t)\| \leq g(\|y(t)\|), \quad g(z) = cz^p.$$  

Moreover, for an $\eta > 0$ to be selected, and for $z \geq \|y(0)\|$, we have

$$g(z) + \eta \leq (1 + \frac{\eta}{c\|y(0)\|^p})z^p := h(z).$$

Now, consider the ODE

$$w_\eta'(t) = h(w_\eta(t)), \quad w_\eta(0) = \|y(0)\|_{op} + \eta.$$  

Let us show that, for $\eta$ sufficiently small, this ODE exists on $[0, 1]$. Indeed, the solution to this ODE is

$$\frac{1}{(p-1)w_\eta^{p-1}(0)} - \frac{1}{(p-1)w_\eta^{p-1}(t)} = c_\eta t.$$  

So that a continuously differentiable solution $w_\eta(t)$ exists for $t \in [0, 1]$ as long as

$$c_\eta < \frac{1}{(p-1)w_\eta^{p-1}(0)} = \frac{1}{(p-1)(\|y(0)\| + \eta)^{p-1}},$$

and the solution is given by

$$w_\eta(t) = \left(\frac{1}{\|y(0)\|^{p-1} + (p-1)c_\eta t}\right)^{-1/(p-1)}.$$  

In particular, if $c < \frac{1}{(p-1)(\|y(0)\|)^{p-1}}$, then since $\lim_{\eta \to 0} c_\eta = c$, there exists an $\eta_0 > 0$ sufficiently small so that the condition in (D.1) the above display holds for all $\eta \in (0, \eta_0)$. Therefore, by Theorem 13,

$$\max_{t \in [0, 1]} \|y(t)\| \leq \inf_{\eta \in (0, \eta_0)} w_\eta(t) = \left(\frac{1}{\|y(0)\|^{p-1} - ct}\right)^{-(p-1)} \leq \left(\frac{1}{\|y(0)\|^{p-1}} - c(p-1)\right)^{-1/(p-1)}.$$  

In particular, when $\alpha = c(p-1)\|y(0)\|^{p-1} < 1$, then

$$\max_{t \in [0, 1]} \|y(t)\| \leq (1 - \alpha)^{-1/(p-1)}\|y(0)\|.$$  

Hence, for all $t \in [0, 1]$, we have that $\|y(t)\| \leq c(1 - \alpha)^{-p/(p-1)}\|y(0)\|$. 

\[41\]
E Concentration and Estimation Bounds

E.1 Ordinary Least Squares Tools

In what follows, we develop a general toolkit for analyzing the performance of ordinary least squares. First, let \( \{z_t\}_{t \geq 1} \in (\mathbb{R}^d)^\mathbb{N} \) and \( \{y_t\}_{t \geq 1} \in (\mathbb{R}^m)^\mathbb{N} \) denote sequences of random vectors adapted to a filtration \( \mathcal{F}_t \) for \( t \geq 0 \). We define the covariance \( \Lambda_T := \sum_{t=1}^{T} z_t z_t^\top \). We begin with a standard self-normalized tail bound, see e.g...

**Lemma E.1** (Self Normalized Tail Bound). That \( \{e_t\}_{t \geq 1} \in \mathbb{R}^m \) is a scalar, \( \mathcal{F}_t \) adapted sequence such that \( e_t \mid \mathcal{F}_{t-1} \) is \( \sigma^2 \) subgaussian. Fix a matrix \( V_0 \succeq 0 \). Then, with probability \( 1 - \delta \),

\[
\left\| \sum_{t=1}^{T} x_t e_t \right\|^2_{(V_0 + \Lambda_T)^{-1}} \leq 2\sigma^2 \log \left\{ \frac{1}{\delta} \det \left( V_0^{-1/2} (V_0 + \Lambda_T) V_0^{-1/2} \right) \right\}.
\]

As a corollary, we can state the following bound for Frobenius-norm regress.

**Lemma E.2** (Frobenius Norm Least Squares, Coarse Bound). Suppose that the the sequence \( e_t := y_t - \Theta_* z_t \in \mathbb{R}^m \) is \( \sigma^2 \) subGaussian conditioned on \( \mathcal{F}_{t-1} \), and define the least squares estimator \( \hat{\Theta}_T := \left( \sum_{t=1}^{T} y_t z_t \right) (\sum_{t=1}^{T} z_t z_t^\top)^{-1} \). Then,

\[
P \left\{ \left\| \hat{\Theta}_T - \Theta_* \right\|^2 \geq 3m \lambda_{\min}(\Lambda_T)^{-1} \log \left\{ \frac{m \det(3\Lambda_0^{-1/2}(\Lambda_T) \Lambda_0^{-1/2})}{\delta} \right\} \right\} \cap \{ \Lambda_T \succeq \Lambda_0 \} \leq \delta.
\]

and that

\[
P \left\{ \left\| \hat{\Theta}_T - \Theta_* \right\|^2 \geq 6m \lambda_{\min}(\Lambda_T)^{-1} (d \log 5 + \log \left\{ \frac{d \det(3\Lambda_0^{-1/2}(\Lambda_T) \Lambda_0^{-1/2})}{\delta} \right\} \right\} \cap \{ \Lambda_T \succeq \Lambda_0 \} \right\} \leq \delta. \quad (E.1)
\]

Unfortunately, this tail bound will lead to a dimension dependence of \( \Omega(d) \), which may be suboptimality if \( \Lambda_T \) has eigenvalues of varying magnitude. Instead, we opt for a related bound that pays for Rayleigh quotients between \( \Lambda_0 \) and \( \Lambda_T \):

**Lemma E.3** (Frobenius Norm Least Squares, Refined Bound). Fix a matrix \( \Lambda_0 > 0 \), and denote its eigenbasis \( v_1, \ldots, v_d \), ordered by decreasing eigenvalue. Define the Raleigh quotients \( \kappa_j := \frac{v_j^\top \Lambda_T v_j}{\Lambda_0 v_j^\top v_j} \). Then, in the setting of Lemma E.2, the least squares estimator \( \hat{\Theta}_T \) admits the following bound on its Frobenius error:

\[
P \left\{ \left\| \hat{\Theta}_T - \Theta_* \right\|^2 \geq 3m \sigma^2 \sum_{j=1}^{d} \lambda_j (\Lambda_0^{-1}) \kappa_j \log \left\{ \frac{3\kappa_j}{\delta} \right\} \right\} \cap \{ \Lambda_T \succeq \Lambda_0 \} \right\} \leq \delta.
\]

**Lemma E.4** (Covariance Lower Bound). Suppose that \( z_t \mid \mathcal{F}_{t-1} \sim \mathcal{N}(\mathbb{R}, \Sigma_t) \), where \( \mathbb{R}, \Sigma_t \in \mathbb{R}^d \) is \( \mathcal{F}_{t-1} \)-measurable, and \( \Sigma_t \succeq \Sigma > 0 \). Lastly, suppose \( E \) is any event, and suppose \( \Lambda_T := E[\Lambda_T I(\mathcal{E})] \) satisfies \( \text{tr}(\Lambda_T) \leq TJ \) for some \( J \geq 0 \). Then, for

\[
T \geq \frac{9J}{1600} \left( 2d \log \frac{100}{\delta} + d \log \frac{J}{\lambda_{\min}(\Sigma)} \right),
\]

it holds that, for \( \Lambda_0 := \frac{9T}{1600} \Sigma \)

\[
P \left\{ \{ \Lambda_T \neq \frac{9T}{1600} \Sigma \} \cap \mathcal{E} \right\} \leq 2 \exp \left( -\frac{9}{2000(d+1)} T \right).
\]

**Remark E.1.** This lemma is most useful if \( \Sigma \) is block diagonal, so that the \( v_i \) eigenbasis decouples nicely.
Finally, we state some useful concentration bounds for Gaussian distributions:

\textbf{Lemma E.5} (Hanson Wright, Lemma K.1 from my PCA paper). Let \( g \sim \mathcal{N}(0, I_d) \) be an isotropic Gaussian vector, and let \( A \) be a symmetric matrix. Then,

\[
\mathbb{P} \left[ |g^T A g - \text{tr}(A)| > 2t^{1/2} \|A\|_F + 2t \|A\|_{\text{op}} \right] \leq 2e^{-t}.
\]

By replacing the Frobenius and operator norms in the above inequality with the Hilbert-Schmidt norm, we obtain the following corollary:

\textbf{Corollary 6.} Let \( A \succeq 0 \), and let \( g \sim \mathcal{N}(0, I_d) \). Then, with probability \( 1 - \delta \) for any \( \delta < 1/e \),

\[
g^T A g \lesssim \text{tr}(A) \log \frac{1}{\delta} = \mathbb{E}[g^T A g] \log \frac{1}{\delta}.
\]

\subsection*{E.3 Proofs from Appendix E.1}

\subsubsection*{E.3.1 Proof of Lemma E.2}

We assume without loss of generality that \( \sigma^2 = 1 \). Let \( e_t = y_t - \Theta_* z_t \). Let \( X \in \mathbb{R}^{T \times d} \) denote the matrix whose rows are \( e_t \), and \( E^{(i)} \in \mathbb{R}^T \) denote the vector \((e_{1,i}, \ldots, e_{T,i})\), where \( e_{t,i} \) is the \( i \)-th coordinate of \( e_t \). Let \( \lambda_{\min} := \lambda_{\min}(A_0) \). Then,

\[
\left\| \tilde{\Theta}_T - \Theta_* \right\|_F^2 = \sum_{i=1}^m \left\| \Lambda_T^{-1} X^T E^{(i)} \right\|_2^2 \\
\leq \lambda_{\min}(A_T)^{-1} \sum_{i=1}^m \left\| \Lambda_T^{-1/2} X^T E^{(i)} \right\|_2^2 \\
= \sum_{i=1}^m \lambda_{\min}(A_T)^{-1} \left\| X^T E^{(i)} \right\|_{\Lambda_T^{-1}}^2 \\
\leq \frac{3}{2} \sum_{i=1}^m \lambda_{\min}(A_T)^{-1} \left\| X^T E^{(i)} \right\|_{(\Lambda_T + A_0)^{-1}}^2,
\]

where the last line holds for \( A_0 \preceq A_T \). Invoking Lemma E.1, we have that with probability at least \( 1 - \delta \), it holds for any fixed \( i \in [m] \) that

\[
\left\| X^T E^{(i)} \right\|_{(\Lambda_T + A_0)^{-1}}^2 \leq 2 \log \left\{ \frac{1}{\delta} \det((A_T - \Lambda_0)/2) \left( (A_T + A_0)/2 \right) \right\}.
\]

Since \( A_0 \preceq A \), we have \( \frac{A_0}{2} + A_T \leq \frac{3}{2} A \), when the above can be bounded by

\[
\left\| X^T E^{(i)} \right\|_{(\Lambda_T + A_0)^{-1}}^2 \leq 2 \log \left\{ \frac{1}{\delta} \det((3A_0)^{-1/2} A_T A_0^{-1/2}) \right\}.
\]

Union bounding over \( i \in [m] \) and summing the bound concludes.

\subsubsection*{E.3.2 Proof of Lemma E.3}

We assume without loss of generality that \( \sigma^2 = 1 \). Let \( e_t = y_t - \Theta_* z_t \). Let \( X \in \mathbb{R}^{T \times d} \) denote the matrix whose rows are \( e_t \), and \( E^{(i)} \in \mathbb{R}^T \) denote the vector \((e_{1,i}, \ldots, e_{T,i})\), where \( e_{t,i} \) is the \( i \)-th coordinate of \( e_t \). Let \( \lambda_{\min} := \lambda_{\min}(A_0) \). Moreover, let \( v_1, \ldots, v_d \) denote an eigenbasis for the matrix \( A_0 \), which we note is
non-random. When \( \Lambda_T = X^\top X \succeq \Lambda_0 \), we can then render
\[
\|\hat{\Theta}_T - \Theta_*\|^2_F = \sum_{i=1}^m \left\| (X^\top X)^{-1} X^\top E^{(i)} \right\|^2_2 \\
\geq \sum_{i=1}^m \left\| \Lambda_0^{-1} X^\top E^{(i)} \right\|^2_2 \\
= \sum_{i=1}^m \sum_{j=1}^d \left( v_j^\top \Lambda_0^{-1} X^\top E^{(i)} \right)^2 \\
= \sum_{i=1}^m \sum_{j=1}^d \lambda_j(\Lambda_0)^{-2} \left( v_j^\top X^\top E^{(i)} \right)^2.
\]

Define the vector \( X_j = X v_j \). Then, \( \left( v_j^\top X^\top E^{(i)} \right)^2 \) can be bounded as
\[
\left( v_j^\top X^\top E^{(i)} \right)^2 = \|X_j\|_2^2 (E^{(i)} X_j (X_j^\top X_j)^{-1} X_j^\top E^{(i)}) \\
\leq \frac{3}{2} \|X_j\|_2^2 (E^{(i)} X_j^\top X_j) \left( \frac{1}{2} \lambda_j(\Lambda_0) + X_j^\top X_j \right)^{-1} X_j^\top E^{(i)},
\]
where we use the fact that \( \Lambda_0 \preceq \Lambda_T = X^\top X \). Hence, by the self normalized tail inequality Lemma E.1, it holds with probability \( 1 - \delta \) that
\[
\left( v_j^\top X^\top E^{(i)} \right)^2 \leq 3 \|X_j\|_2^2 \log \frac{\lambda_j(\Lambda_0) + \|X_j\|_2^2}{\lambda_j(\Lambda_0) \delta} \leq 3 \|X_j\|_2^2 \log \frac{3 \|X_j\|_2^2}{\lambda_j(\Lambda_0) \delta}.
\]

Hence, recalling that \( \kappa_j := \frac{v_j^\top \Lambda_T v_j}{v_j^\top \Lambda_0 v_j} \), we conclude that, with probability \( 1 - \delta \),
\[
\|\hat{\Theta}_T - \Theta_*\|^2_F \leq \sum_{i=1}^m \sum_{j=1}^d \lambda_j(\Lambda_0) \|X_j\|_2^2 \log \frac{3 \|X_j\|_2^2}{\lambda_j(\Lambda_0) \delta} \\
= 3m \sum_{j=1}^d \lambda_j(\Lambda_0)^{-1} \kappa_j \log \frac{3 \kappa_j}{\delta}.
\]

\[\square\]

### E.3.3 Proof of Lemma E.4

By the the Paley-Zygmund inequality [Simchowitz et al., 2018, Equation 3.12], one can easily show that the sequence \( (z_t) \) satisfies the \( (1, \Sigma, \frac{3}{10}) \)-block martingale small ball property, see [Simchowitz et al., 2018, Definition 2.1]. Then, for any matrix \( \Lambda_+ \succeq 0 \), [Simchowitz et al., 2018, Section D.2] (correcting the section for a lost normalization factor of \( T \)) shows that
\[
\mathbb{P} \left\{ \Lambda_T \preceq \frac{T}{10} \left( \frac{3}{10} \right)^2 \Sigma \right\} \cap \{ \Lambda_T \preceq \Lambda_+ \} \leq \exp \left( -\frac{1}{10} \left( \frac{3}{10} \right)^2 + 2d \log \left( \frac{100}{3} \right) + \log \det \Lambda_+ (T \Sigma)^{-1} \right) \\
\leq \exp \left( -\frac{9T}{1000} + 2d \log \left( \frac{100}{3} \right) + d \log \frac{\|\Lambda_+\|_{\text{op}}}{T \lambda_{\text{min}}(\Sigma)} \right). \quad (E.2)
\]
Now, notice that if we select \( \Lambda_+ = \frac{\text{tr}(X_T)}{\delta^2} I \), the bound \( \|\Lambda\|_{\text{op}} \leq \text{tr}(\Lambda) \) for \( \Lambda \geq 0 \) and an application of Markov’s inequality show that, \( P(\{\Lambda_T \not\geq \Lambda_+\} \cap \mathcal{E}) \leq \delta \). Hence, we have

\[
P\left[ \Lambda_T \not\geq \frac{T}{16} \left( \frac{3}{10} \right)^2 \right] \leq \inf_{\delta > 0} \exp \left( -\frac{9T}{1000} + 2d \log \left( \frac{100}{3} \right) + d \log \frac{\text{tr}(X_T)}{T\lambda_{\text{min}}(\Sigma)\delta} \right) + \delta
\]

\[
\leq \inf_{\delta > 0} \delta^{-d} \exp \left( -\frac{9T}{1000} + 2d \log \left( \frac{100}{3} \right) + d \log \frac{\text{tr}(X_T)}{T\lambda_{\text{min}}(\Sigma)\delta} \right) + \delta.
\]

Note that balancing \( a\delta^{-d} = \delta \) selects \( \delta = a^{1/d+1} \), giving that the above is at most

\[
2 \exp \left( -\frac{1}{d+1} \left( \frac{9T}{1000} - 2d \log \left( \frac{100}{3} \right) - d \log \frac{\text{tr}(X_T)}{T\lambda_{\text{min}}(\Sigma)} \right) \right).
\]

We conclude by bounding \( \text{tr}(X_T) \leq JT \) by assumption, and adopting some elementary algebra.

