UPPER BOUND ON SOME HIGHTNESS NOTIONS

LU LIU

Abstract. We give upper bound for several highness properties in computability randomness theory. First, we prove that discrete covering property does not imply the ability to compute a 1-random real, answering a question of Greenberg, Miller and Nies. This also implies that an infinite set of incompressible strings does not necessarily extract a 1-random real. Second, we prove that given a homogeneous binary tree that does not admit an infinite computable path, a sequence of bounded martingale whose initial capital tends to zero, there exists a martingale $S$ majorizing infinitely many of them such that $S$ does not compute an infinite path of the tree. This implies that 1) High(CR,MLR) does not imply PA-completeness, answering a question of Miller; 2) $\leq_{CR}$ does not imply $\leq_T$, answering a question of Nies. The proof of the second result suggests that the coding power of the universal c.e. martingale lies in its infinite variance.

1. Introduction

The relation between different complexity notion, characterize the complexity of a given object are central topic of mathematical logic. It has been established that many lowness (for random) notion coincide. Therefore we naturally wonder: does a similar picture shows up for highness notions? Our goal is to compare the following two pairs of highness notions: 1) PA degree (the Turing degree that compute a complete Peano Arithematic) versus High(CR,MLR), the oracle relative to which every computably random real is 1-random; 2) the Turing degree that compute a 1-random real versus the discrete covering property. In each case, we separate the former notion from the later one.

In computability theory, there are several ways to say an object is of low complexity. Let $C \subseteq 2^\omega$ be a relativizable complexity notion, if $C^A = C$, then this is seen as an evidence that $A$ is of low complexity. For example, let $C^A$ be 1-random relative to $A$, then $C^A = C$ means every 1-random real is still 1-random relative to $A$ (low for 1-random). The second way is by Kolmogorov complexity. $A$ is $K$-trivial iff $\forall n K(A|_n) \leq K(n) + c$ for some constant $c$. The third way is to say that some robust object compute $A$. For example, $A$ is a base for ML-randomness if $A$ is Turing reducible to some 1-random relative to $A$ real. Nies[9] and Hirschfeldt, Nies and Frank [6] showed that these complexity notions coincide (see [10] [3] for background knowledge of computability randomness theory).

Highness notion can be described in a similar fashion as lowness notion but in an opposite direction. For example, in contrast with low for 1-random is the ability to compute some 1-random. A weaker notion in this respect is that $A$
has more efficient way to describe non-1-random real than the computable degree. In this aspect, Franklin, Stephan, and Yu [4] studied the following highness notion. An oracle $D$ is high for computable randomness vs ML-randomness if every real that is computably random relative to $D$ is 1-random. We denote this property as High(CR,MLR). It it known that High(CR,MLR) implies the ability to compute a 1-random real [4]. While conversely, computing a 1-random real is far from being High(CR,MLR) (see [5] figure 1). Meanwhile, [4] observed that every PA degree is High(CR,MLR). Most of highness properties of this type, except High(CR,MLR), has been well understood. A fundamental question about High(CR,MLR) by Miller, is that whether there is an actual gap between PA completeness and High(CR,MLR) (see [11]). Given a set $D \subseteq 2^{<\omega}$, in this paper, a martingale (supermartingale resp) on $D$ is a function $S : D \to \mathbb{R} \geq 0$ such that for every $\rho \in D$ with $\rho_0, \rho_1 \in D$, $2S(\rho) = (\geq \text{resp}) S(\rho_0) + S(\rho_1)$. A nice characterization of High(CR,MLR) given by Kastermans, Lempp, and Miller (or Bienvenu and Miller [1]) is that $D \in \text{High(CR,MLR)}$ if and only if $D$ compute a martingale $S$ succeeding on every non-1-random where $S$ succeed on $X \in 2^{\omega}$ if $\lim \sup_{n \to \infty} S(X |_n) = \infty$.

In Theorem 3.1 we construct such a martingale that does not compute any PA degree, thus answer the question positively. On the other hand, [5] proved that every $D \in \text{High(CR,MLR)}$ compute a DNR $h$ where $h$ is some slow growing computable increasing function. Thus the current upper bound and lower bound of High(CR,MLR) are pretty close. We say $C$ is Low for computable random iff every computably random real is computably random relative to $C$. Relativizing a lowness notion give rise to a reducibility notion. We write $C \leq_{\text{CR}} D$ if $\text{CR}_D \subseteq \text{CR}_C$ where $\text{CR}^A$ is the set of computably random reals relative to $A$. Nies [9] proved that $C$ is Low for computable random if and only if $C$ is computable. Therefore, Nies [11] naturally asked whether $\leq_{\text{CR}}$ implies $\leq_T$. Miyabe confirms the analog question for Schnorr randomness. We show that this is not the case for computable randomness (Corollary 3.3), answering the question negatively.

Another type of highness notion is the ability to compute the solution of certain combinatorial object. PA completeness falls in this category since $A$ is of PA degree if and only if for every computable infinite binary tree $T$, $A$ compute an infinite path through $T$. From the view of reverse math, the tree $T$ is an instance, an infinite path through $T$ is called its solution. Greenberg, Miller and Nies [5] defined a highness notion in a similar fashion. Given a set $X \subseteq \omega \times \omega$, the weight of $X$, written as $\text{wt}(X)$, is $\sum_{(n,m) \in X} 2^{-n}$. The discrete covering property is defined as following.

**Definition 1.1** ([5]). An instance of Discrete Covering (henceforth DC) is a set $X \subseteq \omega \times \omega$ such that $\text{wt}(X) < \infty$. A DC solution to $X$ is a set $Y \supseteq X$ such that $\text{wt}(Y) < \infty$. An oracle $D$ has the discrete covering property if $D$ compute a solution to every c.e. DC instance.

They asked if an oracle $D$ compute DC solution to all c.e. DC instance, then does $D$ necessarily compute a 1-random real? According to the experience in reverse math, two naturally arised combinatorial notion could hardly coincide with each other. It is even harder to approach WWKL (the ability to compute 1-random real) with combinatorial notion involving subset. Where the DC problem involves subset notion since $X$ is a solution and $Y \supseteq X \wedge \text{wt}(Y) < \infty$ implies $Y$ is also a solution. Chong, Li, Liu, Yang [2] shows that even the tree theorem for pairs (which
incorporate tree combinatorics in itself) does not imply the Weak König’s Lemma. Therefore it is foreseeable that discrete covering does not imply the ability to compute 1-random real which is confirmed in Theorem 2.1. An interesting note is that a discrete covering oracle compute an infinite set of incompressible strings (see Proposition 2.3). Thus together with Theorem 2.1 it means that an infinite set of incompressible string does not necessarily extract a 1-random real. Another consequence is that discrete covering property does not imply (strong) continuous covering property since the latter implies computing a 1-random real (see Corollary 2.2).

It is interesting to wonder if we can view High(CR,MLR) as a reverse math problem. To say that, it usually means 1) The set of instance is a closed set (in most cases an effectively closed set); 2) Given an instance X, the solution to X is ”almost” a $\Pi^0_1(X)$ class. For example, given an infinite tree $T$, the set of infinite path through $T$ is a $\Pi^0_1$ class uniformly in $T$. But given a coloring of pairs $C : [\mathbb{N}]^2 \rightarrow k$, the collection of infinite homogeneous set of $C$ is not $\Pi^0_1$, but a $\Pi^0_C$ class intersects with countably many densely open set. Note that the set of martingale $S$ with $S(\bot) \leq c$ is a $\Pi^0_c$ class uniformly in $c$. Therefore, can we define the majorize martingale problem (henceforth MM in this paper) as following? The instance of MM is a martingale $S$, the solution to $S$ is a martingale $S^*$ such that $S^* \geq S$. However, this restriction lose the essence of High(CR,MLR). [5] shows that every martingale majorizing the optimal c.e. submartingale compute a PA degree. On the other hand, we guess that this coding power of the optimal c.e. submartingale lies in its infinite variance. i.e., We guess that for every martingale (not necessarily c.e.) with bounded variance (but not necessarily bounded) admit a majorization that does not compute any PA degree (see section 3.1). We deal with discrete covering property in section 2 and High(CR,MLR) in section 3.

