On the Renyi entropy power and the Gagliardo-Nirenberg-Sobolev inequality on Riemannian manifolds

Songzi Li∗, Xiang-Dong Li †

January 31, 2020

Abstract In this paper, we prove the concavity of the Renyi entropy power for nonlinear diffusion equation (NLDE) associated with the Laplacian and the Witten Laplacian on compact Riemannian manifolds with non-negative Ricci curvature or $CD(0, m)$-condition and on compact manifolds equipped with time dependent metrics and potentials. Our results can be regarded as natural extensions of a result due to Savaré and Toscani [39] on the concavity of the Renyi entropy for NLDE on Euclidean spaces. Moreover, we prove that the rigidity models for the Renyi entropy power are the Einstein or quasi-Einstein manifolds and a special $(K, m)$-Ricci flow with Hessian solitons. Inspired by Lu-Ni-Vazquez-Villani [34], we prove the Aronson-Benilan estimates for NLDE on compact Riemannian manifolds with $CD(0, m)$-condition. We also prove the NIW formula which indicates an intrinsic relationship between the second order derivative of the Renyi entropy power $N_p$, the $p$-th Fisher information $I_p$ and the time derivative of the $W$-entropy associated with NLDE. Finally, we prove the entropy isoperimetric inequality for the Renyi entropy power and the Gagliardo-Nirenberg-Sobolev inequality on complete Riemannian manifolds with non-negative Ricci curvature or $CD(0, m)$-condition and maximal volume growth condition.

1 Introduction

Let $p > 0$. The nonlinear diffusion equation (NLDE) on $\mathbb{R}^n$

$$
\partial_t u = \Delta u^p,
$$

(1.1)

is a nonlinear version of the classical heat equation on $\mathbb{R}^n$

$$
\partial_t u = \Delta u.
$$

(1.2)

In the case $p > 1$, it is called the porous medium equation, and in the case $0 < p < 1$, it is called the fast diffusion equation. For $p > 1$ and $0 < p < 1$, the Cauchy problem of (1.1) in weak sense has been well studied in the literature. Moreover, when $p > 1 - \frac{2}{n}$, the equation (1.1) preserves the mass in the sense that $\int_{\mathbb{R}^n} u(x,t)dv(x)$ is a constant in $t > 0$. Moreover, when $p \in (1 - \frac{2}{n}, 1)$, solutions to (1.1) are regular and positive for $t \geq 0$. However, this is not true when $p < 1 - \frac{2}{n}$, for instance, finite time vanishing may occur. For $p > 1$, it is known that solutions to (1.1) are at least Hölder continuous. See [8].

In [37], F. Otto proved that the porous medium equation and the fast diffusion equation can be regarded as the gradient flow of the Rényi entropy (see (1.3) below) on the infinite dimensional $L^2$-Wasserstein space of probability measures with finite second moment on Euclidean space equipped with an infinite Riemannian metric. See [46, 47] and reference therein for its extension on Riemannian manifolds. For more background about the porous medium equation and the fast diffusion equation, we refer the readers to [44, 34, 39].

Let $p \geq 1 - \frac{2}{n}$, and let $u$ be a positive and smooth solution to the nonlinear diffusion equation (1.1) with $\int_{\mathbb{R}^n} u(x,t)dx = 1$. Let

$$
H_p(u) = \frac{1}{1-p} \log \int_{\mathbb{R}^n} u^p dx
$$

(1.3)

be the $p$-th Rényi entropy associated with the nonlinear diffusion equation (1.1), and define the Rényi entropy power by

$$
N_p(u) = \exp (\sigma H_p(u)),
$$

where $\sigma = p - 1 + \frac{2}{m}$. In [39], Savaré and Toscani proved that the Rényi entropy power $N_p(u(t))$ is concave in $t \in (0, \infty)$, i.e.,

$$
\frac{d^2}{dt^2} N_p(u(t)) \leq 0.
$$

(1.4)

This extends a previous result due to Costa [6], which states that the Shannon entropy power associated with the heat equation on $\mathbb{R}^n$ is concave. More precisely, let $u(x,t)$ be a positive and smooth solution to the heat equation (1.2) on $\mathbb{R}^n$ with $\int_{\mathbb{R}^n} u(x,t)dx = 1$, let

$$
H(u(t)) = -\int_{\mathbb{R}^n} u \log u dx
$$
be the Shannon entropy associated with (1.2), and define the Shannon entropy power by

\[ N(u(t)) = e^{\frac{2}{n}H(u(t))}. \]

Then \( N(u(t)) \) is concave in \( t \in (0, \infty) \), i.e.,

\[ \frac{d^2}{dt^2}N(u(t)) \leq 0. \]

(1.5)

Using an argument based on the Blachman-Stam inequality [3, 41], the original proof of (1.5) has been simplified by Dembo et al. [13, 14]. A direct proof of (1.5) in a strengthened form, with an exact error term, has been obtained by Villani [45], in which it was also pointed out that it is possible to extend (1.5) to Riemannian manifolds with non-negative Ricci curvature using the \( \Gamma_2 \)-calculation.

In our previous work [29], the authors extended Costa’s Entropy Power Concavity Inequality (EPCI) to the Shannon Entropy Power for the heat equation associated with the usual Laplacian and the Witten Laplacian on complete Riemannian manifolds with \( CD(K, m) \) curvature-dimension condition and on compact manifolds equipped with \((K, m)\)-super Ricci flows. We proved that the rigidity models for the Shannon entropy power are the Einstein manifolds, quasi-Einstein manifolds or \((K, m)\)-Ricci flows equipped with Hessian solitons. Moreover, we proved the NFW formula which indicates an essential relationship between the Shannon entropy power \( N \), the \( F \)-functional and the time derivative of the \( W \)-entropy associated with the conjugate heat equation on Ricci flow, which were introduced by G. Perelman [38]. As a consequence, we proved that the Shannon entropy power is convex along the conjugate heat equation on the Ricci flow and the corresponding rigidity models are the shrinking Ricci solitons. This gives us a new understanding of Perelman’s entropy formulae on the Ricci flow [38], which plays an important role in the proof of the no local collapsing theorem of Ricci flow for the final resolution of the Poincaré conjecture and Thurston’s geometrization conjecture.

It is natural to ask the question whether we can extend Savaré and Toscani’s result to the Rényi entropy power for nonlinear diffusion equations on Riemannian manifolds with suitable curvature dimension. The purpose of this paper is to prove the Entropy Power Concavity Inequality (EPCI) of the Rényi Entropy Power for nonlinear diffusion equations associated with the usual Laplacian and more general Witten Laplacian on Riemannian manifolds with \( CD(K, m) \) curvature-dimension condition and on manifolds equipped with time dependent metrics and potentials. Indeed, this part of results have already been proved in our 2017 preprint [24]. Recently, we have also proved the rigidity theorems and the entropy isoperimetric inequality for the the Rényi entropy power, and the Gagliardo-Nirenberg-Sobolev inequality as well as the Nash inequality on manifolds with non-negative Ricci curvature or with \( CD(0, m) \) curvature-dimension condition and with the maximal volume growth condition. Moreover, we prove the NIW formula which indicates an essential relationship between the Rényi entropy power \( N_p \), the \( p \)-th Fisher information \( I_p \) and the time derivative of the \( W \)-entropy associated with the nonlinear diffusion equation, which was introduced by Lu-Ni-Vazquez-Villani [34]. Our work might lead the readers to recognize the importance of information-theoretic approach in the future study of geometric analysis and Ricci flow.

