THE PRINCIPAL $p$-BLOCK WITH A SMALL NUMBER OF CHARACTERS

SHIGEO KOSHITANI, TARO SAKURAI

Abstract. For a prime $p$, we determine a Sylow $p$-subgroup $D$ of a finite group $G$ such that the principal $p$-block $B$ of $G$ has four irreducible ordinary characters. It has been determined already for the cases where the number is up to three by work by R. Brauer, J. Brandt, and V.A. Belonogov thirty years ago. Our proof relies on the classification of finite simple groups.

1. Introduction

As Richard Brauer said, in $p$-modular representation theory of finite groups, where $p$ is a prime, one of the most important and interesting problems is to determine the number $k(B)$ of irreducible ordinary characters of a finite group $G$ in a $p$-block $B$ of $G$ if a defect group $D$ of $B$ is given (see [10, Problem 20]). In particular, we want to know what we can say about the structure of $B$ if $k(B)$ is small. It is known for instance that $k(B) = 1$ if and only if $D$ is trivial, namely, the block algebra $B$ is a simple algebra. Further we know that $k(B) = 2$ if and only if the order of $D$ is two (see [9, Theorem A]). Then, it is quite natural to wonder what happens if $k(B) = 3$. It is kind of surprising that we do not the answer yet. We know that if $k(B) = 3$ and $\ell(B) = 1$ where $\ell(B)$ is the number of irreducible Brauer characters of $G$ belonging to $B$, then the order of $D$ is three. So what is left is to determine $D$ if $k(B) = 3$ and $\ell(B) = 2$. As far as we know, this is still open though we guess that $D$ should have order three. Actually only for a particular case that $B$ is the principal $p$-block, we have an answer, namely in [7] V.A. Belonogov proves that if $B$ is the principal $p$-block and $k(B) = 3$, then $D$ has order three.

The next natural situation is surely looking at the case where $k(B) = 4$. Actually, this is the case of our main result in this paper. Namely our object is to prove the following:

Theorem 1.1. Let $B$ be the principal $p$-block of a finite group $G$ with a Sylow $p$-subgroup $D$. Further, let $k(B)$ and $\ell(B)$ respectively be the numbers of irreducible ordinary and Brauer characters of $G$ belonging to $B$. Assume that $k(B) = 4$. Then the following holds (depending on the classification of finite simple groups):

(i) If furthermore $\ell(B) = 2$, then $D \cong C_5$ (the cyclic group of order 5).
(ii) If furthermore \( \ell(B) = 3 \), then \( D \cong C_2 \times C_2 \) (the Klein four group).

**Remark 1.2.** It is well-known that \( G \) is \( p \)-nilpotent (and hence the principal \( p \)-block is nilpotent) if \( \ell(B) = 1 \). More generally, under the assumption that \( \ell(B) = 1 \) for an arbitrary \( p \)-block \( B \) of \( G \), there are interesting results due to Külshammer and Chlebowitz in \([16, 19]\). There is also a related result \([15]\) where small blocks of (not necessarily of finite groups) finite dimensional \( F \)-algebras are investigated.

**Notation 1.3.** Throughout this paper \( G \) is always a finite group, \( p \) is a prime, \( F \) is an algebraically closed field of characteristic \( p > 0 \), and \( FG \) is the group algebra of \( G \) over \( F \). We usually denote by \( q \) a power of a certain prime unless stated otherwise. For such a \( q \) we write \( \mathbb{F}_q \) for the finite field of \( q \) elements and \( \overline{\mathbb{F}_q} \) for the algebraic closure of \( \mathbb{F}_q \). We denote by \( G_p \) the set of all \( p \)-regular elements of \( G \), by \( G\# \) the set \( G - \{1\} \), by \( \exp(G) \) the exponent of \( G \), and by \( Z(G) \) the center of \( G \). We write \( H \) char \( G \) when \( H \) is a characteristic subgroup of \( G \). We write \( \mathbb{N} \) for the set of all positive integers. For any \( n \in \mathbb{N} \), \( C_n \), \( D_n \) and \( Q_n \) respectively are the cyclic group, the dihedral group and the quaternion group of order \( n \). For any \( n \in \mathbb{N} \) we denote by \( \mathfrak{S}_n \) and \( \mathfrak{A}_n \) respectively the symmetric and the alternating groups of degree \( n \). For \( g \in G \), \( C_g \) denotes the conjugacy class of \( G \) which contains \( g \). We write \( O_p(G) \) and \( O_p'(G) \) respectively for the largest normal \( p \)-subgroup of \( G \) and the largest normal \( p' \)-subgroup of \( G \). We write similarly \( O^p(G) \) and \( O^p'(G) \) respectively for the smallest normal subgroup \( N \) of \( G \) such that \( G/N \) is a \( p \)-group and the smallest normal subgroup \( L \) of \( G \) such that \( G/L \) is a \( p' \)-group. We write \( \text{Syl}_p(G) \) for the set of all Sylow \( p \)-subgroups of \( G \). For two groups \( H \) and \( K \), we denote by \( H \rtimes K \) a semi-direct product of \( H \) by \( K \), namely \( H \triangleleft H \rtimes K \). For two subgroups \( H \) and \( K \) of \( G \), we write \( H = G \) \( K \) if there is an element \( g \in G \) such that \( K = g^{-1} H g \). For elements \( x, g \in G \), we define \( x^g := g^{-1}xg \). We write \( k(G) \) and \( \ell(G) \) for the numbers of the conjugacy classes and the \( p' \)-conjugacy classes of \( G \), respectively. We denote by \( \text{Irr}(G) \) the set of all irreducible ordinary characters of \( G \), and it is well-known that \( |\text{Irr}(G)| = k(G) \). For a \( p \)-subgroup \( P \) of \( G \) we write \( \mathcal{F}_P(G) \) for the fusion system (fusion category) of \( G \) over \( P \) (see [3, I, Part 1]).

Let \( B \) be a block (algebra) of \( FG \), and let \( 1_B \) be the block idempotent of \( B \). As usual, we denote by \( \text{Irr}(B) \) and \( \text{IBr}(B) \) respectively the sets of all irreducible ordinary and Brauer characters of \( G \) belonging to \( B \), and we denote by \( k(B) \) and \( \ell(B) \) respectively \( |\text{Irr}(B)| \) and \( |\text{IBr}(B)| \). For each \( i \) let \( k_i(B) \) be the number of elements in \( \text{Irr}(B) \) of height \( i \). We write \( Z^p(B) \) for the projective center of \( B \) and \( \hat{Z}(B) \) the stable center of \( B \), that is \( \hat{Z}(B) := Z(B)/Z^m(B) \) (see [13] pp.4 and 20 and [38] p.127).

For ordinary characters \( \chi \) and \( \psi \) of \( G \), we denote by \( \langle \chi, \psi \rangle^G \) the (usual) inner product. For an ordinary character \( \psi \) of \( G \) we denote by \( \text{Irr}(G|\psi) \) the set of all elements \( \chi \in \text{Irr}(G) \) such that \( \langle \psi, \chi \rangle \neq 0 \), and we define \( \text{Irr}(B|\psi) := \text{Irr}(G|\psi) \cap \text{Irr}(B) \). Further, let \( C_B \) be the Cartan matrix of \( B \). We write \( 1_G \) for the trivial ordinary character of \( G \). For an ordinary character \( \chi \) of \( G \), we write \( \chi^0 \) for the restriction of \( \chi \) to \( G_p \). We write \( B_0(FG) \) for the principal block (algebra) of \( FG \), and \( F_G \) for the trivial (right) \( FG \)-module. For a subgroup \( H \) of \( G \) and for characters \( \chi \) of \( G \) and \( \theta \) of \( H \), we denote by \( \chi H \) and \( \theta G \) the restriction of \( \chi \) to \( H \) and the induction (induced character) of \( \theta \) to \( G \), respectively. Let \( N \triangleleft G \). For an ordinary character \( \theta \) of \( N \) and an element \( g \in G \) we define \( \theta^g \) by \( \theta^g(n) = \theta(gng^{-1}) \) for
Lemma 2.4. Let \( G_\theta \) be the stabilizer (inertial subgroup) of \( \theta \) in \( G \), namely \( G_\theta := \{ g \in G \mid \theta^g = \theta \} \). Similarly, for a block \( b \) of \( FN \), we define \( G_b \) by \( G_b := \{ g \in G \mid g^{-1} b g = b \} \).

Let \( A \) be a finite dimensional \( F \)-algebra. We denote by \( Z(A) \) the center, by \( J(A) \) the Jacobson radical, and by \( LL(A) \) the Loewy length of \( A \), respectively.

For the other notation and terminology, see the books [53] and [30].

This paper is organized as follows. In \( \S 2 \) we shall give general lemmas that are useful. In \( \S 3 \) we shall reprove Theorem 3.1, namely we shall investigate the principal \( p \)-blocks \( B \) such that \( k(B) = 3 \) and \( \ell(B) = 2 \). In \( \S 4 \) we shall give lemmas which shall be used in \( \S 5 \). In \( \S 5 \) we shall prove our first main result, namely, we shall investigate the principal \( p \)-blocks \( B \) such that \( k(B) = 4 \) and \( \ell(B) = 3 \). Finally in \( \S 6 \) we shall prove our second main result, that is, we shall investigate the principal \( p \)-blocks \( B \) with \( k(B) = 4 \) and \( \ell(B) = 2 \).

2. Preliminaries

In this section we shall list several lemmas which shall be used for the proof of our main results. The next lemma is quite useful for our aim.

**Lemma 2.1.** Let \( B \) be a block of \( FG \) with defect group \( D \).

(i) \( \dim_F Z^{\nu}(B) \) is the multiplicity of 1 as elementary divisor of \( C_B \).

(ii) If further \( C_G(u) \) is \( p \)-nilpotent for every element \( u \in D \) of order \( p \), then

\[
\dim_F Z(B) = k(B) - \ell(B) + 1.
\]

*Proof.* (i) See [13, p.4] or [38, p.143, lines \(-7 \sim -6\)].

(ii) By [28], \( \det(C_B) = |D| \). Hence, [53, Theorem 3.6.35] implies that the elementary divisors of \( C_B \) are \( |D| \) with multiplicity one and 1 with multiplicity \( \ell(B) - 1 \). Hence by (i), \( \dim_F Z^{\nu}(B) = \ell(B) - 1 \). Therefore, \( \dim_F Z(B) = \dim_F Z(B) - \dim_F Z^{\nu}(B) = k(B) - (\ell(B) - 1) \) since \( k(B) = \dim_F Z(B) \) (see [53, Lemma 5.11.3]). □

**Lemma 2.2 (Navarro-Tiep).** Assume that \( p = 2 \) and \( B := B_0(FG) \). If \( k(B) = 4 \), then a Sylow 2-subgroup of \( G \) is abelian.