Notations. We write $(\Psi^T|_X) \downarrow$ if $\Psi^T(n) \downarrow$ for all $n \leq N$; and $(\Psi^T|_X) \uparrow$ if $\Psi^T(n) \uparrow$ for some $n \leq N$. For a string $\rho \in 2^{<\omega}$, we let $[\rho] = \{X \in 2^{\omega} : X \geq \rho\}$; similarly, for $V \subseteq 2^{<\omega}$, let $[V] = \{\sigma \in 2^{<\omega} : \sigma \geq \rho$ for some $\rho \in V\}$; let $X|n = X(0) \cdots X(n-1)$, $X|n = X(n)X(n+1) \cdots X(m)$; for $Q \subseteq 2^{<\omega} \cup 2^{\omega}$, let $X|n = X \cup Q$ to denote the empty string. For an effective object such as a c.e. set $D$, a $\Pi^0_1$ class $Q$, we write $D[t], Q[t]$ to denote the object computed by time $t$. For a set $V \subseteq 2^{<\omega}$, we write $m(V)$ to denote the Lebesgue measure of $|V|$ in $2^{\omega}$.

2. Discrete covering vs 1-randomness

Generally speaking, a problem $P$ admit $\Pi^0_1$ class avoidance of a property, if every non empty $\Pi^0_1$ class of $P$-instance admit a member and a solution $G$ of that member such that $G$ avoid that property. Note that a c.e. DC instance $D$ with, say $wt(D) < 1$, can be approximated by a non empty $\Pi^0_1$ class in the following way: $Q = \{X : \text{For every } t, X \geq D[t] \text{ and } wt(X) \leq 1\}$. Clearly $D$ itself is a member of $Q$ and for every $X \in Q$, every DC solution $Y$ of $X$, $Y$ is a solution to $D$. Our Lemma 2.6 actually shows that DC problem admit $\Pi^0_1$ class avoidance of 1-randomness. We write $X \subseteq^* Y$ if $X \setminus Y$ is finite.

Theorem 2.1. There exists a $G \subseteq \omega \times \omega$ with $wt(G) < \infty$ such that for every c.e. DC instance $D$, $D \subseteq^* G$ and $G$ does not compute any 1-random real.
An oracle $D$ has (strong) continuous covering property if for every computable tree $T$ with $m([T]) > 0$ there exists a $D$-computable subtree $T'$ of $T$ with no leaf such that $m([T']) > 0$. [5] proved that (strong) continuous covering property implies computing a 1-random real. Thus we have:

**Corollary 2.2.** Discrete covering property does not imply (strong) continuous covering property.

An interesting observation is that:

**Proposition 2.3.** There is a c.e. DC instance $D$ such that every DC solution $X$ of $D$ compute an infinite set $W$ of incompressible strings. i.e., $W \subseteq \{\rho: [\rho] \not\in [U_n]\}$ for some $n$ where $(U_n : n \in \omega)$ is the universal ML-test.

**Proof.** For $e \in \omega$, let $D_e$ denote the finite subset of $\omega \times \omega$ whose canonical index is $e$. Let $h : \omega \times 2^{<\omega} \to \omega$ be such a computable function that:

- For every $(n, \rho) \in \omega \times 2^{<\omega}$, $\text{wt}(D_{h(n,\rho)}) = 2^{-|\rho|}$
- $D_{h(n,\rho)}$ are mutually disjoint.

Let $(U_n : n \in \omega)$ be the universal ML-test. We view each $U_n$ as a prefix free c.e. subset of $2^{<\omega}$. Let

$$D = \bigcup_{n \in \omega, \rho \in U_n} D_{h(n,\rho)}.$$ 

Note that for every $n$, $\text{wt}(\bigcup_{\rho \in U_n} D_{h(n,\rho)}) = m(U_n) \leq 2^{-n}$. Thus $\text{wt}(D) < \infty$. It is clear that $D$ is c.e. Suppose $X \supseteq D$ with $\text{wt}(X) < \infty$. Note that this means that there exists an $m^*$ such that for every $n$, there exists a $\rho \in 2^n$ such that $D_{h(m^*,\sigma)} \not\subseteq X$ for all $\sigma \leq \rho$. Thus let

$$W = \{\rho : \forall \sigma \leq \rho \ \text{such that} \ D_{h(m^*,\sigma)} \not\subseteq X\}.$$ 

Clearly $W$ is $X$-computable and infinite. Moreover, if $\exists \sigma \leq \rho \ \sigma \in U_{m^*}$, then $D_{h(m^*,\sigma)} \subseteq X$, which means $\rho \not\in W$. Thus $W \subseteq \{\rho : [\rho] \not\in [U_{m^*}]\}$ and we are done. \[\square\]

An infinite set of incompressible$_K$ string is an infinite set $W \subseteq 2^{<\omega}$ such that for some $c$, $K(\sigma) > |\sigma| - c$ for all $\sigma \in W$. It is well known that $W$ is incompressible$_K$ if and only if $W \subseteq \{\rho : [\rho] \not\in [U_n]\}$ for some $n$. Combine Theorem 2.1 and Proposition 2.3 we have:

**Corollary 2.4.** There exists an infinite set $W$ of incompressible$_K$ strings such that $W$ does not compute any 1-random real.

Meanwhile, Corollary 2.4 can also be interpreted as a 1-enumeration (which is a function $g : \omega \ni n \mapsto g(n) \in 2^n \cap T_n$) of the tree $T_n = \{\rho : [\rho] \not\in [U_n]\}$ does not necessarily compute an infinite path through $T_n$. The remaining of this section will prove Theorem 2.1.

### 2.1. Proof of Theorem 2.1

The framework of the proof follows the usual line in computability theory. We build a sequence of conditions each forces some requirement and thus the oracle $G$ will satisfy all needed requirements. We firstly define the condition we use then we focus on how to force a given requirement (Lemma 2.7).

Fix a computable order on $\omega \times \omega$. Then we can think of a set $X \subseteq \omega \times \omega$ as a binary sequence $X \in 2^{<\omega}$ and Conversely, for every $\rho \in 2^{<\omega}$ or $X \in 2^{<\omega}$, we can think
of $\rho, X$ as subset of $\omega \times \omega$. Therefore it makes sense to write $\wt(\rho)$, $\rho \cap X, \rho \supseteq \sigma, \rho \setminus X$.
We say $\hat{Q}$ dominate $\hat{Q}$ if for every $Y \in \hat{Q}$ there exists an $X \subseteq Y$ such that $X \in \hat{Q}$.
For a class $\hat{Q} \subseteq 2^{\omega}$, let
\[
\wt(\hat{Q}) = \inf_{X \in \hat{Q}} \wt(X) \text{ and }\wt(\hat{Q}) = \infty \text{ if } \hat{Q} = \emptyset.
\]
In this section except section 2.2, all reals appearing as parameters are computable.
In this section, a condition is a tuple $(\tau, Q, a)$ such that
- $\tau \in 2^{<\omega}$;
- $Q \subseteq 2^\omega$ is a $\Pi^0_1$ class such that $\wt(Q) < \infty$;
- For every $X \in Q$, $\tau \supseteq X |_{|\tau|}$ and $\wt(\tau \setminus X) < a$.
Intuitively, a condition is seen as a $\Pi^0_1$ class of candidates of the oracle $G$ we construct, namely
\[
\{ Y > \tau : \text{There exists an } X \in Q, Y \supseteq X, \wt(Y \setminus X) \leq a \}.
\]
We use $(\tau, Q, a)$ to denote this set of candidates. It is not necessary that for every $X \in Q$, $\wt(X) < \infty$. A condition $(\tau', Q', a')$ extends a condition $(\tau, Q, a)$ (written as $(\tau, Q, a) \leq (\tau', Q', a')$) if $(\tau', Q', a') \subseteq (\tau, Q, a)$. The requirement is simply
\[
R_{\varphi, m} : \Psi^G \in [U_m] \text{ or } \Psi^G \text{ is not total.}
\]
A condition $(\tau, Q, a)$ forces $R_{\varphi, m}$ if every $G \in (\tau, Q, a)$ satisfies $R_{\varphi, m}$.
It’s easy to see that:

**Lemma 2.5.** For every condition $(\tau, Q, a)$, every c.e. DC instance $D$, there exists an extension $(\tau', Q', a')$ of $(\tau, Q, a)$ such that for every $Y \in (\tau, Q', a')$, $D \subseteq^* Y$.