### Part II

**Proof of Upper and Lower Bounds**

#### F Proofs for Lower Bound (Section 4)

##### F.1 Proof of Lemma 4.1

Observe that

\[
\max\{\|A_e - A_\star\|_{\text{op}}, \|B_e - B_\star\|_{\text{op}}\} \leq \max\{\|A_e - A_\star\|_F, \|B_e - B_\star\|_F\}
\]

\[
\leq \max\{\|K_\star\|_{\text{op}}^{1/2}, 1\}\|\Delta\|_F
\]

\[
\leq \sqrt{mn\epsilon_{\text{pack}}} \max\{\|K_\star\|_{\text{op}}^{1/2}, 1\} \leq \sqrt{\|P_\star\|_{\text{op}}\sqrt{mn\epsilon_{\text{pack}}}},
\]

where the last inequality is by Lemma B.8. This prove the first point of the lemma. Next, if \( \epsilon_{\text{pack}}^2 \leq \frac{1}{\|P_\star\|_{\text{op}}} C_{\text{safe}}^2(A_\star, B_\star)/nm \), then,

\[
\max\{\|A_e - A_\star\|_{\text{op}}, \|B_e - B_\star\|_{\text{op}}\} \leq \frac{1}{C_{\text{safe}}(A_\star, B_\star)} \leq (1 - 2^{1/5}),
\]

which implies \( \Psi_{\epsilon} \leq 2^{1/3} \max\{1, \|A_\star\|_{\text{op}}, \|B_\star\|_{\text{op}}\} \). Moreover Theorem 5 yields

\[
\|P_e - P_\star\|_{\text{op}} \leq 1.085\|P_\star\|_{\text{op}} \leq 2^{1/5}\|P_\star\|_{\text{op}}.
\]

For the next point, Theorem 12 bounds the error of the Taylor approximation, and implies that for some polynomial \( p \),

\[
\| -(R_u + B_\star^T P_e B_\star)^{-1} \cdot \Delta^T P_e A_{cl,\star} + K_e - K_e \|_F^2
\]

\[
\leq p(\|P_\star\|_{\text{op}}) \max\{\|A_e - A_\star\|_{\text{op}}, \|B_e - B_\star\|_{\text{op}}\}^2 \max\{\|A_e - A_\star\|_F, \|B_e - B_\star\|_F\}^2
\]

\[
\leq p(\|P_\star\|_{\text{op}}) \max\{\|A_e - A_\star\|_F, \|B_e - B_\star\|_F\}^4
\]

\[
\leq (nm)^2 \|P_\star\|_{\text{op}} p(\|P_\star\|_{\text{op}}) \epsilon_{\text{pack}}^4.
\]

\[
:= p_2(p(\|P_\star\|_{\text{op}}))
\]

45
Finally, point 4 follows by bounding

\[
\|K_\star - K_\epsilon\|_F \leq \| (R_u + B_\star^T P_\star B_\star)^{-1} \Delta^T P_\star A_{cl,\star} + K_\star - K_\epsilon \|_F + \|(R_u + B_\star^T P_\star B_\star)^{-1} \Delta^T P_\star A_{cl,\star}\|_F
\]

\[
\leq mn^2 \text{pack} \|P_\star\|_{op} + \| (R_u + B_\star^T P_\star B_\star)^{-1} \Delta^T P_\star A_{cl,\star}\|_F
\]

\[
\leq mn^2 \text{pack} \|P_\star\|_{op} + \|\Delta\|_F \|P_\star\|_{op} \|A_{cl,\star}\|_{op}
\]

\[
\leq mn^2 \text{pack} \|P_\star\|_{op} + \|\Delta\|_F \|P_\star\|_{op}^{3/2} (\text{Lemma B.8})
\]

\[
\leq mn^2 \text{pack} \|P_\star\|_{op} + \epsilon \text{pack} \sqrt{mn} \|P_\star\|_{op}^{3/2}.
\]

By packing $\epsilon^2 \text{pack} \leq 1/mn\text{poly}(\|P_\star\|_{op})$, the above can be made ≤ 2mn$^2$ pack$\|P_\star\|_{op}^3$.

\section*{F.2 Proof of Lemma 4.3}

Our strategy is to relate \(\text{Regret}_T[\pi; A_c, B_c]\) and \(\text{K-Err}_e[\pi]\) to the benchmark induced by following the true optimal policy \(\pi_\star = \pi_\star(A, B)\) which minimizes \(E_{A_c, B_c, \pi} \sum_{t=1}^T c(x_t, u_t)\) over all possible policies \(\pi\).

To begin, consider an arbitrary stabilizable system \((A, B)\). Let \(K_\infty := K_\infty(A, B)\) and \(P_\infty = P_\infty(A, B)\). For \(T\) fixed and a control policy \(\pi\), let

\[
K\text{-Err}[\pi] := E_{A, B, \pi} \left[ \sum_{t=1}^{T/2} \|u_t - K_\infty(A, B)x_t\|_2^2 \right].
\]

We define the \(Q\)-functions and value functions associated with the LQR problem as follows.

\[
Q_{t; T}(x, u) := E_{A, B, \pi_t}[x, u_t, x_u] \sum_{t=1}^T c(x_t, u_t) \mid x_t = x, u_t = u
\]

\[
V_{t; T}(x) := \inf_u Q_{t; T}(x, u),
\]

where \(E_{A, B, \pi_t}(A, B)\) denotes that the state at time \(t\) is \(x_t = x\), inputs is \(u_t = u\), and all future inputs are according to the policy \(\pi_t(A, B)\). Note then that \(\pi_t\) always prescribes the action \(u_t := \arg\min Q_{t; T}(x_t, u)\) at time \(t\). We can now characterize the form of the \(Q_{t; T}\) and \(\pi_t\) using the following lemma:

\textbf{Lemma F.1} (Optimal Finite-Horizon Controllers [Bertsekas, 2005]). Define the elements

\[
P_{t+1} := R_x + A^T P_t A - A^T P_t B \Sigma^{-1}_t B^T P_t A,
\]

\[
\Sigma_{t+1} := R_u + B^T P_t B,
\]

\[
K_{t+1} := -\Sigma^{-1}_{t+1} B^T P_t A,
\]

with the convention that \(P_0 = R_x\). Then, \(V_{t; T}(x) = x^T P_{T-t} x\), and \(Q_{t; T}(x, u) - V_{t; T}(x) = \|u - K_{T-t} x\|_2^2\), and \((\pi_\star)_{t; T}(x_t) = K_{T-t} x_t\).

For completeness, we prove the lemma in Section F.2.1. Having defined the true optimal policy, we that the regret is lower bounded as follows

\textbf{Lemma F.2.} Fix a system \(A, B\), and suppose that \(\text{Regret}_T[\pi; A, B] \leq T J_{A, B}'\). Then,

\[
\text{Regret}_T[\pi; A, B] \geq \frac{1}{2} K\text{-Err}[\pi] - J_{A, B}' 2T \left( \max_{t \geq T/2} \eta_t \right) + \sum_{t \geq 0} \eta_t,
\]

where we define the errors \(\eta_t := \| \Sigma_t^\top (K_\infty - K_t) R_x^{1/2} \|_2^2\).
Proof of Lemma F.2. We compare both the cost under \( \pi \) and the cost under a comparator to \( V_{1:T}(0) \), the value of the optimal policy starting at \( x_1 = 0 \).

\[
\text{Regret}_T[\pi; A, B] = E_{A,B,\pi} \left[ \sum_{t=1}^{T} c_t(x_t, u_t) \right] - V_{1:T}(0) - (TJ^*_A,BK_\infty - V_{1:T}(0))
\]

\[
\geq E_{A,B,\pi} \left[ \sum_{t=1}^{T} c_t(x_t, u_t) \right] - V_{1:T}(0) - (T\sum_{t=1}^{\infty} c_t(x_t, u_t) - V_{1:T}(0)),
\]

where we use the fact that the infinite horizon regret induced by \( K_\star \) on a finite time horizon \( T \) is upper bounded by \( T\times \) the infinite horizon cost (this can be verified by direct computation).

Next, we use the performance difference lemma, which states that for any policy \( \pi' \),

\[
E_{A,B,\pi'} \left[ \sum_{t=1}^{T} c_t(x_t, u_t) \right] - V_{0:T}(0) = \sum_{t=1}^{T} E_{A,B,\pi'} [Q_{t:T}(x_t, u_t) - V_{1:T}(x_t)]
\]

\[
= \sum_{t=1}^{T} E_{A,B,\pi} \left[ \|u_t - K_{T-t}x_t\|_{\Sigma_{T-t}}^2 \right]. \tag{Lemma F.1}
\]

Therefore,

\[
\text{Regret}_T[\pi; A, B] = \sum_{t=1}^{T} E_{A,B,\pi} \left[ \|u_t - K_{T-t}x_t\|_{\Sigma_{T-t}}^2 \right] - \sum_{t=1}^{T} E_{A,B,K_\infty} \left[ \|u_t - K_{T-t}x_t\|_{\Sigma_{T-t}}^2 \right].
\]

Comparator Suboptimality. We begin with the following two claims:

Claim F.3. \( \|(K_\infty - K_{T-t})x_t\|_{\Sigma_{T-t}}^2 \leq \eta_{T-t} \cdot x_t^\top R_x x_t. \)

Proof. We have that

\[
\|(K_\infty - K_{T-t})x_t\|_{\Sigma_{T-t}}^2 = \left\| \Sigma_{T-t}^{1/2} (K_\infty - K_{T-t}) R_x^{-1/2} R_x^{1/2} x_t \right\|^2
\]

\[
\leq \left\| \Sigma_{T-t}^{1/2} (K_\infty - K_{T-t}) R_x^{-1/2} \right\|_2^2 \left\| R_x^{1/2} x_t \right\|^2 = \eta_{T-t} \cdot x_t^\top R_x x_t.
\]

Claim F.4. \( E_{A,B,K_\infty} \sum_{t=1}^{T} x_t^\top R_x x_t \leq T J^*_A,B. \)

Proof. We have

\[
E_{A,B,K_\infty} \sum_{t=1}^{T} x_t^\top R_x x_t \leq E_{A,B,K_\infty} \sum_{t=1}^{T} x_t^\top (R_x + K_\infty^\top R_u K_\infty) x_t
\]

\[
= \text{tr} \left( \sum_{t=1}^{T} \sum_{s=0}^{t} ((A + BK_\infty)^s)^\top (R_x + K_\infty^\top R_u K_\infty)((A + BK_\infty)^s) \right)
\]

\[
\leq \text{tr} \left( \sum_{t=1}^{T} \sum_{s=0}^{t} ((A + BK_\infty)^s)^\top (R_x + K_\infty^\top R_u K_\infty)((A + BK_\infty)^s) \right)
\]

\[
= T \text{tr} (P_\infty(A, B)) = T J^*_A,B,
\]

where the last equalities are by Lemma B.6.

Invoking these two claims, we have

\[
\sum_{t=1}^{T} E_{A,B,K_\infty} \left[ \|u_t - K_{T-t}x_t\|_{\Sigma_{T-t}}^2 \right] \leq \sum_{t=1}^{T} E_{A,B,K_\infty} \eta_t \left[ x_t^\top R_x x_t \right] \leq J^*_A,B \sum_{t=1}^{T} \eta_{T-t} \leq J^*_A,B \sum_{t=0}^{\infty} \eta_t.
\]
Policy Suboptimality. We first make the following claim.

**Claim F.5** (Inner Product Space Give-and-Take). Let \((\mathcal{X}, \langle \cdot, \cdot \rangle_{\mathcal{X}})\) denote an inner product space with induced norm \(\| \cdot \|_{\mathcal{X}}\). Then for any \(x, y \in \mathcal{X}\), \(\| x + y \|_{\mathcal{X}}^2 \geq (1/2) \| x \|_{\mathcal{X}}^2 + (1/2) \| y \|_{\mathcal{X}}^2\).

**Proof.** We have \(\| x + y \|_{\mathcal{X}}^2 = \| x \|_{\mathcal{X}}^2 + \| y \|_{\mathcal{X}}^2 + 2\langle x, y \rangle_{\mathcal{X}}\). Note that, for any \(\alpha > 0\), we have \(2\langle x, y \rangle_{\mathcal{X}} = 2(\alpha^{1/2}x, \alpha^{-1/2}y)_{\mathcal{X}} \leq \alpha \| x \|_{\mathcal{X}}^2 + \alpha^{-1} \| y \|_{\mathcal{X}}^2\). Setting \(\alpha = 1/2\), we have \(2\langle x, y \rangle_{\mathcal{X}} \leq 1/2 \| x \|_{\mathcal{X}}^2 + 2 \| y \|_{\mathcal{X}}^2\). Hence \(\| x + y \|_{\mathcal{X}}^2 \geq \| x \|_{\mathcal{X}}^2 + \| y \|_{\mathcal{X}}^2 - (1/2) \| x \|_{\mathcal{X}}^2 + 2 \| y \|_{\mathcal{X}}^2\) = \(1/2 \| x \|_{\mathcal{X}}^2 - \| y \|_{\mathcal{X}}^2\). \(\square\)

We can now lower bound
\[
\mathbb{E}_{A, B, \pi} \left[ \sum_{t=1}^{T} \| u_t - K_{T-t} x_t \|_{\Sigma_{T-t}}^2 \right]
\geq \mathbb{E}_{A, B, \pi} \left[ \sum_{t=1}^{T/2} \| u_t - K_{T-t} x_t \|_{\Sigma_{T-t}}^2 \right]
\geq \mathbb{E}_{A, B, \pi} \left[ \sum_{t=1}^{T/2} \frac{1}{2} \| u_t - K_{T-t} x_t \|_{\Sigma_{T-t}}^2 - \| (K_{T-t} - K_{\infty}) x_t \|_{\Sigma_{T-t}}^2 \right]
\geq \mathbb{E}_{A, B, \pi} \left[ \sum_{t=1}^{T/2} \frac{1}{2} \| u_t - K_{T-t} x_t \|_{\Sigma_{T-t}}^2 - \| (K_{T-t} - K_{\infty}) x_t \|_{\Sigma_{T-t}}^2 \right].
\]
(\(\Sigma_{T-t} \geq R_\alpha \geq I\))

The above expression is equal to
\[
= \frac{1}{2} K_{\text{Err}}[\pi] - \sum_{t=1}^{T/2} \mathbb{E}_{A, B, \pi} \left[ \| (K_{T-t} - K_{\infty}) x_t \|_{\Sigma_{T-t}}^2 \right]
\geq \frac{1}{2} K_{\text{Err}}[\pi] - \sum_{t=1}^{T/2} \eta_t \mathbb{E}_{A, B, \pi} \left[ x_t^\top R_x x_t \right]
\geq \frac{1}{2} K_{\text{Err}}[\pi] - 2 \max_{t \geq T/2} \eta_t J_{A, B}^* \quad \text{(Claim F.6)}
\]
where the last inequality uses the following claim.

**Claim F.6.** If \(\text{Regret}_{A, B, T}[\pi] \leq T J_{A, B}^*\) (in particular, under Assumption 3), then for any \(\tau \leq T\) and \(Q \leq R_x\), we have \(\sum_{t=1}^{\tau} \mathbb{E}_{A, B, \pi} [x_t^\top Q x_t] \leq 2 T J_{A, B}^*\).

The claim is stated for an arbitrary matrix \(Q\) so that it can be specialized where necessary.

**Proof.** We have \(\sum_{t=1}^{\tau} \mathbb{E}_{A, B, \pi} [x_t^\top Q x_t] \leq \sum_{t=1}^{\tau} \mathbb{E}_{A, B, \pi} [x_t^\top R_x x_t] \leq \sum_{t=1}^{\tau} \mathbb{E}_{A, B, \pi} [x_t^\top R_x x_t + u_t^\top R_u u_t] = \text{Regret}_{A, B, T}[\pi] + T J_{A, B}^* \leq 2 T J_{A, B}^*. \) \(\square\)

Combining the comparator suboptimality and policy suboptimality bounds completes the proof of Lemma F.2.

The next lemma shows that the error sequence \(\eta_t\) has geometric decrease:

**Lemma F.7** (Bound on \(\eta_t\)). Let \((A, B)\) be statibilizable. Then, for \(\eta_t\) defined above, we have
\[
\eta_t \leq \left(1 + \frac{\nu}{2}\right)^{-t}, \quad \text{where} \quad \nu = 2 \| P_\infty(A, B) \|_{\text{op}} \Psi(A, B)^2.
\]

48
Proof of Lemma F.7. Since $R_x \succeq I$, 
\[ \eta_t \leq \frac{1}{\lambda_{\min}(R_x)} \left\| \Sigma_t^{1/2}(K_{\infty} - K_{T-t}) \right\|_{op}^2 \leq \left\| \Sigma_t^{1/2}(K_{\infty} - K_{T-t}) \right\|_{op}^2. \]

Next, observe that from Lemma F.1 we have 
\[ \left\| \Sigma_{T-t}^{1/2}(K_{\infty} - K_{T-t}) \right\|_{op}^2 = \sup_{\|x\| \leq 1} \| (K_{\infty} - K_{T-t})x \|_{\Sigma_{T-t}}^2 = \sup_{\|x\| \leq 1} \| Q_{t:T}(x, K_{\infty}x) - V_{T:t}(x) \|. \]

Since $Q_{t:T}(x, K_{\infty}x)$ is a finite horizon Q-function for a stationary process with non-negative rewards, we have $Q_{t:T}(x, u) \leq Q_{\infty}(x, u)$. Therefore, the above is 
\[
\begin{align*}
\eta_t &\leq \sup_{\|x\| \leq 1} \| Q_{\infty}(x, K_{\infty}x) - V_{T:t}(x) \| \\
&= \sup_{\|x\| \leq 1} \| V_{\infty}(x) - V_{T-t}(x) \| \\
&= \sup_{\|x\| \leq 1} \| x^T P_{\infty} x - x^T P_{t:T} x \| \\
&= \| P_{\infty} - P_{T-t} \|_{op},
\end{align*}
\]

where we use that $P_{\infty}$ is the value function for the infinite horizon process (Lincoln and Rantzer [2006, Proposition 1]). By reparametrizing, we have verified that 
\[ \eta_t \leq \| P_{\infty} - P_t \|_{op}. \]

To conclude, we apply Lemma F.8, which implies that \( \| P_{\infty} - P_{t:T} \|_2 \leq (1 + \frac{1}{\nu})^{-(T-t+1)} \), where $\nu$ is as in the lemma statement:

Lemma F.8 (Dean et al. [2018], Lemma E.6). Consider the Ricatti recursion 
\[ P_{t+1} = R_x + A^T P_t A - A^T B P_t (R_u + B^T P_t B)^{-1} B^T P_t A, \]

where $R_x$ and $R_u$ are positive definite and $P_0 = 0$. When $P_{\infty}$ is the unique solution of the DARE, we have 
\[ \| P_t - P_{\infty} \|_{op} \leq \| P_{\infty} \|_{op} \left( 1 + \frac{1}{\nu} \right)^{-t} \tag{F.1} \]

where $\nu = 2\| P_{\infty} \|_{op} \left( \frac{\| A \|_{op}^2}{\lambda_{\min}(R_x)} \vee \frac{\| B \|_{op}^2}{\lambda_{\min}(R_u)} \right)^{11}.$