*Proof.* Follows by [48, Corollary 1.4(i)] and [54, Theorem A]. □

**Lemma 2.3.** Assume that \( O^{p'}(G) = 1 \), \( O^p(G) = G \) and that a pair \((p,G)\) is one of the finite simple groups listed in [47, (ii) and (iii) in Theorem A], and let \( B := B_0(FG) \). Then

\[ k(B) - \ell(B) \neq 2 \text{ and } k(B) - \ell(B) = 1 \]

*Proof.* Follows from [47, (ii) and (iii) in Theorem A] and [53, Tables 1 and 2]. □

**Lemma 2.4 ([33]).** Assume that \( p \) is odd, and that for every element \( u \in G \) of order \( p \), \( C_G(u) \) is \( p \)-nilpotent. Set \( H := N_G \left( Z(J(D)) \right) \) where \( D \in Syl_p(G) \) and \( J(D) \) is the Thompson subgroup of \( D \). Then \( p \mid |G : H| \), and \( H^*(G, F) \cong H^*(H, F) \).

*Proof.* Follows by [33, Proposition 9.2 and lines \(-7 \sim -4, p.62\)]. □

It seems that the following lemma demands too strong assumption, however it will be quite useful for our aim because of the stable equivalence of Morita type due to M. Broué.
Lemma 2.5. Suppose that $D \in \text{Syl}_p(G)$ with $D \triangleleft G$ and that $G = D \rtimes E$ for a $p'$-subgroup $E$ of $G$ such that $E$ acts on $D$ faithfully (and hence $O_{p'}(G) = 1$, so that $B := B_{0}(FG)$ is the unique block of $FG$ by \cite{26}). Assume furthermore that $k(B) - \ell(B) = 2$ and that $C_{G}(u)$ is $p$-nilpotent for every element $u \in D$ of order $p$. Then it holds the following:

(i) Every $p'$-conjugacy class $C$ with $C \neq \{1\}$ is of defect zero.

(ii) $E$ acts on $D^\#$ semi-regularly (i.e. freely).

(iii) Let $C_{0} := \{1\}, C_{1}, \cdots , C_{\ell(G)-1}$ be all $p'$-conjugacy classes of $G$. Then,

$$\bigsqcup_{i=1}^{\ell(G)-1} C_{i} = \{vy \mid v \in D, y \in E^\#\} = DE^\#.$$  

(iv) $D$ is abelian.

(v) There are elements $u, v \in D^\#$ such that $D^\# = C_{u} \sqcup C_{v}$ (disjoint union) and $|C_{u}| = |C_{v}| = |E|$.

(vi) The projective center $Z(B)$ is a symmetric $F$-algebra of $F$-dimension $3$.

Proof. (i) It follows from the assumption that $C_{G}(u)$ is $p$-nilpotent for every $u \in G$ of order $p$ and \cite{28} that $\det(C_{B}) = p^d$. Hence \cite[Theorem 3.6.35]{53} implies that all the elementary divisors of $C_{B}$ is $p^d$ with multiplicity one and $1$ with multiplicity $\ell(B) - 1$. Thus the assertion follows from \cite[Theorem 5.11.6(iv)]{53}.

(ii) Apparently, $E$ acts on $D^\#$. Take any element $v \in D^\#$ and any $p'$-element $y \in C_{E}(v)$. Assume that $y \neq 1$. Then, $C_{v}$ has defect zero by (i), which means that $p \nmid |C_{G}(y)|$. Since $v$ is a $p$-element in $C_{G}(y)^\#$, this is a contradiction. Hence $y = 1$, so that $C_{E}(v) = 1$.

(iii) The second equality holds trivially. So, we look at only the first equality. Take any element $g \in C_{i}$ for some $i \in \{1, \cdots , \ell(G) - 1\}$. Since $G = D \rtimes E$, we can write $g = vy$ for some $v \in D$ and $y \in E$. Since $g$ is a non-identity $p'$-element, $y \neq 1$, so that $y \in E^\#$.

Conversely, take any element $g = vy$ with $v \in D$ and $y \in E^\#$. Hence $g \neq 1$. Let $g_{p}$ and $g_{p'}$ respectively be the $p$-part and the $p'$-part of $g$. Since $y \neq 1$ and since $D \triangleleft G$, $g$ is not a $p$-element. Hence $g_{p'} \neq 1$. Thus we can assume that $g_{p'} \in C_{i}$. Then, (i) yields that $g_{p} = 1$. That is, $g = g_{p'}$, which means that $g$ is a non-identity $p'$-element, and hence $g \in \bigsqcup_{i=1}^{\ell(G)-1} C_{i}$.

(iv) Let $r$ be the number of all conjugacy classes of $G$ that contain $p'$-elements (possibly the identity element). Since $k(B) - \ell(B) = 2$ by the assumption, it follows by \cite[Theorems 5.4.13(ii) and 5.6.1]{53} that $r = 2$ or $3$. If $r = 2$, then for every $p$-element $u \in C^\#$, $\ell(B_{0}(F[C_{G}(u)])) = 2$, contradicting the assumption that $C_{G}(u)$ is $p$-nilpotent. Thus, $r = 3$. So, we can pick up two non-identity $p'$-elements, say $z, u$ such that $z \in Z(D)$ and that $u$ and $z$ are not conjugate in $G$. Then, since $D \triangleleft G$, $D = \{1\} \sqcup C_{z} \sqcup C_{u}$ (disjoint union).

Suppose that $D$ is non-abelian. Then, $u$ can be chosen as $u \notin Z(D)$. First we claim $C_{u} \cap Z(D) = \emptyset$. If there is an element $z' \in C_{u} \cap Z(D)^\#$, then $u$ is $G$-conjugate to an element in $Z(D)$, so that $u \in Z(D)$ since $Z(D) \text{char} D \text{char} G$, a contradiction. Thus, $C_{u} \cap Z(D) = \emptyset$.

Now, we claim that $Z(D)^\# = C_{z}$. Since $D \triangleleft G$ and $Z(D) \text{char} D$, $C_{z} \subseteq Z(D)^\#$. Conversely, take any element $z' \in Z(D)^\#$. Then, since $C_{u} \cap Z(D) = \emptyset$ from the above,
$z' \not\in u$, so that $z' \in C_z$. Namely, $Z(D)^* \subseteq C_z$, so the claim is proved. Thus, by (iii)
(1) $G = C_0 \cup C_z \cup C_u \cup C_1 \cup \cdots \cup C_{\ell(G)-1}$, $Z(D)^* = C_z$, $D^* = C_z \cup C_u$.

We next claim that $E$ acts on $C_z$ regularly. Clearly $E$ acts on $C_z$ semi-regularly by (ii). Further, take any two elements $z_1, z_2 \in C_z$. As we have seen above, $z_1, z_2 \in Z(D)$. There is an element $g \in G$ such that $z_2 = g^{-1}z_1g$. We can write $g = vy$ for some $v \in D$ and $y \in E$. Then, $z_2 = z_1^g = z_1^vy = z_1^y$, so that $z_1$ and $z_2$ are conjugate in $E$. So that $E$ acts on $C_z$ transitively. Hence $E$ acts on $C_z$ regularly. Therefore
(2) $|C_z| = |E|$.

Further we claim that $C_G(u) = C_D(u)$. Take any element $g \in C_G(u)$. First note that $C_D(u)$ is a Sylow $p$-subgroup of $C_G(u)$ since $D \triangleleft G$. Clearly, $C_G(u) \triangleleft C_G(u)$. On the other hand, since $C_G(u)$ is $p$-nilpotent by the assumption, we have

$$C_G(u) = O_p(C_G(u)) \times C_D(u).$$

Then, (i) implies that $O_p(C_G(u)) = 1$, so that $C_G(u) = C_D(u)$. Thus $|C_u| = |G : C_G(u)| = |G : C_D(u)| = |D||E|/|C_D(u)| = |E||D : C_D(u)|$. Set $e := |E|$. Hence
(3) $|C_u| = e|D : C_D(u)|$.

Then,

$$e|D| = |G|$$
$$= 1 + e + e|D : C_D(u)| + |D|(e - 1) \quad \text{by} \quad [1], [2], [3] \text{ and } (iii)$$
$$= 1 + e + e|D : C_D(u)| + |D|e - |D|$$

so that

$$|D| - 1 = e(1 + |D : C_D(u)|)$$
$$= (|Z(D)| - 1)(1 + |D : C_D(u)|) \quad \text{by} \quad [1], [2]$$
$$= |Z(D)| + |Z(D)||D : C_D(u)| - |D : C_D(u)| - 1$$

and hence
(4) $|D| = |Z(D)| + |Z(D)||D : C_D(U)| - |D : C_D(u)|$.

Now, recall and set

$$|D| = p^d, \quad |Z(D)| =: p^s, \quad |C_D(u)| =: p^t \quad \text{for some integers} \quad d, s, t \geq 1.$$ 

Thus, by [4],

$$p^d = p^s + p^s p^d/p^t - p^d/p^t$$

so that

$$p^d p^t = p^{s+t} + p^{s+d} - p^d$$

and hence
(5) $p^t = p^{s+t-d} + p^s - 1.$
Clearly $Z(D) \subseteq Z(D)(u) \subseteq C_D(u)$ since $u \in D - Z(D)$, so that $Z(D) \nsubseteq C_D(u)$, and hence $p^s < p^t$. Hence we can set that
\[ t - s =: n \quad \text{for some integer } n \geq 1. \]

Thus, by (5),
\[ p^s - 1 = p^{t} - p^{s+t-d} = p^{s+n} - p^{2s+n-d}. \]
Since $s \geq 1$, $p^s - 1$ is a positive integer. Furthermore since $s + n > 1$, we have to have that
\[ 2s + n - d = 0. \]

Hence by the above,
\[ p^s - 1 = p^{s+n} - 1. \]
So that $s = s + n$, and hence $n = 0$, a contradiction. Therefore, $D$ is abelian.

(v) By (iv) and the proof of (iv), we get the assertion immediately.

(vi) By the assumption, for every $p$-element $u' \in G^\#$, $C_G(u')$ is $p$-nilpotent, so that $\ell(B_0(F[C_G(u')])) = 1$. Further, by (iv), every element $u'$ in $D$ is conjugate to an element in $Z(D)$. Thus, the condition (ii) in [38, Theorem 3.1] is satisfied, so that by the theorem $\bar{Z}(B)$ is a symmetric algebra. On the other hand, by the assumption that $k(B) - \ell(B) = 2$ and Lemma 2.1, we have $\dim_F \bar{Z}(B) = 3$. \qed

Although the first part of the next lemma is essentially due to Dade, we give an elementary proof for convenience of the readers.

**Lemma 2.6** (Dade, Lemma 9.9 in [24]). Assume that $N \triangleleft G$ with $p \nmid |G/N|$, and $B$ and $b$ are blocks of $FG$ and $FN$, respectively, such that $B$ covers $b$. Let $D$ be a defect group $B$ such that $C_G(D) \leq N$.

(i) If furthermore $b$ is $G$-invariant, then $1_B = 1_b$, namely $B$ is a unique block of $FG$ covering $b$, and $b$ is a unique block of $FN$ covered by $B$.

(ii) If in particular $B = B_0(1_G)$, then, $\operatorname{Irr}(B | 1_N^G) = \operatorname{Irr}(G/N)$ where we identify $\operatorname{Irr}(G/N)$ as a subset of $\operatorname{Irr}(G)$.