**Proof.** Simply let $n > |\tau|$ be sufficiently large so that $\wt(D \setminus (\omega \times \omega|_n)) < \delta$ with $\delta$ being sufficiently small such that for some $X^* \in Q$ with $\wt(X^*) < \infty$, we have $\wt(\tau \setminus X^*) < a' < a - \delta$. Let $Q' = \{ X' > X^* |_{|\tau|} : \text{There exists an } X \in Q \text{ such that } \wt(X' \setminus X) \leq \delta, X' \supseteq X \cup (D \setminus (\omega \times \omega|_n)) \}$. To see $(\tau, Q', a') \subseteq (\tau, Q, a)$, fix a $Y \in (\tau, Q', a')$ with $X'$ being a witness. i.e., $Y \supseteq X' \land \wt(Y \setminus X') \leq a'$. By definition of $Q'$, there exists an $X \in Q$ such that $X' \supseteq X$ and $\wt(X' \setminus X) \leq \delta$. Therefore $\wt(Y \setminus X) = \wt(Y \setminus X') + \wt(X' \setminus X) \leq a' + \delta < a$.
Meanwhile $X^* \cup (D \setminus (\omega \times \omega|_n)) \in Q'$, thus $\wt(Q') < \infty$. It’s trivial to verify that for every $Y \in (\tau, Q', a')$, $D \subseteq^* Y$. \hfill $\square$

Now it remains to prove the following:

**Lemma 2.6.** Every condition admit an extension forcing a given requirement $R_{\varphi, m^*}$.

Using Lemma 2.6, we can build a sequence of conditions $d_0 \geq d_1 \geq \cdots$ where $d_s = (\tau_s, Q_s, a_s)$ such that every requirement is forced by one of these conditions and $d_0$ is weight-bounded in the sense that for some $b < \infty$, $\wt(X) < b$ for all $X \in Q_0$. By compactness, $G = \cup_s \tau_s$ is contained in all conditions and thus satisfy all requirements. We also have $\wt(G) < \infty$ since $G \in d_0$ and $d_0$ is weight-bounded.

Lemma 2.6 will follows from the following:

---

1 Recall that we think of $\omega \times \omega$ as an element in $2^\omega$ so $\omega \times \omega|_n$ is its initial segment of length $n$. 

---
Lemma 2.7. For a condition \((\tau, Q, a)\) and \(a \varepsilon > 0\), there exists a tuple \((\tau^*, Q^*, a^*, V^*)\) such that

- \(\tau^* \succeq \tau\) and \(Q^*\) dominate \(Q\);
- \(\text{wt}(Q^*) + a^* < a\);
- For every \(X \in Q^*\), \(\tau^* \supseteq X\) and \(\text{wt}(\tau^* \setminus X) < a^*\);
- \(V^* \subseteq 2^{\omega}\) is c.e. with \(m(V^*) < \varepsilon\). Moreover, its index can be computed from the index of \(Q\), an upper bound of \(\text{wt}(Q)\), and \(\tau, a, \varepsilon\).
- Either for some \(n\), \(\Psi^* \mid_n \in V^*\) (in which case we say \((\tau^*, Q^*, a^*, V^*)\) forces \(R_{\Psi, m}\) in a \(\Sigma_0^0\) way); Or for every \(X \in Q^*\), every \(Y \supseteq X\) with \(\text{wt}(Y \setminus X) < a^*\), \(\Psi^*\) is non total (in which case we say \((\tau^*, Q^*, a^*)\) forces \(R_{\Psi, m}\) in a \(\Pi_1\) way).

In this case, \((\tau^*, Q^* \cap \{X : w(X) \leq \text{wt}(Q^*) + \delta\}, a^*)\) is a condition extending \((\tau, Q, a)\) and forces \(R_{\Psi, m}\) if \([V^*] \subseteq [U_n]\) (where \(\delta\) is sufficiently small so that \(\text{wt}(Q^*) + a^* + \delta < a\)). To see this, let \(Y \in (\tau^*, Q^* \cap \{X : w(X) \leq \text{wt}(Q^*) + \delta\}, a^*)\) with \(X^* \in Q^* \cap \{X : w(X) \leq \text{wt}(Q^*) + \delta\}\) being a witness. That is:

\[ Y \supseteq X^*, Y \supseteq \tau^*, w(Y \setminus X^*) \leq a^*. \]

Since \(Q^*\) dominate \(Q\), there exists \(X \subseteq X^*\), such that \(X \in Q\). Then we have:

\[ \text{wt}(Y \setminus X) = \text{wt}(Y \setminus X^*) + \text{wt}(X^* \setminus X) \leq a^* + \text{wt}(X^*) \leq a^* + \text{wt}(Q^*) + \delta < a. \]

i.e., \(Y \in (\tau, Q, a)\). Therefore \((\tau^*, Q^* \cap \{X : w(X) \leq \text{wt}(Q^*) + \delta\}, a^*)\) extends \((\tau, Q, a)\).

Now it remains to prove Lemma 2.7. For a condition \((\tau, Q, a)\), note that we can select a \(X \in Q\) with \(w(X) < \infty\) and extends \(\tau\) to \(\tau' \supseteq X\) so that \(w(X \setminus (\omega \times \omega[\tau]))\) is very small compared to \(a - w(\tau' \setminus X)\) (simply let \(\tau'^{\omega[\tau]} = X^{\omega[\tau]}\)). Therefore, for convenience, we prove Lemma 2.7 for \((\tau, Q, 3)\) and assume that \(w(Q) < 1\) (but make no assumption on \(\varepsilon\)). Before that, we firstly establish some combinatorics.

2.2. Small set in partition-large collection. It is corollary 2.10 that we are going to use (actually we will only use it for \(k = 2\)). The Hamming distance between \(\rho, \sigma \in 2^n\), denoted as \(d_H(\rho, \sigma)\), is \(|\{m < n : \rho(m) \neq \sigma(m)\}|\); for a set \(A \subseteq 2^n\), \(d_H(\rho, A) = \min_{\sigma \in A} d_H(\rho, \sigma)\); for a \(Z \subseteq N\), \(d_H(\rho, Z) = |Z\Delta\{n < N : \rho(n) = 1\}|\).

Recall that a sequence of random variable \(x_0, x_1, \ldots\) is \(o_p(n)\) if for every \(c > 0\), \(\lim_{N \to \infty} \Pr(|x_N| < cN) = 1\). Applying Theorem 3 of [7], we have the following.

Theorem 2.8. Let \(c > 0\) and \(N\) be very large; let \(A \subseteq 2^N\) satisfy \(|A|/2^N \geq c\); let \(\rho\) be uniformly random in \(2^N\). Then, \(d_H(\rho, A) = o_p(N)\).

A collection \(A \subseteq \mathcal{P}(N)\) is \(k\)-large in \(N\) if for every \(k\)-partition \(N_0, \ldots, N_{k-1}\) of \(N\), there exists an \(i \in k\) such that \(N_i \in A\). \(A\) is upward closed if for every \(A \supseteq B, B \in A\) implies \(A \in A\). Let \(N\) be very large and \(\delta > 0\) be a constant.

Theorem 2.9. Suppose \(A \subseteq \mathcal{P}(N)\) is \(k\)-large in \(N\) and upward closed; let \(Z\) be a uniformly random \(N/k\)-element subset of \(N\), we have that: with high probability (as \(N \to \infty\)), there exists a \(A \subseteq N\) with \(|A| < \delta N\) such that \(A \cup Z \in A\).

Proof. We only prove for \(k = 2\). The general case follows by coding \(k^N\) into \(2^{N'}\) in a bit wise fashion. Firstly, let

\[ A' = \{\rho \in 2^N : \{n : \rho(n) = 1\} \in A\}. \]
Corollary 2.10. For every $\delta > 0$, every $j \in \omega$, every $j$ many collections $A_0, \cdots, A_{j-1}$ with each being $k$-large in $N$ and upward closed (where $N$ is sufficiently large), there exists a subset $Z$ of $N$ with $|Z| < (1/k + \delta)N$ such that $Z \subseteq A_j$.

2.3. Proof of Lemma 2.7. For $a > 0, n \in \omega, V \subseteq 2^n$, let

$$Q(V,a) = \{Y \in 2^\omega : \text{There exists an } X \in Q \text{ with } X \subseteq Y;$$

$$\text{For every } Z \supseteq Y \text{ with } wt(Z \setminus Y) \leq a \wedge (\Psi^Z|_n) \downarrow \text{ we have that } \Psi^Z|_n \notin V\}.$$  

Clearly $Q(V,a)$ is a $\Pi_1^0$ class uniformly in $V$ and the index of the computable representation of $a$. Note that if there is no desired tuple to force $\mathcal{R}_{\Psi,m}$, in a $\Sigma_1^0$ way, then $\text{wt}(Q) \geq \text{wt}(Q(V^*,a))$ for all $a < 3/2$. To see this, suppose $\text{wt}(Q) < \text{wt}(Q(V^*,a))$ for some $a < 3/2$, then there exists an $X \in Q$ with $\text{wt}(X) < \text{wt}(Q(V^*,a)) \wedge \text{wt}(X) < 1$, which means $X \notin Q(V^*,a)$. By definition of $Q(V^*,a)$, there exists a $\tau \supseteq X|_{\tau}$ with $\text{wt}(\tau \setminus X) \leq a$ such that $(\Psi^\tau|_n) \downarrow \in V^*$ for some $n$. Therefore, the tuple $(\tau, [X|_{\tau}] \cap Q, 3/2, V^*)$ is the desired extension of $(\bot, Q, 3)$ forcing $\mathcal{R}_{\Psi,m}$, in a $\Sigma_0^0$ way.