2 Notation and main results

Let \((M, g)\) be a complete Riemannian manifold, \( \phi \in C^2(M) \) and \( d\mu = e^{-\phi}dv \), where \( v \) is the Riemannian volume measure on \((M, g)\). The Witten Laplacian acting on smooth functions is defined by

\[ L = \Delta - \nabla \phi \cdot \nabla. \]
For any $u, v \in C_0^\infty(M)$, the integration by parts formula holds
\[ \int_M \langle \nabla u, \nabla v \rangle d\mu = - \int_M Luv d\mu = - \int_M uLvd\mu. \]

Thus, $L$ is the infinitesimal generator of the Dirichlet form
\[ \mathcal{E}(u, v) = \int_M \langle \nabla u, \nabla v \rangle d\mu, \quad u, v \in C_0^\infty(M). \]

By Itô’s theory, the Stratonovich SDE on $M$
\[ dX_t = \sqrt{2} U_t \circ dW_t - \nabla \phi(X_t) dt, \quad \nabla_{sdX_t} U_t = 0, \]
where $U_t$ is the stochastic parallel transport along the trajectory of $X_t$, with initial data $X_0 = x$ and $U_0 = \text{Id}_{T_x M}$, defines a diffusion process $X_t$ on $M$ with infinitesimal generator $L$. Moreover, the transition probability density of the $L$-diffusion process $X_t$ with respect to $\mu$, i.e., the heat kernel $p_t(x, y)$ of the Witten Laplacian $L$, is the fundamental solution to the heat equation
\[ \partial_t u = Lu. \quad (2.1) \]

In [1], Bakry and Emery proved the generalized Bochner formula
\[ L|\nabla u|^2 - 2\langle \nabla u, \nabla Lu \rangle = 2|\nabla^2 u|^2 + 2Ric(L)(\nabla u, \nabla u), \quad (2.2) \]
where $u \in C_0^\infty(M)$, $\nabla^2 u$ denotes the Hessian of $u$, $|\nabla^2 u|$ is its Hilbert-Schmidt norm, and
\[ Ric(L) = Ric + \nabla^2 \phi \]
is now called the (infinite dimensional) Bakry-Emery Ricci curvature associated with the Witten Laplacian $L$. For $m \in [n, \infty)$, the $m$-dimensional Bakry-Emery Ricci curvature associated with the Witten Laplacian $L$ is defined by
\[ Ric_{m,n}(L) = Ric + \nabla^2 \phi - \frac{\nabla \phi \otimes \nabla \phi}{m-n}. \]

In view of this, we have
\[ L|\nabla u|^2 - 2\langle \nabla u, \nabla Lu \rangle \geq 2 \frac{|Lu|^2}{m} + 2Ric_{m,n}(L)(\nabla u, \nabla u). \]

Here we make a convention that $m = n$ if and only if $\phi$ is a constant. By definition, we have
\[ Ric(L) = Ric_{\infty,n}(L). \]

Following [1], we say that $(M, g, \phi)$ satisfies the curvature-dimension $CD(K, m)$-condition for a constant $K \in \mathbb{R}$ and $m \in [n, \infty]$ if and only if
\[ Ric_{m,n}(L) \geq Kg. \]

Note that, when $m = n$, $\phi = 0$, we have $L = \Delta$ is the usual Laplacian on $(M, g)$, and the $CD(K, n)$-condition holds if and only if the Ricci curvature on $(M, g)$ is bounded from below by $K$, i.e.,
\[ Ric \geq Kg. \]
In the case of Riemannian manifolds with a family of time dependent metrics and potentials, we call \((M, g(t), \phi(t), t \in [0, T])\) a \((K, m)\)-super Ricci flow if the metric \(g(t)\) and the potential function \(\phi(t)\) satisfy
\[
\frac{1}{2} \frac{\partial g}{\partial t} + \text{Ric}_{m,n}(L) \geq Kg,
\]
(2.3)
where
\[
L = \Delta_{g(t)} - \nabla_{g(t)} \phi(t) \cdot \nabla_{g(t)}
\]
is the time dependent Witten Laplacian on \((M, g(t), \phi(t), t \in [0, T])\), and \(K \in \mathbb{R}\) is a constant. When \(m = \infty\), i.e., if the metric \(g(t)\) and the potential function \(\phi(t)\) satisfy the following inequality
\[
\frac{1}{2} \frac{\partial g}{\partial t} + \text{Ric}(L) \geq Kg,
\]
we call \((M, g(t), \phi(t), t \in [0, T])\) a \((K, \infty)\)-super Ricci flow or a \(K\)-super Perelman Ricci flow. Indeed the \((K, \infty)\)-Ricci flow (called also the \(K\)-Perelman Ricci flow)
\[
\frac{1}{2} \frac{\partial g}{\partial t} + \text{Ric}(L) = Kg
\]
is a natural extension of the modified Ricci flow \(\frac{\partial g}{\partial t} = -2 \text{Ric}(L)\) introduced by Perelman \[38\] as the gradient flow of \(F(g, \phi) = \int_M (R + |\nabla \phi|^2) e^{-\phi} dv\) on \(M \times C^\infty(M)\) under the constraint condition that the measure \(d\mu = e^{-\phi} dv\) is preserved. For the study of the Li-Yau or Hamilton differential Harnack inequalities, \(W\)-entropy formulas and related functional inequalities on \((K, m)\) or \((K, \infty)\)-super Ricci flows, see \[21, 22, 23, 25, 26, 27, 28\] and references therein.

For super Ricci flows on metric and measure spaces, see \[42\] and references therein.

We now introduce the Renyi entropy power for the nonlinear diffusion equation associated with the Witten Laplacian on Riemannian manifolds. Let \(u\) be a positive solution to the nonlinear diffusion equation associated with the Witten Laplacian on \((M, g, \mu)\)
\[
\frac{\partial u}{\partial t} = Lu^p,
\]
(2.4)
where \(0 < p < \infty\) and \(p \neq 1\). Following Otto \[37\], Villani \[46, 47\], Savaré and G. Toscani \[39\], for \(p \neq 1\), the \(p\)-th Renyi entropy is defined by
\[
H_p(u) = \frac{1}{1-p} \log \int_M u^p d\mu,
\]
and the \(p\)-Renyi entropy power is defined by
\[
N_p(u) = \exp(\sigma H_p(u)),
\]
where \(\sigma = p - 1 + \frac{2}{m}\). The \(p\)-Fisher information is defined by
\[
I_p(u) := \frac{1}{\int_M u^p d\mu} \int_{\{u > 0\}} \frac{|
abla u|^2}{u} du.
\]
(2.5)
When \(p \to 1\), the Renyi entropy \(H_p(u)\), the Renyi entropy power \(N_p(u)\) and the \(p\)-th Fisher information \(I_p(u)\) converge to the Shannon entropy \(H(u)\), the Shannon entropy power \(N(u)\) and the Fisher information \(I(u)\) associated with the heat equation (2.1). More precisely,
\[
H(u) := -\int_M u \log u d\mu = \lim_{p \to 1} H_p(u),
\]
\[
N(u) := e^{\sigma H(u)} = \lim_{p \to 1} N_p(u),
\]
\[
I(u) := \int_{\{u > 0\}} \frac{|
abla u|^2}{u} d\mu = \lim_{p \to 1} I_p(u).
\]
Now we state the main results of this paper.

**Theorem 2.1** Let $M$ be an $n$-dimensional compact Riemannian manifold with $\text{Ric} \geq Kg$ for some constant $K \in \mathbb{R}$. Let $p \geq 1 - \frac{1}{m}$, $\sigma = p - 1 + \frac{1}{m}$ and $\kappa = \sigma^{-1}$. Let $u$ be a positive solution to the nonlinear diffusion equation

$$\partial_t u = \Delta u^p.$$  

Then the Renyi entropy power $N_p = N_p(u(t))$ satisfies

$$\frac{d^2 N_p}{dt^2} \leq -2\sigma KN_p \frac{\|u\|_p^p}{\|u\|_p^p} \int_M |\nabla e'(u)|^2 u^p dv.$$ (2.6)

In particular, when $\text{Ric} \geq 0$, we have

$$\frac{d^2 N_p}{dt^2} \leq 0.$$ (2.7)

Moreover, under the condition $\text{Ric} \geq Kg$ (respectively, $\text{Ric} \geq 0$), the equality in (2.6) (respectively, (2.7)) holds on $[0, T]$ for some $T > 0$ if and only if $(M, g)$ is Einstein, i.e., $\text{Ric} = Kg$ (respectively, $(M, g)$ is Ricci flat, i.e., $\text{Ric} = 0$), and $e'(u)$ satisfies

$$\Delta e'(u) = \|u\|_p^{-p} \int_M \Delta e'(u) u^p du = -I_p, \quad \nabla^2 e'(u) = -\frac{I_p}{n} g,$$

where $I_p := \frac{d}{dt} H_p(u(t))$ is the $p$-th Fisher information and satisfies the differential equation

$$I_p' + \sigma I_p^2 + 2KI_p = 0.$$ (2.10)