In our setting, we can take $\nu \leq 2\| P_{\infty} \|_{op} \max\{\| A \|_{op}^2, \| B \|_{op}^2 \} \leq 2\Psi(A, B)\| P_{\infty} \|_{op}^2$, since $R_x, R_u \succeq I$.\]

We can now conclude the proof of Lemma 4.3:

Proof of Lemma 4.3. From Lemma F.2, we have the lower bound 
\[ \text{Regret}_T[\pi; A, B_e] \geq \frac{1}{2} K\text{-Err}_e[\pi] - J_{e} \left( 2T \left( \max_{t \geq T/2} \eta_t \right) + \sum_{t \geq 0} \eta_t \right), \]

Recall $\nu := 2\| P_{t:T} \|_{op} \Psi_e^2$ from Lemma F.7, and that $\eta_t \leq \| P_t \|_{op} \left( 1 + \nu^{-1} \right)^t \leq \exp(-t/\nu)$. Therefore 
\[ \sum_{t \geq 0} \eta_t \leq 2\| P_{t:T} \|_{op} \Psi_e^2. \]

\[ 11 \text{The bound in Dean et al. [2018] is slightly incorrect in that it is missing a factor of } \| P_{\infty} \|_{op}. \text{ The reader can verify the correctness of our statement by examining Lincoln and Rantzer [2006, Proposition 1].} \]
Hence, if $T \geq 2\nu \log(2T)$, we have that

$$2T \left( \max_{t \geq T/2} \eta_t \right) \leq \|P_e\|_\op \leq \|P_e\|_\op^2,$$

where we use $P_\infty(\cdot, \cdot) \succeq I$ (Lemma B.5). Hence, for such $T,$

$$\text{Regret}_T[\pi; A, B] \geq \frac{1}{2} K\text{-Err}_e[\pi] - 3\|P_e\|_\op^2 \Psi^2_e$$

$$\geq \frac{1}{2} K\text{-Err}_e[\pi] - J \|P_e\|_\op^2 \Psi^2_e$$

$$\geq \frac{1}{2} K\text{-Err}_e[\pi] - d_\infty^2 \|P_e\|_\op^3 \Psi^4_e.$$

Since $\nu \geq 1,$ the condition $T \geq 2\nu \log(2T)$ holds as long as $T \geq c' \nu^2 = c' \|P_e\|_\op^2 \Psi_e^4 c'.$ Reparametrizing in terms of $P_e, \Psi_e$ in view of Lemma 4.1 concludes the proof. \hfill \square

### F.2.1 Proof of Lemma F.1

We first recall a standard expression for the value function [Bertsekas, 2005, Section 4.1]:

$$V_t(x) = \|x\|^2_{P_{T-t}} + \sum_{s=t+1}^T \tr(P_{T-s}).$$

To obtain the expression for the $Q_t,$ we have

$$Q_t(x, u) = c(x, u) + \mathbb{E}_{w_t}[V_{t+1}(Ax + Bu + w_t)]$$

$$= c(x, u) + (Ax + Bu)\top P_{T-(t+1)}(Ax + Bu) + \mathbb{E}[w_t\top P_{T-(t+1)}w_t] + \sum_{s=t+2}^T \tr(P_{T-s})$$

$$= c(x, u) + (Ax + Bu)\top P_{T-(t+1)}(Ax + Bu) + \sum_{s=t+1}^T \tr(P_{T-s}).$$

Note that $V_t(x) := \min_u Q_t(x, u),$ and $Q_t(x, u)$ is a quadratic function. We can compute

$$\arg\min_u Q_t(x, u) = \arg\min_u c(x, u) + (Ax + Bu)\top P_{T-(t+1)}(Ax + Bu) + \beta_t$$

$$= \arg\min_u x\top Rx + u\top Ru + (Ax + Bu)\top P_{T-(t+1)}(Ax + Bu) + \beta_t$$

$$= \arg\min_u (Ru + B\top P_{t+1:T}B)u + 2u\top B\top P_{T-(t+1)}Ax$$

$$= -(Ru + B\top P_{T-(t+1)}B)^{-1}B\top P_{t+1:T}Ax$$

$$= K_{t:T}x.$$ 

Moreover, since $Q_t(x, u)$ is quadratic in $u$ with quadratic form $\Sigma_{T-t} = (Ru + B\top P_{T-(t+1)}B)$ and the gradient $\nabla_u Q_t(x, u)$ vanishes at the minimizer $u = K_{t:T}x,$ we have

$$Q_t(x, u) - V_t(x) = Q_t(x, u) - Q_t(x, K_{t:T}x) = \|u - K_{t:T}x\|_{\Sigma_{T-t}}^2.$$

\hfill \square

### F.3 Proof of Lemma 4.4

Again, let us prove the lemma for an arbitrary stabilizable $(A, B),$ and then specialize to the packing instances $(A_\varepsilon, B_\varepsilon).$ For a fixed policy $\pi,$ and let all probabilities and expectations be under the law $\mathbb{P}_{\pi, A, B}.$ Let
$K_\infty = K_\infty(A, B)$ and let $\delta_t := u_t - K_\infty x_t$, and note that $\text{K-Err}[\pi] = \mathbb{E}_{A, B, \pi}[\sum_{t=1}^T \|\delta_t\|^2]$. Define the covariance matrix

$$
\Lambda_{\frac{T}{2}} := \sum_{t=1}^{\frac{T}{2}} x_t x_t^T .
$$

For some constant $c > 0$ to be chosen at the end of the proof, consider a 'thresholded' least squares estimator defined as follows:

$$
\hat{K}_{\text{LS}} := \mathbb{I}\left\{ \Lambda_{\frac{T}{2}} \preceq \frac{T}{2} I \right\} \cdot \left( \sum_{t=1}^{\frac{T}{2}} u_t x_t^T \right) \Lambda_{\frac{T}{2}}^{-1}
$$

$$
= \mathbb{I}\left\{ \Lambda_{\frac{T}{2}} \preceq \frac{T}{2} I \right\} \left( \sum_{t=1}^{\frac{T}{2}} \delta_t x_t^T \right) \Lambda_{\frac{T}{2}}^{-1} + \mathbb{I}\left\{ \Lambda_{\frac{T}{2}} \preceq \frac{T}{2} I \right\} \left( \sum_{t=1}^{\frac{T}{2}} K_\infty x_t x_t^T \right) \Lambda_{\frac{T}{2}}^{-1}
$$

$$
= \mathbb{I}\left\{ \Lambda_{\frac{T}{2}} \preceq \frac{T}{2} I \right\} K_\infty + \mathbb{I}\left\{ \Lambda_{\frac{T}{2}} \preceq \frac{T}{2} I \right\} \left( \sum_{t=1}^{\frac{T}{2}} \delta_t x_t^T \right) \Lambda_{\frac{T}{2}}^{-1} .
$$

Hence, introducing the matrices $X := [x_1 | x_2 | \ldots | x_{\frac{T}{2}}]$, and $\Delta := [\delta_1 | \delta_2 | \ldots | \delta_{\frac{T}{2}}]$, we have

$$
\mathbb{E} \left[ \| \hat{K}_{\text{LS}} - K_\infty \|_F^2 \right] = \mathbb{E} \left[ \| K_\infty \|_F^2 \mathbb{I}\left\{ \Lambda_{\frac{T}{2}} \preceq \frac{T}{2} I \right\} \right] + \mathbb{E} \left[ \left\| \left( \sum_{t=1}^{\frac{T}{2}} \delta_t x_t^T \right) \Lambda_{\frac{T}{2}}^{-1} \right\|_F^2 \right]
$$

$$
= \mathbb{E} \left[ \left\| \sum_{t=1}^{\frac{T}{2}} \delta_t x_t^T \right\|_F^2 \right] + \mathbb{E} \left[ \left\| \left( \sum_{t=1}^{\frac{T}{2}} \delta_t x_t^T \right) \Lambda_{\frac{T}{2}}^{-1} \right\|_F^2 \right]
$$

$$
\leq \mathbb{E} \left[ \left\| \sum_{t=1}^{\frac{T}{2}} \delta_t x_t^T \right\|_F^2 \right] + \frac{1}{c^2 T} \mathbb{E} \left[ \| \Lambda_{\frac{T}{2}} \|_F^2 \right] + \frac{1}{c T} \text{K-Err}[\pi]
$$

$$
\leq 2\mathcal{J}_\infty(A, B) \mathbb{E} \left[ \left\| \sum_{t=1}^{\frac{T}{2}} \delta_t x_t^T \right\|_F^2 \right] + \frac{2}{c T} \text{K-Err}[\pi]
$$

where the second-to-last line follows since $\| \Lambda_{\frac{T}{2}} \|_F^2 = \sum_{t=1}^{\frac{T}{2}} \| \delta_t \|^2$, and the last line uses by Lemma B.8 which bounds $K_\infty^T K_\infty \preceq P_\infty(A, B)$, so that $\| K_\infty \|_F^2 \leq \text{tr}(P_\infty(A, B)) = \mathcal{J}_A^* B$.

In order to conclude the proof, we need to select show that, for some constant $c$ sufficiently small and $\frac{T}{2}$ sufficiently large, $\mathbb{P} \left[ \Lambda_{\frac{T}{2}} \preceq \frac{T}{2} I \right]$ is negligible. Let us now apply Lemma E.4. Let $\mathcal{F}_t$ denote the filtration generated by $(x_s, u_s)_{s \leq t}$ and $u_{t+1}$. Observe that $x_t | \mathcal{F}_{t-1} \sim \mathcal{N}(\theta_t, I)$, where $\theta_t$ is $\mathcal{F}_{t-1}$-measurable.

Let $x_t \neq 0$. We can then bound

$$
\mathbb{E} \left[ \text{tr} \left( \sum_{t=1}^{\frac{T}{2}} x_t x_t^T \right) \right] \leq \mathbb{E} \left[ \sum_{t=1}^{\frac{T}{2}} x_t^T R x_t + u_t^T R u_t \right] \leq 2 \mathcal{J}_A^* B T ,
$$

by the Assumption 3 and Claim F.6. Hence, $\text{tr}(\mathbb{E}[\Lambda_{T/2}]) \leq \frac{T}{2} \cdot (4 \mathcal{J}_A^* B)$. Therefore, if

$$
T \geq \frac{2000}{9} \left( 2d_x \log \frac{100}{\delta} + d_x \log 4 \mathcal{J}_A^* B \right),
$$

51
we have that
\[
\mathbb{P} \left[ A_{T/2} \neq \frac{9(T/2)}{1600} \right] \leq 2 \exp \left( -\frac{9}{2000} d_s + \log T \right).
\]
In particular, there exists a universal constants \( c, c_{LS} \) such that (recalling \( J_{A_s, B_s}^\ast = \text{tr}(P_\infty(A_s, B_s)) \))
\[
T \geq c d_s \log(1 + d_s \| P_\infty(A_s, B_s) \|_{op}) \geq c d_s \log(1 + J_{A_s, B_s}^\ast).
\]
then for a universal constant \( c_{LS} \), we have
\[
\mathbb{E} \left[ \| \bar{K}_{LS} - K_\infty \|_F^2 \right] \leq \gamma_{hs} + \frac{1}{T c_{LS}} - \text{K-Err}[\pi].
\]
Moreover, for \((A_s, B_s)\), we can upper bound \( \| P_s \|_{op} \lesssim \| P_1 \|_{op} \) (and ammend \( c \) accordingly) (Lemma 4.1), concluding the proof.

**F.4 Proof of Lemma 4.5**

Let \( \tau = T/2 \). Recall that our packing consists of systems \((A_s, B_s)\) indexed by sign-vectors \( e \in \{-1, 1\}^{[n] \times [m]} \):
\[
(A_s, B_s) := (A_s - \Delta_s K_s, B_s + \Delta_s), \quad \text{where } \Delta_s = \epsilon \sum_{i=1}^n \sum_{j=1}^m e_{i,j} w_i v_j^\top.
\]

To avoid the use of too many indices, we let \( q := (i, j) \) denote a stand in for the double indices \( i, j \), with \( q_1 = i \) and \( q_2 = j \). Given an indexing vector \( e \in \{-1, 1\}^{[n] \times [m]} \), \( e^\epsilon \) denote the vector consisting of coordinates of \( e \) other than \((q_1, q_2)\). For \( a \in \{-1, 1\} \), we set
\[
\Delta_{a,q,e^\epsilon} := \epsilon \left( a e_{q_1,q_2} + \sum_{q' \neq q} e_{q_1,q_2}' w_{q_1} v_{q_2}^\top \right).
\]
and define \( A_{a,q,e^\epsilon}, B_{a,q,e^\epsilon} \) analogously, let \( \mathbb{P}_{a,q,e^\epsilon} \) denote the law of the first \( \tau = T/2 \) rounds under \( \mathbb{P}_{A_{a,q,e^\epsilon}, B_{a,q,e^\epsilon}, \mathbb{A}^\epsilon} \).

In the proof, we will now consider an indexing vector \( e \) drawn uniformly from \( \{-1, 1\}^{[n] \times [m]} \). We will then let \( \mathbb{P}_{e^\epsilon} [\mathbb{P}_{a,q,e^\epsilon}] \), marginalizing over the entries \( e_{q}^\epsilon \). Our proof now follows. We note then that, for any \( q \) and any \( \hat{e} \) that depends only on the first \( \tau = T/2 \) time steps, we can bound
\[
\mathbb{E}_{e^\epsilon} \mathbb{E}_{A_s, B_s} [\| e_q - \hat{e}_q \|] = \mathbb{E}_{e^\epsilon \sim \{-1, 1\}} \mathbb{E}_{e^\epsilon} [\mathbb{E}_{A_{e^\epsilon,q,e^\epsilon}, B_{e^\epsilon,q,e^\epsilon}} [\| e_q - \hat{e}_q \|]]
\]
\[
= \mathbb{E}_{e^\epsilon \sim \{-1, 1\}} \mathbb{E}_{e^\epsilon,q} [\| e_q - \hat{e}_q \|] \geq \frac{1}{2} (1 - \text{TV}(\mathbb{P}_{0,q}, \mathbb{P}_{1,q})).
\]
Hence, by Cauchy Schwartz,
\[
\mathbb{E} \left[ \sum_q | e_q - \hat{e}_q \| \right] \geq \sum_q \frac{1}{2} (1 - \text{TV}(\mathbb{P}_{0,q}, \mathbb{P}_{1,q}))
\]
\[
\geq \frac{nm}{2} \sum_q \left( 1 - \sqrt{\frac{1}{nm} \sum_q \text{TV}(\mathbb{P}_{0,q}, \mathbb{P}_{1,q})^2} \right).
\]
Moreover, by Jensen’s inequality followed by a symmetrized Pinsker’s inequality,
\[
\text{TV}(\mathbb{P}_{0,q}, \mathbb{P}_{1,q})^2 \leq \mathbb{E}_{e^\epsilon} \left[ \text{TV}(\mathbb{P}_{-1,q,e^\epsilon}, \mathbb{P}_{1,q,e^\epsilon})^2 \right]
\]
\[
\leq \frac{1}{2} \mathbb{E}_{e^\epsilon} \left[ \frac{\text{KL}(\mathbb{P}_{-1,q,e^\epsilon}, \mathbb{P}_{1,q,e^\epsilon})^2}{2} + \frac{\text{KL}(\mathbb{P}_{1,q,e^\epsilon}, \mathbb{P}_{-1,q,e^\epsilon})^2}{2} \right].
\]
We now require the following lemma to compute the relevant KL-divergences, which we prove shortly below:
Lemma F.9. Let $\Delta^{(0)}, \Delta^{(1)} \in \mathbb{R}^{d_x \times d_q}$, $\tau \in \mathbb{N}$, and let $A_*, B_*$ be the nominal systems defined above. For $i \in \{0, 1\}$, let $\mathbb{P}_i$ denote the law of the first $\tau$ iterates under $\mathbb{P}_{A_* - \Delta^{(i)} K, \mathbb{B} + \Delta^{(i)} \cdot \text{Alg}}$. Then,

$$\text{KL}(\mathbb{P}_0, \mathbb{P}_1) = \frac{1}{2} \text{tr} \left( \left( \Delta^{(0)} - \Delta^{(1)} \right) \Lambda_{\tau}(\Delta^{(0)}) \left( \Delta^{(0)} - \Delta^{(1)} \right)^\top \right).$$

where we have defined the matrix

$$\Lambda_{\tau}(\Delta) := \mathbb{E}_{A_* - \Delta K, B_* + \Delta \cdot \text{Alg}} \left[ \sum_{t=1}^{\tau} (u_t - K x_t) (u_t - K x_t)^\top \right].$$

We can then compute

$$\text{KL}(\mathbb{P}_{1, q, \epsilon_1}, \mathbb{P}_{1, q, \epsilon_2}) = \text{tr}((\Delta_{1, q, \epsilon_1} - \Delta_{1, q, \epsilon_2})^\top \Lambda_{\tau}(\Delta_{1, q, \epsilon_1} - \Delta_{1, q, \epsilon_2}))$$

$$= 2\epsilon^2 \text{tr}(u_{q_1} w_{q_1}^\top \Lambda_{\tau}(\Delta_{1, q, \epsilon_1} - \Delta_{1, q, \epsilon_2}) w_{q_1}^\top)$$

$$= 2\epsilon^2 w_{q_2}^\top \Lambda_{\tau}(\Delta_{1, q, \epsilon_1} - \Delta_{1, q, \epsilon_2}) w_{q_2}.$$ 