Remark 2.11. Intuitively, $\text{wt}(Q(V,a))$ can be seen as a measure of how much effort $Q$ has to make in order to ensure that $\Psi^G \notin [V]$, the larger $\text{wt}(Q(V,a))$ is the harder it is for $Q$ to ensure $\Psi^G \notin [V]$. The c.e. set $V^*$ will try to enumerate $V'$ so that at some time $t$, $\text{wt}(Q(V',a)[t]) - \text{wt}(Q[t])$ is considerably larger than $m(V')$. By the above observation, this will force $\text{wt}(Q)$ to increase (compared to $\text{wt}(Q[t])$) considerably large. The key Lemma 2.13 shows that for every sufficiently small $\Delta \lambda > 0$, we can force $\text{wt}(Q)$ to increase by at least $\Delta \lambda/2$ through enumerating a "small" set $V'$ into $V^*$ where $m(V') < \left(\frac{4}{3}\right)^{\pi\lambda}$.

We firstly make some observations on $Q(V,a)$. For convenience, whenever we write $Q(V,a)$, it automatically implies that $a$ is irrational (see footnote below for the reason).

Lemma 2.12. Let $\rho \in 2^{<\omega}, V_0, V_1 \subseteq 2^n, V \subseteq 2^m$; let $a, \lambda, \lambda' > \delta > 0$.

1. If $a' \geq a$, then $Q(V,a') \subseteq Q(V,a)$; If $V' \supseteq V$, then $Q(V',a) \subseteq Q(V,a)$.
2. Suppose $\text{wt}([\rho] \cap Q(V_i,a)) < \lambda + \lambda'$ for $i \in 2$ and $\text{wt}(\rho) > \lambda - \delta$, then we have: $\text{wt}([\rho] \cap Q(V_0 \cup V_1, a - 2\lambda')) < \lambda + 3\lambda'$.
3. Suppose $a < 3/2$, $V' = [V]^2 \cap 2^n$ and $\text{wt}([\rho] \cap Q(V',a)) < 3/2 < \text{wt}([\rho] \cap Q(V,a))$. Then there exists a desired tuple forcing $\mathcal{R}_{\Psi,m}$ in a $\Pi_1^0$ way.
(4) Suppose $a \leq 3/2$, $\text{wt}(Q(2^n, a)) < 3/2$, then there exists a desired tuple forcing $\mathcal{R}_{\Psi,m^*}$ in a $\Pi^0_1$ way.

Remark 2.13. Intuitively, item (2) says that if we can avoid each $V_0, V_1$ with a small price, namely $\lambda'$, then we can avoid them together with a small price, namely $3\lambda'$. The intuition for item (3) is that if we cannot avoid $V$ with a certain price, then we can not avoid $|V| \leq \leq 2^n$ since if $\Psi^G$ is total, then $\Psi^G \in [V] \Leftrightarrow \Psi^G \in [|V| \leq 2^n]$.

Proof. Item (1) is trivial and its proof is skipped.

Proof of item (2): Let $X_i \in [\rho] \cap Q(V_i, a)$ with $\text{wt}(X_i) < \lambda + \lambda'$ and let $X = X_0 \cup X_1$. We show that $X$ is a $\mathcal{DC}$ instance avoiding $V_0 \cup V_1$ (in the sense of (2.1)). Clearly $X \in [\rho]$. Meanwhile,

$$\text{wt}(X) = \text{wt}(X_0) + \text{wt}(X_1) - \text{wt}(X_0 \cap X_1) < 2\lambda + 2\lambda' - \lambda + \delta < \lambda + 3\lambda'.$$

Note that for every $Y \supseteq X$ with $\text{wt}(Y \setminus X) \leq a - 2\lambda'$, it holds that

$$(2.2) \quad \text{wt}(Y \setminus X_i) = \text{wt}(Y \setminus X) + \text{wt}(X \setminus X_i) \leq a - 2\lambda' + \text{wt}(X_1 \setminus X_i) = a - 2\lambda' + \text{wt}(X_1 \setminus (X_0 \cap X_1)) \leq a - 2\lambda' + \text{wt}(X_1 \setminus \rho) < a - 2\lambda' + \lambda + \lambda' - \lambda + \delta < a$$

This means that for every $Y \supseteq X$ with $\text{wt}(Y \setminus X) \leq a - 2\lambda'$, it holds that

$$(\Psi^Y_{\uparrow \rho} \downarrow \Psi^Y_{\uparrow \rho} \notin V_0 \cup V_1 \text{ i.e., } X \in Q(V_0 \cup V_1, a - 2\lambda')).$$

Thus $\text{wt}(\rho \cap Q(V_0 \cup V_1, a - 2\lambda')) < \lambda + 3\lambda'$.

Proof of item (3): Let $X^* \in [\rho] \cap Q(V', a)$ with $\text{wt}(X^*) < 3/2$. Clearly $X^* \notin Q(V, a)$. Therefore there exists a $\tau \supseteq X^*_{\uparrow \tau}$ with $\text{wt}(\tau \setminus X^*) < a$ such that $(\Psi^Y_{\uparrow m} \downarrow \Psi^Y_{\uparrow m} \notin V)$. We show that $(\tau, [X^*_{\uparrow \tau}] \cap Q(V', a), a)$ is a desired tuple forcing $\mathcal{R}_{\Psi,m^*}$ in a $\Pi^0_1$ way. Clearly

$$\text{wt}([(X^*_{\uparrow \tau}] \cap Q(V', a)) + a \leq \text{wt}(X^*) + 3/2 < 3,$$

and $[X^*_{\uparrow \tau}] \cap Q(V', a)$ dominate $Q$. Fix a $X \in [X^*_{\uparrow \tau}] \cap Q(V', a)$, a $Y \supseteq X$ with $Y > \tau \wedge \text{wt}(Y \setminus X) \leq a$. Note that $(\Psi^Y_{\uparrow m} \downarrow \Psi^Y_{\uparrow m} \notin V'$. But $\Psi^Y_{\uparrow m} \in V$ and $V' = [V] \leq \leq 2^n$. This means $(\Psi^Y_{\uparrow m}) \uparrow$.

Proof of item (4): We show that $(\bot, Q(2^n, a), a)$ is the desired tuple forcing $\mathcal{R}_{\Psi,m^*}$ in a $\Pi^0_1$ way. Fix a $X \in Q(2^n, a)$. Clearly for every $Y \supseteq X$ with $\text{wt}(Y \setminus X) \leq a$, $(\Psi^Y_{\uparrow m}) \uparrow$. Meanwhile $\text{wt}(Q(2^n, a)) + a < 3$.

The following is the key Lemma and is the only part of the proof concerning the combinatorics in section 2.22.

Lemma 2.14. Let $0 \leq \lambda \leq 1, 0 < a \leq 3/2, V \subseteq 2^n$ and let $\Delta \lambda < 1/6$. Suppose $\text{wt}(Q) \geq \lambda$ and $\text{wt}(Q(V, a)) \geq \lambda + \Delta \lambda$. Suppose there does not exists a desired tuple forcing $\mathcal{R}_{\Psi,m^*}$ in a $\Pi^0_1$ way. Then for every $\delta > 0$, there exists a finite set $V' \subseteq 2^{<\omega}$ with $m(V') < \frac{2}{3}m(V)$ such that $\text{wt}(Q(V', a + 2\Delta \lambda)) > \lambda + \Delta \lambda - \delta$.

Since $a$ is irrational and $\text{wt}(\tau \setminus X^*) \leq a$ is rational, therefore $\text{wt}(\tau \setminus X^*) < a$. 