When $\text{Ric}_{m,n}(L) \geq 0$, it holds

$$I_p \leq \frac{\kappa}{t}.$$  

**Theorem 2.2** Let $(M, g)$ be an $n$-dimensional compact Riemannian manifold with a potential $\phi \in C^2(M)$ such that $\text{Ric}_{m,n}(L) \geq Kg$ for some constant $m \geq n$ and $K \in \mathbb{R}$. Let $p \geq 1 - \frac{1}{m}$, $\sigma = p - 1 + \frac{2}{m}$ and $\kappa = \sigma^{-1}$. Let $u$ be a positive solution to the nonlinear diffusion equation

$$\partial_t u = L u^p.$$  

Then the Renyi entropy power $N_p = N_p(u(t))$ satisfies

$$\frac{d^2 N_p}{dt^2} \leq -2\sigma KN_p \frac{\|u\|_p^p}{\|u\|_p^p} \int_M |\nabla e'(u)|^2 u^p d\mu.$$ (2.8)

In particular, when $\text{Ric} \geq 0$, we have

$$\frac{d^2 N_p}{dt^2} \leq 0.$$ (2.9)

Moreover, under the condition $\text{Ric}_{m,n}(L) \geq Kg$ (respectively, $\text{Ric}_{m,n}(L) \geq 0$), the equality in (2.8) (respectively, (2.9)) holds on $[0, T]$ for some $T > 0$ if and only if $(M, g)$ is quasi-Einstein, i.e., $\text{Ric}_{m,n}(L) = Kg$ (respectively, quasi-Ricci flat, i.e., $\text{Ric}_{m,n}(L) = 0$), and $e'(u)$ satisfies

$$Le'(u) = \int_M Le'(u) d\gamma = -I_p, \quad \nabla^2 e'(u) = -\frac{I_p}{m} g, \quad \frac{m}{m - n} \nabla \phi \cdot \nabla e'(u) = I_p.$$ (2.10)
where \( I_p := \frac{d}{dt} H_p(u(t)) \) is the \( p \)-th Fisher information and satisfies the differential equation

\[
I_p' + \sigma I_p^2 + 2KI_p = 0.
\]

When \( \text{Ric}_{m,n}(L) \geq 0 \), it holds

\[
I_p \leq \frac{\kappa}{t}.
\]  

(2.11)

**Theorem 2.3** Let \((M, g(t), \phi(t), t \in [0, T])\) be an \( n \)-dimensional compact Riemannian manifold with potentials \( \phi(t) \in C^2(M) \) such that

\[
\text{Ric}_{m,n}(L) \geq K_1 g, \quad \partial_t g \geq 2K_2 g, \quad \partial_t \phi = \frac{1}{2} \text{Tr} \left( \frac{\partial g}{\partial t} \right),
\]  

(2.12)

where \( m \geq n \) and \( K_1, K_2 \in \mathbb{R} \) are constants. Let \( p \geq 1 - \frac{1}{m} \) and \( \sigma = p - 1 + \frac{2}{m} \). Let \( u \) be a positive solution to the nonlinear diffusion equation

\[
\partial_t u = Lu^p.
\]

Then the Renyi entropy power \( N_p = N_p(u(t)) \) satisfies

\[
\frac{d^2 N_p}{dt^2} \leq -\frac{2\sigma K_1 N_p}{\|u\|^p} \int_M |\nabla e'(u)|^2 u^p d\mu - \frac{2\sigma K_2 N_p}{\|u\|^p} \int_M |\nabla e'(u)|^2 u d\mu.
\]

Moreover, the equality in (2.13) holds on \([0, T]\) for some \( T > 0 \) if and only if

\[
\text{Ric}_{m,n}(L) = K_1 g, \quad \partial_t g = 2K_2 g, \quad \partial_t \phi = nK_2,
\]

and \( e'(u) \) satisfies

\[
\text{Le}'(u) = \int_M \text{Le}'(u)d\gamma = -I_p, \quad \nabla^2 e'(u) = -\frac{I_p}{m} g, \quad \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) = I_p.
\]

where \( I_p \) is the \( p \)-th Fisher information and satisfies the differential equation

\[
I_p' + \sigma I_p^2 + 2KI_p = 0.
\]

The condition (2.12) in Theorem 2.3 implies that \((M, g(t), \phi(t))\) is a \((K, m)\)-super Ricci flow with \( K = K_1 + K_2 \). Conversely, if \((M, g(t), \phi(t))\) is a \((K, m)\)-super Ricci flow and with \( K_1 g \leq \text{Ric}_{m,n}(L) \leq K_3 g \), then \( \partial_t g \geq 2K_2 g \) with \( K_2 = K - K_3 \).

The above results extend the result due to Savaré and Toscani on the concavity of the Renyi entropy for the nonlinear diffusion equation on Euclidean space to Riemannian manifolds and super Ricci flows.

We will give two proofs for the entropy power concavity inequalities in Theorems 2.1, 2.2 and 2.3. The first proof uses the similar idea of Savaré and Toscani [39] for the proof on the concavity of the Renyi entropy power along the nonlinear diffusion equation (1.11) on Euclidean spaces, while the second proof is similar to the one in our previous paper [29] for the linear heat equation (2.11) on Riemannian manifolds and super Ricci flows, and is based on an explicit formula for the second order derivative of the Renyi entropy power associated with the nonlinear diffusion equation of the usual Laplacian or the Witten Laplacian on Riemannian manifolds. In the case \( p = 1 \), such an explicit formula for the second order derivative of the Shannon entropy power associated with the heat equation of the usual Laplacian or the Witten Laplacian on Riemannian manifolds was first proved in our previous paper [29]. We would like point out that each of these two proofs has its own advantage: the first one can be extended to the setting of porous medium equation and
fast diffusion equation on the so-called RCD($K, N$) metric measure spaces, which we will develop in a forthcoming paper, and the second one enables us to prove the rigidity theorems for the Renyi entropy power on compact Riemannian manifolds with CD($K, m$)-condition or on compact $(K, m)$-super Ricci flows.

The rest of this paper is organized as follows. In Section 2, we prove the dissipation formulae for the Renyi entropy on compact Riemannian manifolds with time dependent or time independent metrics and potentials. In Section 3 we give the first proof of the concavity inequality for the Renyi entropy power in Theorem 2.1, Theorem 2.2, and Theorem 2.3. In Section 4, we prove an explicit formula for the second order derivative of the Renyi entropy power on manifolds with the CD($K, m$)-condition or time dependent metrics and potentials. We will see that there is a significant difference for the linear heat equation and the nonlinear diffusion equation on manifolds with time dependent metrics and potentials. In Section 5, we prove an explicit formula for the second order derivative of the Renyi entropy power associated with the nonlinear diffusion equation of the usual Laplacian or the Witten Laplacian on Riemannian manifolds and super Ricci flows. In Section 6, we give the second proof of the concavity inequality and prove the rigidity theorems for the Renyi entropy power associated with the nonlinear diffusion equation on Riemannian manifolds with the CD($K, m$)-condition or $(K, m)$-super Ricci flows. In Section 7, we prove the Aronson-Benilan estimates for the nonlinear diffusion equation on compact Riemannian manifolds with CD($0, m$)-condition. Moreover, we prove the NIW formula which gives an intrinsic relationship between the second order derivative of the Renyi entropy power $N_p$, the $p$-th Fisher information $I_p$ and the time derivative of the $W$-entropy associated with the nonlinear diffusion equation, which was introduced by Lu-Ni-Vazquez-Villani [34]. In Section 8, we prove an entropy isoperimetric inequality for the Renyi entropy power, the Gagliardo-Nirenberg-Sobolev inequality and the Nash inequality on complete Riemannian manifolds with non-negative Ricci curvature or CD($0, m$)-condition and the maximal volume growth condition.

### 3 Entropy dissipation formulae for nonlinear diffusion equation

In this section, we prove two entropy dissipation formulae for the Renyi entropy associated with the nonlinear diffusion equation on manifolds with fixed metric and potential or time dependent metrics and potentials.

For $p > 1 - 2/m$ and $p \neq 1$, let

$$e(r) = \frac{1}{p - 1} r^p.$$  

Define

$$E(u) := \int_M e(u(x)) d\mu(x),$$

and

$$E'(u) := \int_M |\nabla e'(u)|^2 u d\mu,$$

$$E''(u) := 2 \int_M (|\nabla^2 e'(u)|^2 + Ric(L)(\nabla e'(u), \nabla e'(u))) u^p d\mu + 2(p - 1) \int_M (L e'(u))^2 u^p d\mu + \int_M \frac{\partial}{\partial t} (\nabla e'(u), \nabla e'(u)) u d\mu.$$
Theorem 3.1 Let \((M,g(t),\phi(t), t \in [0,T])\) be a compact manifold equipped with a family of time dependent metrics and potentials \((g(t),\phi(t), t \in [0,T])\) which satisfies the conjugate heat equation

\[
\frac{\partial \phi}{\partial t} = \frac{1}{2} \text{Tr} \left( \frac{\partial g}{\partial t} \right). \tag{3.1}
\]

Let \(u\) be a positive and smooth solution to the nonlinear diffusion equation

\[
\frac{d}{dt} E(u) = -E'(u),
\]

\[
\frac{d^2}{dt^2} E(u) = E''(u).
\]

In particular, when \((M,g,\phi)\) is a compact Riemannian manifold with time independent metric and potential, the above formulae holds with \(\frac{\partial g}{\partial t} = 0\) in \(E''(u)\).