Hence, we have

$$\text{TV}(\mathbb{P}_{0, q, \epsilon}, \mathbb{P}_{1, q}) \leq \frac{1}{2} \cdot 2\epsilon^2 w_{q_2}^\top \left( \mathbb{E}_{\epsilon_1} \left[ \frac{\Lambda_{\tau}(\Delta_{0, q, \epsilon_1} - \Delta_{0, q, \epsilon_2}) + \Lambda_{\tau}(\Delta_{1, q, \epsilon_1} - \Delta_{1, q, \epsilon_2})}{2} \right] \right) w_{q_2}$$

$$= \epsilon^2 w_{q_2}^\top (\mathbb{E}_{\epsilon} \left[ \Lambda_{\tau}(\Delta_\epsilon) \right]) w_{q_2}.$$ 

Hence, since $\{w_j\}$ for an orthonormal basis,

$$\sum_q \text{TV}(\mathbb{P}_{0, q, \epsilon}, \mathbb{P}_{1, q}) \leq \sum_q \epsilon w_{q_2}^\top (\mathbb{E}_{\epsilon} \left[ \Lambda_{\tau}(\Delta_\epsilon) \right]) w_{q_2}$$

$$= \epsilon \sum_{i=1}^{m} \sum_{j=1}^{n} w_{j}^\top (\mathbb{E}_{\epsilon} \left[ \Lambda_{\tau}(\Delta_\epsilon) \right]) w_{j}$$

$$\leq m \epsilon^2 \text{tr}(\mathbb{E}_{\epsilon} \left[ \Lambda_{\tau}(\Delta_\epsilon) \right]).$$

We can simplify further

$$\text{tr}(\mathbb{E}_{\epsilon} \left[ \Lambda_{\tau}(\Delta_\epsilon) \right]) = \mathbb{E}_{\epsilon} \left[ \text{tr}(\Lambda_{\tau}(\Delta_\epsilon)) \right]$$

$$= \mathbb{E}_{\epsilon} \left[ \text{tr} \left( \mathbb{E}_{A_* - \Delta K, B_* + \Delta \cdot \text{Alg}} \left[ \sum_{t=1}^{\tau} (u_t - K x_t) (u_t - K x_t)^\top \right] \right) \right]$$

$$= \mathbb{E}_{\epsilon} \left[ \mathbb{E}_{A_* B_* \cdot \text{Alg}} \left[ \sum_{t=1}^{\tau} \text{tr} \left( (u_t - K x_t) (u_t - K x_t)^\top \right) \right] \right]$$

$$= \mathbb{E}_{\epsilon} \left[ \mathbb{E}_{A_* B_* \cdot \text{Alg}} \left[ \sum_{t=1}^{\tau} \|u_t - K x_t\|^2 \right] \right].$$

Therefore, we conclude

$$\mathbb{E} \left[ \sum_q |e_q - \hat{e}_q| \right] \geq \frac{nm}{2} \sum_q \left( 1 - \sqrt{\frac{\epsilon^2}{n} \mathbb{E}_{\epsilon} \left[ \mathbb{E}_{A_* B_* \cdot \text{Alg}} \left[ \sum_{t=1}^{\tau} \|u_t - K x_t\|^2 \right] \right]} \right).$$

This concludes the proof of the proposition. \qed
F.4.1 Proof of Lemma F.9

By convexity of KL and Jensen’s inequality, one can see that the KL under a randomized algorithm Alg_{rand} is upper bounded by the largest KL divergence attained by one of the deterministic algorithms corresponding to a realization of its random seeds. Hence, we may assume without loss of generality that Alg is deterministic.

By first conditioning the performance of Alg on its random seed, then integrating the KL combination Note that by we may assume that Alg is deterministic. Let \( F_{t-1} \) denote the filtration generated by \((x_{i:t-1}, u_{i:t-1})\).

\[
\text{KL}(P_0, P_t) = \sum_{t=1}^{\tau} \mathbb{E}_{A((\Delta(0), B(\Delta(0)), \text{Alg})[\text{KL}(P_0(x_t, u_t | F_{t-1}), P_{\Delta,t}(x_t, u_t | F_{t-1})]],
\]

where \( P_0(x_t, u_t | F_{t-1}) \) denotes the conditional probability law. Note that \( u_t \) is deterministic given \( F_{t-1} \). Moreover, \( x_t | F_{t-1} \) has the distribution of \( \mathcal{N}((A + \Delta(1)K_x)x_t + (B + \Delta(1))u_t, I) \) under \( P_t(. | F_{t-1}) \). Hence, using the standard formula for Gaussian KL,

\[
\text{KL}(P_t(x_t, u_t | F_{t-1}), P_t(x_t, u_t | F_{t-1})) = \frac{1}{2} \| (A - \Delta(0)K_x)x_t + (B + \Delta(0)) - (A - \Delta(1)K_x)x_t + (B + \Delta(1)) \|_2^2
\]

\[
= \frac{1}{2} \| (\Delta(0) - \Delta(1))(u_t - K_x) \|_2^2
\]

\[
= \frac{1}{2} \text{tr}((\Delta(0) - \Delta(1))^\top(u_t - K_x)(u_t - K_x)(\Delta(0) - \Delta(1))).
\]

The lemma now follows from summing from \( t = 1, \ldots, \tau \) and taking expectations.

F.5 Proof of Lemma 4.6

We have \( \mathbb{I}(\hat{e}_{i,j} \neq \hat{e}_{i,j}(\hat{K})) = \mathbb{I}(\hat{e}_{i,j} \neq \hat{e}_{i,j}(\hat{K})) \) and \( \mathbb{I}(\hat{e}_{i,j} = \hat{e}_{i,j}(\hat{K})) \neq 0 \). Define the Taylor approximation error matrix \( \Delta_{2,\varepsilon} := K_e - (R_u + B_i^\top P_s)\varepsilon^{-1}(\Delta_e A_{cl, s} P_s) - K_e \). We then have

\[
e_i,j w_i^\top (K - K_e) e_j \geq e_i,j w_i^\top (K_e - K_e) e_j - |w_i^\top (K - K_e) e_j|
\]

\[
\geq e_i,j w_i^\top (R_u + B_i^\top P_s)\varepsilon^{-1}(\Delta_e A_{cl, s} P_s) e_j - |w_i^\top \Delta_{2,\varepsilon} e_j| - |w_i^\top (K - K_e) e_j|
\]

\[
= e_i,j \frac{\sigma_j(A_{cl, s} P_s)}{\sigma_j(R_u + B_i^\top P_s)\varepsilon^{-1}} w_i^\top \Delta_{2,\varepsilon} e_j - \left( |w_i^\top \Delta_{2,\varepsilon} e_j| + |w_i^\top (K - K_e) e_j| \right).
\]

where we use the definition of \( w_i \) and \( e_j \), as less as \( \sigma_j(A_{cl, s} P_s) \geq \sigma_j(A_{cl, s}) \) since \( P_s \geq I \). Since \( \{w_i\} \) and \( \{v_j\} \) form an orthonormal basis, we have \( w_i^\top \Delta_{2,\varepsilon} e_j = \sum_{i' = 1}^n \sum_{j' = 1}^m (e_{pack,e_{i',j'}} w_i v_j) e_{pack,e_{i',j'}} \). Hence,

\[
e_i,j w_i^\top (K - K_e) e_j \geq \nu_m \epsilon_{\text{pack}} - \left( |w_i^\top \Delta_{2,\varepsilon} e_j| + |w_i^\top (K - K_e) e_j| \right).
\]

Hence, for any \( u \in (0,1) \),

\[
\mathbb{I}\left( e_i,j w_i^\top (K - K_e) e_j \leq 0 \right) \leq \mathbb{I}\left( |w_i^\top (K - K_e) e_j| \geq \sqrt{u} \nu_m \epsilon_{\text{pack}} \right) + \mathbb{I}\left( |w_i^\top \Delta_{2,\varepsilon} e_j| \geq (1 - \sqrt{u}) \nu_m \epsilon_{\text{pack}} \right)
\]

\[
\leq \frac{|w_i^\top (K - K_e) e_j|^2}{u \nu_m^2 \epsilon_{\text{pack}}^2} + \frac{|w_i^\top \Delta_{2,\varepsilon} e_j|^2}{(1 - \sqrt{u})^2 \nu_m^2 \epsilon_{\text{pack}}^2}.
\]

Since \( w_i, v_j \) form an orthonormal basis, we have

\[
d_{\text{ham}}(e_i,j, \hat{e}_{i,j}(\hat{K})) = \sum_{i=1}^n \sum_{j=1}^m \mathbb{I}\left( e_i,j w_i^\top (K - K_e) e_j \leq 0 \right)
\]

\[
\leq \frac{||\hat{K} - K||^2}{u \nu_m^2 \epsilon_{\text{pack}}^2} + \frac{||\Delta_{2,\varepsilon}||^2}{(1 - \sqrt{u})^2 \nu_m^2 \epsilon_{\text{pack}}^2}.
\]
Finally, since $\|\Delta_{2,e}\|_F^2 \leq (nm)^2 \epsilon_p^2 \mathcal{P}_2(\|P_e\|_\infty)^2$ by Lemma 4.1, we have that for $u = 1/\sqrt{2}$ and for $\epsilon_p^2 \leq \frac{1}{16nm} \mathcal{P}_2(\|P_e\|_\infty) \leq \frac{1}{16m} (1 - 1/\sqrt{2}) \sqrt{20/\mathcal{P}_2(\|P_e\|_\infty)}$ that the above is at most

$$d_{\text{ham}}(e_{i,j}, \hat{e}_{i,j}(\hat{K})) \leq \frac{2\|\hat{K} - K\|_F}{\mu^2 m^2} - \frac{nm}{20}.$$ 

\[\square\]

**F.6 Proof of Lemma 4.7**

Introduce the shorthand $K_{-\text{Err}} := K_{-\text{Err}}T/2[\pi; A_e, B_e]$. We then have

$$\mathbb{E}_e K_{-\text{Err}}[\pi] = \mathbb{E}_e E_{A_e, B_e, \pi} \left[ \sum_{t=1}^{T/2} \|x_t - K_e u_t\|^2 \right]$$

$$\leq 2\mathbb{E}_e \left[ E_{A_e, B_e, \pi} \left[ \sum_{t=1}^{T/2} \|x_t - K_e, u_t\|^2 + \|(K_e, u) - K_e, u_t\|^2 \right] \right]$$

$$= 2\mathbb{E}_e K_{-\text{Err}}[\pi] + 2\mathbb{E}_e \text{tr} \left( (K_e, u) - K_e, u_t\right) E_{A_e, B_e, \pi} \left[ \sum_{t=1}^{T/2} x_t x_t^\top \right] (K_e, u) - K_e, u_t\right)$$

$$\leq 2\mathbb{E}_e K_{-\text{Err}}[\pi] + 2 \left( \max_e \|K_e - K_e, u\|_F \right) \mathbb{E}_e \left[ E_{A_e, B_e, \pi} \left[ \sum_{t=1}^{T/2} x_t x_t^\top \right] \right] \|_{\text{op}}$$

$$\leq 2\mathbb{E}_e K_{-\text{Err}}[\pi] + 4nm \|P_e\|_{\text{op}}^2 \mathcal{P}_{\text{pack}} E_e \mathbb{E}_e \left[ E_{A_e, B_e, \pi} \left[ \sum_{t=1}^{T/2} x_t x_t^\top \right] \right] \|_{\text{op}}, \quad (F.2)$$

where the last inequality uses Lemma 4.1.

**Lemma F.10.** Suppose $\epsilon$ is sufficiently small. Given matrices $A_e, B_e$ and optimal controller $K_e$,

$$\left\| E_{A_e, B_e, \pi} \left[ \sum_{t=1}^{T/2} x_t x_t^\top \right] \right\|_{\text{op}} \leq (3/2)T \|P_e\|_{\text{op}} + 2J_e \|B_e\|_{\text{op}} \mathcal{P}_{\text{pack}} K_{-\text{Err}}[\pi]$$

$$\leq 2T \|P_e\|_{\text{op}} + 3J_e \Psi_e^2 \mathcal{P}_{\text{pack}} K_{-\text{Err}}[\pi],$$

where the last inequality uses Lemma 4.1.

In particular, note that by Assumption 3 and Lemma 4.3, we have the bound

$$\mathbb{E}_e K_{-\text{Err}}[\pi] \leq 2\mathbb{E}_e \mathbb{E}_e \text{Regret}_e[\pi] + \gamma_{\text{err}} \leq 2\gamma_{\text{err}} T \leq \frac{T}{3d_e \Psi_e^2}.$$ 

Then, noting $J_e \leq d_e \|P_e\|_{\text{op}}$, we can bound $E_e \left[ E_{A_e, B_e, \pi} \left[ \sum_{t=1}^{T/2} x_t x_t^\top \right] \right] \|_{\text{op}} \leq 3T \|P_e\|_{\text{op}}$. Combining with Eq. (F.2), we have either

$$\mathbb{E}_e K_{-\text{Err}}[\pi] \leq 2\mathbb{E}_e K_{-\text{Err}}[\pi] + 4nm T \|P_e\|_{\text{op}}^2 \mathcal{P}_{\text{pack}}.$$ 

\[\square\]
F.6.1 Proof of Lemma F.10

Let $x_t$ denote the sequence induced by playing the algorithm $\pi$. Recalling the notation $\delta_t = u_t - B_e K_e x_t$, we then have

\[ x_t = A_e x_{t-1} + u_t + w_t = (A_e + B_e K_e) x_{t-1} + B_e \delta_t + w_t. \]

We further define the comparison sequence

\[ \bar{x}_t := (A_e + B_e K_e) \bar{x}_{t-1} + w_t \]

corresponding to playing the optimal infinite horizon inputs. As shorthand, let $K-Err := K-Err_{T/2}[\pi; A_e, B_e]$. We can bound the desired operator norm of the algorithms

\[
\left\| E_e \int_1^{T/2} \sum_{t=1}^{T/2} x_t x_t^\top \right\|_{\text{op}} \leq T \| P_e \|_{\text{op}} \quad (\text{F.3})
\]

\[
\left\| E_e \int_1^{T/2} \sum_{t=1}^{T/2} \bar{x}_t \bar{x}_t^\top - x_t x_t^\top \right\|_{\text{op}} \leq \frac{1}{2} T \| P_e \|_{\text{op}} + 2 J_e \| B_e \|^2 \text{K-Err}. \quad (\text{F.4})
\]

Let us first prove Equation (F.3). We can compute

\[
\left\| E_e \int_1^{T/2} \sum_{t=1}^{T/2} x_t x_t^\top \right\|_{\text{op}} \leq \left\| \sum_{t=1}^{T/2-1} (A_e + B_e K_e)^s ((A_e + B_e K_e)^s)^\top \right\|_{\text{op}}
\]

\[
\leq \frac{T}{2} \| \text{dlyap}((A_e + B_e K_e)^\top, I) \|_{\text{op}} = \frac{T}{2} \| \text{dlyap}((A_e + B_e K_e)^\top I) \|_{\text{op}} \leq \frac{T}{2} \| P_e \|_{\text{op}},
\]

where the last two steps are by Lemma B.5.

Next, we prove Equation (F.4). By Jensen’s inequality, the triangle inequality, and Cauchy-Schwartz, we can bound

\[
\left\| E_e \int_1^{T/2} \sum_{t=1}^{T/2} \bar{x}_t \bar{x}_t^\top - x_t x_t^\top \right\|_{\text{op}} \leq E_e \left\| \int_1^{T/2} \sum_{t=1}^{T/2} (\bar{x}_t \bar{x}_t^\top - x_t x_t^\top) \right\|_{\text{op}}
\]

\[
\leq E_e \left\| \int_1^{T/2} \sum_{t=1}^{T/2} 2 \| \bar{x}_t \| \| \bar{x}_t \| + \| \bar{x}_t - x_t \|^2 \right\|
\]

\[
\leq 2 \sqrt{E_e \int_1^{T/2} \| \bar{x}_t \|^2} \sqrt{E_e \int_1^{T/2} \| x_t - x_t \|^2} + E_e \int_1^{T/2} \| \bar{x}_t - x_t \|^2.
\]

Now, we have that

\[
\bar{x}_t - x_t = (A_e + B_e K_e) \bar{x}_{t-1} - (A_e + B_e K_e) x_{t-1} - B_e \delta_t
\]

\[
= (A_e + B_e K_e)(\bar{x}_{t-1} - x_{t-1}) - B_e \delta_t
\]

\[
= - \sum_{s=1}^t (A_e + B_e K_e)^{t-s} B_e \delta_s.
\]
Therefore, we have that
\[
\sum_{t=1}^{T/2} \|x_t - x_t^r\|_2^2 \leq \sum_{t=1}^{T/2} \sum_{s=1}^t \|A_e + B_e K_e\) t^{-s} B_e \delta_s\|_2^2
\]
\[
\leq \sum_{t=1}^{T/2} \delta_i^T \left( B_e^T \sum_{s=0}^\infty (A_e + B_e K_e)^s (A_e + B_e K_e)^s \right) B_e \delta_i^T
\]
\[
= \sum_{t=1}^{T/2} \delta_i^T (B_e^T d \text{lyap}(A_e + B_e K_e, I) B_e \delta_i
\]
\[
\leq \|B_e\|_{op}^2 \|P_e\|_{op} \sum_{t=1}^{T/2} \|\delta_i\|_2^2,
\]
where we use Lemma B.5 in the last inequality. Taking expectations, we have
\[
\sum_{t=1}^{T/2} \mathbb{E}_e [\|x_t - x_t^r\|_2^2] \leq \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err}.
\]
This yields
\[
\mathbb{E}_e \left[ \sum_{t=1}^{T/2} x_t x_t^T - x_t^r x_t^r^T \right] \leq 2 \mathbb{E}_e \left[ \sum_{t=1}^{T/2} \|x_t\|^2 \right] \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err} + \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err}
\]
\[
\leq 2 \sqrt{T/2 \cdot J_e \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err}} + \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err}
\]
\[
= \sqrt{2T \cdot J_e \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err}} + \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err},
\]
where use the bound that \(\sum_{t=1}^{T/2} \mathbb{E}[\|x_t\|^2] \leq (T/2) J_e\) using similar arguments to Lemma F.6. The above can be bounded by
\[
\leq \frac{1}{2} T \|P_e\|_{op} + J_e \|B_e\|_{op}^2 \text{K-Err} + \|B_e\|_{op}^2 \|P_e\|_{op} \text{K-Err}
\]
\[
\leq \frac{1}{2} T \|P_e\|_{op} + 2 J_e \|B_e\|_{op}^2 \text{K-Err},
\]
since \(J_e = \text{tr}(P_e)\). The last inequality

**F.7 Additional Corollaries of Theorem 1**

For scaled identity systems, we can remove the requirement that \(d_u \leq (1 - \Omega(1)) d_u\):

**Corollary 7 (Scaled Identity System).** Suppose that \(A_* = (1 - \gamma)I\) for \(\gamma \in (0, 1)\), that \(B_* = U^T\) where \(U\) has orthonormal columns, and \(R_x, R_u = I\). Then, for \(T \geq c_1 \gamma^{-p} \left( d_u d_x \vee d_x (1 - \gamma)^{-1} \right) \vee c_1 d_x \log(1 + d_x \gamma^{-1})\),
\[
\mathcal{R}_{A_*, B_*} (\sqrt{d_u^2 d_x/T}) \geq \gamma^{-4} (1 - \gamma)^2 \sqrt{d_u^2 d_x T}.
\]

**Proof of Corollary 7.** By the same arguments as in Corollary 1, we have \(\Psi_* \leq 1\) and \(\|P_*\|_{op} \leq \gamma^{-1}\). To conclude, let us lower bound \(\sigma_{\min}(A_{cl,*}) \geq 1 - \gamma\), which yields \(\nu_{d_x} \geq \frac{1 - \gamma}{\gamma}\).