**Proof.** (i) Since $b$ is $G$-invariant, it holds that $b$ is a unique block of $FN$ covered by $B$ (see [53, Lemma 5.5.3]) and that $1_b \in Z(FG)$. Surely $1_b$ is an idempotent. Set $B_1 := B$. Hence we can write that $1_B = 1_{B_1} + 1_{B_2} + \cdots + 1_{B_n}$ for an integer $n \geq 1$ and for distinct blocks $B_1, \cdots, B_n$ of $FG$ since $B_1$ covers $b$. Note that $B_1, \cdots, B_n$ are all blocks of $FG$ covering $b$. So it suffices to prove that $n = 1$.

Since $C_G(D) \leq N$ and $D$ is a defect group of $B$, [53, Lemma 5.5.14] implies that $B$ is regular with respect to $N$. Hence, by [53, Theorem 5.5.13(ii)], $B = b^G$. Now, by [41, 4.2.Proposition], there is a defect group $\mathbb{D}$ of $b$ such that $\mathbb{D} =_G D \cap N$. Obviously $D \cap N = D$ since $D/(D \cap N) \cong D/N \leq G/N$ and $G/N$ is a $p'$-group. Hence $\mathbb{D} =_G D$, so that there is an element $g \in G$ such that $\mathbb{D} = g^{-1} Dg$. Then, by replacing $g^{-1} Dg$ by $D$, we can assume that $\mathbb{D} = D$. Namely, $D$ is a defect group of $b$ as well.

Assume that $n \geq 2$. So, there exists the block $B_2$ as above. Let $D_2$ be a defect group of $B_2$. Since $B_2$ covers $b$ and $D$ is a defect group of $b$, [41, 4.2.Proposition] implies that $D =_G D_2 \cap N$. Again by replacing some $G$-conjugate of $D_2$ by $D_2$, we can assume that
$D = D_2 \cap N$. Hence $D \leq D_2$, so that $C_G(D_2) \leq C_G(D)$. Thus, the assumption that $C_G(D) \leq N$ yields that $C_G(D_2) \leq N$. Therefore again by [53, Lemma 5.5.14], $B_2$ is regular with respect to $N$. Hence $B$ and $B_2$ are both regular with respect to $N$ and also both cover $b$, that contradicts to the uniqueness in [53, Theorem 5.5.13(ii)].

(ii) Set $b := B_0(FN)$. From (i), $1_B = 1_b$. Since the character $1_N$ extends to the character $1_G$, the assertion follows by [36, (6.17)Corollary].

Lemma 2.7. Assume that $N \triangleleft G$ such that $G/N$ is a $p$-group, and $B$ and $b$ are blocks of $FG$ and $FN$, respectively, such that $B$ covers $b$.

(i) If furthermore $b$ is $G$-invariant, then $1_B = 1_b$.

(ii) If particularly $B = B_0(FG)$, then $\text{Irr}(B \mid 1_N^{G}) = \text{Irr}(G/N)$ where we identify $\text{Irr}(G/N)$ as a subset of $\text{Irr}(G)$.

Proof. (i) Follows by [53, Corollary 5.5.6].

(ii) Follows by (i) and [36, (6.17)Corollary] just as in the proof of Lemma 2.6(ii).

The authors thank Radha Kessar for informing them the next lemma, which is useful for our aim.

Lemma 2.8. Suppose that $G$ is a simple, simply connected linear algebraic group defined over the algebraic closure $\bar{\mathbb{F}}_q$ of $\mathbb{F}_q$ for a power $q$ of a prime, and that $\mathcal{F} : G \to G$ is a Steinberg (Frobenius) morphism. Set $G := G_{\mathcal{F}}$, and let $Z$ be a subgroup of $Z(G)$. Further, if $\ell$ is a prime with $\ell \geq 5$ and $G/Z$ has an abelian Sylow $\ell$-subgroup, then we have that $\ell \nmid |Z|$ and hence that a Sylow $\ell$-subgroup of $G$ is abelian.

Proof. It follows from [51, Table 24.2] that if $G$ is neither $\text{SL}_n(q)$ for $n \geq 2$ nor $\text{SU}_n(q)$ for $n \geq 3$, then $\ell \nmid |Z|$ since $\ell \geq 5$.

Case 1: $G := \text{SL}_n(q)$ for $n \geq 2$: Suppose $\ell \mid |Z|$. By the above table, $|Z| \mid |Z(G)| = \gcd(n, q-1)$. Since $\ell \mid |Z| \mid \gcd(n, q-1) \mid (q-1)$, there exists a primitive $\ell$-th root of unity in $(\mathbb{F}_q)^\times$, which we denote by $\zeta$. Let $a$ be an element in $G$ such that $a := \text{diag}(\zeta, \zeta^{-1}, 1, 1, \cdots, 1)$. Note that $\ell \leq n$ since $\ell \mid |Z| \mid \gcd(n, q-1) \mid n$. Further, let $b$ be an element in $\text{GL}_\ell(q)$ such that $b$ is a permutation matrix corresponding to the cycle $(1 2 3 \cdots \ell) \in S_\ell$, namely,

$$b := \begin{pmatrix} 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \ddots & 1 \\ 1 & 0 & 0 & 0 & \cdots & 0 \end{pmatrix} \in \text{GL}_\ell(q)$$

Since $\ell$ is odd, the cycle $(1 2 3 \cdots \ell)$ is an even permutation, and hence $b \in \text{SL}_\ell(q)$. Then, $b$ is considered as an element of $G = \text{SL}_n(q)$ via $\text{SL}_\ell(q) \times \langle J_{n-\ell} \rangle \leq \text{SL}_n(q)$ where $J_{n-\ell}$ is the identity matrix of degree $n-\ell$. It is easy to see that $a^{-1}b^{-1}ab = \text{diag}(\zeta^{-1}, \zeta^2, \zeta^{-1}, 1, \cdots, 1)$, so that

$$(6) \quad [a, b] := a^{-1}b^{-1}ab \notin Z$$

7
since $\ell \neq 3$. Now, let $m$ be the largest integer such that $\ell^m \mid q - 1$, so that $m \geq 1$ since $\ell \mid q - 1$ as we have seen above. Let $Q$ be a subgroup of $G$ such that $Q$ is the set of all the diagonal matrices in $G$ which satisfy that their diagonal parts are elements in the cyclic group $C_{\ell^m}$ (we consider that $C_{\ell^m} \leq (\mathbb{F}_q)^\times$). Clearly, $Q$ is an abelian $\ell$-group and $a \in Q$. Now, since $b$ acts on $Q$ canonically, we can define a semi-direct product $P := Q \rtimes (b)$. Apparently, $P$ is an $\ell$-subgroup of $G$, and $a, b \in P$. Since we are assuming that a Sylow $\ell$-subgroup of $G/Z$ is abelian, $PZ/Z$ is abelian, so that $[a, b] \in Z$, a contradiction by (6).

**Case 2:** $G := \text{SU}_n(q)$ for $n \geq 3$: Suppose $\ell \mid |Z|$. By [51, Table 24.2],

$$
\ell \mid |Z| \mid |Z(G)| = \gcd(n, q + 1) \mid q + 1 \mid (q^2 - 1) = |(\mathbb{F}_q)^\times|,
$$

so that there is a primitive $\ell$-th root of unity in $(\mathbb{F}_q)^\times$, which we denote by $\zeta$ (recall that in the classical notation $G$ is denoted by $\text{SU}(n, q^2)$, namely, $G$ is defined over the field $\mathbb{F}_{q^2}$). Note also that $\ell \leq n$ since $\ell \mid n$ from the above. Then, just exactly as in Case 1 we can define $a$ and $b$, and precisely by the same argument, and hence we finally have a contradiction. □

The following wonderful result due to Broué and Michel shall play a very important role to prove Theorems 3.1, 5.1 and 6.1.

**Lemma 2.9** (Broué-Michel [15]). Suppose that $G$ is a connected reductive algebraic group defined over the algebraic closure $\overline{\mathbb{F}}_q$ of $\mathbb{F}_q$ for a power $q$ of a prime $\ell$ and $F : G \to G$ is a Steingery (Frobenius) morphism. Set $G := GF$. If furthermore a prime $\ell$ satisfies that $5 \leq \ell \mid q$ and a Sylow $\ell$-subgroup of $G/Z(G)$ is abelian, then the principal $\ell$-blocks of $G$ and $N_G(D)$ are isotypic, where $D$ is a Sylow $\ell$-subgroup of $G$.

**Proof.** By Lemma 2.8. $\ell \mid |Z(G)|$. Hence, by the assumption, a Sylow $\ell$-subgroup of $G$ is abelian. Thus, [15, Théorème] yields the assertion. □

**Lemma 2.10.** Assume that $G$ be one of the 26 sporadic simple groups, $D \in \text{Syl}_p(G)$, and $B := B_0(FG)$. If $p \geq 5$ and $D$ is non-cyclic elementary abelian, then $k(B) > 9$. (Surely this bound is very loose.)

**Proof.** By [20] and [60] it is enough to check the next four cases for $G$:

1. Th and $|D| = 7^2$, 2. Fi$_{24}'$ and $|D| = 5^2$, 3. B and $|D| = 7^2$, 4. M and $|D| = 11^2$

where the four groups are the Thompson simple group, the derived subgroup of Fischer’s 24 group, the baby monster and the monster, respectively. So we get the assertion for these by GAP for the Th for $p = 7$, [32, Table 6.1.3]. □

**Lemma 2.11.** Suppose that $G$ is one of the 16 non-abelian simple groups in the list [51, Table 24.3] (cf. [32, Table 6.1.3]). Further assume that $p \geq 5$ and $D \in \text{Syl}_p(G)$ is non-cyclic elementary abelian, and let $B := B_0(FG)$. Then $k(B) > 9$. (Surely this bound is very loose.)

**Proof.** By [20] and [60], we much check only the case where $G = G(q) = 2E_6(2)$. By [20, p.191], we have to take care of only the cases that $|D| = 5^2$ and $|D| = 7^2$. 8
First assume $p = 5$. By \cite{14,18} (cf. \cite{25}, Table 28, p.1118 and \cite{12} Theorem 3.10), we have $\ell(B) = 16$ since the $e$, that is the order of $q = 2$ modulo $\ell = p = 5$, is 4 and the principal $\Phi_1$-block has 16 unipotent characters. Hence we can exclude this case.

Next, assume $p = 7$. Then, by \cite{12} Theorem 3.10, $\ell(B) \geq 9$ (note that the $e$ is three since $q = 2$ and $\ell = p = 7$, and note also that by \cite{14,18} we can know the precise value of $\ell(B)$ since the $e$ is 3 and the principal $\Phi_3$-block has 15 unipotent characters, though we do not need it). Thus we can exclude this case, too. □

3. What we can say if $k(B) = 3$ and $\ell(B) = 2$

The purpose of this section is to give another proof of Belonogov’s Theorem.