Proof. Let \(f(u) = u^p\). Then \(f(u) = ue'(u) - e(u),\ f'(u) = ue''(u) = pu^{p-1}\), and the nonlinear diffusion equation \(2.4\) can be rewritten as

\[
\partial_t u = \nabla^*_{\mu}(u \nabla e'(u)),
\]

where \(-\nabla^*_{\mu}\) denotes the \(L^2\)-adjoint of \(\nabla\) with respect to \(\mu\).

Under the conjugate heat equation \(3.1\), we have

\[
\frac{\partial}{\partial t} d\mu = 0. \tag{3.2}
\]

Taking time derivative and integrating by parts, we have

\[
\frac{d}{dt} E(u) = \int_M e'(u) \partial_t u d\mu = \int_M e'(u) \nabla^*_{\mu}(u \nabla e'(u)) d\mu = -\int_M |\nabla e'(u)|^2 u d\mu = -E'(u).
\]

Taking time derivative again and using the fact (cf. \[32, 21\])

\[
\partial_t |\nabla e'(u)|^2 = -\frac{\partial g}{\partial t} (\nabla e'(u), \nabla e'(u)) + 2(\nabla e'(u), \nabla \partial_t e'(u)),
\]

the derivative of \(E'(u)\) is given by

\[
\frac{d}{dt} E'(u) = \int_M \left[ |\nabla e'(u)|^2 \partial_t u + 2\nabla e'(u) \cdot \nabla (e''(u) \partial_t u) - \frac{\partial g}{\partial t} (\nabla e'(u), \nabla e'(u)) u \right] d\mu.
\]

Note that

\[
e''(u) \partial_t u = e''(u) \nabla^*_{\mu}(u \nabla e'(u)) = ue'(u) Le'(u) + e''(u) \nabla u \cdot \nabla e'(u) = f'(u) Le'(u) + |\nabla e'(u)|^2.
\]
This yields
\[
\frac{d}{dt} E'(u) = \int_M |\nabla e'(u)|^2 L u^p \, d\mu + 2 \int_M u \nabla e'(u) \cdot \nabla (f'(u) Le'(u)) \, d\mu \\
+ 2 \int_M u \nabla e'(u) \cdot \nabla|\nabla e'(u)|^2 \, d\mu - \int_M \frac{\partial g}{\partial t}(\nabla e'(u), \nabla e'(u)) \, d\mu \\
= I_1 + I_2 + I_3 + I_4.
\]

Integration by parts yields
\[
I_1 = \int_M L |\nabla e'(u)|^2 u^p \, d\mu = \int_M L |\nabla e'(u)|^2 f(u) \, d\mu.
\]

Splitting \(I_2\) into two terms
\[
I_2 = 2 \int_M u \nabla e'(u) \cdot \nabla(f'(u) Le'(u)) \, d\mu = I_{21} + I_{22},
\]

where
\[
I_{21} = 2 \int_M u f'(u) \nabla e'(u) \cdot \nabla Le'(u) \, d\mu, \\
I_{22} = 2 \int_M u \nabla e'(u) \cdot \nabla f'(u) Le'(u) \, d\mu \\
= 2 \int_M \nabla f(u) \cdot \nabla f'(u) Le'(u) \, d\mu.
\]

Moreover, we have
\[
I_3 = 2 \int_M u \nabla e'(u) \cdot \nabla|\nabla e'(u)|^2 \, d\mu \\
= 2 \int_M \nabla f(u) \cdot \nabla|\nabla e'(u)|^2 \, d\mu \\
= -2 \int_M f(u) |\nabla e'(u)|^2 \, d\mu,
\]

and
\[
I_4 = - \int_M \frac{\partial g}{\partial t}(\nabla e'(u), \nabla e'(u)) \, d\mu.
\]

Combining the above calculation together, we can derive that
\[
\frac{d}{dt} E'(u) = - \int_M f(u) L |\nabla e'(u)|^2 - 2 \nabla e'(u) \cdot \nabla Le'(u) \, d\mu \\
+ 2 \int_M (uf'(u) - f(u)) \nabla e'(u) \cdot \nabla Le'(u) \, d\mu \\
+ 2 \int_M \nabla f(u) \cdot \nabla f'(u) Le'(u) \, d\mu - \int_M \frac{\partial g}{\partial t}(\nabla e'(u), \nabla e'(u)) \, d\mu.
\]

Denote
\[
2\Gamma_2(\nabla e'(u), \nabla e'(u)) := L |\nabla e'(u)|^2 - 2 \nabla e'(u) \cdot \nabla Le'(u).
\] (3.3)

Integrating by parts, and using
\[
(r f'(r) - f(r))' = rf''(r), \quad rf''(r)e''(r) = f'(r)f''(r),
\]
we have

\[
\frac{d}{dt} E'(u) = -2 \int_M f(u) \Gamma_2(\nabla e'(u), \nabla e'(u)) d\mu - 2 \int_M (uf'(u) - f(u)) |Le'(u)|^2 d\mu
\]

\[
-2 \int_M (uf'(u) - f(u))' \nabla u \cdot \nabla e'(u) Le'(u) d\mu
\]

\[
+2 \int_M \nabla f(u) \cdot \nabla f'(u) Le'(u) d\mu - \int_M \frac{\partial g}{\partial t} (\nabla e'(u), \nabla e'(u)) u d\mu.
\]

This completes the proof of Theorem 3.1. \(\square\)

\section{4 Proof of EPCI in Theorem 2.1, 2.2 and 2.3}

We now use Theorem 3.1 to give the first proof of the entropy power concavity inequality (EPCI) for the Rényi entropy associated with the nonlinear diffusion equation on compact Riemannian manifolds with \(CD(K, m)\)-condition and compact Riemannian manifolds equipped with \((K, m)\)-super Ricci flows. The advantage of this proof is that it can be easily extended to prove the entropy power concavity inequality (EPCI) for the Rényi entropy associated with the nonlinear diffusion equation on the so-called RCD(\(K, N\)) metric measure spaces. As Theorem 2.1 can be regarded as the special case of Theorem 2.2 for \(m = n\) and \(\phi = 0\), we need only to prove Theorem 2.2 and Theorem 2.3. In Section 6, we will give the second proof of EPCI in Theorem 2.1, 2.2 and 2.3. The rigidity part of Theorem 2.2 and Theorem 2.3 will be also proved in Section 6.

\begin{lemma}
Under the same condition as in Theorem 3.1 we have

\[
\frac{d^2}{dt^2} E(u) \geq 2 \left( p - 1 + \frac{1}{m} \right) \left( \int_M |\nabla e'(u)|^2 u d\mu \right)^2 \left( \int_M u^p d\mu \right)^{-1}
\]

\[
+2 \int_M \text{Ric}_{m,n}(L)(\nabla e'(u), \nabla e'(u)) u^p d\mu + \int_M \frac{\partial g}{\partial t} (\nabla e'(u), \nabla e'(u)) u d\mu. \quad (4.1)
\]

\end{lemma}

\begin{proof}
By the trace inequality we have

\[
|\nabla^2 e'(u)|^2 \geq \frac{|\Delta e'(u)|^2}{n}.
\]

Applying the elementary inequality

\[
(a + b)^2 \geq \frac{a^2}{1 + \varepsilon} - \frac{b^2}{\varepsilon}
\]
to \( a = Le'(u) \), \( b = \nabla \phi \cdot \nabla e'(u) \) and \( \varepsilon = \frac{m - n}{m} \), we have
\[
|\nabla^2 e'(u)|^2 \geq \frac{|Le'(u)|^2}{m} - \nabla \phi \otimes \nabla \phi \left( \nabla e'(u), \nabla e'(u) \right).
\] (4.2)