Reparameterize \(a = (1 - \gamma)\). Then for \(A_* = aI\) and \(B_* = U^T\). Then, we can see that the DARE decouples into scalar along the columns of \(U\) and their orthogonal complement. That is, if \(p, k\) is the solution to
\[
(1 - a^2)p = -p^2 a^2 (1 + p)^{-1} + 1, \quad k = -(1 + p)^{-1} pa,
\]
(5)
then \( A_{\text{cl}*} = (A_* - kUU^T) = (a - k)UU^T + \alpha(I -UU^T) \), so that
\[
\sigma_{\min}(A_{\text{cl}*}) \geq \min\{a, a - k\} = \min\{a, \frac{a}{1 + p}\} = \frac{a}{1 + p}.
\]
To conclude, we solve (F.5) and show that \( p \) is bounded above by a universal constant. For scalar \((a, b)\), the solution to the DARE is
\[
(1 - a^2)p + p^2(1 - a^2) = -p^2a^2 + (1 + p) \quad \text{and thus} \quad -a^2p + p^2 - 1 = 0.
\]
The solution \( p \) is then given by
\[
p = \frac{a^2 + \sqrt{a^4 + 4}}{2} \leq 1 + \sqrt{\frac{5}{2}},
\]
as needed. \(\square\)

G Proofs for Upper Bound (Section 5)

G.1 Proof of Lemma 5.1 (Correctness of Perturbations)

On the event \( \mathcal{E}_{\text{safe}} \) of Lemma 5.5, the condition defining \( k_{\text{safe}} \) yields
\[
\left\| \left[ \hat{A}_{\text{safe}} - A_* \mid \hat{B}_{\text{safe}} - B_* \right] \right\|_{\text{op}} \leq \text{Conf}_{\text{safe}} \leq 1/3C_{\text{safe}}(\hat{A}_{\text{safe}}, \hat{B}_{\text{safe}}).
\]
By the continuity of \( C_{\text{safe}} \) given by Theorem 11, we then have that, for any \((\hat{A}, \hat{B}) \in B_{\text{safe}} \),
\[
\left\| \left[ \hat{A} - A_* \mid \hat{B} - B_* \right] \right\|_{\text{op}} \leq C_{\text{safe}}(A_* B_*).
\]
In particular, the projection step ensures that the above holds for any \((\hat{A}_k, \hat{B}_k)\).

Let’s now go point by point. Theorem 5 then implies that

1. \( P_k \preceq \frac{21}{20} P_* \), and thus \( J_k \preceq J_* \).
2. \( J_k - J_* = J_{A_* B_* [K_\infty(\hat{A}_k, \hat{B}_k)]} - J_{A_* B_*} \preceq C_{\text{est}}(A_* B_*) \epsilon_k^2 \).
3. By Lemma B.8,
\[
\| K_\infty(\hat{A}_k, \hat{B}_k) \|_{\text{op}} \preceq \| \text{dlyap}(A_* + B_* \hat{K}_k, R_x + \hat{K}_k^\top R_u \hat{K}_k) \|_{\text{op}} = \| P_k \|_{\text{op}} \preceq \frac{21}{20} \| P_* \|_{\text{op}}.
\]
The next two points of the lemma follow from Theorem 8.

For the last point, recall that \( \sigma_{\min}^2 = \sqrt{\text{dlyap}(A_{\text{cl}*}, B_{\text{cl}*})} \|_{\text{op}}^{9/2} \max\{1, \| \hat{B}_{\text{cl}*} \|_{\text{op}}\} \sqrt{\log \| P_{\infty}(A_{\text{cl}*}, B_{\text{cl}*}) \|_{\text{op}}}. \]
Since \( \text{Conf}_{\text{safe}} \preceq 1 \), we have \( \max\{1, \| \hat{B}_{\text{cl}*} \|_{\text{op}}\} \approx \Psi_{B_*} \). Let us show \( \| P_* \|_{\text{op}} \approx \| P_{\infty}(\hat{A}_{\text{cl}*}, \hat{B}_{\text{cl}*}) \|_{\text{op}} \).

By Lemma B.6, \( P_{\infty}(\hat{A}_{\text{cl}*}, \hat{B}_{\text{cl}*}) \preceq P_{\text{safe}} \), which is \( \preceq P_* \) by point 1 of this lemma. On the other hand, \( \| P_* \|_{\text{op}} \preceq \| P_{\infty}(\hat{A}_{\text{cl}*}, \hat{B}_{\text{cl}*}) \|_{\text{op}} \) by Theorem 11.

G.2 Proof of Main Regret Decomposition (Lemma 5.2)

We establish Lemma 5.2 by establishing a more general regret decomposition for arbitrary feedback controllers \( K \), noise-input variances \( \sigma_u \), and control costs \( R_1, R_u \). This will allow us to reuse the same computations for similar calculations in the initial estimation phase (Lemma 5.5), and for covariance-matrix upper bounds as well.
Definition G.1 (Control Evolution Distribution). We define the law $\mathcal{D}(K, \sigma_u, x_1)$ to denote the law of the following dynamical system evolution: $x_1 = x_1$, and for $t \geq 2$, the system evolves according to the following distribution:

$$x_t = A_t x_{t-1} + w_t, \quad u_t = K x_t + \sigma_g g_t,$$

where $w_t \sim \mathcal{N}(0, I_{d_w})$ and $g_t \sim \mathcal{N}(0, I_{d_g})$

We begin with the following characterization of the quadratic forms that will arise in our regret bounds. Note that we use arbitrary cost matrices $R_1, R_2$.

Lemma G.1. Let $K$ be a stabilizing controller, and let $(x_t, u_t)_{t \geq 1}$ denote the linear dynamical system described by the evolution of the law $\mathcal{D}(K, \sigma_u, x_1)$. For cost matrices $R_1, R_2 \geq 0$, define the random variable

$$\text{Cost}(R_1, R_2; x_1, t, \sigma_u) := \sum_{s=1}^{t} x_s^\top R_1 x_s + u_s^\top R_2 u_s = \hat{g}^\top \Lambda_\varepsilon \hat{g} + x_1^\top \Lambda_{x_1} x_1 + 2 \hat{g}^\top \Lambda_{\text{cross}} x_1.$$

Further, define $R_K = R_1 + K^\top R_2 K$, $A_K = A_S + B_K$, $P_K = \text{dlyap}(A_K, R_K)$, and $J_K := \text{tr}(P_K)$.

1. In expectation, we have

$$\mathbb{E}[\text{Cost}(R_1, R_2; x_1, t, \sigma_u)] \leq t J_K + 2 \sigma_d^2 \|d_u\|_{\text{op}} \left( \|R_2\|_{\text{op}} + \|B_S\|_{\text{op}}^2 \|P_K\|_{\text{op}} \right) + x_1^\top P_K x_1 \quad (G.1)$$

2. Set $d_{\text{eff}} := \min\{d_u, \text{rank}(R_1) + \text{rank}(R_2)\}$. With a probability $1 - \delta$, we have

$$\text{Cost}(R_1, R_2; x_1, t, \sigma_u) \lesssim t \log \frac{1}{\delta} \left( J_K + 2 \sigma_d^2 d_{\text{eff}} \left( \|R_2\|_{\text{op}} + \|B_S\|_{\text{op}}^2 \|P_K\|_{\text{op}} \right) + 2 x_1^\top P_K x_1 \right) \quad (G.2)$$

Let us now apply the above lemma to our present setting. For $k \geq k_{\text{safe}}$, define the terms

$$\text{Cost}_{\text{noise}, k} := d_u \left( \|R_u\|_{\text{op}} + \|B_S\|_{\text{op}}^2 \|P_k\|_{\text{op}} \right)$$

$$\text{Cost}_{\text{conc}, k} := \left( 1 + \sigma_d^2 \|B_S\|_{\text{op}}^2 \right) \|R_x + \hat{K}_k R_u \hat{K}_k\|_{\text{op}}^2 \|A_{\text{cl}, k}\|_{\text{H}_\infty}^2 + \sigma_d^2 \|R_u\|_{\text{op}}.$$

By Lemma G.1 and the fact $J_* \leq J_k$,

$$\sum_{t=k_{\text{safe}}}^{T} \left( x_t^\top R_x x_t + u_t^\top R_u u_t - J_* \right) \lesssim \sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} \tau_k (J_k - J_*) + \tau_k \sigma_d^2 \text{Cost}_{\text{noise}, k}$$

$$+ \sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} (\sqrt{\tau_k d_{\text{eff}}} \log(1/\delta) + \log(1/\delta)) \text{Cost}_{\text{conc}, k} + \sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} x_{\tau_k}^\top P_k x_{\tau_k}.$$

Let us first bound the $\text{Cost}_{\text{noise}, k}$-terms. Since $1 \leq \|P_k\|_{\text{op}} \lesssim \|P_s\|_{\text{op}}$ on event $\mathcal{E}_{\text{safe}}$ (Lemma 5.1) and $\|R_u\|_{\text{op}} = 1$, we have

$$\text{Cost}_{\text{noise}, k} \leq d_u \left( \|R_u\|_{\text{op}} + \|B_S\|_{\text{op}}^2 \|P_k\|_{\text{op}} \right) \lesssim d_u \psi_{\hat{P}_k} \|P_s\|_{\text{op}}.$$
Since $\sigma_k^2 \leq \sigma_{\text{in}}^2 \tau_k^{-1/2}$ and $\|P_k\|_{\text{op}} \lesssim \|P\|_{\text{op}}$, we then obtain

$$\sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} \tau_k \sigma_k^2 \text{Cost}_{\text{noise},k} \lesssim \sqrt{T} d u \sigma_{\text{in}}^2 \Psi_{B_\bullet}^2 \|P\|_{\text{op}}$$

Next, let us bound

$$\text{Cost}_{\text{conc},k} := \left( (1 + \sigma_k^2 \|B_\bullet\|_{\text{op}}^2) \|R_x + \tilde{K}_k R_u \tilde{K}_k\|_{\text{op}} \|A_{cl,k}\|_{H_{\infty}}^2 \right) + \sigma_k^2 \|R_u\|_{\text{op}}.$$ 

Observe that $R_x + \tilde{K}_k R_u \tilde{K}_k \leq \text{dlyap}[A_{cl,k}, R_x + \tilde{K}_k R_u \tilde{K}_k] = P_k$. On the good event $\mathcal{E}_{\text{safe}}$, we have $\|P_k\|_{\text{op}} \leq \|P\|_{\text{op}}$, $\|A_{cl,k}\|_{H_{\infty}} \lesssim \|A_{cl}\|_{H_{\infty}} \leq \|P\|_{\text{op}}^{3/2}$ (Lemma 5.1), and by definition, $\|B_\bullet\|_{\text{op}}^2 \leq \Psi_{B_\bullet}^2$. Thus, the above is at most (again taking $R_u = I$)

$$\text{Cost}_{\text{conc},k} \lesssim \|P\|_{\text{op}}^4 + \sigma_k^2 (\|R_u\|_{\text{op}} + \Psi_{B_\bullet}^2 \|P\|_{\text{op}}^4) \leq \|P\|_{\text{op}}^4 (1 + \Psi_{B_\bullet}^2 \sigma_k^2).$$

Therefore,

$$\sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} (\sqrt{T} d \log(1/\delta) + \log(1/\delta)) \text{Cost}_{\text{conc},k} \lesssim \sqrt{T} d \log(1/\delta) \|P\|_{\text{op}}^4 + \log(T) \log(1/\delta) \|P\|_{\text{op}}^4$$

$$+ \sigma_k^2 \log(T) \log(1/\delta) \sqrt{d} \Psi_{B_\bullet}^2 \|P\|_{\text{op}}^4.$$ 

$$\leq \sqrt{T} d \log(1/\delta) \|P\|_{\text{op}}^4 + \log^2 \left( \frac{1}{\delta} \right) (1 + \sqrt{d} \sigma_{\text{in}}^2 \Psi_{B_\bullet}^2) \|P\|_{\text{op}}^4,$$

where we use $\log(T) \leq \log(1/\delta)$. Finally, we have the bound

$$\sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} \sqrt{T} \max_{k \leq \log T} \|P_k\|_{\text{op}} \lesssim \sqrt{T} \max_{k \leq \log T} \|P_k\|_{\text{op}}$$ 

$$\lesssim \log T \max_{k \leq \log T} \|P_k\|_{\text{op}}.$$

Hence, putting things together, we have

$$\sum_{t=t_{\text{safe}}}^{T} (x_t^T R_x x_t + u_t^T R_u u_t - J_\bullet) \lesssim \sum_{k=k_{\text{safe}}}^{k_{\text{fin}}} \tau_k (J_k - J_\bullet) + \log \max_{k \leq \log T} \|x_t\|_{2}^2$$

$$+ \sqrt{T} \left( d u \sigma_{\text{in}}^2 \Psi_{B_\bullet}^2 \|P\|_{\text{op}} + \sqrt{d} \log(1/\delta) \|P\|_{\text{op}}^4 \right)$$

$$+ \log^2 \left( \frac{1}{\delta} \right) (1 + \sqrt{d} \sigma_{\text{in}}^2 \Psi_{B_\bullet}^2) \|P\|_{\text{op}}^4.$$

Reparametrize $\delta \leftarrow \frac{\delta}{67}$ and using presents the above inequality up to constants ($\log T \leq \log \frac{1}{\delta}$), and reduces the failure probability across all episodes to $\delta/6$.

### G.3 Bounding the States: Lemma 5.3

**Lemma G.2.** Let $x_t$ denote the $t$-th iterate form the law $\mathcal{D}(K, x_1, \sigma_u)$. Then, with probability at least $1 - \delta$,

$$\|x_t - A_{K}^{-1} x_1\| \leq O \left( \sqrt{J_K (1 + \sigma_u^2) \log \frac{1}{\delta}} \right).$$

Let $\alpha_0 = \sqrt{J_0 \Psi_{B_\bullet}^2} \log \frac{1}{\delta}$. We conclude by arguing an upper bound on $\tau_{k_{\text{safe}}}$. We rely on the following guarantee and $\alpha_1 = \sqrt{J_{\text{max}} \Psi_{B_\bullet}^2} \log \frac{1}{\delta}$. For $k > k_{\text{safe}}$, define the vector $e_k := x_t - A_{cl,k-1}^{-1} x_{t-1}$. Since
\( \delta < 1/T, \sigma_k^2 \leq 1, \) and \( J_k \subseteq J_*, \) a union bound and reparametrization of \( \delta \) implies that, \( e_k \preceq \alpha_1 \) and \( \|x_{r_{\text{safe}}}\|_2 \leq \alpha_0 \) with probability \( 1 - \delta/8. \) Now, we can write

\[
x_{r_k} = e_k + A_{cl,k-1}^{T-1} x_{r_{k-1}}
\]

\[
= e_k + A_{cl,k-1}^{T-1} \left( e_{k-1} + A_{cl,k-2}^{T-1} x_{r_{k-2}} \right)
\]

\[
= \sum_{j=k_{\text{safe}}+1}^{k} \left( \prod_{i=j}^{k-1} A_{cl,i}^{T_i} \right) e_j + \left( \prod_{i=k_{\text{safe}}}^{k-1} A_{cl,i}^{T_i} \right) x_{r_{\text{safe}}}.
\]

Since \( \text{dlyap}[A_{cl,*}] \geq I, \) we have

\[
\left\| \text{dlyap}[A_{cl,*}]^{1/2} \prod_{i=j}^{k-1} A_{cl,i} \right\|_\text{op} \leq \left\| \text{dlyap}[A_{cl,*}] \right\|_\text{op}^{1/2} \prod_{i=j}^{k-1} \left\| A_{cl,i} \right\|_\text{op}^{1/2}
\]

Moreover, by Lemma 5.1, we have that for all \( i \geq k_{\text{safe}}, \) \( A_{cl,i} \text{dlyap}[A_{cl,*}] A_{cl,i} \leq (1 - \frac{1}{2\|\text{dlyap}[A_{cl,*}]\|_\text{op}}) \) \( \text{dlyap}[A_{cl,*}] \). This yields that

\[
\left\| \text{dlyap}[A_{cl,*}]^{1/2} \prod_{i=j}^{k-1} A_{cl,i} \right\|_\text{op} \leq \left( \prod_{i=j}^{k-1} \left( 1 - \frac{1}{2\|\text{dlyap}[A_{cl,*}]\|_\text{op}} \right) \right)^{\tau_i} \left\| \text{dlyap}[A_{cl,*}] \right\|_\text{op}
\]

\[
= \left( 1 - \frac{1}{2\|\text{dlyap}[A_{cl,*}]\|_\text{op}} \right)^{\tau_{k-1}} \left\| \text{dlyap}[A_{cl,*}] \right\|_\text{op}
\]