Proof. By compactness, there exist $t, n \in \omega$ so that for every $\rho \in Q(V, a)[t]|_n$, \(\text{wt}(\rho) > \lambda + \Delta \lambda - \delta\) and for every $\rho \in Q[t]|_n$, \(\text{wt}(\rho) > \lambda - \delta\). Fix a $\rho \in 2^n$ with $\lambda - \delta < \text{wt}(\rho) \leq \lambda + \Delta \lambda - \delta$ (which means $[\rho] \cap Q(V, a) = \emptyset$). We firstly prove that for every 2-partition $V_0, V_1$ of $[V]^\omega \cap 2^n$, there exists an $i \in 2$ such that \(\text{wt}([\rho] \cap Q(V_i, a + 2\Delta \lambda)) \geq \lambda + \Delta \lambda\) (where $n' > n$ is sufficiently large). Since $[\rho] \cap Q(V, a) = \emptyset$, so $\text{wt}(\rho) \geq 3/2$. By item (3) of Lemma 2.12
\[
\text{wt}([\rho] \cap Q(V_0 \cup V_1, a)) \geq 3/2 \geq \lambda + 3\Delta \lambda.
\]

By Lemma 2.12 item (2), we have that for some $i \in 2, \text{wt}([\rho] \cap Q(V_i, a + 2\Delta \lambda)) \geq \lambda + \Delta \lambda$. Let $n'$ be sufficiently large and for every $\rho \in 2^n$ with $\lambda - \delta < \text{wt}(\rho) \leq \lambda + \Delta \lambda - \delta$, let
\[
A_\rho = \{V' \subseteq 2^n : \text{wt}([\rho] \cap Q(V', a + 2\Delta \lambda)) > \lambda + \Delta \lambda\}
\]
We’ve shown that $A_\rho$ is 2-large in $2^n \cap [V]^\omega$. By Lemma 2.12 item (1), $A_\rho$ is upward closed. By Corollary 2.14 there exists a $V' \subseteq 2^n$ with $m(V') < \frac{2}{\rho} m(V)$ such that $V' \in \bigcap_{\rho \in 2^n, \lambda - \delta < \text{wt}(\rho) \leq \lambda + \Delta \lambda - \delta} A_\rho$. Meanwhile, for every $\rho$ with $\text{wt}(\rho) \leq \lambda - \delta$, if $X' > \rho$, then there exists no $X \in Q$ such that $X' \supseteq X$ since otherwise $\text{wt}(X'_n) \leq \lambda - \delta$, a contradiction to our setting for $n$. This means $[\rho] \cap Q(V', a + 2\Delta \lambda) = \emptyset$ if $\text{wt}(\rho) \leq \lambda - \delta$. Thus $\text{wt}([\rho] \cap Q(V', a + 2\Delta \lambda)) > \lambda + \Delta \lambda - \delta$ for all $\rho \in 2^n$, which means $\text{wt}(Q(V', a + 2\Delta \lambda)) > \lambda + \Delta \lambda - \delta$.

Now fix $0 < \underline{\alpha} < \underline{\pi} < 3/2$, a sufficiently small $1/6 > \Delta \lambda > 0$ and an $r \in \omega$ be such that:
\[
\begin{aligned}
\{ \underline{\alpha} + 2(r + 1)\Delta \lambda < \underline{\pi}, \\
2\Delta \lambda (\frac{2}{\rho})^r < \varepsilon
\}
\]

Lemma 2.15. Let $0 \leq \lambda \leq 1$. Suppose $\text{wt}(Q) \geq \lambda$ and suppose there does not exist a desired tuple forcing $\mathcal{R}_{\Psi, m'}$ in a $\Pi_1^0$ way. Then there exists a $V' \subseteq 2^{n'}$ for some $n'$ with $m(V') < \frac{2}{\rho} m(V)$ such that $\text{wt}(Q(V', \underline{\pi})) > \lambda + \Delta \lambda/2$.

Proof. Firstly, by Lemma 2.12 item (4), $Q(2^n, \underline{\alpha}) \geq \lambda + \Delta \lambda$. Now repeatedly apply Lemma 2.14 for $r + 1$ times (where $\delta$ is sufficiently small) we have that there exists a $V' \subseteq 2^{n'}$ for some $n'$ with $m(V') < \frac{2}{\rho} m(V)$ such that $\text{wt}(Q(V', \underline{\alpha} + 2(r + 1)\Delta \lambda)) > \lambda + \Delta \lambda - (r + 1)\delta$. Therefore $\text{wt}(Q(V', \underline{\pi})) > \lambda + \Delta \lambda/2$.

Proof of Lemma 2.7. Now we define the following c.e. set $V^*$:

Definition 2.16. At step 0, search for a $V_0 \subseteq 2^{n'}$ (for some $n'$) with $m(V_0) < \frac{2}{\rho} m(V)$ such that $\text{wt}(Q(V_0, \underline{\pi})) > \Delta \lambda/2$ and enumerate $V_0$ into $V^*$ (if such $V_0$ is not found it never enters the next step).

At step $s \geq 1$, wait for a time $t$ so that $\text{wt}(Q[t]) > s\Delta \lambda/2$ (if such time $t$ does not appear, do nothing; and we say $V^*$ enters phase II at step $s$ if such $t$ exists); then search for a $V_s \subseteq 2^{n'}$ (for some $n'$) with $m(V_s) < \frac{2}{\rho} m(V)$ such that $\text{wt}(Q(V_s, \underline{\pi})) > (s + 1)\Delta \lambda/2$ and enumerate $V_s$ into $V^*$ (if such $V_s$ is not found it never enters the next step).

Note that $V^*$ is indeed c.e. since by compactness, for every $\Pi_1^0$ class $\hat{Q}$, $\text{wt}(\hat{Q}) > \hat{\lambda}$ is a $\Sigma_1^0$ relation uniformly in the index of $\hat{Q}$ and $\hat{\lambda}$. Suppose there does not exists
a desired tuple forcing $\mathcal{R}_\Psi$ in a $\Pi^0_1$ way. Then by Lemma 2.10 at each step $s \geq 1$, if $V^*$ enters phase II, the set $V_n$ exists.

Therefore, if there does not exists a desired tuple forcing $\mathcal{R}_\Psi,m_*$ in a $\Pi^0_1$ way, the program ends up by entering a step $s$ and never found a $t$ so that $\text{wt}(Q[t]) > s\Delta \lambda/2$, which means $\text{wt}(Q) \leq s\Delta \lambda/2$. But entering step $s$ implies $\text{wt}(Q(V^*,\vec{\pi})) > s\Delta \lambda/2$ and $\text{wt}(Q) > (s-1)\Delta \lambda/2$ (since $V^*$ enters Phase II at step $s-1$). Since $\text{wt}(Q) < 1$, we have

$$s\Delta \lambda/2 = (s-1)\Delta \lambda/2 + \Delta \lambda/2 < 1 + \Delta \lambda/2 < 3/2.$$ 

Therefore there exists an $X \in Q \setminus Q(V^*,\vec{\pi})$ with $\text{wt}(X) < 3/2$. By definition of $Q(V^*,\vec{\pi})$, there exists a $\tau^* \supseteq X|_{\tau^*}$ with $\text{wt}(\tau^* \setminus X) < \vec{\pi}$ such that $(\Psi \tau^*|_{\tau^*}) \in V^*$ for some $n^*$.

Meanwhile, since $\text{wt}(Q) < 1$, the algorithm of $V^*$ enters at most $2/n^*$ many steps and at each step, $m(V^*)$ is increased by less than $(\frac{2}{\Delta \lambda})^r$. Therefore, by (2.3),

$$m(V^*) < \frac{2}{\Delta \lambda} \left(\frac{2}{3}\right)^r < \epsilon.$$ 

Thus $(\tau^*,[X|_{\tau^*}] \cap Q,\vec{\pi},V^*)$ is the desired tuple since

$$\text{wt}([X|_{\tau^*}] \cap Q) + \vec{\pi} \leq \text{wt}(X) + \vec{\pi} < 3/2 + 3/2 = 3.$$ 

\end{flushright}

3. THE WEAKNESS OF MAJORIZING BOUNDED MARTINGALE

Kastermans, Leppe, and Miller showed that $D \in \text{High(CR,MLR)}$ if and only if there exists a $D$-computable martingale $S$ such that $S$ succeed on every non-1-random real (see also [II]). Therefore, in order to separate PA completeness from $\text{High(CR,MLR)}$, it suffices (and necessary) to construct a martingale $S$ succeeding on all non-1-random while does not compute a PA degree. A function $S$ is bounded if $\text{range}(S)$ is a bounded subset of $\mathbb{R}$. In this section, the domain of a martingale (supermartingale resp) is $2^{<\omega}$ if not claimed otherwise. A tree $T \subseteq 2^{<\omega}$ is homogeneous if there exists a sequence of set $B_0, B_1, \cdots \subseteq \{0, 1\}$ such that $\rho \in T$ if and only if $\rho(n) \in B_n$ for all $n < |\rho|$.

**Theorem 3.1.** Let $\overline{S}_0, \overline{S}_1, \cdots$ be a sequence of bounded martingales (not necessarily c.e.) such that $\lim_{n \to \infty} \overline{S}_n(\perp) = 0$; let $T \subseteq 2^{<\omega}$ be a homogeneous tree that does not admit a computable infinite path. There exists a martingale $S$ such that $S \geq \overline{S}_n$ for infinitely many $n$ and $S$ does not compute an infinite path through $T$.