**Theorem 3.1** (Belonogov \cite{7}). If the principal $p$-block $B := B_0(FG)$ of $FG$ satisfies that $k(B) = 3$, then a Sylow $p$-subgroup $D$ of $G$ is of order 3.

The result here can be considered as an easy but nice application of the CFSG. Actually even better is that by the same method in princip we shall be able to determine a Sylow $p$-subgroup of $G$ when the number $k(B)$ is four for the principal $p$-block $B$ of $G$.

**Hypothesis 3.2.** We assume the following from now on till the end of this section.

- $D$ is a Sylow $p$-subgroup of a finite group $G$ with $|D| = p^d$.
- Set $B := B_0(FG)$ with $k(B) = 3$ and $\ell(B) = 2$, and set $\text{Irr}(B) =: \{\chi_0 := 1_G, \chi_1, \chi_2\}$ and $\text{IBr}(B) =: \{\phi_0 := (1_G)^0, \phi_1\}$.

**Lemma 3.3.** We have that $p \neq 2$, and that Theorem 3.1 holds provided $D$ is cyclic or $D \triangleleft G$.

*Proof.* If $p = 2$, then we have a contradiction by \cite{22} and \cite{48, Corollary 1.3(i)]. If $D$ is cyclic, then the assertion follows from \cite{22}. If $D \triangleleft G$, then the assertion is implied by \cite{47, Theorem 4.1]. □

**Lemma 3.4.** $D$ is elementary abelian.

*Proof.* Follows by \cite{47, Theorem 3.6]. □

**Lemma 3.5** (Navarro-Sambale-Tiep \cite{55}). If $p = 3$, then $|D| = 3$.

*Proof.* First, $k_0(B) \equiv 0 \pmod{3}$ by \cite{48, Corollary 1.6], so that $k_0(B) = 3$. Hence \cite{55, Theorem C] implies that $|D| = 3$ (note that the CFSG is used in \cite{55}). □

The next aim is that we can assume that $G$ is non-abelian simple to prove Theorem 3.1.

**Hypothesis 3.6.** Besides Hypothesis 3.2, we assume the following from now on till just before the proof of Theorem 3.1 because of Lemmas 3.3, 3.4 and 3.5

- $p$ is a prime with $p \geq 5$.
- $D$ is a non-cyclic elementary abelian Sylow $p$-subgroup of $G$ with $|D| = p^d$.
- For every finite group $\mathfrak{G}$ such that $|\mathfrak{G}| < |G|$ and $k(B_0(F\mathfrak{G})) = 3$, it holds that Sylow $p$-subgroup of $\mathfrak{G}$ is of order 3.

**Lemma 3.7.** We can assume that $O_{p'}(G) = 1$ and $O_p(G) = 1$. 9
Proof. Since $B$ is principal, we can assume that $O_p'(G) = 1$ (see [53, Theorem 5.8.1]). Assume that $Q := O_p(G) \neq 1$. Set $G := G/Q$, $D := D/Q$ and $B := B_0(FG)$. Then, $B$ dominates $B$ since both blocks have the trivial characters. So, by [53, Theorem 5.8.10 and Lemma 5.8.6(ii)], $\text{Irr}(B) \subseteq \text{Irr}(B)$, and hence $k(B) = 1, 2$ or $3$ by Hypothesis 3.2.

If $k(B) = 1$, then $D = 1$, so that $D \triangleleft G$, hence $|D| = 3$ by Lemma 3.3, a contradiction by Hypothesis 3.6.

Assume $k(B) = 2$. Then $\ell(B) = 1$, so that $G$ is $p$-nilpotent (see [53, Theorem 5.8.3]), and hence $G$ is $p$-solvable. Since $D$ is abelian by Lemma 3.4, $G$ is $p$-solvable of $p$-length one by [30, Theorem 6.3.3]. So $|D| = 3$ by Lemma 3.3. This is a contradiction as above.

Finally, if $k(B) = 3$, then $\text{Irr}(B) = \text{Irr}(\tilde{B})$, so that $Q \leq \bigcap_{\chi \in \text{Irr}(B)} \ker(\chi)$, and hence $Q \leq O_p'(G)$ by [53, Theorem 5.8.1], a contradiction. $\square$

Actually, the following is the key lemma of this section, which makes it possible for us to reduce to the case where $G$ is non-abelian simple.

**Lemma 3.8.** We can assume that $O_p'(G) = G$.

Proof. Assume that $O_p'(G) \neq G$. Then, there is a normal subgroup $N \triangleleft G$ such that $p \nmid |G/N|$ and $G/N$ is a simple group. Set $b := B_0(FN)$, and $H := N \cdot C_G(D)$. Then, $H \triangleleft G$ by the Frattini argument. Since $G/N$ is simple, $H = G$ or $H = N$.

Assume first that $H = G$. Then, by [1] and [23, Theorem], $B \cong b$ as $F$-algebras. Hence $k(b) = 3$ and $\ell(b) = 2$ (note that $\dim_F Z(B) = k(B)$), so that by induction on $|G|$ (see Hypothesis 3.6) $|D| = 3$ since $D \in \text{Syl}_p(N)$. But this is a contradiction by Hypothesis 3.6.

So we have $H = N$. Thus, by Lemma 2.6(ii), $\text{Irr}(B|1_N^G) = \text{Irr}(G/N)$. So that $k(G/N) \leq 3$, which implies that $G/N$ is solvable by [53, Table 1, p.309]. Since $G/N$ is simple, $G/N \cong C_r$ for a prime $r$ with $r \neq p$. Since $G/N$ is cyclic and $1_N$ is $G$-invariant, Clifford’s Theorem and [53, Chapter 3 Problem 11(1)] imply that

$$(7) \quad \text{if } \chi \in \text{Irr}(G) \text{ with } \langle \chi \downarrow_N, 1_N \rangle^N \neq 0, \text{ then } \chi \downarrow_N = 1_N, \text{ so } \chi(1) = 1.$$ 

Hence, it follows by Lemma 2.6(i) and the Frobenius Reciprocity (and also by recalling that $\text{Irr}(B) = \{\chi_0, \chi_1, \chi_2\}$ in Hypothesis 3.2) that

$1_{N^G} \in \{\chi_0 := 1_G, \chi_0 + \chi_1, \chi_0 + \chi_2, \chi_0 + \chi_1 + \chi_2\}.$

Clearly, $1_{N^G} \neq \chi_0$ since $|G/N| = r > 1$. So $\langle 1_{N^G}, \chi_1 \rangle^G \neq 0$ or $\langle 1_{N^G}, \chi_2 \rangle^G \neq 0$. So, without loss of generality, we can assume the first case. Then, $\chi_1 \downarrow_N = 1_N$ by (7), so that $\chi_1(u) = 1$ for every $p$-element $u \in G$ since $p \nmid |G/N|$ (and hence $u \in N$). Since $\chi_1 \neq \chi_0 = 1_G$, there exists an element $g \in G$ with $\chi_1(g) \neq 1$. Write $g = g_pg_{p'} = g_{p'} g_p$ where $g_p$ and $g_{p'}$ respectively are the $p$-part and the $p'$-part of $g$. Thus, since $\chi_1$ is linear (and hence $\chi_1$ is a group homomorphism) and since $\chi_1(g_p) = 1$, we have that

$1 \neq \chi_1(g) = \chi_1(g_pg_{p'}) = \chi_1(g_p) \chi_1(g_{p'}) = \chi_1(g_{p'})$.

This means that $(\chi_1)^0 \neq \phi_0$ (recall that $\phi_0 = (1_N)^0$). Then, since $\text{IBr}(B) = \{\phi_0, \phi_1\}$ by Hypothesis 3.2 and since $\chi_1(1) = 1$, we must have that $(\chi_1)^0 = \phi_1$. This yields that $\phi_0(1) = \phi_1(1) = 1$. Therefore, by [42, 43, Theorem (7) $\Leftrightarrow$ (10)], $B \cong B$ as $F$-algebras.
where $\mathbb{B} := B_0(F N_G(D))$. Hence, by Hypothesis 3.2 and 53. Lemma 5.11.3, we have $3 = k(B) = k(\mathbb{B})$. So Lemma 3.3 implies $|D| = 3$, a contradiction by Hypothesis 3.6. □

**Lemma 3.9.** We can assume that $G$ is a non-abelian simple group.

**Proof.** By Lemmas 3.7 and 3.8 we have that $O_p^e(G) = 1 = O_p^e(G)$ and $G = O_p^e(G)$. Since $D$ is abelian by Lemma 3.4 it follows from [40, 2.1 Theorem] that there are non-abelian simple groups $G_1, \ldots, G_n$ such that $p \mid |G_i|$ for each $i$ and that $G = G_1 \times \cdots \times G_n$ for some $n \in \mathbb{N}$. Set $B_i := B_0(F G_i)$ for each $i$. Then $B \cong B_1 \otimes_F \cdots \otimes_F B_n$ as $F$-algebras, so that $\ell(B) = \ell(B_1) \times \cdots \times \ell(B_n)$. Since each $G_i$ is not $p$-nilpotent, we have that $\ell(B_i) \geq 2$ for every $i$. Since $\ell(B) = 2$ by Hypothesis 3.6 it has to hold that $n = 1$. □

**Lemma 3.10.** If we assume moreover that $G$ is a finite simple group $G(q)$ of Lie type defined over $\mathbb{F}_q$ such that $p \nmid q$, then $|D| = 3$ and hence this contradicts to Hypothesis 3.6.

**Proof.** By Hypothesis 3.6 $p \geq 5$ and $D$ is noncyclic elementary abelian. Thus Lemma 2.11 yields that there are a simple, and simply connected reductive algebraic group $G$ defined over the algebraically closed field $\overline{\mathbb{F}}_q$ and a Steinberg (Frobenius) endomorphism $\mathcal{F} : G \to G$ with $G = G^\mathcal{F}/Z(G^\mathcal{F})$ (see [50, 2.3] or [17, p.185]). It follows from Lemma 2.9 that $k(B) = k(B_1) \times \cdots \times k(B_n)$. Then, [52, Theorem 5.4], Lemma 3.4 and [2, Consequence 6] imply that $3 = k(B) = k(\mathbb{B})$ where $\mathbb{B} := B_0(F N_G(D))$. So that by Hypothesis 3.2 $k(\mathbb{B}) = 3$. Thus, by Lemma 3.3 $|D| = 3$, contradicting Hypothesis 3.6. □

Now, we are ready to reprove Belonogov’s Theorem.

**Proof of Theorem 3.1.** We use induction on $|G|$. If $D \trianglelefteq G$, then $|D| = 3$ by Lemma 3.3. If $p = 2$ or $D$ is cyclic, then $|D| = 3$ by Lemma 3.3. Furthermore if $p = 3$ then $|D| = 3$ by Lemma 3.5. Thus, we can assume the same as Hypothesis 3.6. So, we can assume that $G$ is non-abelian simple by Lemma 3.9.

First, assume that $G$ is an alternating group $\mathfrak{A}_n$ for some $n \geq 5$. Then, [52, Theorem 5.4], Lemma 3.4 and [2, Consequence 6] imply that $3 = k(B) = k(\mathbb{B})$, where $\mathbb{B} := B_0(F N_G(D))$. Hence Lemma 3.3 yields that $|D| = 3$, a contradiction.