Hence, we have that, with probability \( 1 - \mathcal{O}(\delta), \)

\[
\|x_{r_k}\|_2 \preceq \alpha_1 \sqrt{\|\text{dlyap}[A_{cl,*}]\|_\text{op} \left( 1 + k \left( 1 - \frac{1}{2\|\text{dlyap}[A_{cl,*}]\|_\text{op}} \right)^{\tau_{k-1}} \right)} + \alpha_0 \sqrt{\|\text{dlyap}[A_{cl,*}]\|_\text{op}}.
\]

Since \( \max_k k(1 - \rho)^k \leq \frac{1}{\rho} \) and since \( I \leq \text{dlyap}[A_{cl,*}] \preceq P_* \) (see Lemma 5.1), the above implies the crude bound

\[
\|x_{r_k}\|_2 \preceq \sqrt{\|\text{dlyap}[A_{cl,*}]\|_\text{op} \left( \alpha_0 + \alpha_1 \|\text{dlyap}[A_{cl,*}]\|_\text{op} \right)} \leq \|P_*\|_\text{op}^{3/2} \left( \alpha_0 + \alpha_1 \right)
\]

\[
\preceq \sqrt{\Psi_{B_*}(\mathcal{J}_0 + \mathcal{J}_*) \log(1/\delta)} \|P_*\|_\text{op}^{3/2}
\]

\[
\preceq \sqrt{\Psi_{B_*}(\mathcal{J}_0) \log(1/\delta)} \|P_*\|_\text{op}^{3/2}.
\]

\[\square\]

**G.4 Proof of Estimation Bound (Lemma 5.4)**

**Definition G.2** (Round-wise projections). Given \( v \in \mathbb{R}^d, \) let \( v = (v^x, v^u) \) denote its decomposition along the \( x \) and \( u \) directions. For a given round \( k \geq k_{\text{safe}}, \) let \( \mathcal{V}_k := \{ v \in \mathbb{R}^d : v^x + \hat{K}_k v^u = 0 \}, \) and let \( \mathcal{V}_k^\perp \) denote its orthogonal complement. Finally, let \( P_k \) denote the orthogonal projection onto \( \mathcal{V}_k, \) and let \( P_k^\perp := (I - P_k) \) denote the projection on \( \mathcal{V}_k^\perp. \)

The first step in our bound will be to lower bound the relevant, centered covariances.
Lemma G.3 (Round-wise covariance lower bound). Let $k \geq k_{\text{safe}} + 1$, at let $t \in \{\tau_k, \ldots, \tau_{k+1} - 1\}$. Then, on $E_{\text{safe}}$. If $\sigma_k^2$ satisfies $\sigma_k^2 \lesssim \frac{1}{6.2 \|P_*\|_{\text{op}}}$, we have that

$$E \left[ (z_t - E[z_t | F_{t-1}]) (z_t - E[z_t | F_{t-1}])^\top \right] \geq \Gamma_k := \frac{\sigma_k^2}{6.2 \|P_*\|_{\text{op}}} P_k + \frac{1}{2} P_k^\perp.$$

Proof. Full proof given in Section G.4.1.

We now convert the above bound into a Lowner lower bound on $\Gamma_k$. We conclude by arguing an upper bound on $\tau_{k_{\text{safe}}}$. We rely on the following guaranteed $A_k$. We introduce the notation $f \gtrsim g$. We say that $f(x) \gtrsim g(x)$ denote “if $f \geq C g$ for a sufficiently large constant $C$.”

Further, let $v_{k,1}, \ldots, v_{k,d}$ denote an eigenbasis of $\Gamma_k$. Let us prove the following.

Lemma G.4. The following bounds hold simultaneously with probability $1 - \delta/2$, if $E_{\text{bound}} \cap E_{\text{safe}}$ holds:

1. $i \in \{d_x + 1, \ldots, d\}$, we have $v_{k,i}^* A_k v_{k,i} \lesssim \kappa_k \sigma_k^2$ if $\tau_k \gtrsim \sqrt{\log(d/\delta)}$.

2. Suppose that $\tau_k \geq \|P_*\|_{\text{op}}^3 \mathcal{J}_0 \lor \Psi_{B_1} \sigma_k^4$. Then,

$$v_{k,i}^* A_k v_{k,i} \lesssim \kappa_k \|P_*\|_{\text{op}} \log(d/\delta) .$$

3. If $\tau_k \gtrsim \tau_k : d \left( \|P_*\|_{\text{op}}^3 \mathcal{J}_0 + \|P_*\|_{\text{op}} \Psi_{B_1} \sigma_k^4 \right) \log d, \text{ then the above two conditions hold, } \sigma_k^2 \text{ satisfies the conditions of Lemma G.3, and } A_k \gtrsim \kappa_k \Gamma_k \text{ for some universal constant } c > 0.$

The proof is defered to Appendix G.4.2. From Lemma E.3 with covariate dimension $d$ and output dimension $d_x$, we have that with probability $1 - \delta/2$ on the events of Lemma E.4 that

$$\| \hat{A} - A_* \|^2_{F} + \| \hat{B} - B_* \|^2_{F} \lesssim d_x \sum_{j=1}^{d_x} \lambda_j (\tau_k \Gamma_k)^{-1} \kappa_j \log \frac{3\kappa_j}{\delta},$$

where $\kappa_j \lesssim v_{k,j}^* A_k v_{k,j}$. Let us decompose the above sum intro the sum over the first $k$ indices, and the second. For $i \in \{d_x\}$, we have $\lambda_i (\Gamma_k) \gtrsim \frac{1}{2}$, and on the events of Lemma E.4, we can bound $v_{k,i}^* A_k v_{k,i} \lesssim \kappa_k \|P_*\|_{\text{op}} \log(1/\delta)$, yielding $\kappa_i \lesssim \|P_*\|_{\text{op}} \log(1/\delta)$.

$$\sum_{j=1}^{d_x} \lambda_j (\tau_k \Gamma_k)^{-1} \kappa_j \log \frac{3\kappa_j}{\delta} \lesssim \frac{d_x^2 \|P_*\|_{\text{op}} \log(1/\delta)}{\tau_k} \log \left( \frac{\|P_*\|_{\text{op}} \log(1/\delta)}{\delta} \right) \lesssim \frac{d_x^2 \|P_*\|_{\text{op}} \log(1/\delta)}{\tau_k} \log \frac{\|P_*\|_{\text{op}} \log(1/\delta)}{\delta} \lesssim \frac{d_x^2 \|P_*\|_{\text{op}} \log(1/\delta)}{\tau_k} \log \frac{\|P_*\|_{\text{op}} \log(1/\delta)}{\delta} .$$

For $i > d_x$, $\lambda_i (\Gamma_k) \gtrsim \frac{\sigma_k^2}{\|P_*\|_{\text{op}}}$, on the events of Lemma E.4, we can bound $v_{k,i}^* A_k v_{k,i} \lesssim 1$, yielding $\kappa_i \lesssim \|P_*\|_{\text{op}}$, and thus

$$\sum_{j=d_x+1}^{d} d_x \lambda_j (\tau_k \Gamma_k)^{-1} \kappa_j \log \frac{3\kappa_j}{\delta} \lesssim d_x d_x \|P_*\|_{\text{op}}^2 \log \frac{\|P_*\|_{\text{op}} \log(1/\delta)}{\delta} \frac{1}{\delta} \sigma_k \Gamma_k \lesssim d_x \|P_*\|_{\text{op}}^2 \log \frac{\|P_*\|_{\text{op}} \log(1/\delta)}{\delta} \frac{1}{\delta} \sigma_k \Gamma_k .$$

Combining the two summations gives the desired bound:

$$\| \hat{A} - A_* \|^2_{F} + \| \hat{B} - B_* \|^2_{F} \lesssim \frac{d_x d_x}{\sigma_k \sqrt{\Gamma_k}} \|P_*\|_{\text{op}} \log \frac{\|P_*\|_{\text{op}} \log(1/\delta)}{\delta} \frac{1}{\delta} \sigma_k \Gamma_k \lesssim \frac{d_x d_x}{\sigma_k \sqrt{\Gamma_k}} \|P_*\|_{\text{op}} \log \frac{\|P_*\|_{\text{op}} \log(1/\delta)}{\delta} \frac{1}{\delta} \sigma_k \Gamma_k .$$

Finally, reparametrizing $\delta \leftarrow \delta/8$ gives the desired probability.
G.4.1 Proof of Lemma G.3

We now turn to the proof:

\[ \Sigma_k = \begin{bmatrix} I_{d_k} \\ \hat{K}_k \end{bmatrix} \begin{bmatrix} I_{d_k} & \hat{K}_k \end{bmatrix} = \begin{bmatrix} I_{d_k} & \hat{K}_k \\ \hat{K}_k^\top & \hat{K}_k + \sigma_k^2 I \end{bmatrix}. \]

We see that \( k \geq k_0 + 1 \) and \( t \geq \tau_k \), we have that \( z_t \mid \mathcal{F}_{t-1} \sim \mathcal{N}(\zeta_t, \Sigma_k) \), where \( \zeta_t, \Sigma_t \) are \( \mathcal{F}_{t-1} \) measurable.

Our goal will now be to lower bound \( \Sigma_k \succeq \gamma_1 P_k + \gamma_2 P_k^\perp \). To this end, let \( v \in S^{d-1} \), and write \( v = P_k v + P_k^\perp v := v_\parallel + v_\perp \). Observe then that

\[
\begin{align*}
|v_\perp^\top \Sigma_k v_\parallel| &\leq |v_\perp^\top \begin{bmatrix} I_{d_k} \\ \hat{K}_k \end{bmatrix} \begin{bmatrix} I_{d_k} & \hat{K}_k \end{bmatrix} v_\parallel| = |v_\perp^\top \begin{bmatrix} 0 \\ \sigma_k^2 I \end{bmatrix} v_\parallel| = |v_\perp^\top \begin{bmatrix} 0 \\ \sigma_k^2 I \end{bmatrix} v_\parallel| \leq \sigma_k^2 v_\parallel \|v_\parallel\|,
\end{align*}
\]

where we use that \( \begin{bmatrix} I_{d_k} \\ \hat{K}_k \end{bmatrix} v_\parallel = 0 \). On the other hand, since \( v_\perp \in \text{null}\left(\begin{bmatrix} I_{d_k} & \hat{K}_k \end{bmatrix}\right)^\perp \), we have

\[
\begin{align*}
v_\perp^\top \Sigma_k v_\perp &\geq \begin{bmatrix} I_{d_k} \\ \hat{K}_k \end{bmatrix} v_\perp \\
&= \|\begin{bmatrix} I_{d_k} \\ \hat{K}_k \end{bmatrix} v_\perp\|^2 \\
&\geq \|v_\perp\|^2 \sigma_{d_k} \left(\begin{bmatrix} I_{d_k} \\ \hat{K}_k \end{bmatrix}\right)^2 = \|v_\perp\|^2 \lambda_{\min}(I_{d_k} + \hat{K}_k^\top \hat{K}_k) \geq \|v_\perp\|^2.
\end{align*}
\]

We can therefore bound, for any \( \alpha > 0 \),

\[
v^\top \Sigma_k v = v_\perp^\top \Sigma_k v_\perp + 2v_\perp^\top \Sigma_k v_\parallel + v_\parallel^\top \Sigma_k v_\parallel \\
\geq \|v_\perp\|^2 - 2\sigma_k^2 \|v_\perp\| \|v_\parallel\| + \lambda_{\min}(\Sigma_k) \|v_\parallel\|^2 \\
\geq \|v_\perp\|^2 - \sigma_k^2 (\alpha \|v_\parallel\|^2 + \frac{1}{\alpha} \|v_\parallel\|^2) + \lambda_{\min}(\Sigma_k) \|v_\parallel\|^2.
\]

Taking \( \alpha = \lambda_{\min}(\Sigma_k)/2\sigma_k^2 \), we have

\[
v^\top \Sigma_k v \geq \|v_\perp\|^2 \left(1 - \frac{2\sigma_k^2 \cdot \lambda_{\min}(\Sigma_k)}{\lambda_{\min}(\Sigma_k) \|v_\parallel\|^2}\right) + \frac{1}{2} \lambda_{\min}(\Sigma_k) \|v_\parallel\|^2.
\]

Hence, we have show that, for \( \gamma_1, \gamma_2 \) defined in the above display, \( \Sigma_k \succeq \gamma_1 P_k + \gamma_2 P_k^\perp \). Let us now lower bound each of these quantities. From [Dean et al., 2018, Lemma F.6], since \( \|\hat{K}_k\|^2 \lesssim \|P_*\|_\text{op} \) (Lemma 5.1), and \( \|P_*\|_\text{op} \geq 1 \geq \sigma_k^2 \),

\[
\lambda_{\min}(\Sigma_k) \geq \sigma_k^2 \min \left\{ \frac{1}{2}, \frac{1}{2\|\hat{K}_k\|_\text{op}^2 + \sigma_k^2} \right\} \geq \sigma_k^2 \min \left\{ \frac{1}{2}, \frac{1}{2.1\|P_*\|_\text{op}^2 + \sigma_k^2} \right\} = \sigma_k^2 = \frac{\sigma_k^2}{6.2\|P_*\|_\text{op}}.
\]

Hence, for \( \sigma_k^2 \leq \frac{1}{6.2\|P_*\|_\text{op}} \), we have \( \gamma_1 \geq \frac{1}{2} \), and \( \gamma_2 \geq \frac{\sigma_k^2}{3.1\|P_*\|_\text{op}} \).

G.4.2 Proof of Lemma G.8

Proof. All union bounds will be aborded into \( \delta \) factors, as \( \delta \leq 1/T \) and \( T \geq d \). We decompose \( v_{k,i} = v_{k,i}^x + v_{k,i}^u \) along its \( x \) and \( u \) coordinate. It suffices to show that each bound holds individually with probability \( 1 - \delta \) for a fixed \( i \), and \( k \), since the union bound over \( k \) can be absorbed into the \( \delta \) factor (as \( \delta \leq 1/T \)), and dimension addressed by reparametrizing \( \delta \leftarrow \delta/d \).
**Point 1:** For $i \in \{d_x + 1, \ldots, k\}$, $v_{k,i}$ lies in the vector space $\mathcal{V}_k$. Therefore

$$v_{k,i}^\top \Lambda_k v_{k,i} = \sum_{t=\tau_k}^{2\tau_k-1} |v_{k,i}^\top| \left[ \begin{array}{c} x_t \\ u_t \end{array} \right] \left[ \begin{array}{c} x_t \\ u_t \end{array} \right]^\top v_{k,i}$$

$$= \sum_{t=\tau_k}^{2\tau_k-1} |v_{k,i}^\top| \left[ \begin{array}{c} x_t \\ \hat{K}_k x_t + \sigma_k g_t \end{array} \right] \left[ \begin{array}{c} x_t \\ \hat{K}_k x_t + \sigma_k g_t \end{array} \right]^\top v_{k,i}$$

$$= \sum_{t=\tau_k}^{2\tau_k-1} |v_{k,i}^\top| \left[ \begin{array}{c} x_t \\ x_t + \sigma_k g_t \end{array} \right] \left[ \begin{array}{c} x_t \\ x_t + \sigma_k g_t \end{array} \right]^\top v_{k,i}$$

$$= \sum_{t=\tau_k}^{2\tau_k-1} \langle |v_{k,i}^\top|, g_t \rangle^2 \sim \|v_{k,i}^\top\|_2^2 \sigma_k^2 \cdot \chi^2(\tau_k).$$

By standard $\chi^2$-concentration, the above is $\lesssim \tau_k \|v_{k,i}^\top\|_2^2 \sigma_k^2 \leq \tau_k \sigma_k^2$ for $\tau_k \geq \sqrt{\log(1/\delta)}$.