This yields
\[
\frac{1}{2} \frac{d^2}{dt^2} E(u) \geq \int_M \left( p - 1 + \frac{1}{m} \right) |Le'(u)|^2 + \text{Ric}_{m,n}(L) \left( \nabla e'(u), \nabla e'(u) \right) \, u^p \, d\mu
+ \frac{1}{2} \int_M \frac{\partial}{\partial t} \left( \nabla e'(u), \nabla e'(u) \right) u \, d\mu.
\] (4.3)

By integration by parts and a direct calculation, we have
\[
- \int_M Le'(u) u^p \, d\mu = \int_M \nabla e'(u) \cdot \nabla u^p \, d\mu
= p \int_M \nabla e'(u) \cdot u^{p-1} \nabla u \, d\mu
= \frac{p}{p - 1} \int_M \nabla e'(u) \cdot \nabla u^{p-1} \, d\mu
= \int_M |\nabla e'(u)|^2 u \, d\mu.
\] (4.4)

By the Cauchy-Schwarz inequality
\[
E'(u)^2 = \left( \int_M |\nabla e'(u)|^2 u \, d\mu \right)^2 \leq \left( \int_M u^p \, d\mu \right) \left( \int_M |Le'(u)|^2 u^p \, d\mu \right).
\] (4.5)

Combining (4.3), (4.4) and (4.5), we derive (4.1).

**Proof of EPCI in Theorem 2.2.** In the case the metric and potential on \( M \) are time independent, under the assumption \( \text{Ric}_{m,n}(L) \geq K_g \),
\[
\frac{1}{2} \frac{d^2}{dt^2} E(u) \geq \int_M \left( p - 1 + \frac{1}{m} \right) |Le'(u)|^2 + \text{Ric}_{m,n}(L) \left( \nabla e'(u), \nabla e'(u) \right) \, u^p \, d\mu
\] \[
\geq \left( p - 1 + \frac{1}{m} \right) \int_M |Le'(u)|^2 u^p \, d\mu + K \int_M |\nabla e'(u)|^2 u^p \, d\mu.
\]

Combining this with (4.4), we have
\[
\frac{1}{2} \frac{d^2}{dt^2} E(u) \geq \left( p - 1 + \frac{1}{m} \right) \left( \int_M |\nabla e'(u)|^2 u \, d\mu \right)^2 \left( \int_M u^p \, d\mu \right)^{-1}
+ K \int_M |\nabla e'(u)|^2 u^p \, d\mu,
\]
whence
\[
(p - 1) E(u) E''(u) \geq 2 \left( p - 1 + \frac{1}{m} \right) E'(u)^2 + 2(p - 1) K E(u) \left( \int_M |\nabla e'(u)|^2 u^p \, d\mu \right).
\]

Note that
\[
\frac{d}{dt} N_p(u) = \sigma H_p' N_p(u),
\]
\[
\frac{d^2}{dt^2} N_p(u) = (\sigma H_p'' + \sigma^2 H_p'^2) N_p(u).
\] (4.6)
Replacing $\sigma_H$

Hence

The proof of EPCI in Theorem 2.2 is completed. □

Proof of EPCI in Theorem 2.3.

By Lemma 4.1, under the condition of Theorem 2.3,

By (4.7), we then derive

Now

$$H'_p(u) = \frac{1}{p-1} \frac{E'(u)}{E(u)} = I_p(u), \quad (4.7)$$

and

$$H''_p(u) = \frac{1}{p-1} \frac{\partial_t E'(u) E(u) - E'(u) \partial_t E(u)}{E^2(u)} = \frac{1}{p-1} \frac{E'(u)^2 - E''(u) E(u)}{E^2(u)}.$$

Hence

$$\sigma H''_p + \sigma^2 H'^2_p = \frac{\sigma}{p-1} \frac{E'(u)^2 - E''(u) E(u)}{E(u)^2} + \frac{\sigma^2}{(p-1)^2} \frac{E'(u)^2}{E(u)^2}$$

$$= \frac{\sigma^2}{(p-1)^2} \left[ \frac{p-1}{\sigma} \frac{E'(u)^2}{E(u)^2} - \frac{E''(u) E(u)}{E(u)^2} + \frac{E'(u)^2}{E(u)^2} \right]$$

$$= \frac{\sigma^2}{(p-1)^2 E(u)^2} \left[ (p-1 + \sigma) E'(u)^2 - (p-1) E''(u) E(u) \right].$$

Replacing $\sigma = \frac{1}{m} + p - 1$ into the above identity, we then derive

$$Z : = (p-1 + \sigma) E'(u)^2 - (p-1) E''(u) E(u)$$

$$= 2 \left( p - 1 + \frac{1}{m} \right) E'(u)^2 - (p-1) E''(u) E(u)$$

$$\leq -2(p-1) K E(u) \left( \int_M |\nabla e'(u)|^2 u^p \, d\mu \right).$$

Then

$$\sigma H''_p + \sigma^2 H'^2_p = \frac{\sigma Z}{(p-1)^2 E(u)^2} \leq -\frac{2 \sigma K \int_M |\nabla e'(u)|^2 u^p \, d\mu}{(p-1) E(u)}.$$

By (4.6), we then derive

$$\frac{d^2}{dt^2} N_p(u) \leq -\frac{2 \sigma K N_p(u)}{\|u\|^p_p} \int_M |\nabla e'(u)|^2 u^p \, d\mu.$$

The proof of EPCI in Theorem 2.2 is completed. □

**Proof of EPCI in Theorem 2.3** By Lemma 4.1 under the condition of Theorem 2.3, we have

$$\frac{1}{2} \frac{d^2}{dt^2} E(u) \geq \left( p - 1 + \frac{1}{m} \right) \left( \int_M |\nabla e'(u)|^2 u \, d\mu \right)^2 \left( \int_M u^p \, d\mu \right)^{-1}$$

$$+ K_1 \int_M |\nabla e'(u)|^2 u^p \, d\mu + K_2 \int_M |\nabla e'(u)|^2 u \, d\mu.$$

That is to say

$$(p-1) E(u) E''(u) \geq 2 \left( p - 1 + \frac{1}{m} \right) E'(u)^2 + 2(p-1) K_1 E(u) \left( \int_M |\nabla e'(u)|^2 u^p \, d\mu \right)$$

$$+ 2(p-1) K_2 E(u) E'(u).$$

13
We then derive that
\[
Z : = (p - 1 + \sigma)E'(u)^2 - (p - 1)E''(u)E(u) = 2 \left( p - 1 + \frac{1}{m} \right) E'(u)^2 - (p - 1)E''(u)E(u) \\
\leq -2(p - 1)K_1E(u) \left( \int_M |\nabla e'(u)|^2 u^p d\mu \right) - 2(p - 1)K_2E(u)E'(u),
\]
and hence
\[
\sigma H''_p + \sigma^2 H''_p = \frac{\sigma Z}{(p - 1)E(u)^2} \\
\leq -\frac{2\sigma}{(p - 1)E(u)^2} \left( K_1 \int_M |\nabla e'(u)|^2 u^p d\mu + K_2 \int_M |\nabla e'(u)|^2 u d\mu \right).
\]
By (4.6), we then derive
\[
\frac{d^2}{dt^2} N_p(u) \leq -\frac{2\sigma N_p(u)}{\|u\|^p} \left( K_1 \int_M |\nabla e'(u)|^2 u^p d\mu + K_2 \int_M |\nabla e'(u)|^2 u d\mu \right).
\]
The proof of EPCI in Theorem 2.3 is completed. \qed

5 The second order derivative of Renyi entropy power

In this section we prove an explicit formula for the second order derivative of the Renyi entropy power for the nonlinear diffusion equation on compact manifolds with time dependent metrics. When $p = 1$, such an explicit formula for the second order derivative of the Shannon entropy power for the linear heat equation on manifolds with time dependent metrics was first proved in our previous paper [29].

Theorem 5.1 Under the same condition and notation as in Theorem 2.3, we have
\[
\frac{d^2}{dt^2} N_p = -2\sigma N_p \left( p - 1 + \frac{1}{m} \right) \int_M \left[ \Delta e'(u) - \int_M \Delta e'(u)d\gamma \right]^2 d\gamma + 2\sigma N_p \int_M \nabla \cdot \nabla e'(u) d\gamma - 2\sigma N_p \int_M \frac{\partial g}{\partial t} \left( \nabla e'(u), \nabla e'(u) \right) u d\mu \\
-2\sigma \int_M \left[ \frac{m - n}{mn} \left( Le'(u) + \frac{m}{m - n} \nabla \phi \cdot \nabla e'(u) \right)^2 + \left\| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n}g \right\|_{HS}^2 \right] d\gamma,
\]
where $d\gamma = \frac{u^p d\mu}{\|u\|^p}$ with $\|u\|^p = \int_M u^p d\mu$. In particular, when $g$ and $\phi$ are time independent, the above result holds with $\frac{\partial g}{\partial t} = 0$.