Note that every open set $U$ of $2^{<\omega}$ give rise to a bounded martingale $S_U$ such that $S_U(\rho) = m(U \cap [\rho])/m([\rho])$. For every sequence of open set $U_n$ with $m(U_n) \leq 1/2^n$, consider the induced bounded martingale sequence $n \cdot S_{U_n}$. Clearly $\lim_{n \to \infty} n \cdot S_{U_n}(\perp) = 0$. Thus by Theorem 3.1 with $\overline{S}_n = n \cdot S_{U_n}$ where $(U_n : n \in \omega)$ is the universal ML-test and with $T$ be the homogenous tree defining PA degree, we directly have:

**Corollary 3.2.** There exists a $D \in \text{High(CR,MLR)}$ such that $D$ is not of PA degree.

Another corollary is that $\leq_{CR}$ does not imply $\leq_T$.

**Corollary 3.3.** For every incomputable set $C$, there exists a $D \nleq_T C$ such that $\text{CR}^D \subseteq \text{MLR}^C$.
Proof. Let $(U^n_C : n \in \omega)$ be the universal ML-test relative to $C$ and let $\overline{S}_n = n \cdot U^n_C$; let $T = \{C|_n\}_{n \in \omega}$. Thus the conclusion follows directly from Theorem 3.1.

\[\square\]

The boundness restriction in Theorem 3.1 might not be necessary but is for the sake of convenience (see the end of section 3.1). Now we prove Theorem 3.1.

Let’s first recall some probability notions. The main object of section 3.1 is Lemma 3.4. Given a martingale $S$, a $\rho \in 2^{<\omega}$, let

\[\text{Var}(S|\rho) = \lim_{t \to \infty} \frac{1}{2^{|\rho|}} \sum_{\sigma \in [\rho]^2 \cap 2^t} (S(\sigma) - S(\rho))^2.\]

We show that a sufficient condition is that $c > \max\{S_j(\perp)\}$, under what condition does there guarantee a martingale $S^*$ majorizing $\max\{S_j(\rho)\}$ while $S^*(\perp) < c$. The condition $c > \sum_{j<k} S_j(\perp)$ is too strong for our application. For a martingale $S$, a $\rho \in 2^{<\omega}$, let

\[\text{Var}(S|\rho) = \frac{1}{2} (\text{Var}(S|\rho 0) + \text{Var}(S|\rho 1)) + \frac{1}{2} ((S(\rho 0) - S(\rho))^2 + (S(\rho 1) - S(\rho))^2).\]

We address the question that given $k$ martingales $S_0, \cdots, S_k-1$, a $c > \max\{S_j(\perp)\}$, under what condition does there guarantee a martingale $S^*$ majorizing $\max\{S_j(\rho)\}$ while $S^*(\perp) < c$. The condition $c > \sum_{j<k} S_j(\perp)$ is too strong for our application. For a martingale $S$, a $\rho \in 2^{<\omega}$, let

\[\text{Var}(S|\rho) = \lim_{t \to \infty} \frac{1}{2^{|\rho|}} \sum_{\rho \in 2^t \cap [\rho]^{>\omega}} \text{Var}(S|\rho) = 0 \text{ for all } \rho'.\]

Since $\sqrt{x}$ is concave, for every non negative random variable $x$, $\sqrt{E[x]} \geq E[\sqrt{x}]$. Combine with (3.1), we have that:

\[\lim_{t \to \infty} \frac{1}{2^{|\rho|}} \sum_{\rho \in 2^t \cap [\rho]^{>\omega}} \sqrt{\text{Var}(S|\rho)} = 0 \text{ for all } \rho'.\]

Lemma 3.4. Given a martingale $S'$ with $\text{Var}(S'|\perp) < \infty$ and a $c > S'(\perp)$. For every $\hat{c}$, there exists a martingale $S$ such that:

- $S(\perp) < c$ and $S(\rho) > S'(\rho)$ for all $\rho \in 2^{<\omega}$;
- For some $t \in \omega$, $S(\rho) > S'(\rho) + \hat{c} \cdot \sqrt{\text{Var}(S'|\rho)}$ for all $\rho \in 2^t$.

Proof. It’s trivial to see that a martingale $S$ satisfying the first item exists. Suppose $S(\perp) < c - \delta$ for some $\delta > 0$. By (3.2), there exists a $t$ such that

\[\hat{c} \cdot \frac{2^t}{2^{|\rho|}} \sum_{\rho \in 2^t} \sqrt{\text{Var}(S_j|\rho)} < \delta.\]

Let $\hat{S}$ be the unique martingale such that for every $\rho \in 2^t$ and $\sigma \in [\rho]^{>\omega}$, $\hat{S}(\sigma) = \hat{S}(\rho) = \hat{c} \cdot \sqrt{\text{Var}(S_j|\rho)}$. Clearly $\hat{S}(\perp) < \delta$. Thus $\hat{S} + S$ satisfy all items.

\[\square\]
Lemma 3.5. For any random vector \( \bar{x} \) (not necessarily with mutually independent component),

\[
\mathbb{E}[\max_{j<k}\{\bar{x}(j)\}] - \max_{j<k}\{\mathbb{E}[\bar{x}(j)]\} \leq \frac{1}{2} \sum_{j<k} \sqrt{\text{Var}(\bar{x}(j))}.
\]

Proof. Without loss of generality, we may assume that \( \mathbb{E}[\bar{x}(j)] = \mu \) for all \( j < k \).
Let \( A_j \) denote the event \( \{\bar{x}(j) = \max_{j' < k}\{\bar{x}(j')\} \wedge \bar{x}(j) > \bar{x}(j') \text{ for all } j' < j\} \). Note that \( \cup_j A_j \) is the whole space. Suppose \( \mathbb{E}[\bar{x}(j)|A_j] = \mu + a_j \) and \( \mathbb{E}[\bar{x}(j)|A_j^c] = \mu - b_j \). Clearly \( P(A_j) = \frac{b_j}{a_j + b_j} \). By decomposition of variance:

\[
\text{Var}(\bar{x}(j)) = P(A_j)[\text{Var}(\bar{x}(j)|A_j) + a_j^2] + P(A_j^c)[\text{Var}(\bar{x}(j)|A_j^c) + b_j^2] \\
\geq \frac{b_j}{a_j + b_j} a_j^2 + \frac{a_j}{a_j + b_j} b_j^2 \\
= a_j b_j
\]

Meanwhile, since \( \frac{\sqrt{a_j b_j}}{a_j + b_j} \leq 1/2 \),

\[
\mathbb{E}[\max_{j<k}\{\bar{x}(j)\}] - \max_{j<k}\{\mathbb{E}[\bar{x}(j)]\} = \sum_{j<k} P(A_j) a_j \\
= \sum_{j<k} \sqrt{\frac{a_j b_j}{a_j + b_j}} \sqrt{a_j b_j} \\
\leq \frac{1}{2} \sum_{j<k} \sqrt{\text{Var}(\bar{x}(j))}.
\]

\( \Box \)

The following Lemma 3.7 is key to our proof.

Definition 3.6. For vectors \( \bar{\mu} \in \mathbb{R}^k, \bar{v} \in (\mathbb{R}_{\geq 0})^k \), define \( f(\bar{\mu}, \bar{v}) \) to be the supreme of \( \mathbb{E}[\max_{j<k}\{\bar{x}(j)\}] \) where the supreme is taken over all random vector \( \bar{x} \) such that \( \mathbb{E}[\bar{x}] = \bar{\mu} \) and \( \text{Var}(\bar{x}(j)) = \bar{v}(j)^2 \) for all \( j < k \).

Lemma 3.7. For every \( \bar{\mu} \in \mathbb{R}^k, \bar{v} \in (\mathbb{R}_{\geq 0})^k \) we have:

1. \( \max_{j<k}\{\bar{\mu}(j)\} \leq f(\bar{\mu}, \bar{v}) \leq \max_{j<k}\{\bar{\mu}(j)\} + \frac{1}{2} \sum_{j<k} \bar{v}(j) \); 
2. Suppose \( \bar{\mu}_i, \bar{v}_i, i \in 2 \) satisfy \( \bar{\mu} = \frac{1}{2} \sum_{i \in 2} \bar{\mu}_i, \bar{v}(j) = \frac{1}{2} \sum_{i \in 2} \bar{v}_i(j)^2 = \frac{1}{2} \sum_{i \in 2} [\bar{\mu}_i(j) - \bar{\mu}(j)]^2 \) for all \( j < k \). Then we have: \( \frac{1}{2} (f(\bar{\mu}_0, \bar{v}_0) + f(\bar{\mu}_1, \bar{v}_1)) \leq f(\bar{\mu}, \bar{v}) \).

Proof. For item (1): Note that for every random vector \( \bar{x} \), it holds trivially that \( \mathbb{E}[\max_{j<k}\{\bar{x}(j)\}] \geq \max\{\mathbb{E}(\bar{x}(j))\} \), which gives the first inequality. The second inequality follows by (3.3).