If $G$ is one of the 26 sporadic simple groups, then the assertion follows by Lemma 2.10.

Assume that $G = G(q)$ is a simple group of Lie type defined over $\mathbb{F}_q$ with $p \mid q$. Then $G = \text{PSL}_2(q)$ since $D$ is abelian (see e.g. [58, Theorem]). Thus, by [11, p.588], [16, Satz 9.1] and [35, 8.5, Theorem p.70], we have that $\ell(B) = (q - 1)/2$, and hence $q = 5$ since $\ell(B) = 2$, so that $|D| = 5$, a contradiction since $D$ is non-cyclic.

Finally suppose that $G = G(q)$ is a simple group of Lie type defined over $\mathbb{F}_q$ for a power $q$ of a prime such that $p \nmid q$. Then, Lemma 3.10 yields that $|D| = 3$, a contradiction.

Therefore, by the classification of finite simple groups CFSG in [31, p.6], we get a contradiction. The proof is completed. □

**Remark 3.11.** There is an interesting observation by Sambale in [57, Proposition 15.7], that says that e.g. $p \geq 11$, $d$ is odd even without the CFSG.
4. What we can say if \( k(B) = 5 \) and \( \ell(B) = 3 \)

The purpose of this section is to state lemmas which shall be useful for the proof of Theorem 5.1.

**Lemma 4.1.** Let \( D \in \text{Syl}_p(G) \) such that \( D \triangleleft G \) and \( D \) is non-cyclic abelian. Let \( B := B_0(\text{FG}) \). Then, it does not happen that \( k(B) = 5 \) and \( \ell(B) = 3 \).

**Proof.** Assume that such a case occurs. Since \( B \) is the principal \( p \)-block, we can assume that \( O_p'(G) = 1 \). We can write \( G = D \times E \) for a \( p' \)-subgroup \( E \) by Schur-Zassenhaus’ Theorem. Clearly \( G \) is \( p \)-solvable, so that Fong-Gaschütz’s Theorem says that \( G \) has only one \( p \)-block, say \( B \). Hence \( k(G) = k(B) = 5 \) and \( 3 = \ell(B) = \ell(G) = \ell(G/D) = \ell(E) = k(E) \). Thus, by [59, Table 1], we know that \( G \in \{C_5, D_8, Q_8, D_{14}, C_5 \times C_4, C_7 \times C_3, \mathcal{S}_4, \mathfrak{A}_5\} \) and \( E \in \{C_3, \mathcal{S}_3\} \). So that \( p \neq 3 \). Since \( 3 \mid |E| \mid |G| \), \( G \) is \( p \)-solvable and \( D \) is non-cyclic, we have \( G = \mathcal{S}_4 \). So that \( p = 2 \), and this is a contradiction since \( D \) is abelian. \( \square \)

**Lemma 4.2.** Suppose that \( B := B_0(\text{FG}) \) with \( k(B) = 5 \) and \( \ell(B) = 3 \). Assume, further, that \( p \geq 5 \) and a Sylow \( p \)-subgroup of \( G \) is non-cyclic elementary abelian.

(i) If \( G \) is a non-abelian simple group, then this case does not happen.

(ii) If \( G = O^p(G) = O^p(D) \) and \( O_p'(G) = O_p'(D) = 1 \), then this case does not happen.

**Proof.** (i) Assume that such a case happens. We use the CFSG. Let \( D \in \text{Syl}_p(G) \).

First, assume that \( G \) is an alternating group \( \mathfrak{A}_n \) for some \( n \geq 5 \). Then, since \( D \) is abelian (and hence by Burnside’s Theorem), [32, Theorem 5.4] and [2] Consequences 5 and 6 imply that \( 5 = k(B) = k(\mathbb{B}) \) and \( 3 = \ell(B) = \ell(\mathbb{B}) \), where \( \mathbb{B} := B_0(F_N G(D)) \). Thus we have a contradiction by Lemma 4.1.

If \( G \) is one of the 26 sporadic simple groups, then the assertion follows by Lemma 2.10.

Assume that \( G = G(q) \) is a simple group of Lie type defined over \( \mathbb{F}_q \) with \( p \nmid q \). Then \( G = \text{PSL}_2(q) \) since \( D \) is abelian (see e.g. [58, Theorem]). Thus, by [11, p.588], [16, Satz 9.1] and [35, 8.5. Theorem p.70], we have that \( \ell(B) = (q - 1)/2 \), and hence \( q = 7 \) since \( \ell(B) = 3 \), so that \( |D| = 7 \) since \( p \nmid q \), a contradiction since \( D \) is non-cyclic.

Finally suppose that \( G = G(q) \) is a simple group of Lie type defined over a certain finite field \( \mathbb{F}_q \) for some \( q \) with \( p \nmid q \). Since \( p \geq 5 \), \( D \) is non-cyclic elementary abelian and \( k(B) = 5 \), all the sixteen finite simple groups in [31, Table 24.3] (cf. [32, Table 6.1.3]) cannot be our \( G \) by Lemma 2.11.

Just as in the proof of Theorem 3.1, we can assume that there are a simple, and simply connected reductive algebraic group \( \mathfrak{G} \) defined over the algebraically closed field \( \mathbb{F}_q \) and a Steinberg (Frobenius) endomorphism \( F : \mathfrak{G} \to \mathfrak{G} \) with \( G = \mathfrak{G}^F/\text{Z}(\mathfrak{G}^F) \) (see [50, 2.3] or [17, p.185]). Then we get by Lemma 2.9 that \( k(B) = k(\mathbb{B}) \) and \( \ell(B) = \ell(\mathbb{B}) \) where \( \mathbb{B} := B_0(F_N G(D)) \). Hence \( k(\mathbb{B}) = 5 \) and \( \ell(\mathbb{B}) = 3 \), a contradiction by Lemma 4.1.

Therefore just as in the proof of Theorem 3.1 by making use of the CFSG in [31, p.6], the proof of (i) is completed.

(ii) It follows from [10, 2.1. Theorem] that there are non-abelian simple groups \( G_1, \ldots, G_n \) such that \( p \nmid |G_i| \) for each \( i \) and that \( G = G_1 \times \cdots \times G_n \) for some \( n \in \mathbb{N} \). Set \( B_i := B_0(\text{FG}_i) \)
Theorem 5.1. Let $|B_1| = 3$. Then, $|B_1| = 3$. Hence the assertion follows by (i).

5. What we can say if $k(B) = 4$ and $\ell(B) = 3$

The purpose of this section is to prove the following theorem:

**Theorem 5.1.** Let $B := B_0(FG)$ and $D \in \text{Syl}_p(G)$. If $k(B) = 4$ and $\ell(B) = 3$, then $D \cong C_2 \times C_2$.

In the following we list many lemmas whose aim is just to give a complete proof of Theorem 5.1. Because of this we shall use the following notations and assume the following entirely throughout of this section from now on. Namely,

**Notation 5.2.** Throughout this section we assume that $G$ is a finite group with a Sylow $p$-subgroup $D$ with $|D| = p^d$ for some $d \geq 1$ and $B := B_0(FG)$.

**Lemma 5.3.** If $k(B) = 4$ and $\ell(B) = 3$, then we have that $D$ is non-cyclic and elementary abelian and that $p \neq 3$.

*Proof.* Assume first that $D$ is cyclic. By [22], the inertial index $e$ of $B$ is 3 since $e = \ell(B)$. Then, $|D| = me + 1$, where $m$ is the multiplicity of the exceptional characters of $B$, and also $k(B) = e + m$. Hence $4 = 3 + m$, so that $m = 1$. Thus, $|D| = 3 + 1 = 4$, and hence $p = 2$. This is a contradiction since $e|(p-1)$.

Since $k(B) - \ell(B) = 1$ and $B$ is principal, $D$ is elementary abelian by [47, Theorem 3.6].

Finally suppose $p = 3$. Since $D$ is abelian, by [39], $k(B) = k_0(B)$. By [48, Corollary 1.6], $k_0(B) \equiv 0 \pmod{3}$ since $D$ is non-cyclic. Since $k(B) = 4$, this is a contradiction. □

**Lemma 5.4.** If $k(B) = 4$, $\ell(B) = 3$ and $D \triangleleft G$, then $D \cong C_2 \times C_2$, in fact $B \cong F \mathfrak{A}_4$ as $F$-algebras, and also as internal $D$-algebras.

*Proof.* Since $B$ is principal, we can assume that $O_p(G) = 1$. Then by Fong-Gaschütz’s Theorem, $FG$ has only one block, say $B$. Then, by Schur-Zassenhaus’ Theorem, $G = D \rtimes E$ for a $p'$-subgroup $E$ of $G$. Thus, $k(G) = k(B) = 4$ and $3 = \ell(B) = \ell(G) = \ell(G/D) = \ell(E) = k(E)$. Hence, [59, Table 1] implies that

$$E \in \{C_3, S_3\} \text{ and } G \in \{C_4, C_2 \times C_2, \mathfrak{A}_4\}.$$  

Then, since $3|E||G|$, $G = \mathfrak{A}_4$, so that the assertion follows. □

**Hypothesis 5.5.** Suppose that $k(B) = 4$ and $\ell(B) = 3$ till just before the proof of Theorem 5.1. Further, because of Lemmas 5.3 and 5.4, we can assume that $p \neq 3$, $D$ is non-cyclic elementary abelian and also that Theorem 5.1 holds for any finite group $G$ such that $|G| < |G|$.

**Lemma 5.6.** It holds the following:

(i) If $G$ is non-abelian simple, then $D \cong C_2 \times C_2$, so that $G \cong \text{PSL}_2(q)$ for a power $q$ of a prime such that $q \equiv 3$ or $5 \pmod{8}$.  

13
(ii) If \( G = O_p(G) = O_p'(G) = O_p(G) = 1 \), then \( G \) is non-abelian simple, and hence \( D \cong C_2 \times C_2 \) and further \( G \cong \text{PSL}_2(q) \) for a power \( q \) of a prime such that \( q \equiv 3 \) or 5 \((\text{mod } 8)\).

Proof. (i) As in Lemma 4.2, we have a contradiction if \( p \geq 5 \). So by Hypothesis 5.5, \( p = 2 \). Then since \( D \) is abelian by Hypothesis 5.5, and Lemma 5.4 imply the assertion.

(ii) By using (i) we can prove (ii) just as in the proof of Lemma 4.2(ii). \( \square \)

Lemma 5.7. We can assume that \( O_p'(G) = O_p(G) = 1 \).

Proof. Since \( B \) is principal, we can assume \( O_p'(G) = 1 \). Next, assume that \( O_p(G) \neq 1 \). Set \( Q := O_p(G) \), \( D := D/Q \), \( G := G/Q \), and \( B := B_0(FG) \). Since \( B \) dominates \( \bar{B} \), \( \text{Irr}(\bar{B}) \subseteq \text{Irr}(B) \) (see [53, Theorem 5.8.10 and Lemma 5.8.6(ii)]). So \( k(\bar{B}) = 1, 2, 3 \) or 4.