In particular, when $m = n, \phi = 0, L = \Delta, \sigma = p - 1 + \frac{2}{n}$, and $g$ is time independent, we have

Theorem 5.2 Under the same condition and notation as in Theorem 2.3, we have
\[
\frac{d^2}{dt^2} N_p = -2\sigma N_p \left( p - 1 + \frac{1}{n} \right) \int_M \left[ \Delta e'(u) - \int_M \Delta e'(u)d\gamma \right]^2 d\gamma + 2\sigma N_p \int_M \nabla \cdot \nabla e'(u) d\gamma - 2\sigma N_p \int_M \left\| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n}g \right\|_{HS}^2 d\gamma,
\]
where $d\gamma = \frac{u^p dv}{\|u\|^p}$ with $\|u\|^p = \int_M u^p dv$. 

We need only to prove Theorem 5.1.

**Proof of Theorem 5.1** Using

\[ \|A\|_{HS}^2 = \frac{\|\text{tr}A\|}{n} + \left\| A - \frac{\text{tr}A}{n} g \right\|_{HS}^2, \]

we have

\[ \|\nabla^2 e'(u)\|_{HS}^2 = \frac{|\Delta e'(u)|^2}{n} + \left\| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n} g \right\|_{HS}^2. \]

Applying the elementary equality

\[ (a + b)^2 = \frac{a^2}{1 + \varepsilon^2} - \frac{b^2}{1 + \varepsilon^2} + \frac{\varepsilon}{1 + \varepsilon} \left( a + \frac{1}{\varepsilon} b \right)^2 \]

to \( a = \text{Le}'(u) \), \( b = \nabla \phi \cdot \nabla e'(u) \) and \( \varepsilon = \frac{m-n}{n} \), we have

\[ |\Delta e'(u)|^2 = \frac{n}{m} |\text{Le}'(u)|^2 - \frac{n}{m-n} |\nabla \phi \cdot \nabla e'(u)|^2 + \frac{m-n}{m} \left( \text{Le}'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right)^2. \]

Therefore

\[ \|\nabla^2 e'(u)\|_{HS}^2 = \frac{|\text{Le}'(u)|^2}{m} - \frac{|\nabla \phi \cdot \nabla e'(u)|^2}{m-n} + \frac{m-n}{mn} \left( \text{Le}'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right)^2 \]

\[ + \left\| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n} g \right\|_{HS}^2. \]

This yields

\[ \frac{1}{2} \frac{d^2}{dt^2} E(u) = \int_M \left( |\nabla^2 e'(u)|^2 + \text{Ric}(L)(\nabla e'(u), \nabla e'(u)) + (p-1)(\text{Le}'(u))^2 \right) u^p d\mu \]

\[ + \int_M \frac{1}{2} \frac{\partial}{\partial t} (\nabla e'(u), \nabla e'(u)) u^p d\mu \]

\[ = \int_M \left( p - 1 + \frac{1}{m} \right) |\text{Le}'(u)|^2 + \text{Ric}_{m,n}(L)(\nabla e'(u), \nabla e'(u)) \right) u^p d\mu \]

\[ + \int_M \left( \frac{m-n}{mn} \left( \text{Le}'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right)^2 \right) + \left\| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n} g \right\|_{HS}^2 u^p d\mu, \]

Therefore

\[ H''_p + \sigma H'^2_p = \frac{1}{(p-1)^2 E(u)^2} \left[ (p-1 + \sigma) E'(u)^2 - (p-1) E''(u) E(u) \right] \]

\[ = (p-1 + \sigma) \left( \frac{E'(u)}{(p-1) E(u)} \right)^2 - \frac{E''(u)}{(p-1) E(u)} \]

\[ = 2 \left( p - 1 + \frac{1}{m} \right) \left[ \left( \int_M \text{Le}'(u) d\gamma \right)^2 - \int_M |\text{Le}'(u)|^2 d\gamma \right] \]

\[ - 2 \int_M \text{Ric}_{m,n}(L)(\nabla e'(u), \nabla e'(u)) d\gamma \frac{\partial}{\partial t} (\nabla e'(u), \nabla e'(u)) u \| u \|^2_p d\mu \]

\[ - 2 \int_M \left[ \frac{m-n}{mn} \left( \text{Le}'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right)^2 \right] + \left\| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n} g \right\|_{HS}^2 \right] d\gamma. \]
Using (4.6) and (4.6), we complete the proof of Theorem 5.1.

6 Rigidity theorems for Renyi entropy power

Based on Theorem 5.1, we now give the second proof of EPCI in Theorem 2.1, 2.2 and 2.3. Moreover, we prove the rigidity part of Theorem 2.1, 2.2 and 2.3.

Proof of Theorem 2.2 By Theorem 5.1 under the condition \(Ric_{m,n}(L) \geq Kg\), we have

\[
\frac{d^2 N_p}{dt^2} \leq -2\sigma KN_p \int_M \left| \nabla e'(u) \right|^2 d\gamma - 2\sigma N_p \left( p - 1 + \frac{1}{m} \right) \int_M \left[ Le'(u) - \int_M Le'(u)d\gamma \right]^2 d\gamma
\]

\[
-2\sigma N_p \int_M \left[ \frac{m-n}{mn} \left( Le'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right)^2 + \left\| \nabla^2 e'(u) \right\|_E^2 \right] d\gamma.
\]

Thus, for \(p > 1 - \frac{1}{m}\), we have

\[
\frac{d^2 N_p}{dt^2} \leq -2\sigma KN_p \int_M \left| \nabla e'(u) \right|^2 d\gamma.
\]

Moreover, the equality holds if and only if

\(Ric_{m,n}(L) = Kg\),

and

\(Le'(u) = \int_M Le'(u)d\gamma, \ (m-n) \left( Le'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right) = 0, \ \nabla e'(u) = \frac{\Delta e'(u)}{n} g.\)

This yields (2.10) in Theorem 2.2. The inequality (2.11) follows from the Aronson-Benilan inequality. The proof of Theorem 2.2 is completed.

Proof of Theorem 2.3 By Theorem 5.1 under the assumption \(Ric_{m,n}(L) \geq K_1g\) and \(\partial_t g \geq 2K_2g\), we have

\[
\frac{d^2 N_p}{dt^2} \leq -2\sigma K_1 N_p \int_M \left| \nabla e'(u) \right|^2 d\gamma - 2\sigma K_2 N_p \int_M \left| \nabla e'(u) \right|^2 u d\mu
\]

\[
-2\sigma N_p \left( p - 1 + \frac{1}{m} \right) \int_M \left[ Le'(u) - \int_M Le'(u)d\gamma \right]^2 d\gamma
\]

\[
-2\sigma N_p \int_M \left[ \frac{m-n}{mn} \left( Le'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right)^2 + \left\| \nabla^2 e'(u) \right\|_E^2 \right] d\gamma.
\]

Hence, for \(p > 1 - \frac{1}{m}\), we have

\[
\frac{d^2 N_p}{dt^2} \leq - \frac{2\sigma K_1 N_p}{\|u\|^p} \int_M \left| \nabla e'(u) \right|^2 u d\mu - \frac{2\sigma K_2 N_p}{\|u\|^p} \int_M \left| \nabla e'(u) \right|^2 u d\mu. \quad (6.1)
\]

Moreover, the equality holds if and only if

\(Ric_{m,n}(L) = K_1g, \ \partial_t g = 2K_2g, \ \partial_t \phi = nK_2,\)

and

\(Le'(u) = \int_M Le'(u)d\gamma, \ (m-n) \left( Le'(u) + \frac{m}{m-n} \nabla \phi \cdot \nabla e'(u) \right) = 0, \ \nabla e'(u) = \frac{\Delta e'(u)}{n} g.\)