**Point 2:** For arbitrary $i$, set $R_1 := v_{k,i}^\top (v_{k,i}^\top)^\top$ and $R_2 := v_{k,i}^\top (v_{k,i}^\top)^\top u$.

$$v_{k,i}^\top \Lambda_k v_{k,i} = \sum_{t=\tau_k}^{2\tau_k-1} |v_{k,i}^\top| \left[ \begin{array}{c} x_t \\ u_t \end{array} \right] \left[ \begin{array}{c} x_t \\ u_t \end{array} \right]^\top v_{k,i} \leq 2 \sum_{t=\tau_k}^{2\tau_k-1} |x_t| R_1 x_t + |u_t| R_2 u_t.$$ 

Thus, Lemma G.1 ensures that, with probability $1 - \delta$, we have that for the matrix $P := \text{dlyap} (A, B, \hat{K}_k, R_1 + \hat{K}_k^\top R_2 \hat{K}_k)$

$$v_{k,i}^\top \Lambda_k v_{k,i} \lesssim \tau_k \log \frac{1}{\delta} \left( \text{tr}(P) + 2 \sigma_2^2 \|P\|_{op} \|B_\ast\|_{op} \|P\|_{op} \|P\|_{op} \right) + \|P\|_{op} \|x_{\tau_k}\|_2^2,$$

where $d_{eff} \leq \text{rank}(R_1) + \text{rank}(R_2) = 2$. Since $R_1 \preceq I \preceq R_x$ and $R_2 \preceq I \preceq R_u$, we have $R_1 + \hat{K}_k^\top R_2 \hat{K}_k \preceq R_x + \hat{K}_k^\top R_u \hat{K}_k$, and thus (by Lemma B.5), $P = \text{dlyap} (A, B, \hat{K}_k, R_1 + \hat{K}_k^\top R_2 \hat{K}_k) \leq \text{dlyap} (A, B, \hat{K}_k, R_x + \hat{K}_k^\top R_u \hat{K}_k) = P_k$. Moreover Lemma 5.1, we get $\|P_k\|_{op} \lesssim \|P_\ast\|_{op}$. Moreover, since $P$ can be shown to have rank at most 2, $\text{tr}(P) \lesssim \|P_\ast\|_{op}$. Finally, $\|x_{\tau_k}\|_2 \leq \sqrt{J_0 \log(1/\delta)} \|P_\ast\|_{op}^{3/2}$ from Lemma G.3.

$$v_{k,i}^\top \Lambda_k v_{k,i} \lesssim \tau_k \log \frac{1}{\delta} \left( \|P_\ast\|_{op} + \sigma_2^2 \left( 1 + \|B_\ast\|_{op} \|P_\ast\|_{op} \right) \right) + J_0 \log(1/\delta) \|P_\ast\|_{op}^4$$

$$\lesssim \tau_k \log \frac{1}{\delta} \left( \|P_\ast\|_{op} + \sigma_2^2 \|P_\ast\|_{op} \|P_\ast\|_{op} \|P_\ast\|_{op} \|P_\ast\|_{op} \|P_\ast\|_{op} \right) + J_0 \log(1/\delta) \|P_\ast\|_{op}^4.$$

In particular, if $\tau_k \geq J_0 \|P_\ast\|_{op}^{3/2}$, and $\sigma_k \leq 1/\Psi_{B_\ast}^4$ (for which it suffices $\tau_k \leq \sigma_{\min}^4 \Psi_{B_\ast}^4$), we have

$$v_{k,i}^\top \Lambda_k v_{k,i} \lesssim \tau_k \|P_\ast\|_{op} \log(1/\delta).$$

**Point 3:** Suppose now that $\tau_k \geq \|P_\ast\|_{op}^3 J_0 \log(1/\delta) \lor \Psi_{B_\ast}^4 \sigma_{\min}^4$. Then, by using the expectation bound statement of Lemma G.1, and summing over indices $i$, we have

$$E[\text{tr}(\Lambda_k) \cap \mathcal{E}_\text{bound} \cap \mathcal{E}_\text{safe}] \lesssim d \tau_k \|P_\ast\|_{op}.$$

Hence, by Lemma E.4, if

$$\tau_k \gtrsim d \log \left( \frac{d \|P_\ast\|_{op}}{\sigma_{\min}(\Gamma_k)} \right),$$

then with probability $1 - e^{-\tau_k/d}$ on $\mathcal{E}_\text{bound} \cap \mathcal{E}_\text{safe}$, we have that $\Lambda_k \gtrsim \tau_k \Gamma_k$. Note that since $\tau_k \geq \|P_\ast\|_{op}^3 J_0 \log(1/\delta) \geq d \log(1/\delta)$ (since $J_0 \geq d$ and $\|P_\ast\|_{op} \geq 1$), we have also $1 - e^{-\tau_k/d} \geq 1 - \delta$. 

64
Now, if in addition \( \tau_k \gtrsim \sigma^2_{in} \| P_* \|_{op}^2 \), Lemma G.4.1 entails that \( \Gamma_k \gtrsim \frac{\sigma^2_{in}}{\| P_* \|_{op}} \) (note that for such \( k \), \( \frac{\sigma^2_{in}}{\sqrt{\tau_k}} \leq 1 \)). With a few simplifications, we see then that

\[
\tau_k \gtrsim d \log \tau_k + d \log \left\{ \frac{d \| P_* \|_{op}}{1 + \sigma^2_{in}} \right\} \vee \| P_* \|_{op}^3 \log (1/\delta) \vee \sigma^4_{in} \max \{ \Psi_{B,*}^2, \| P_* \|_{op}^2 \},
\]

then with probability \( 1 - O(\delta) \), \( A_k \gtrsim \tau_k \Gamma_k \). Since \( \tau_k \gtrsim d \log \tau_k \gtrsim d \log d \), we need simply \( \tau_k \gtrsim \delta \log \delta \), \( d \log \left\{ \frac{d \| P_* \|_{op}}{1 + \sigma^2_{in}} \right\} \vee \| P_* \|_{op}^3 \log (1/\delta) \vee \sigma^4_{in} \max \{ \Psi_{B,*}^2, \| P_* \|_{op}^2 \} \) to ensure \( A_k \gtrsim \tau_k \Gamma_k \) with probability \( 1 - O(\delta) \).

Shrinking \( \delta \) by a constant reduces the failure probability to \( 1 - \delta \). Lastly, using \( \sigma^2_{in} \geq 1 \) by definition, and \( \sigma^2_{in} \lesssim \sqrt{d_x} \| P_* \|_{op}^2 \Psi_{B,*} \sqrt{\log \frac{\| P_* \|_{op}}{\delta}} \) by Lemma 5.1, we can bound

\[
\delta \log \left\{ \frac{d \| P_* \|_{op}}{1 + \sigma^2_{in}} \right\} \vee \| P_* \|_{op}^3 \log (1/\delta) \vee \sigma^4_{in} \max \{ \Psi_{B,*}^2, \| P_* \|_{op}^2 \} \lesssim \delta \log \| P_* \|_{op} + \| P_* \|_{op}^3 \log (1/\delta) + d_x \| P_* \|_{op}^9 \Psi_{B,*}^2 \log \frac{\| P_* \|_{op}}{\delta} \Psi_{B,*}^2 \| P_* \|_{op} \lesssim \delta \left( \| P_* \|_{op}^3 \Psi_{B,*} \| P_* \|_{op} \right) \log \frac{\| P_* \|_{op}}{\delta} := \tau_s.
\]

where in the last line we use \( \Psi_{B,*} \| P_* \|_{op} \geq 1, d_x \leq d, \) and \( \Psi_{B,*} = J_0/d_x \).

\[\Box\]

G.5 Proof of Lemma 5.5 \((k < k_{safe})\)

We analyze the rounds \( k < k_{safe} \), which correspond to the rounds before the least-squares procedure produces a sufficiently close approximation to \((A_*, B_*)\) that we can safely implemented certainty equivalence control.

In order to avoid directly conditioning on events \( \{k_{safe} \leq \ldots \} \), let us define the sequence \( z_{t,0} := (x_{t,0}, u_{t,0}) \) on the same probability space as \((x_t, u_t)\) to denote the system driven by the same noise \( w_t \), and with the same random perturbations \( g_t \), but where the evolution is with respect to the dynamics

\[
x_{t,0} = A_* + B_* u_{t,0} \quad u_{t,0} = K_0 x_{t,0} + g_t,
\]

that is, the dynamics defined by the distribution \( D(K_0, \sigma^2_* = 1, x_1 = 0) \). Observe that, for any \( t < \tau_{k_{safe}} \), it holds that \( x_{t,0} = x_t \) and \( u_{t,0} = u_t \), so it will suffice to reason about this sequence.

**Proof that \( E_{safe} \) holds** As above, to reason rigorously about probabilities, we introduce \( \hat{A}_{k,0}, \hat{B}_{k,0} \) as the OLS estimators on the \( z_{k,0} := (x_{k,0}, u_{k,0}) \) sequence, and define the covariance matrix

\[
\Lambda_{k,0} := \sum_{i=\tau_k}^{2\tau_k-1} z_{k,0} z_{k,0}^\top.
\]

We also define the induced confidence term:

\[
Conf_{k,0} = 6\lambda_{min}(\Lambda_{k,0})^{-1} (d \log 5 + \log \left\{ \frac{4k^2 \sigma_{in} \Lambda_{k,0} \log (1/\delta)}{\delta} \right\}).
\]

**Lemma G.5.** The following event holds with probability \( 1 - \delta \):

\[
E_{conf} := \left\{ \forall k \leq k_{safe} with \Lambda_{k,0} \succeq I, \quad \left\| \left[ \hat{A}_k - A_* \right] \| B_k - \hat{B}_k \right\|_{op} \leq \text{Conf}_{k,0} \right\}.
\]

**Proof.** Applying (E.1) in Lemma E.2 with \( A_0 = I \), we see that for any fixed \( k \) for which \( \Lambda_{k,0} \succeq I, \text{Conf}_{k,0} \) is a valid \( \delta/4k^2 \)-confidence interval; that is \( \| [A_* - \hat{A}_{k,0}] \| B_k - \hat{B}_{k,0} \|_{op} \leq \text{Conf}_{k,0} \). By a union bound, the confidence intervals are valid with probability \( 1 - \delta/2 \), simultaneously. Since the the sequence \( x_{t,0} \) coincides with \( x_t \) for \( t \leq \tau_{k_{safe}} \), and \( u_{t,0} \) with \( u_t \) for \( t \leq \tau_{k_{safe}} - 1 \), we see that \( \text{Conf}_{k,0} = \text{Conf}_k \) for all \( k \leq k_{safe} \). \[\Box\]
Proof of Regret Bound  We begin with the following regret bound:

**Lemma G.6.** For \( \delta < 1/T \), the following hold with probability \( 1 - \delta \),

\[
\sum_{t=1}^{\tau_{\text{safe}}-1} x_{t,0}^T R x_{t,0} + u_{t,0}^T R u_{t,0} \lesssim d \tau_{\text{safe}} \Psi_B^2 \mathcal{P}_0 \log \frac{1}{\delta}).
\]

**Proof.** It suffices to show that the \((x_{t,0}, u_{t,0})\) sequences satisfies the following bound:

\[
\sum_{t=1}^{\tau_{\text{safe}}-1} x_{t,0}^T R x_{t,0} + u_{t,0}^T R u_{t,0} \lesssim \tau_0 \left( J_0(1 + \|B^*\|_{\text{op}}^2) + \text{tr}(R_u) \right) \log \frac{1}{\delta},
\]

where the inequality suffices since \( \mathcal{P}_0 \geq 1 \) (indeed, \( J_0 \geq J_*) \geq d \) by Lemma B.6), and thus \( J_0(1 + \|B^*\|_{\text{op}}^2) + \text{tr}(R_u) = \mathcal{P}_0(1 + \|B^*\|_{\text{op}}^2) + \|u\| \leq \mathcal{P}_0 \Psi^* \).

For the second, we have from Lemma G.9 and the fact that \( x_1 = 0 \) that there is a Gaussian quadratic form \( \mathbb{E}^T \Lambda x \mathbb{E} \) which is equal to \( \sum_{t=1}^{\tau_{\text{safe}}-1} x_{t,0}^T R x_{t,0} \) and where \( \text{tr}(\Lambda x) \leq \tau_0 \left( J_0(1 + \|B^*\|_{\text{op}}^2) + \text{tr}(R_u) \right) \). The second bound now follows from the crude statement of Hanson Wright in Corollary 6. The last statement follows by a union bound, noting that we need to bound over \( k_{\text{max}} = \log_2 T \leq T \leq 1/\delta \), rounds, and absorbing constants.

We conclude by arguing an upper bound on \( \tau_{\text{safe}} \). We rely on the following guarantee.

**Lemma G.7.** Suppose \( \mathcal{E}_{\text{safe}} \) holds. Then for all \( k < k_{\text{safe}} \) for which \( \Lambda_k \succeq I \), we must have that \( \text{Conf}_k \gtrsim \epsilon_{\text{safe}} \), where \( \epsilon_{\text{safe}} = \|P^*\|_{\text{op}}^{-10} \).

**Proof.** For all \( k < k_{\text{safe}} \) for which \( \Lambda_k \succeq I \), we must have that \( \text{Conf}_k > 1/C_{\text{safe}}(\hat{A}_k, \hat{B}_k) \). If \( \text{Conf}_k \leq c/C_{\text{safe}}(A^*_k, B^*_k)^2 \) for a sufficiently small \( c \), then the same perturbation argument as in Theorem 11 entails that we have \( \text{Conf}_k \leq 1/9C_{\text{safe}}(A_k, B_k)^2 \), yielding a contradiction. Finally, we substitute in \( C_{\text{safe}}(A^*_k, B^*_k)^2 \lesssim \|P^*\|_{\text{op}}^{-10} \) by Equation (3.1).

Recall that we say \( f \gtrsim_s f \) if \( \text{“} f \geq C g \text{”} \) for a sufficiently large constant \( C \) (Definition G.3). In light of the above lemma, Part 2 will follow as soon as we can show that, for any \( \epsilon \in (0, 1) \),

\[
\text{if } \tau_k \gtrsim_s \frac{d(1 + \|K^0\|_{\text{op}}^2)}{\epsilon} \log - \frac{\Psi_B^2}{\delta} J_0, \quad \text{then } \text{Conf}_{k,0} \leq \epsilon, \text{ and } \Lambda_{k,0} \succeq I \text{ w.p. } 1 - O(\delta). \quad (G.3)
\]

We begin with a lower bound the matrices \( \Lambda_{k,0} \):

**Lemma G.8.** for a sufficiently large constant \( C \). Finally, set \( \tau_{\text{min}} = d \log(1 + \Psi_B J_0) \). Then, for any \( k \) such that \( \tau_k \gtrsim_s \tau_{\text{min}} \vee d \log(\frac{1}{\delta}) \), it holds that

\[
\mathbb{E}[\text{tr}(\Lambda_{k,0})] \lesssim \Psi_B^2 J_0 \tau_k, \quad \mathbb{P} \left[ \lambda_{\text{min}}(\Lambda_{k,0}) \gtrsim_s \frac{\tau_k}{1 + \|K^0\|_2^2} \right] \leq \delta.
\]

The bound above is proven in Section G.5.1. We can now verify Eq. (G.3), concludes the proof of Part 2:

**Proof.** (G.3). Suppose that \( k \) is such that \( \tau_k \gtrsim_s \tau_{\text{min}} \vee d \log(\frac{1}{\delta}) \). Then, by the above lemma, and using \( \det(cX) = c^d \det(X) \) for \( X \in \mathbb{R}^{d \times d} \), we have, with probability \( 1 - O(\delta) \),

\[
\text{Conf}_{k,0} \lesssim \frac{1 + \|K^0\|_2^2}{\tau_k}(d + \log \frac{k^2}{\delta}) + \log \det((\Lambda_{k,0})) \leq \frac{1 + \|K^0\|_2^2}{\tau_k}(d + \log \frac{k^2}{\delta}) + d \log \text{tr}((\Lambda_{k,0})),
\]

66
where we use that $X \succeq 0$, we have $\log \det(X) = \sum_{i=1}^d \log \lambda_i(X) \leq d \log \det(X)$. By Markov’s inequality, we have with probability $1-\delta$ that $\text{tr}((A_{k,0})) \leq \mathbb{E}[\text{tr}(\Lambda_{k,0}(A_{k,0}))]/\delta \lesssim \Psi^2_{B_{\ast}} J_0 \tau_k \leq \Psi^2_{B_{\ast}} J_0/\delta$, since $\tau_k \leq T \leq 1/\delta$. Hence, with some elementary operators, we can bound

$$\text{Conf}_{k,0} \lesssim \frac{d}{\tau_k} \log \frac{\Psi^2_{B_{\ast}} J_0}{\delta}.$$ 

Hence, for $\tau_k \gtrsim \frac{d}{\varepsilon} \log \frac{\Psi^2_{B_{\ast}} J_0}{\delta}$, we have with probability $1-\delta$ that we have $\text{Conf} \leq \varepsilon$. \hfill \square

**G.5.1 Proof of Lemma G.8**

1. We first need to argue a lower bound on matrices $\Sigma_t$ such that that $z_{t,0} \mid F_{t-1} \sim \mathcal{N}(z_{t,0}, \Sigma_{t,0})$, where $\overline{z}_{t,0}, \Sigma_{t,0}$ are $F_{t-1}$ measurable. It is straightforward to show that

$$\Sigma_{t,0} = \begin{bmatrix} I & K_0^\top & K_0 \\ K_0 & K_0^\top + I \end{bmatrix},$$

which by [Dean et al., 2018, Lemma F.6], has least singular value bounded below as

$$\lambda_{\min}(\Sigma_{t,0}) \geq \min \left\{ \frac{1}{2}, \frac{1}{1+2\|K_0\|^2} \right\} \geq \frac{1}{2 + 2\|K_0\|^2}.$$

2. Next, we need an upper bound on

$$\mathbb{E}[\text{tr}(\Lambda_{k,0})] = \mathbb{E}\left[ \sum_{t=1}^{\tau_k-1} \|x_t\|^2 + \|z_t\|^2 \right]$$

$$\leq \mathbb{E}\left[ \sum_{t=1}^{\tau_k-1} \|x_t\|^2 + \|z_t\|^2 \right]$$

$$\leq \tau_k (1 + \|B.x\|^2) \text{tr}(\text{dlyap}(A_{K_0}, I + K_0^\top K_0)) + \text{tr}(\tau_k I)$$

$$\leq 2\tau_k (1 + \|B.x\|^2) \text{tr}(\text{dlyap}(A_{K_0}, I + K_0^\top K_0))$$

$$\leq 2\tau_k (1 + \|B.x\|^2) J_{K_0} = 4(\tau_k - \tau_{k-1})(1 + \|B.x\|^2) J_{K_0}$$

$$\leq 4(\tau_k - \tau_{k-1})(1 + \Psi^2_{B_{\ast}}) J_{K_0} \lesssim \tau_k \Psi^2_{B_{\ast}} J_{K_0},$$

where we use that $I \preceq \text{dlyap}(A_{K_0}, I + K_0^\top K_0) \preceq \text{dlyap}(A_{K_0}, R_x + K_0^\top R_u K_0) = J_{K_0}$ for $R_u, R_x \succeq I$. This proves the trace upper bound.