If \( k(\bar{B}) = 1 \), then \( p \nmid |G| \), so that \( Q \in \text{Syl}_p(G) \). So the assertion follows by Lemma 5.4.

If \( k(\bar{B}) = 4 \), then \( Q \subseteq \bigcap_{\chi \in \text{Irr}(\bar{B})} \ker \chi = O_p'(G) \), a contradiction since \( Q \neq 1 \).

Assume finally that \( k(\bar{B}) = 2 \). Then [9, Theorem A] implies that \( |\bar{D}| = 2 \), and hence \( p = 2 \) and \( G \) is 2-nilpotent by [30, Theorem 7.6.1]. Hence \( G \) is 2-solvable. Then, \( G \) is of 2-length one since \( D \) is abelian by Lemma 5.3. Further, since we assume that \( O_2'(G) = 1 \), \( D \triangleleft G \). Thus the assertion follows from Lemma 5.3.

Assume finally that \( k(\bar{B}) = 3 \). Then, Theorem 3.1 yields that \( |\bar{D}| = 3 \), so that \( p = 3 \), a contradiction by Lemma 5.3. \( \square \)

Lemma 5.8. We can assume that \( O_p(G) = G \).

Proof. Suppose \( O_p(G) \overset{\sim}{\subseteq} G \). Then, there is an \( N \) with \( N \triangleleft G \) and \( |G/N| = p \). Since \( D \) is elementary abelian and non-cyclic by Lemma 5.3, we can write \( G = N \times R \) and \( D = Q \times R \) where \( Q \in \text{Syl}_p(N) \) and \( R \leq G \) with \( R \cong C_p \). Set \( b := B_0(FN) \). Then it follows from [44, Theorem] that \( B \cong b \otimes_F FR \) as \( F \)-algebras. Then, by [53, Lemma 2.4.2(ii)], \( Z(b) \otimes_F FR = Z(b) \otimes_F Z(FR) = Z(b) \otimes_F FR \cong Z(B) \) as \( F \)-algebras. Since \( \text{dim}_F Z(B) = k(B) = 4 \) by Hypothesis 5.5, it holds that \( k(b) \cdot p = 4 \). Hence \( k(b) = 2 \) and \( p = 2 \). Then, [9, Theorem A] implies that \( Q \cong C_2 \). So that \( D \cong C_2 \times C_2 \). \( \square \)

Lemma 5.9. If furthermore \( G = O_p'(G)\cdot C_G(D) \), then \( D \cong C_2 \times C_2 \).

Proof. By Lemmas 5.7 and 5.8, we can assume that \( O_p'(G) = O_p(G) = 1 \) and \( O_p(G) = G \). Set \( L := O_p'(G) \) and \( b' := B_0(FL) \). Then, it follows from [11, 23] that \( B \cong b' \) as \( F \)-algebras, so that \( k(b') = 4 \) and \( \ell(b') = 3 \) by [53, Lemma 5.11.3]). Obviously \( O_p'(L) = O_p(L) = 1 \). Now, since \( O_p(G) = G \), [49, Chap.I Corollary 10.13] implies that \( \text{Ext}^1_G(F, F) = 0 \), so that \( \text{Ext}^1_G(F, F) = 0 \) since the isomorphism \( B \cong b' \) sends \( F_G \) to \( F_L \), which yields that \( O_p(L) = L \) again by [49, Chap.I Corollary 10.13]. By the definition of \( L \), \( O_p(L) = L \). Hence Lemma 5.6(ii) yields that \( D \cong C_2 \times C_2 \). \( \square \)

Now, we are ready to prove our main theorem of this section, that is in fact the first half of the main result of this paper (see Theorem 1.1). Namely,

Proof of Theorem 5.11 By Lemmas 5.7 and 5.8, we can assume that \( O_p'(G) = O_p(G) = 1 \) and \( O_p(G) = G \). Set \( N := O_p'(G)\cdot C_G(D) \) and \( b := B_0(FN) \). Thus, \( N \triangleleft G \) by the
Frattini argument, and obviously \( C_G(D) \leq N \). If \( G = N \), then Lemma 5.9 yields that \( D \cong C_2 \times C_2 \). Hence we can assume that \( N \not\leq G \). Set \( \bar{G} := G/N \) and \( B := B_0(FG) \). Now, by Lemma 2.6(i)–(ii), we know that
\[
\chi_{\bar{G}} \mid_{\bar{G}} = 1_b \quad \text{and} \quad \text{Irr}(\bar{G}) = \text{Irr}(B \mid 1_N \uparrow^G) \subseteq \text{Irr}(B).
\]

Since \( k(B) = 4 \) and \( |\bar{G}| > 1 \), \( k(\bar{G}) = 2, 3 \) or 4.

Assume first that \( k(\bar{G}) = 4 \). Then, by [39], Table 1 p.309], \( \bar{G} \in \{C_4, C_2 \times C_2, D_{10}, \mathfrak{A}_4\} \). If \( \bar{G} \cong C_4 \) or \( C_2 \times C_2 \), then all irreducible ordinary characters in \( B \) are linear, so that [42, 43, Theorem (7)], that \( k(B) = k(\mathbb{B}) \) and \( \ell(B) = \ell(\mathbb{B}) \) where \( \mathbb{B} := B_0(F N_G(D)) \), so that Lemma 5.4 yields that \( D \cong C_2 \times C_2 \). Suppose next that \( \bar{G} \cong D_{10} \) or \( \mathfrak{A}_4 \). Then \( |\{\chi(1) | \exists \chi \in \text{Irr}(B)\}| = 2 \). Apparently, \( p \neq 2 \) since \( p \mid |\bar{G}| \). Hence by Lemma 5.3, \( p \geq 5 \). Thus, by [29] Theorem A, \( G \) is \( p \)-solvable. Hence, by Lemma 5.3 and [30] Theorem 6.3.3, \( G \) is of \( p \)-length one. So \( D < G \) since \( O_p(G) = 1 \). Thus, Lemma 5.4 yields the assertion.

Assume next that \( k(\bar{G}) = 3 \). Then, again by [39], Table 1 p.309], \( \bar{G} \cong C_3 \) or \( \mathfrak{S}_3 \). If \( G \cong C_3 \), then \( B \) has three distinct linear ordinary characters \( \chi_0, \chi_1 \) and \( \chi_2 \), so that \( (\chi_i)^0 \) for \( i = 1, 2, 3 \) are three different linear Brauer characters in \( B \), and hence again by [42, 43, Theorem (7)\( \leftrightarrow \)(10)] and Lemma 5.4, we have \( D \cong C_2 \times C_2 \). Now, assume that \( G \cong \mathfrak{S}_3 \). Let \( \chi \) be the unique ordinary character \( \mathfrak{S}_3 \) of degree 2, and consider \( \chi \) as an ordinary character in \( \text{Irr}(B) \) (see (8)). Then, (8) and the Frobenius Reciprocity imply that \( (\chi \downarrow_N, 1_N)^N \neq 0 \). But since \( \text{H}^2(\mathfrak{S}_3, \mathbb{C}^\times) = 1 \) (see [37] 2.12.3 Theorem (i)) and since \( 1_N \) is \( G \)-invariant, we get by Clifford’s Theorem (see [53] Chap.3, the solution of Problem 11)] that \( \chi \downarrow_N = 1_G \), a contradiction since \( \chi(1) = 2 \).

Assume finally that \( k(\bar{G}) = 2 \). Hence \( \bar{G} \cong C_2 \) by [39], Table 1]. By (8), \( \text{Irr}(B) \) has at least two linear characters, say \( \chi_0 := 1_G \) and \( \chi_1 \) (sign character). Since \( \bar{G} \) is cyclic and \( 1_N \) is \( G \)-invariant, by Clifford’s Theorem and [39], \( \chi_1 \downarrow_N = 1_N \), so that \( \chi_1(u) = 1 \) for every \( p \)-element \( u \in G \) since \( p \mid |G/N| \) (and hence \( u \in N \)). Since \( \chi_1 \neq \chi_0 = 1_G \), there exists an element \( g \in G \) with \( \chi_1(g) \neq 1 \). Write \( g = g_p g_{p'} = g_{p'} g_p \) where \( g_p \) and \( g_{p'} \) respectively are the \( p \)-part and the \( p' \)-part of \( g \). Thus, since \( \chi_1 \) is linear (and hence \( \chi_1 \) is a group homomorphism) and since \( \chi_1(g_p) = 1 \), we have that
\[
1 \neq \chi_1(g) = \chi_1(g_p g_{p'}) = \chi_1(g_p) \chi_1(g_{p'}) = \chi_1(g_{p'}).
\]
This means that \( (\chi_1)^0 \neq \phi_0 \) (recall that \( \phi_0 = (1_N)^0 \)). Thus we can set \( \phi_1 := (\chi_1)^0 \). Since \( \ell(B) = 3 \), there is another one, say \( \phi_2 \) so that \( \text{IBr}(B) = \{\phi_0, \phi_1, \phi_2\} \) and \( \phi_0 := (1_N)^0 \). Let \( S_i \) be a simple \( FG \)-module in \( B \) with \( S_i \leftrightarrow \phi_i \) for \( i = 0, 1, 2 \). Obviously, \( \dim_F S_i = 1 \) and \( S_i \downarrow_N = F_N \) for \( i = 0, 1 \). Since \( 1_B = 1_b \) by (8), there is a simple \( FN \)-module \( T \) in \( b \) such that \( \text{Hom}_{FG}(T \uparrow^G, S_2) \neq 0 \). Then, again by Clifford’s Theorem and by the fact that \( \bar{G} \cong C_2 \),
\[
S_2 \downarrow_N = T \quad \text{or} \quad T \oplus T^g
\]
where \( g \in G \) with \( G = (N, g) \).

Assume that \( S_2 \downarrow_N = T \). Since \( 1_B = 1_b \) by (8) and since \( S_i \downarrow_N = F_N \) for \( i = 0, 1 \), we get that \( \text{IBr}(b) = \{\psi_0, \psi_1\} \) where \( \psi_0 := (1_N)^0 \) and \( \psi_1 \leftrightarrow T \). Recall that \( |\bar{G}| = 2 \) and this is a \( p' \)-number. Hence, by Maschke’s Theorem, \( T \uparrow^G \) is semi-simple (recall that
\[ J(FG) = FG \cdot J(FN) = J(FN) \cdot FG \]. Now, by the Frobenius Reciprocity,
\[
\text{Hom}_{FG}(S_i, T^G) \cong \text{Hom}_{FN}(S_i \downarrow_N, T) = \text{Hom}_{FN}(F_N, T) = 0 \quad \text{for} \quad i = 0, 1
\]
\[
\text{Hom}_{FG}(S_2, T^G) \cong \text{Hom}_{FN}(S_2 \downarrow_N, T) \cong F \quad \text{as} \quad F\text{-spaces}
\]
since \( T \not\cong F_N \) (if \( T \cong F_N \), then \( S_2 \downarrow_N = F_N \), so that \( S_2 \) is considered as a simple \( FG \)-module, and hence \( FG \) has three non-isomorphic simple modules, a contradiction since \( |G| = 2 \)). Thus, by noting \( 1_B = 1_b \) in (8) again, we have \( T^G = S_2 \), so that \( \dim_{FG} S_2 = 2 \times \dim_F T \), a contradiction.