This concludes Theorem 2.3. □
7 NIW formula for nonlinear diffusion equation

In his seminal paper [38], Perelman introduced the $W$-entropy and proved its variational formula along the conjugate heat equation on the Ricci flow. More precisely, let $M$ be a compact manifold equipped with the Ricci flow

$$\partial_t g(t) = -2\text{Ric}_{g(t)}. \hspace{1cm} (7.1)$$

Let $u(t) = \frac{e^{-t}}{(4\pi t)^{n/2}}$ be the fundamental solution to the conjugate heat equation

$$\partial_t u = -\Delta u + Ru. \hspace{1cm} (7.2)$$

Let $\tau$ be such that

$$\partial_t \tau = -1.$$

Let

$$H(g, u) = -\int_M u \log udv$$

be the Shannon entropy. In [38], Perelman introduced the following $F$-function and $W$-entropy

$$F(g, u) = \int_M (R + |\nabla \log u|^2)udv,$$

$$W(g, u)) = \int_M (\tau(R + |\nabla f|^2) + f - n) udv,$$

and proved the following beautiful formulae

$$\frac{d}{dt} H(g(t), u(t)) = -F(g(t), u(t)),$$

$$\frac{d}{dt} F(g(t), u(t)) = 2 \int_M |\text{Ric} + \nabla^2 \log u|^2 udv,$$

$$\frac{d}{dt} W(g(\tau), u(\tau)) = 2\tau \int_M |\text{Ric} + \nabla^2 f - \frac{g}{2\tau}|^2 udv.$$

In particular, the $W$-entropy is always monotone increasing along the Ricci flow, and its equilibrium state (i.e., the critical point such that $\frac{d}{d\tau} W(g(\tau), u(\tau)) = 0$) is the so-called shrinking Ricci soliton

$$\text{Ric} + \nabla^2 f = \frac{g}{2\tau}.$$

In [35, 39], Ni introduced the $W$-entropy and proved its variational formula for the heat equation $\partial_t u = \Delta u$ on Riemannian manifolds with non-negative Ricci curvature. In [31], Li and Xu extended Ni’s result to Riemannian manifolds with Ricci curvature bounded from below by a uniform constant. In [19, 20], the second named author extended the $W$-entropy formula to the heat equation associated with the Witten Laplacian on complete Riemannian manifolds with $\text{CD}(0, m)$-condition and proved that the rigidity model of the $W$-entropy is the Euclidean spaces equipped with the Gaussian solitons. In [21, 22, 23, 24, 27, 28], the authors of this paper extended the $W$-entropy formula to the heat equation associated with the Witten Laplacian on complete Riemannian manifolds with $\text{CD}(K, m)$-condition and on compact $(K, m)$-super Ricci flows. In [22, 26], the authors of this paper introduced the $W$-entropy and proved the $W$-entropy formula along the geodesic flow on the infinite dimensional $L^2$-Wasserstein space over a complete Riemannian manifold with
This recovers and improves an earlier result due to Lot and Villani [32, 33] on the displacement convexity of the Boltzmann entropy functional on complete Riemannian manifold with non-negative Ricci curvature. In [16], Kuwada and the second named author proved the monotonicity and rigidity theorem of the $W$-entropy on $\text{RCD}(0, N)$ metric measure spaces.

In [29], the authors proved the NIW formula between the Shannon entropy power $N$, the Fisher information $I$ and the $W$-entropy for the heat equation $\partial_t u = Lu$ associated with the Witten Laplacian on complete Riemannian manifolds. More precisely, we proved the following

**Theorem 7.1** Let $M$ be a complete Riemannian manifold with natural bounded geometry condition. Let $\phi \in C^4(M)$ be such that $\nabla^k \phi \in C_b(M), k = 1, 2, 3$. Let $u$ be the fundamental solution to the heat equation $\partial_t u = Lu$ associated with the Witten Laplacian $L = \Delta - \nabla \phi \cdot \nabla$. The following NIW formula holds

$$\frac{d^2 N}{dt^2} = \frac{2N}{m} \left( \frac{2}{m} \left( I - \frac{m}{2t} \right)^2 + \frac{1}{\tau} \frac{dW}{dt} \right),$$

where $N(u) = e^{-\frac{2}{m} H(u)}$ is the Shannon entropy power, $I(u) = \int_M |\nabla u|^2 d\mu$ is the Fisher information, and $W$ is the $W$-entropy defined by

$$W(u) = \int_M \left( t|\nabla f|^2 + f - m \right) u d\mu.$$  

As a consequence of (7.3), under the CD$(0, m)$-condition, we have

$$\frac{dW(u)}{dt} \leq -\frac{2t}{m} \left| I(u) - \frac{m}{2t} \right|^2.$$  

In particular, the NIW formula (7.3) and the W-entropy inequality (7.5) hold for the heat equation $\partial_t u = \Delta u$ with $m = n$, $\mu = v$ and $L = \Delta$ on $n$-dimensional complete Riemannian manifolds with non-negative Ricci curvature and with natural bounded geometry condition.

Moreover, we proved the NFW formula in [29] for the Shannon entropy power $N$, the Perelman $F$-functional and the Perelman $W$-entropy along the conjugate heat equation on the Ricci flow. It provide us a new understanding for Perelman’s mysterious $W$-entropy formula for Ricci flow and can be used to characterize the shrinking Ricci solitons.

**Theorem 7.2** Let $(M, g(t), t \in [0, T])$ be a compact Ricci flow $\partial_t g = -2\text{Ric}_g$. Let $u(t)$ be the fundamental solution to the conjugate heat equation

$$\partial_t u = -\Delta u + Ru.$$  

Let

$$H(u(t)) = -\int_M u \log u d\nu, \quad N(u(t)) = e^{\mathcal{F}(u(t))}.$$  

Then

$$\frac{d^2 N}{dt^2} = \frac{2N}{n} \left[ \frac{2}{n} \left( \mathcal{F} - \frac{n}{2t} \right)^2 + \frac{1}{\tau} \frac{dW}{dt} \right],$$

where

$$\mathcal{F} = \int_M (R + |\nabla \log u|^2) u d\nu.$$
and
\[ \frac{dW}{dt} = 2\tau \int_M \left| \text{Ric} + \nabla^2 f - \frac{g}{2\tau} \right|^2 udv. \]

In particular, the Shannon entropy power is convex on \((0, T]\), i.e.,
\[ \frac{d^2}{dt^2} N(u(\tau)) \geq 0. \]

Moreover, \(\frac{d^2}{dt^2} N(u(\tau)) = 0\) holds at some \(\tau = \tau_0 \in (0, T]\) if and only if \((M, g(\tau), u(\tau))\) is a shrinking Ricci soliton
\[ \text{Ric} + \nabla^2 \log u = \frac{g}{2\tau}. \]

In [34], Lu-Ni-Vazquez-Villani introduced the \(W\)-entropy for the porous medium equation and the fast diffusion equation on compact Riemannian manifolds and proved their monotonicity on compact Riemannian manifolds with non-negative Ricci curvature. Inspired by our previous work on the NIW formula and NIW inequality for the heat equation on Riemannian manifolds, it is natural to ask the question whether we can extend the NIW formula and the NIW inequality to the porous medium equation and the fast diffusion equation on Riemannian manifolds. The purpose of this section is to study this problem.

7.1 NIW formula for NLDE for Laplacian

In this section we prove the NIW formula for nonlinear diffusion equation for usual Laplacian on compact Riemannian manifolds. To state the main result of this subsection, let us briefly recall Lu-Ni-Vazquez-Villani’s work [34] on the entropy formulae for the nonlinear diffusion equation
\[ \partial_t u = \Delta u^p, \] (7.6)
where \(p > 1 - \frac{1}{n}\). Let \(v = \frac{p}{p-1} u^{p-1}\). Then
\[ \partial_t v = (p - 1) v \Delta v + |\nabla v|^2. \]

For any \(\alpha \geq 1\), let
\[ F_\alpha = (p - 1) \Delta v + (\alpha - 1) \frac{|v|^2}{v}, \]
in particular, \(F_1 = (p - 1) \Delta v\). Let \(\kappa = \frac{n}{n(p-1) + 2}, a = (p - 1)\kappa,\) and \(b = n(p - 1)\). Define
\[ N_u(t) = -t^a \int_M v udv = \frac{p}{1 - p} t^a \int_M u^p dv. \] (7.7)

By Lemma 5.1 in [34], it holds
\[ \frac{d}{dt} N_u(t) = -t^a \int_M \left( F_1 + \frac{a}{t} \right) v udv. \] (7.8)