For item (2): Suppose otherwise with \( \bar{\mu}_i, \bar{v}_i, \bar{\mu}, \bar{v}, i \in 2 \) being a witness. Let \( \bar{x}_i, i \in 2 \) be random vectors such that \( \mathbb{E}(\bar{x}_i) = \bar{\mu}_i, \text{Var}(\bar{x}_i(j)) = \bar{v}_i(j) \) and \( \mathbb{E}[\max_{j<k}\{\bar{x}_i(j)\}] > f(\bar{\mu}_i, \bar{v}_i) - \delta \) for all \( i \in 2 \). Where \( \delta > 0 \) satisfy \( \frac{1}{2} (f(\bar{\mu}_0, \bar{v}_0) + f(\bar{\mu}_1, \bar{v}_1)) > f(\bar{\mu}, \bar{v}) + \delta \). Let \( z \sim \text{Bin}(1, 1/2) \) where \( \text{Bin}(n, p) \) is the Bernoulli distribution and let \( \bar{x} \) be such
a random vector that conditional on \( z = i \), \( \bar{x} \sim \text{Law}(\bar{x}_i) \) for all \( i \in 2 \) (where \( \text{Law}(\bar{x}_i) \) denote the distribution of \( \bar{x}_i \)). Clearly

\[
E[\max_j \{\bar{x}(j)\}] = \frac{1}{2} \sum_{i \in 2} E[\max_j \{\bar{x}_i(j)\}]
\]

\[
> \frac{1}{2} (f(\bar{\mu}_0, \bar{\nu}_0) + f(\bar{\mu}_1, \bar{\nu}_1)) - \delta
\]

\[
> f(\bar{\mu}, \bar{\nu}) + \delta - \delta
\]

\[
= f(\bar{\mu}, \bar{\nu}).
\]

Meanwhile, \( E[\bar{x}] = \frac{1}{2} \sum_{i \in 2} E[\bar{x}_i] = \frac{1}{2} \sum_{i \in 2} \bar{\mu}_i = \bar{\mu} \), and

\[
\text{Var}(\bar{x}(j)) = \frac{1}{2} \sum_{i \in 2} \text{Var}(\bar{x}_i(j)) + \frac{1}{2} \sum_{i \in 2} (\bar{\mu}_i(j) - \bar{\mu}(j))^2
\]

\[
= \frac{1}{2} \sum_{i \in 2} [\bar{\nu}_i(j)^2 + (E[\bar{x}_i(j)] - E[\bar{x}(j)])^2] = \bar{\nu}(j)^2
\]

A contradiction to the definition of \( f(\bar{\mu}, \bar{\nu}) \).

\[\square\]

**Lemma 3.8.** Given \( k \) martingales \( S_0, \cdots, S_{k-1} \), a \( c > \max\{S_j(\perp)\} + \frac{1}{2} \sum_{j<k} \sqrt{\text{Var}(S_j | \perp)} \), there exists a martingale \( S^* \) with \( S^*(\perp) < c \) such that \( S^*(\rho) > \max\{S_j(\rho)\} \) for all \( \rho \in 2^{\omega} \). Moreover, \( S^* \) could be bounded if each \( S_j \) is bounded.

**Proof.** Let \( \bar{S} = (S_0, \cdots, S_{k-1}) \), we write \( \bar{S}(\rho) \) for \( (S_0(\rho), \cdots, S_{k-1}(\rho)) \); we write \( \sqrt{\text{Var}(\bar{S} | \rho)} \) for \( (\sqrt{\text{Var}(S_0 | \rho)}, \cdots, \sqrt{\text{Var}(S_{k-1} | \rho)}) \). Consider the function \( \rho \mapsto f(\bar{S}(\rho), \sqrt{\text{Var}(\bar{S} | \rho)}) \).

By Lemma 3.7 item (2), \( f(\bar{S}(\rho), \sqrt{\text{Var}(\bar{S} | \rho)}) \) is a supermartingale. Moreover, by Lemma 3.7 item (1), \( f(\bar{S}(\perp), \sqrt{\text{Var}(\bar{S} | \perp)}) < c \). Thus there exists a martingale \( S^* \) such that \( S^*(\perp) < c \) and \( S^*(\rho) > f(\bar{S}(\rho), \sqrt{\text{Var}(\bar{S} | \rho)}) \) for all \( \rho \in 2^{\omega} \). Moreover, \( S^* \) could be bounded if \( S_j \) is bounded for each \( j < k \) (note that \( S \) is bounded implies \( \text{Var}(S | \rho) \) is bounded). By Lemma 3.7 item (1), \( f(\bar{S}(\perp), \sqrt{\text{Var}(\bar{S} | \perp)}) \leq c \). Thus we can use Lemma 3.7 item (1), \( S^*(\rho) > f(\bar{S}(\rho), \sqrt{\text{Var}(\bar{S} | \rho)}) \geq \max\{S_j(\rho)\} \) for all \( \rho \in 2^{\omega} \). Thus we are done.

\[\square\]

To remove the boundedness restriction in Theorem 3.1 we need to prove that \( S^* \) could have finite variance without the boundedness of \( S_0, \cdots, S_{j-1} \). This is entirely possible.

### 3.2. Proof of Theorem 3.1

Again, the frame work of the proof follows the usual line in computability theory. We build a sequence of conditions each forces some requirement and thus the martingale \( \bar{S} \) we construct will satisfy all needed requirements. We firstly define the condition we use then we focus on how to force a given requirement (Lemma 2.7). Readers who are familiar with representation of reals and martingales can skip the following introduction on this representation.

For every \( x \in \mathbb{R}^{\geq 0} \), we represent \( x \) as an \( X = (b, a_0 a_1 \cdots) \in \omega \times 2^{\omega} \cup \omega \times 2^{<\omega} \) so that: 1) \( x = \sum_{|X| \geq n \geq 1} X(n) \cdot 2^{X(0)-n} \) where \( X(0) = b, X(n) = a_{n-1} \); 2) \( b > 0 \rightarrow a_0 = 1 \). The second item means that 1/2 cannot be represented as \((2, 0.0100 \cdots)\)
or $(1, 0, 100, \ldots)$. Conversely every element of $\omega \times 2^\omega \cup \omega \times 2^{<\omega}$ is seen as a real. Meanwhile, given a real, its representation is not unique. For example, $1/2$ can be represented as $(0, 1, 0, 0, \ldots)$ and $(0, 0, 1, 1, \ldots)$. An initial segment of $a X \in \omega \times 2^\omega$ with length $n$ is a $\rho \in \omega \times 2^n$ such that $\rho = X|_n$. An initial segment of a function $S : 2^{<\omega} \rightarrow \omega \times 2^\omega$ is a function $s$ with $\text{dom}(s) = 2^{\leq n}$ for some $n$ such that for every $\rho \in 2^{\leq n}$, $s(\rho)$ is an initial segment of $S(\rho)$. We still use $\geq$ to denote extension relation in these spaces. Clearly

- $\{Y \in \omega \times 2^\omega : X_1 \geq Y \geq X_0\}$ is a $\Pi^0_1 X_0 \oplus X_1$ class uniformly in $X_0 \oplus X_1$;
- $\{\hat{S} : \hat{S} \text{ is a martingale and } \hat{S} \preceq Y \land \text{Var}(\hat{S}) \subseteq X\}$ is a $\Pi^0_1 X \oplus Y$ class uniformly in $X \oplus Y$;
- $\{\hat{S} : \hat{S} \text{ is a martingale and } \hat{S} \succeq s \land \hat{S} \succeq S\}$ is a $\Pi^0_1 S$ class uniformly in $s, S$ where $S$ is a function $2^{<\omega} \rightarrow \omega \times 2^\omega$, $s$ is an initial segment of some function.
- If $X$ is the representation of an irrational and $Y \geq X$, then for every $\sigma \prec Y$, there exists a $\tau \geq \sigma$ such that $\tau > X$.
- For every $s$ that is an initial segment of a martingale with $\text{dom}(s) = 2^{\leq n}$, every martingale $S$ with $S(\rho) < s(\rho)$ for all $\rho \in 2^n$, there exists a martingale $\hat{S} \succeq s$ such that $\hat{S}(\rho) > S(\rho)$ for all $\rho \in 2^{\geq n}$.
- For every $s \prec S$, there exists a $\delta > 0$ such that for every function $\hat{S}$, if $S(\rho) + \delta \geq \hat{S}(\rho) \geq S(\rho)$ for all $\rho \in \text{dom}(s)$, then $\hat{S} \succeq s$.
- Suppose $S$ is a martingale with $\text{range}(S) \cap \mathbb{Q} = \emptyset$, and suppose $s$ is an initial segment of some martingale with $s(\rho) > S(\rho)$ for all $\rho \in 2^n$ where $\text{dom}(s) = 2^{\leq n}$; suppose $\hat{s} \succeq s'$ is a martingale such that $\hat{s}(\rho) \geq S(\rho)$ for all $\rho \in 2^{\geq n}$. Then for every $s \preceq s' < \hat{s}$, there exists a initial segment $\hat{s} \succeq s'$ of some martingale (not necessarily an initial segment of $\hat{S}$) such that $\hat{s}(\rho) > S(\rho)$ for all $\rho \in 2^{\geq n} \cap \text{dom}(\hat{s})$.