Hence, \( S_2 \downarrow_N = T \oplus T^g \). So that, since \( S_0 = F_G, S_1, S_2 \) are all non-isomorphic simple \( FG \)-modules in \( B \) and since \( 1_B = 1_b \), all non-isomorphic simple \( FN \)-modules in \( b \) are \( T_0 \) := \( F_N, T, T^g \), and hence
\[
(9) \quad \ell(b) = 3.
\]
Now, we have known that \( \text{Irr}(B) = \{ \chi_0 = 1_G, \chi_1 = \text{sign}, \chi_2, \chi_3 \} \) and that \( \chi_i \downarrow_N = \theta_0 := 1_N \) for \( i = 0, 1 \). Since \( |G| = 2 \) and since \( 1_B = 1_b \) in (8), we obtain that
\[
\chi_2 \downarrow_N = \theta_1 \text{ or } \theta_1 + \theta_1^g \quad \text{for some} \quad \theta_1 \in \text{Irr}(b) - \{ \theta_0 \}
\]
and that
\[
\chi_3 \downarrow_N = \theta_3 \text{ or } \theta_3 + \theta_3^g \quad \text{for some} \quad \theta_3 \in \text{Irr}(b) - \{ \theta_0 \}.
\]
Hence, again by \( 1_B = 1_b \) in (8), \( k(b) \leq 5 \). Since \( \ell(b) = 3 \) by (9), \( k(b) \geq 4 \). So that \( k(b) = 4 \) or \( 5 \). Now recall that \( p \neq 3 \) by Lemma 5.3. Obviously, \( p \neq 2 \) since \( 2 = |G/N| |G/L| \). So that \( p \geq 5 \). Moreover, since \( b = B_0(F[L\cdot C'_G(D)]) \) and \( b' = B_0(FL) \), \([1, 23]\) implies that \( b \cong b' \) as \( F\)-algebras. So that
\[
(10) \quad k(b) = k(b') \text{ and } \ell(b) = \ell(b').
\]
Hence, if \( k(b) = 5 \), then \( k(b') = 5 \) and \( \ell(b') = 3 \), so that Lemma 4.2 yields that we have a contradiction. Thus, \( k(b) = 4 \). Namely
\[
k(b) = 4 \text{ and } \ell(b) = 3.
\]
Again by (10), \( k(b') = 4 \) and \( \ell(b') = 3 \). Then since \( b' = B_0(FL) \), we finally have that \( D \cong C_2 \times C_2' \) by Lemma 5.6(ii).

6. WHAT WE CAN SAY IF \( k(B) = 4 \) AND \( \ell(B) = 2 \)

The purpose of this section is to prove the following theorem:

**Theorem 6.1.** Let \( B := B_0(FG) \), and let \( D \) be a Sylow \( p \)-subgroup of \( G \). If \( k(B) = 4 \) and \( \ell(B) = 2 \), then \( |D| = 5 \).

In the following we list lemmas to give a complete proof of Theorem 6.1

**Notation 6.2.** Throughout this section we assume that \( G \) is a finite group with a Sylow \( p \)-subgroup \( D \) with \( |D| =: p^d \) for some \( d \geq 1 \), \( B := B_0(FG) \), and we set \( H := N_G(Z(J(D))) \) where \( J(D) \) is the Thompson subgroup of \( D \), and \( \bar{H} := H/O_{p'}(H) \).
Lemma 6.3. If $D < G$, then $|D| = 5$ and $B \cong FD_{10}$ as $F$-algebras and also as interior $D$-algebras.

Proof. Since $B$ is principal, we can assume $O_p'(G) = 1$. Then by Fong-Gaschütz’s Theorem, $FG$ has only one block, say $B$. By Schur-Zassenhaus’ Theorem, $G = D \times E$ for a $p'$-subgroup $E$ of $G$. Thus, $k(G) = k(B) = 4$ and $2 = \ell(B) = \ell(G) = \ell(G/D) = \ell(E) = k(E)$. Hence, [59, Table 1] implies the assertion. \hfill \Box

Hypothesis 6.4. Suppose that $k(B) = 4$ and $\ell(B) = 2$ till just before the proof of Theorem 6.6. Further, because of Lemma 6.3, we assume that Theorem 6.1 holds for any finite group $\mathcal{G}$ such that $|\mathcal{G}| < |G|$.

Lemma 6.5. We can assume that $G = O_p'(G)$.

Proof. Set $L := O_p'(G)$ and $b := B_0(FL)$. Suppose $G \neq L$. Set $N := LC_G(D)$. If $N = G$, then Lemma 2.6(i)–(ii), it holds $k(\bar{G}) \leq k(B) = 4$. Since $\bar{G} \neq 1$, $k(\bar{G}) \in \{2, 3, 4\}$. If $k(\bar{G}) = 4$, then $N \leq \bigcap_{\chi \in \text{Irr}(B)} \ker(\chi) = O_p'(G)$ by [59, Theorem 5.8.1], so $p \nmid |N|$, and hence $p \nmid |G|$, a contradiction.

Suppose $k(\bar{G}) = 3$. Then, by [59, Table 1], $G = C_3$ or $S_3$. Hence $\bar{G}$ has two distinct linear ordinary characters, so that $B$ has two distinct linear ordinary characters since $\text{Irr}(\bar{G}) \subseteq \text{Irr}(B)$, say $\chi_0 := 1_G$ and $\chi_1$, by Lemma 2.6(i)–(ii). Set $\phi_i := (\chi_i)^0$ for $i = 0, 1$. Then, $\phi_0$ and $\phi_1$ are Brauer characters of $B$ and note that $\phi_0 \neq \phi_1$ as in the middle of the proof of Theorem 5.1. Hence $\text{IBr}(B) = \{\phi_0, \phi_1\}$ since $\ell(B) = 2$. Namely, all irreducible Brauer characters in $B$ are of degree one.

Finally, suppose $k(\bar{G}) = 2$. Then $\bar{G} \cong C_2$ by [59, Table 1]. Thus as above, $B$ has two distinct linear ordinary characters, and hence we have the assertion. \hfill \Box

Lemma 6.6. If $O_p'(G) \not\subseteq G$, then $D$ is abelian.

Proof. First of all, by Lemma 2.2, $D$ is abelian if $p = 2$. Hence we can assume that $p \neq 2$. Suppose that $D$ is non-abelian, and hence $d \geq 3$.

We want to have a contradiction. By the assumption, $G$ has a normal subgroup $N \triangleleft G$ such that $|G/N| = p$. Let $b := B_0(FN)$. Then, $b$ is $G$-invariant, so that from Lemma 2.7
\begin{align}
1_B &= 1_b & \text{and} \\
\text{Irr}(B \mid 1_N^G) &= \text{Irr}(G/N).
\end{align}

This means that $B$ has $p$ distinct linear ordinary characters since $G/N \cong C_p$. That is, $p \leq |\text{Irr}(B)| = k(B)$. Then, since $k(B) = 4$ and we are assuming $p \geq 3$, it holds that $p = 3$. Then, by [48, Corollary 1.6], $k_0(B) = 3$ since $k(B) = 4$. On the other hand, since $G/N \cong C_3$, [12] implies that $B$ has three distinct linear ordinary characters. So that we can write $\text{Irr}(B) = \{\chi_0 := 1_G, \chi_1, \chi_2, \chi_3\}$ such that $N \leq \ker(\chi_i)$ for $i = 0, 1, 2$ and hence $\chi_0(1) = \chi_1(1) = \chi_2(1) = 1$, and that $\chi_2$ has positive height. There is a character $\theta \in \text{Irr}(b)$ such that $(\chi_3 \downarrow_N, \theta)^N \neq 0$ by (11). Obviously, $\theta \neq 1_N$, because $\chi_3 \notin \{\chi_0, \chi_1, \chi_2\}$.
Assume first that \( G_\theta = G \). Then, \( \chi_{3\downarrow_N} = \theta \) since \( G/N \) is cyclic. So that \( (\theta \uparrow^G, \chi_3)^G = 1 \). By the above, \( (\theta \uparrow^G, \chi_i)^G = 0 \) for \( i = 0, 1, 2 \). Hence \([11]\) implies that \( \text{Irr}(b) = \{1_N, \theta\} \). Thus \( k(b) = 2 \), so that \([9] \) Theorem A] yields that \( p = 2 \), a contradiction since \( p = 3 \).

Thus \( G_\theta \not\leq G \), and hence \( \chi_{3\downarrow_N} = \theta + \theta^q + \theta^{q^2} \) where \( G/N = (gN) \) for an element \( g \in G \). This implies that \( \text{Irr}(b) = \{1_N, \theta, \theta^q, \theta^{q^2}\} \) by \([11]\]. Namely, \( k(b) = 4 \). Since \( \ell(B) = 2 \), there is a simple \( FG \)-module \( S \) in \( B \) with \( S \not\cong F_G \). Since \( G/N \cong C_p = C_3 \) which is cyclic, we know by \([11]\) and Clifford’s Therem that

\[
S_{\downarrow_N} = T \oplus T^g \oplus T^{q^2} \quad \text{or} \quad S_{\downarrow_N} = T \quad \text{for a simple } FN\text{-module } T \text{ in } b.
\]

If the first case occurs, then since \( T \not\cong F_N \) (otherwise the multiplicity of \( T \) in \( S_{\downarrow_N} \) as a direct summand is not one, that contradicts to the fact that \( G/N \) is cyclic), \( F_N, T, T^g, T^{q^2} \) are all non-isomorphic simple \( FN\)-modules in \( b \) by \([11]\), which yields that \( \ell(b) \geq 4 \), a contradiction since \( k(b) = 4 \). Hence only the second case happens. Namely, \( S_{\downarrow_N} = T \). Obviously, \( N \) is not 3-nilpotent (otherwise \( G \) is 3-nilpotent since \( |G/N| = 3 \), contradicting the fact that \( \ell(B) = 2 \)). Now, since all non-isomorphic simple \( FG\)-modules in \( B \) are \( F_G \) and \( S \), it follows again from \([11]\) that all non-isomorphic simple \( FN\)-modules in \( b \) are \( F_N \) and \( T \). This means that \( \ell(b) = 2 \). Apparently, \( |N| < |G| \). Hence Hypothesis 6.4 implies that a Sylow \( p\)-subgroup of \( N \) must be of order 5, namely, \( p = 5 \), a contradiction. \( \square \)

In fact the next lemma and Lemma 2.5 do work quite well to prove Theorem 6.1.

**Lemma 6.7** (\([8]\)). Assume that

\[(13) \quad p \text{ is odd, and for every element } u \in G \text{ of order } p, \quad C_G(u) \text{ is } p\text{-nilpotent.}\]

(i) It holds that \( H = N_G(D) \) and that \( N_G(D) \) controls \( p\)-fusion in \( G \), namely \( \mathcal{F}_D(G) = \mathcal{F}_D(N_G(D)) \).