3. Using the second to last inequality in the above display, we see that for

$$\tau_k - \tau_{k-1} = \frac{1}{2} \tau_k \geq \frac{2000}{9} \left( 2d \log \frac{100}{4} + d \log (8(1 + \|K_0\|^2)(1 + \Psi^2_{B_{\ast}}) J_{K_0}) \right).$$

Lemma E.4 implies (taking $E = \Omega$ to be the entire probability space and $T = \tau_k/2$) that, if $\tau_k \gtrsim \tau_{\min}$, we have

$$\mathbb{P}\left[ A_{k_0} \not\succeq \frac{9\tau_k}{3200} \Sigma_0 \right] \leq 2 \exp \left( -\frac{9}{4000(d+1)} \tau_k \right).$$

Routine manipulations of give $\text{dlyap}(1 + \|K_0\|^2 \leq \text{dlyap}(A_{K_0}, I + \|K_0\|^2) \leq \text{dlyap}(A_{K_0}, R_x + K_0^\top R_u K_0) = J_{K_0}$ for $R_u, R_x \succeq I$. Hence, with a bit of algebra, we can bound

$$\tau \leq \tau_{\min} := d \log (1 + \Psi_{B_{\ast}} J_{K_0}).$$

Using the lower bound on $\Sigma_0$ concludes the proof. \hfill \square
G.6 Proof of Lemma G.1

In order to prove Lemma G.1, we first show that we can represent the Cost functional as a quadratic form in Gaussian variables:

**Lemma G.9.** Let \((x_1, x_2, \sigma_u)\) denote the linear dynamical system described by the evolution of \(D(K, x_1)\). Then for any \(t \geq 1\), there exists a standard gaussian vector \(\mathbf{g} \in \mathbb{R}^{O(td)}\) such that for any cost matrices \(R_1, R_2 \geq 0\), we have

\[
\text{Cost}(R_1, R_2; x_1, \sigma_u, t) = \mathbf{g}^\top \Lambda_\mathbf{g} \mathbf{g} + x_1^\top \Lambda_{x_1} x_1 + 2\mathbf{g}^\top \Lambda_{\text{cross} x_1},
\]

where, letting \(R_K = R_1 + K^\top R_2 K\), \(A_K = A_\star + B_\star K\), \(P_K = \text{dlyap}(A_K, R_K)\) \(J_K := \text{tr}(P_K)\), and \(d_{\text{eff}} := \min\{d_u, \dim(R_1) + \dim(R_2)\}\),

\[
\begin{align*}
\text{tr}(\Lambda_\mathbf{g}) &\leq t J_K + 2\sigma_u^2 t d_{\text{eff}} \left(\|R_2\|_{\text{op}} + \text{rank}(\|B_\star\|_{\text{op}} \|P_K\|_{\text{op}})\right), \\
\|\Lambda_{\mathbf{g}}\|_{\text{op}} &\lesssim (1 + \sigma_u^2 \|B_\star\|_{\text{op}}^2) \|R_K\|_{\text{op}} \|A_K\|_{\text{op}} \|\sigma_u^2 R_2\|_{\text{op}}^2, \\
|\Lambda_{\text{cross} x_1}|_2 &\leq \sqrt{\|\Lambda_{\mathbf{g}}\|_{\text{op}} \cdot x_1^\top P_K x_1}.
\end{align*}
\]

Let us continue to prove Lemma G.1. The expectation result follow since \(E[\text{Cost}(R_1, R_2; x_1, \sigma_u, t)] = \text{tr}(\Lambda_{\mathbf{g}}) + x_1^\top \Lambda_{x_1} x_1\) for a Gaussian quadratic form.

For the high probability result, observe that by Gaussian concentration and Lemma G.9, we have with probability \(1 - \delta\)

\[
2\mathbf{g}^\top \Lambda_{\text{cross} x_1} \lesssim \sqrt{\log(1/\delta)}\|\Lambda_{\text{cross} x_1}\|_2 \lesssim \sqrt{\log(1/\delta)}\|\Lambda_{\mathbf{g}}\|_{\text{op}} \cdot x_1^\top P_K x_1.
\]

Hence, by AM-GM, \(2\mathbf{g}^\top \Lambda_{\text{cross} x_1} \leq O(\log(1/\delta)\|\Lambda_{\mathbf{g}}\|_{\text{op}}) + x_1^\top P_K x_1\).

On the other hand, by Hanson-Wright

\[
\mathbf{g}^\top \Lambda_{\mathbf{g}} \mathbf{g} \leq \text{tr}(\Lambda_{\mathbf{g}}) + O \left(\|\Lambda_{\mathbf{g}}\|_F \sqrt{\log(1/\delta)} + \|\Lambda_{\mathbf{g}}\|_{\text{op}} \log(1/\delta)\right) \quad (G.4)
\]

\[
\leq \text{tr}(\Lambda_{\mathbf{g}}) + O \left(\sqrt{td \log(1/\delta)} + \|\Lambda_{\mathbf{g}}\|_{\text{op}} \log(1/\delta)\right),
\]

where we use the dimension of \(\Lambda_{\mathbf{g}}\) in the last line. Combining with the previous result, and adding in \(x_1^\top \Lambda_{x_1} x_1 \leq x_1^\top P_K x_1\), we have that with probability \(1 - \delta\),

\[
\text{Cost}(R_1, R_2; x_1, \sigma_u, t) \leq \text{tr}(\Lambda_{\mathbf{g}}) + O \left(\sqrt{td \log(1/\delta)} + \log(1/\delta))\|\Lambda_{\mathbf{g}}\|_{\text{op}} + x_1^\top P_K x_1\right).
\]

The first high-probability statement follows by substituting in \(\text{tr}(\Lambda_{\mathbf{g}})\) and \(\|\Lambda_{\mathbf{g}}\|_{\text{op}}\). Then second statement follows from returning to Eq. G.4 and using \(\|X\|_{\text{op}}, \|X\|_F \leq \text{tr}(X)\) for \(X \succeq 0\).

We shall now prove Lemma G.9, but first, we establish some useful preliminaries.

G.6.1 Linear Algebra Preliminaries

**Definition G.4** (Toeplitz Operator). For \(\ell \in \mathbb{N}\), and \(j, \ell \geq i\), define the matrices

\[
\text{Toep}_{i,j,\ell}(A) := \begin{bmatrix}
A^i \mathbb{I}_{i \geq 0} & A^{i+1} \mathbb{I}_{i \geq -1} & \cdots & A^{i+\ell} \mathbb{I}_{i \geq -\ell} \\
A^{i-1} \mathbb{I}_{i \geq 1} & A^i \mathbb{I}_{i \geq 0} & \cdots & A^{i+\ell-1} \mathbb{I}_{i \geq -1} \\
\cdots & \cdots & \cdots & \cdots \\
A^{i-j} \mathbb{I}_{i \geq j} & \cdots & \cdots & A^{i+\ell-j} \mathbb{I}_{i+\ell-j \geq 0}
\end{bmatrix}, \quad \text{ToepCol}_{i,j}(A) := \begin{bmatrix}
A^{j-1} \\
A^{j-2} \\
\cdots \\
\mathbb{I}_{i \geq 1} A^{i-1}
\end{bmatrix},
\]

We shall use the following lemma.
Lemma G.10. For any $i \leq j, \ell$, we have $\|\text{ToepCol}_{i,j}\|_{op} \leq \|\text{Toep}_{i,j,\ell}(A)\|_{op} \leq \|A\|_{\mathcal{H}_\infty}$, and, for $Y \in \mathbb{R}^{d_2}$, and $\text{diag}_{j-i}(Y)$ denoting a $j - i$-block block matrix with blocks $Y$ on the diagonal, we have the bound

$$\text{tr}(\text{ToepCol}_{i,j}(A)^T \text{diag}_{j-i}(Y) \text{ToepCol}_{i,j}(A)) \leq (j - i) \cdot \text{tr}(\text{dlyap}(Y, A))$$

Proof. The first bound is a consequence of the fact that $\text{Toep}_{i,j,\ell}(A)$ is a submatrix of the infinite-dimensional linear operator mapping inputs sequences in $\ell_2(\mathbb{R}^{d_2})$ to outputs $\ell_2(\mathbb{R}^{d_2})$; thus, the operator norm of $\text{Toep}_{i,j,\ell}(A)$ is bounded by the operator norm of this infinite dimensional linear operator, which is equal to $\|A\|_{\mathcal{H}_\infty}$ (see e.g. Tili [1998, Corollary 4.2]). The second bound follows from direct computation, as

$$\text{tr}(\text{ToepCol}_{i,j}(A)^T \text{diag}_{j-i}(Y) \text{ToepCol}_{i,j}(A)) \leq \text{tr}(\sum_{s=0}^{\infty} A^T Y A) = \text{tr}(\text{dlyap}(A, Y)).$$

\[ \square \]

G.6.2 Proof of Lemma G.9

Lemma G.11 (Form of the Covariates). Introduce the vector $x_{[t]} = (x_1, \ldots, x_1)$ and $u_{[t]} := (u_1, \ldots, u_1)$, set $w_{[t-1]} = (w_{t-1}, \ldots, w_1)$ and $g_{[t]} = (g_t, \ldots, g_1)$. Then, we can write

$$\begin{bmatrix} x_{[t]} \\ u_{[t]} \end{bmatrix} = M_{K,t} \begin{bmatrix} w_{[t-1]} \\ g_{[t]} \end{bmatrix} + \begin{bmatrix} I_t \\ \text{diag}_t(K) \end{bmatrix} \text{ToepCol}_{1,t}(0) x_1,$n

where we have defined the matrix

$$M_{K,t} := \begin{bmatrix} \text{Toep}_{0,t,t-1}(A_K) & \sigma_u \text{Toep}_{0,t,t}(A_K) \text{diag}_t(B_*) \\ K \text{Toep}_{0,t,t-1}(A_K) & \sigma_u \text{diag}_t(I) + \sigma_u K \text{Toep}_{0,t,t}(A_K) \text{diag}_t(B_*) \end{bmatrix}. $$

In light of the above lemma, we have for $g := \begin{bmatrix} w_{[t-1]} \\ g_{[t]} \end{bmatrix}$, we have that

$$\sum_{s=1}^{t} x_s^T R_1 x_s + u_\star^T R_2 u_\star$$

$$= \begin{bmatrix} x_{[t]} \\ u_{[t]} \end{bmatrix}^T \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} \text{diag} \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} \begin{bmatrix} x_{[t]} \\ u_{[t]} \end{bmatrix} + M_{0,t} x_1$$

$$= (M_{K,t} g_t + M_{0,t} x_1)^T \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} (M_{K,t} g_t + M_{0,t} x_1)$$

$$= g_t^T M_{K,t}^T \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} M_{K,t} g_t + 2 x_1^T M_{0,t}^T \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix} M_{0,t} x_1. $$

We can evaluate each term separately.

Bounding $\text{tr}(A_{g})$: Let us recall

$$M_{K,t} := \begin{bmatrix} \text{Toep}_{0,t,t-1}(A_K) & \sigma_u \text{Toep}_{0,t,t}(A_K) \text{diag}_t(B_*) \\ K \text{Toep}_{0,t,t-1}(A_K) & \sigma_u \text{diag}_t(I) + \sigma_u K \text{Toep}_{0,t,t}(A_K) \text{diag}_t(B_*) \end{bmatrix}. $$

69
Introduce the shorthand

\[
\begin{bmatrix} A \\ B \end{bmatrix}_{\text{diag}} := \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix},
\]

We find that the diagonal terms of \( \Lambda_\mathbf{g} \) coincide with the diagonals of the matrix \( \Lambda_{\mathbf{g}}_{\text{diag}} \) defined as

\[
\begin{bmatrix} \text{Toep}_{0,t-1}(A_K)^\top \text{diag}_{t-1}(R_K)\text{Toep}_{0,t-1}(A_K) \\ \sigma_n^2 \text{diag}(B_*)^\top \text{Toep}_{1,t-1}(A_K)^\top \text{diag}(R_K)\text{Toep}_{1,t-1}(A_K) \text{diag}(B_*) + \sigma_n^2 \text{diag}(R_2) \end{bmatrix}_{\text{diag}}
\]

Finally, we can bound \( \text{tr}(\sigma_n^2 \text{diag}(B_*)^\top \text{Toep}_{1,t-1}(A_K)^\top \text{diag}(R_K)\text{Toep}_{1,t-1}(A_K) \text{diag}(B_*) + 2\sigma_n^2 \text{diag}(R_2)) \)

By Lemma G.10, we have

\[
\text{tr}(\text{Toep}_{0,t-1}(A_K)^\top \text{diag}_{t-1}(R_K)\text{Toep}_{0,t-1}(A_K)) \leq t \cdot \text{tr}(\text{dyap}(A_K, R_K)) = J_k.
\]

Similarly, since \( \text{dyap}(A_K, R_K) = P_K \), and thus \( \text{rank}(P_K) \leq \text{rank}(R_K) \leq \text{rank}(R_1) + \text{rank}(R_2) \)

\[
\begin{align*}
&\text{tr}(\text{dyap}(A_K, R_K)B_*) \\
&\leq t \cdot \text{tr}(B_*) \text{dyap}(A_K, R_K)B_* \\
&= t \cdot \text{tr}(B_*) \text{dyap}(A_K, R_K)B_* \\
&\leq t \|B_*\|_2^2 \|P_*\|_2 \min\{\text{rank}(B_*), \text{rank}(P_K)\} \leq \text{td}_{\text{eff}} \|B_*\|_2^2 \|P_*\|_2.
\end{align*}
\]

Finally, we can bound \( \text{tr}(\sigma_n^2 \text{diag}(B_*)^\top \text{Toep}_{1,t-1}(A_K)^\top \text{diag}(R_K)\text{Toep}_{1,t-1}(A_K) \text{diag}(B_*) + 2\sigma_n^2 \text{diag}(R_2)) \)

Bounding \( \|\Lambda_\mathbf{g}\|_{\text{op}} \)

Observe that, for any PSD matrix \( M = \begin{bmatrix} A & X \\ X^\top & B \end{bmatrix} \), we have that

\[
M \preceq 2 \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix}_{\text{diag}}.
\]

Since \( \Lambda_\mathbf{g} \succeq 0 \) (it is a non-negative form), in particular, we have \( \Lambda_\mathbf{g} \preceq 2\Lambda_{\mathbf{g}}_{\text{diag}} \). Thus

\[
\|\Lambda_\mathbf{g}\|_{\text{op}} \lesssim \|\Lambda_{\mathbf{g}}_{\text{diag}}\|_{\text{op}} \lesssim 2\sigma_n^2 \|\text{Toep}_{-1,t}(A_K)\|_{\text{op}}^2 + \|\text{Toep}_{-1,t}(A_K)\|_{\text{op}}^2 + 2\sigma_n^2 \|\text{Toep}_{0,t-1}(A_K)\|_{\text{op}}^2.
\]

Since we can bound \( \|\text{Toep}_{-1,t}(A_K)\|_{\text{op}}^2 \leq \|A_K\|_{\mathcal{H}_\infty} \) by Lemma G.10, we obtain

\[
\|\Lambda_\mathbf{g}\|_{\text{op}} \lesssim \|\text{Toep}_{-1,t}(A_K)\|_{\text{op}}^2 + 2\sigma_n^2 \|\text{Toep}_{-1,t}(A_K)\|_{\text{op}}^2 + \|\text{Toep}_{0,t-1}(A_K)\|_{\text{op}}^2.
\]

Finally, we obtain

Bounding \( \Lambda_\mathbf{x}_1 \):

Let us recall,

\[
M_{0,t} := \begin{bmatrix} I_t \\ \text{diag}(K) \end{bmatrix}_{\text{diag}} \text{ToepCol}_{1,t}(A_K).
\]

Thus,

\[
\Lambda_\mathbf{x}_1 = M_{0,t}^\top \begin{bmatrix} \text{diag}(R_1) \\ \text{diag}(R_2) \end{bmatrix}_{\text{diag}} M_{0,t} = \text{ToepCol}_{1,t}(A_K)^\top \text{diag}(R_1 + K^\top R_2 K)\text{ToepCol}_{1,t}(A_K)
\]

\[
\leq \text{dyap}(A_K, R_K) = P_K.
\]
Bounding $\Lambda_{\text{cross}}$: We can directly verify that there exists a matrix $A$ with $AA^\top = \Lambda_\Sigma$ and a matrix $B$ with $BB^\top = \Lambda_{\mathbf{x}_1}$ such that $\Lambda_{\text{cross}} = 2AB^\top$. Hence,

$$\|\Lambda_{\text{cross}}x_1\|_{\text{op}} \leq \sqrt{\|\Lambda_\Sigma\|_{\text{op}} \cdot x_1^\top \Lambda_{\mathbf{x}_1} x_1} \leq \sqrt{\|\Lambda_\Sigma\|_{\text{op}} \cdot x_1^\top P_K x_1}.$$ 

G.7 Proof of Lemma G.2

Set $\mathbf{g} = \begin{bmatrix} \mathbf{w}_{[t-1]} \\ \mathbf{g}_{[t-1]} \end{bmatrix}$. We then have that

$$x_t - A_K^{t-1}x_1 = \text{ToepCol}_{1,t-1}(A_K) \mathbf{w}_{[t-1]} + \sigma_u \text{ToepCol}_{1,t-1}(A_K) \text{diag}(B_\star) \mathbf{g}_{[t]} \mathbf{g}_{[t]}$$

$$\mathbb{E}[\|x_t - A_K^{t-1}x_1\|_2^2 \mid x_1] = \text{tr}(\text{ToepCol}_{1,t-1}(A_K) \text{ToepCol}_{1,t-1}(A_K)^\top) + \sigma_u^2 \text{tr}(\text{diag}_{t-1}(B_\star^\top) \text{ToepCol}_{1,t-1}(A_K) \text{ToepCol}_{1,t-1}(A_K)^\top \text{diag}_{t-1}(B_\star))$$

$$\leq (1 + \sigma_u^2 \|B_\star\|_2^2) \text{tr}(\text{ToepCol}_{1,t-1}(A_K) \text{ToepCol}_{1,t-1}(A_K)^\top)$$

$$\leq (1 + \sigma_u^2 \|B_\star\|_2^2) \|\text{ToepCol}_{1,t-1}(A_K)\|_F^2$$

$$\leq (1 + \sigma_u^2 \|B_\star\|_2^2) \text{tr}(\text{dlyap}(A_K, I))$$

$$\leq (1 + \sigma_u^2 \|B_\star\|_2^2) J_K,$$

where the last inequality uses Lemma B.5. Since $x_t - A_K^{t-1}x_1$ is a Gaussian quadratic form, the simplified Hanson Wright inequality Corollary 6 gives

$$\|x_t - A_K^{t-1}x_1\|_2^2 \lesssim (1 + \sigma_u^2 \|B_\star\|_2^2) J_K \log \frac{1}{\delta}.$$