A condition in this section is a pair $(s, S)$ such that

- $s$ is an initial segment of some martingale with $\text{dom}(s) = 2^{\leq n}$.
- $S$ is a bounded martingale with $\text{range}(S) \cap \mathbb{Q} = \emptyset$.
- For every $\rho \in 2^n$, $s(\rho) > S(\rho)$.

We emphasize that there is no complexity requirement on $S$. Again, a condition is regarded as the following set of martingales:

$$\{\hat{S} \succeq s : \hat{S}(\rho) \geq S(\rho) \text{ for all } \rho \in 2^{\geq n}\}.$$  

This is a set of candidates of the martingale we construct and we use $(s, S)$ to denote this set. A condition $d' = (s', S')$ extends $d = (s, S)$ (written as $d' \leq d$) if $d' \subseteq d$. Suppose $B_0, B_1, \ldots \subseteq \{0, 1\}$ witness $T$ being homogenous. The requirements are:

- $R_\Psi$ : For some $n, \Psi \hat{S}(n) \nsubseteq B_n$ or $\Psi \hat{S}$ is not total.
- $R'_n$ : There exists $n' > n$ such that $\hat{S} \succeq \overline{S}_{n'}$.

A condition $d$ forces $R_\Psi$ if every $\hat{S} \in d$ satisfy $R_\Psi$. By our hypothesis on $(\overline{S}_0, \overline{S}_1, \ldots)$, for every $n$, every condition $d = (s, S)$, $d$ admit an extension forcing $R'_n$ (simply consider the condition $(s, S + \overline{S}_{n'})$ where $\overline{S}_{n'}(\bot)$ is small enough. Therefore, it remains to prove the following:

**Lemma 3.9.** Every condition admit an extension forcing a given requirement $R_\Psi$.  

Using Lemma 3.3, we can build a sequence of conditions \( d_0 \geq d_1 \geq \cdots \) where \( d_i = \langle s_i, S_i \rangle \) such that every requirement is forced by one of these conditions. By compactness, \( G = \bigcup_i s_i \) is a martingale contained in all conditions and thus satisfy all requirements.

**Proof.** Fix a condition \( (s, S) \). The basic idea of this proof follows a proof separating WKI from RT2\(^2\) [3], illustrated as following. If for some \( m^* \), \( B_{m^*} = \{ i^* \} \) and no condition can force \( \neg (\Psi^\hat{S}(m^*) \downarrow = 1 - i^*) \), then in particular, \( (s, S) \) can not force this. We show that in this case we can extend \( s \) to \( \hat{s} \) (which does not violate the condition \( (s, S) \)) so that \( \Psi^\hat{S}(m^*) \downarrow = 1 - i^* \). If for each \( i \in \{0, 1\} \), there is a condition \( (s, S_i) \) forcing \( \neg (\Psi^\hat{S}(m^*) \downarrow = i) \), then we consider the three condition \( (s, S), (s, S_0), (s, S_1) \) and show that there exists a condition \( (s, S^*) \) extending all of them (simply let \( S^* \) be a martingale majorizing \( S, S_0, S_1 \) which exists by Lemma 3.3). Note that for every \( \hat{S} \in (s, S^*) \), \( \Psi^\hat{S}(m^*) \uparrow \) since otherwise, either \( \Psi^\hat{S}(m^*) \downarrow = 0 \) or \( \Psi^\hat{S}(m^*) \downarrow = 1 \).

Suppose \( \text{dom}(s) = 2^{\leq n} \). By Lemma 3.3, we may assume that, for some \( 0 < \delta \in \mathbb{Q} \), for every \( \rho \in 2^n \),

\[
(3.4) \quad s(\rho) > S(\rho) + 3/2 \cdot v(\rho) + \delta.
\]

where \( \mathbb{Q} \ni v(\rho) > \sqrt{\text{Var}(S(\rho))} \) for all \( \rho \in 2^n \). For every \( m \in \omega \), every \( i \in 2 \), consider the following class \( Q_{m, i} \) such that \( S' \in Q_{m, i} \) if and only if:

1. \( S' \) is a martingale;
2. \( S'(\rho) \leq s(\rho) - 3/2 \cdot v(\rho) - \delta \text{ and } \sqrt{\text{Var}(S'(\rho))} \leq v(\rho) \) for all \( \rho \in 2^n \);
3. For every \( \hat{S} \in (s, S') \), \( \Psi^\hat{S}(m) \downarrow = i^* \).

Note that \( Q_{m, i} \) is a \( \Pi^0_1 \) class uniformly in \( m, i \). Consider the following partial computable function:

\[
g(m) = \text{ the first } i \in 2 \text{ which is found that } Q_{m, i}[t] = \emptyset \text{ for some } t.
\]

Since \( T \) does not admit a computable infinite path, one of the following two cases occurs.

**Case 1:** There exists an \( m^* \in \omega \), \( g(m^*) \notin B_{m^*} \).

This means \( Q_{m^*, i} = \emptyset \) where \( g(m^*) = i^* \notin B_{m^*} \). In this case, in particular, \( S \notin Q_{m^*, i} \), while \( S \) satisfy the first two items of \( Q_{m^*, i} \). By definition of \( Q_{m, i} \), there exists a martingale \( \hat{S} \succ s \) such that

- \( \hat{S}(\rho) \geq S(\rho) \) for all \( \rho \in 2^{\geq n} \);
- \( \Psi^\hat{S}(m^*) \downarrow = i^* \).

Since \( \text{range}(S) \cap \mathbb{Q} = \emptyset \), there exists an initial segment \( \hat{s} \succeq s \) of some martingale such that \( \hat{s}(\rho) > S(\rho) \) for all \( \rho \in 2^{\geq n} \cap \text{dom}(\hat{s}) \) (which means \( \langle \hat{s}, S \rangle \) is a condition extending \( (s, S) \)); and \( \Psi^\hat{S}(m^*) \downarrow = i^* \notin B_{m^*} \). Thus we are done in this case.

**Case 2:** There exists an \( m^* \) such that \( g(m^*) \uparrow \).

This means \( Q_{m^*, 0}, Q_{m^*, 1} \neq \emptyset \). Fix \( S_i \in Q_{m^*, i} \) for \( i \in 2 \) (not necessarily low). Consider the sequence \( S, S_0, S_1 \). By [3.4] and the definition of \( Q_{m, i} \), for every \( \rho \in 2^n \),

\[
s(\rho) > \max\{S(\rho), S_0(\rho), S_1(\rho)\} + \frac{1}{2}(\sqrt{\text{Var}(S(\rho))} + \sqrt{\text{Var}(S_0(\rho))} + \sqrt{\text{Var}(S_1(\rho))}).
\]
By Lemma 3.8 there exists a martingale $S^*$ such that

- $S^*$ is a bounded martingale with range $S^* \cap \mathbb{Q} = \emptyset$;
- $S^*(\rho) < s(\rho)$ for all $\rho \in 2^n$;
- $S^*(\rho) > \max\{S(\rho), S_0(\rho), S_1(\rho)\}$ for all $\rho \in 2^{2^n}$.

Thus the pair $(s, S^*)$ is a condition. Clearly $(s, S^*)$ extends $(s, S)$ since $S^*(\rho) \geq \max\{S(\rho), S_0(\rho), S_1(\rho)\}$ for all $\rho \in 2^{2^n}$. It remains to show that $(s, S^*)$ forces $\mathcal{R}_\Psi$. For every $\hat{S} \in (s, S^*)$, we have that $\hat{S} > s$ and $\hat{S}(\rho) \geq S^*(\rho) \geq S_i(\rho)$ for all $\rho \in 2^{2^n}$ (which means $\hat{S} \in (s, S_i)$). By definition of $Q_{m,i}$, we have that $\Psi^{\hat{S}}(m^\ast) \downarrow \Psi^{\hat{S}}(m^\ast) \notin \{0, 1\}$. Which means $\Psi^{\hat{S}}(m^\ast) \uparrow$. Thus we are done.

\[ \square \]