(ii) Set \( \mathbb{B} := B_0(FN_G(D)) \). Then, the Scott module \( \text{Sc}(G \times N_G(D), \Delta D) \) with vertex \( \Delta D \) induces a splendid stable equivalence of Morita type between \( B \) and \( \mathbb{B} \) where \( \Delta D := \{(u, u) \in G \times N_G(D) \mid u \in D\} \) (see \([53]\) Chap.5 §8 for the Scott modules).

**Proof.** (i) If \( D \) is abelian, then by Burnside’s fusion theorem, \( N_G(D) \) controls \( p\)-fusion in \( G \) and \( J(D) = D \) by the definition of Thompson’s subgroup \( J(D) \), and hence \( H = N_G(D) \).

Thus we may assume that \( D \) is non-abelian. Then, by Lemma 6.6 \( O^p(G) = G \). So that \( \text{Ext}^1_{FG}(F, F) = H^1(G, F) = 0 \) (see e.g. \([19]\) Chap.I Corollary 10.13]), and hence \( O^p(H) = H \) by Lemma 2.4 and \([19]\) Chap.I Corollary 10.13]. Set \( \bar{H} := H/O^p(H) \), and then \( O^p(H) \). Now, since we may assume that \( D \in \text{Syl}_p(H) \) by Lemma 2.4, it follows from \([13]\) and \([8]\) Lemma 9.3] that \( \bar{H} \) is a Frobenius group whose kernel is \( \bar{D} := (DO^p(H))/O^p(H) \cong D \). Hence \( \bar{D} < \bar{H} \), so that \( D < H \). This yields that \( H 

\text{the proof of Theorem 8.3}, \text{we know that } G \text{ does not have } \text{Qd}(p) \text{ in any subquotient of } G. \text{Hence well-known Glauberman’s ZJ-theorem (see e.g. \([21]\) Theorem 1.21]) implies that } \mathcal{F}_D(G) = \mathcal{F}_D(H). \text{Therefore } \mathcal{F}_D(G) = \mathcal{F}_D(N_G(D)) \text{ since we have proved that } H = N_G(D). \)

(ii) Since we know \( H = N_G(D) \) by (i), \([8]\) Theorem 8.3] implies the assertion. \( \square \)

**Lemma 6.8.** One of the following two cases happens:
(I) $D$ is elementary abelian.

(II) There are precisely two conjugacy classes of $G$ of non-trivial $p$-elements, and $C_G(u)$ is $p$-nilpotent for every element $u \in D^\#$. 

Proof. Since $k(B) - \ell(B) = 2$, [53 Theorems 5.9.4 and 5.6.1] yields that the number of the conjugacy classes of $p$-elements in $G^\#$ is one or two.

So, assume first that the number is one. Then, $\ell(B_0(F[C_G(u)])) = 2$ for every non-trivial $p$-element $u$ in $G$ by [53 Theorems 5.9.4 and 5.6.1], and all $p$-elements in $G^\#$ are $G$-conjugate. If $G$ were one of the finite groups in [47 (ii), (iii) of Theorem A], then, by Lemma 2.3, $k(B) - \ell(B) \neq 2$, a contradiction. Thus, by [47 Theorem A], $D$ is elementary abelian, so that Case (I) occurs.

Hence we can assume that the number is two, namely $k(B) - \ell(B) = 2 = \ell(b_u) + \ell(b_v)$ and $\ell(b_u) = \ell(b_v) = 1$, where $b_u := B_0(FC_G(u))$ and $b_v := B_0(FC_G(v))$ for two distinct elements $u, v \in D^\#$. This implies that for every element $w \in D^\#$, $C_G(w)$ is $p$-nilpotent. So, Case II happens. □

Lemma 6.9. We can assume that $D$ is abelian.

Proof. First of all, the assertion holds for $p = 2$ by Lemma 2.2. So, suppose that $p$ is odd. Then, from Lemma 6.8, it suffices to consider the case that the case (II) happens in Lemma 6.8. So that for every element $u \in D^\#$, $C_G(u)$ is $p$-nilpotent.

We may assume that $D$ is non-abelian. Set $L := N_G(D)$ and $B := B_0(FL)$. Hence it follows from Lemma 6.7 (ii) that $B$ and $B$ are stably equivalent of Morita type. Thus, by [13 Propositions 5.3 and 5.4], it holds that $k(B) - \ell(B) = k(B) - \ell(B)$ and that $Z(B) \cong Z(B)$ as $F$-algebras. Namely, $k(B) - \ell(B) = 2$. Set $L := L/O_{0'}(L)$. Since $B$ is the principal block of $FL$, $B \cong B_0(FL)$ as $F$-algebras and also as interior $D$-algebras. Obviously, $C_L(\bar{w})$ is $p$-nilpotent for every element $\bar{w} \in D^\#$ where $D := (D_0)/(O_{0'}(L)) \cong D$. Thus we can apply $L$ to the group $G$ in Lemma 2.5 (note that the action of $E$ on $D$ is faithful where $E$ is a $p$-complement of $L$). Therefore, it follows from Lemma 2.5 (iv) that $D$ is abelian, which means that $D$ is abelian, a contradiction. □

Lemma 6.10. We can assume that $D$ is elementary abelian.

Proof. We can assume $O_{0'}(G) = 1$ and $O_{0'}(G) = G$ by Lemma 6.5. Since $k(B) - \ell(B) = 2$, it follows from the proof of Lemma 6.8 that all non-identity $p$-elements are conjugate in $G$; or that there are precisely two conjugacy classes of $G$ which have non-identity $p$-elements and $C_G(u)$ is $p$-nilpotent for every $u \in D^\#$.

If the first case occurs, then [47 Theorem A] and Lemma 2.3 imply that $D$ is elementary abelian. Hence we can assume that the second case occurs. Namely, there are precisely two conjugacy classes of $G$ which have non-identity $p$-elements and $C_G(u)$ is $p$-nilpotent for every $u \in D^\#$. Note that $D$ is abelian by Lemma 6.9 Set $E := N_G(D)/C_G(D)$. Hence Burnside’s fusion theorem says that there are exactly three $E$-conjugacy classes of $D$, that is $\dim_F((FD)^E) = 3$ where $(FD)^E := \{a \in FD | y^{-1}ay = a, \forall y \in E\}$. Now, by [53 Proof of Theorem F],

$$(p^e + p - 2)/(p - 1) \leq LL \left((FD)^E\right)$$

where $p^e := \exp(D)$.
since $D$ is abelian. Clearly $LL((FD)^E) \leq \dim_F((FD)^E)$, so that

$$(p^\epsilon + p - 2)/(p - 1) \leq 3.$$ 

So $p^\epsilon + p - 2 \leq 3(p - 1)$, and hence if $\epsilon \geq 2$ then $0 < (p - 1)^2 = p^2 - 2p + 1 \leq p^\epsilon - 2p + 1 \leq 0$, a contradiction. Hence $\epsilon = 1$, which means that $D$ is elementary abelian. □

**Lemma 6.11.** We can assume that $O_p(G) = 1$ and $O_p(G) = 1$.

**Proof.** Since we treat with only the principal block of $FG$, the first assertion is trivial. Next, set $Q := O_p(G)$, $\tilde{G} := G/Q$, $\tilde{D} := D/Q$ and $\tilde{B} := B_0(F\tilde{G})$.

Assume $Q \neq 1$. It follows from [33, Lemma 5.8.6] that $B$ dominates $\bar{B}$ and that $\text{Irr}(\bar{B}) \subseteq \text{Irr}(B)$. Hence $k(\bar{B})$ is 1, 2, 3 or 4. If $k(\bar{B}) = 1$, then $\bar{p} \not| |\tilde{G}|$, and hence $D = Q < G$, so that the assertion follows from Lemma 6.3. If $k(\bar{B}) = 4$, then $\text{Irr}(\bar{B}) = \text{Irr}(B)$, which means that $Q \leq \bigcap_{\chi \in \text{Irr}(\bar{B})} \ker \chi = O_p'(G)$, that is a contradiction since $Q \neq 1$.

Next suppose that $k(\bar{B}) = 2$. Then $|\tilde{D}| = 2$ by [9, Theorem A], so that $p = 2$ and $\tilde{G}$ is 2-nilpotent by Burnside’s Theorem. Hence $G$ is 2-solvable, which yields that $G$ is of 2-length one since $D$ is abelian by Lemma 6.9. Now, since $O_p(G) = 1$, $D < G$. Hence we have a contradiction by Lemma 6.3.

Finally suppose that $k(\bar{B}) = 3$. Then Theorem 3.1 yields that $|\tilde{D}| = 3$, so that $p = 3$. Hence, by [48, Corollary 1.6], $k_0(B) = 3$ since $k(\bar{B}) = 4$. But this is a contradiction since we know that $D$ is abelian by Lemma 6.9 so that $k(\bar{B}) = k_0(B)$ by [39]. □

**Lemma 6.12.** We can assume that $G$ is a non-abelian simple group with an abelian Sylow $p$-subgroup $D$ of $G$.

**Proof.** By Lemmas 6.11 and 6.5 we can assume $O_p'(G) = 1 = O_p(G)$ and $G = O_p'(G)$. Since $D$ is abelian by Lemma 6.9 the same argument as the proof of Lemma 4.2(ii) follows the assertion. □

Now we are ready to prove the main result of this section.

**Proof of Theorem 6.1.** First, assume that $D$ is cyclic. Then [22] implies that $4 = k(B) = \ell(B) + m = 2 + m$, so that $m = 2$ where $m$ is the multiplicity of the exceptional characters in $B$, which implies that $|D| = 2 \cdot 2 + 1 = 5$, so we are done. Hence we can assume that $D$ is non-cyclic, so that $d \geq 2$.

Assume $p = 2$. By Lemma 6.9 $D$ is abelian. Let $\mathbb{B} := B_0(FN_G(D))$. Then, by [27, Theorem], $k(\mathbb{B}) = k_0(B) = 4$ and $\ell(\mathbb{B}) = \ell(B) = 2$. Thus, by Lemma 6.3 $p = 5$, a contradiction.

If $p = 3$, then [48, Corollary 1.6] implies that $k_0(B) = 3$, so that $k_0(B) = 3 < 4 = k(B)$, that is a contradiction by [39] since $D$ is abelian by Lemma 6.9.

Hence $p \geq 5$. By Lemmas 6.10 and 6.12 we can assume that $G$ is a non-abelian simple group with the non-cyclic elementary abelian Sylow $p$-subgroup $D$.

Then, just as in the proof of Lemma 4.2 it follows from Lemmas 6.3, 2.10, 2.9 and also the CFSG that the assertion follows as before. □
Acknowledgments. The authors would like to thank Vyacheslav Aleksandrovich Belonogov and Benjamin Sambale for useful information; and Radha Kessar for Lemma 2.8. They are grateful also to Ron Brown, Marc Cabanes, Silvio Dolfi, Olivier Dudas, Klaus Lux, Leo Margolis, Yoshihiro Otokita, and Atumi Watanabe for comments and advice.