Note that when \(\text{Ric} \geq 0\), the Aronson-Benilan inequality was proved in [34]. When \(p > 1\), it holds
\[ F_1 + \frac{a}{t} \geq 0, \] (7.9)
and the inverse inequality in (7.9) holds when \( p \in \left( 1 - \frac{2}{n}, 1 \right) \). Equivalently, for all \( p > 1 - \frac{2}{n} \) and \( p \neq 1 \), it holds

\[
\Delta v + \frac{\kappa}{t} \geq 0.
\]  

(7.10)

Following [34], we introduce the Perelman \( W \)-entropy associated with (7.6) as follows

\[
W_{\alpha}(t) := t \frac{d}{dt} \mathcal{N}_{\alpha}(t) + \mathcal{N}_{\alpha}(t).
\]  

(7.11)

To emphasis the dependence on \( p \), we use the notation \( W_{\alpha}(u) \) instead of \( W_{\alpha} \). By [34], we have

\[
W_{\alpha}(u) = t^{\alpha + 1} \int_{M} \left( \frac{\| \nabla v \|^2_v}{v} - \frac{a + 1}{t} \right) v u d v.
\]  

(7.12)

The following \( W \)-entropy formula is due to Lu-Ni-Vazquez-Villani (Theorem 5.5 in [34]).

\[
\frac{d}{dt} W_{\alpha}(u) = -2(p - 1)t^{\alpha + 1} \int_{M} \left( \left| \nabla^2 e'(u) + \frac{g}{(n(p - 1) - 2)t} \right|^2 + \text{Ric}(\nabla e'(u), \nabla e'(u)) \right) u^p v u d v
\]

\[
-2t^{\alpha + 1} \int_{M} \left( (p - 1)\Delta e'(u) + \frac{a}{t} \right)^2 u^p v u d v.
\]  

(7.13)

Recall that \( e(u) = \frac{u^p}{p} \), \( e'(u) = \frac{p}{p - 1} u^{p - 1} \). Thus \( v = e'(u) \), and we can reformulate (7.13) as follows

\[
\frac{1}{t^{\alpha + 1}} \frac{d}{dt} W_{\alpha}(u) = -2p \int_{M} \left( \left| \nabla^2 e'(u) + \frac{g}{(n(p - 1) + 2)t} \right|^2 + \text{Ric}(\nabla e'(u), \nabla e'(u)) \right) u^p v u d v
\]

\[
-2 \frac{2p}{p - 1} \int_{M} \left( (p - 1)\Delta e'(u) + \frac{a}{t} \right)^2 u^p v u d v.
\]  

(7.14)

On the other hand, by Theorem 5.1, the second order derivative of the Renyi entropy power associated with the nonlinear diffusion equation (7.6) is given by

\[
\frac{\| u \|^p_{\alpha}}{2 \sigma \mathcal{N}_{\alpha}(u)} \frac{d^2 \mathcal{N}_{\alpha}(u)}{dt^2} = - \left( p - 1 + \frac{1}{n} \right) \int_{M} \left| \Delta e'(u) - \int_{M} \Delta e'(u) d \gamma \right|^2 u^p v u d v
\]

\[
- \int_{M} \text{Ric}(\nabla e'(u), \nabla e'(u)) u^p v u d v
\]

\[
- \int_{M} \left| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n} g \right|^2_{\text{HS}} u^p v u d v.
\]  

(7.15)

where \( d \gamma = \frac{u^p v u d v}{\int_{M} u^p v u d v} \).

Now we state the main result of this subsection.

**Theorem 7.3** Let \( M \) be a compact Riemannian manifold, \( u \) be a positive smooth solution to the nonlinear diffusion equation (7.6) with \( p > 0 \). Then, under the above notations, we have the following NIW formula

\[
\frac{d^2 \mathcal{N}_{\alpha}(u)}{dt^2} = 2 \sigma \mathcal{N}_{\alpha}(u) \left( 1 + n(p - 1) \right) \left| I_{\alpha}(u) - \frac{\kappa}{t} \right|^2 + \frac{1}{2p\| u \|^p_{\alpha}} \int_{M} \frac{d}{dt} W_{\alpha}(u).
\]  

(7.16)
Under the condition $Ric \geq 0$, we have
\[
\frac{1}{2p\|u\|_p^{p+1}} \frac{d}{dt} W_p(u) \leq - \frac{1+n(p-1)}{n} I_p(u) - \frac{\kappa^2}{t}.
\]

In particular, under the condition $Ric \geq 0$, the equality in the above inequality holds if and only if $\frac{d^2 N_p}{dt^2} = 0$, which is equivalent to say that $(M,g)$ is Ricci flat, i.e., $Ric = 0$, and $\nabla^2 v = -\frac{I_p(u)}{n} g$, where $I_p(u) := \frac{d}{dt} H_p(u(t))$ is the $p$-th Fisher information and satisfies the differential equation
\[
I'_p(u) + \sigma I''_p(u) = 0.
\]

Proof. To simplify the notation, let $I_1 = \frac{\|u\|^p}{2e N_p(u)} \frac{d^2 N_p(u)}{dt^2}$, $I_2 = \frac{1}{2p\|u\|_p^{p+1}} \frac{d}{dt} W_p(u)$, and $I_3 = I_1 - I_2$. By (7.13) and (7.15), we have
\[
I_3 = \int_M \left\| \nabla^2 e'(u) + \frac{g}{(n(p-1)+2)t} \right\|^2_{HS} u^p dv - \int_M \left\| \nabla^2 e'(u) - \frac{\Delta e'(u)}{n} g \right\|^2_{HS} u^p dv
+ \frac{1}{p-1} \int_M \left( (p-1) \Delta e'(u) + \frac{a^2}{t} \right) u^p dv - \left( p-1 + \frac{1}{n} \right) \int_M \left( \int_M \Delta e'(u) u^p dv \right) - \left( \int M u^p dv \right)^{-1},
\]

which yields
\[
I_3 = \int M \left[ \frac{2}{(2+n(p-1))t} \Delta e'(u) + \frac{1}{n} \left| \Delta e'(u) \right|^2 + \frac{n}{(n(p-1)+2)^2} \right] u^p dv,
\]
\[
I_{32} = \int M \left[ -\frac{1}{n} \left| \Delta e'(u) \right|^2 + \frac{a^2}{t} \Delta e'(u) + \frac{a^2}{(p-1)t^2} \right] u^p dv
+ \left( p-1 + \frac{1}{n} \right) \left( \int M \Delta e'(u) u^p dv \right)^2 \left( \int M u^p dv \right)^{-1},
\]

Now
\[
I_{31} = \int M \left[ \frac{2}{(2+n(p-1))t} \Delta e'(u) + \frac{1}{n} \left| \Delta e'(u) \right|^2 + \frac{n}{(n(p-1)+2)^2} \right] u^p dv,
\]
\[
I_{31} = \int M \left[ \frac{1}{t^2} \left( \frac{n}{(2+n(p-1))^2} + \frac{a^2}{p-1} \right) \int M u^p dv + \frac{2}{t} \left( a + \frac{1}{2+n(p-1)} \right) \int M \Delta e'(u) u^p dv \right.
+ \left( p-1 + \frac{1}{n} \right) \left( \int M \Delta e'(u) u^p dv \right)^2 \left( \int M u^p dv \right)^{-1}
\]
\[
= \frac{1+n(p-1)}{n} \int M \Delta e'(u) u^p dv + \frac{n}{(2+n(p-1))} \int M u^p dv \right]^2 \left( \int M u^p dv \right)^{-1}
\]
\[
= \frac{1+n(p-1)}{n} \left[ \int M \Delta e'(u) u^p dv + \frac{n}{(2+n(p-1))} \int M u^p dv \right]^2 \left( \int M u^p dv \right)^{-1}
\]

Note that $\kappa = \frac{n}{2+n(p-1)}$ and integration by parts yields
\[
\int M \Delta e'(u) u^p dv = -\int M \nabla e'(u) \cdot \nabla u^p dv
\]
\[
= -p^2 \int M u^{2p-3} |\nabla u|^2 dv - p^2 \int M u^{p-3} |\nabla u|^2 d\gamma
= -I_p(u).
\]
Hence

\[ I_3 = \frac{1 + n(p - 1)}{n} \|u\|^p \left[ I_p(u) - \frac{\kappa}{\ell} \right]^2. \]

That is to say

\[ \frac{\|u\|^p}{2\sigma N_p(u)} \frac{d^2 N_p(u)}{dt^2} = \frac{1 + n(p - 1)}{n} \|u\|^p \left[ I_p(u) - \frac{\kappa}{\ell} \right]^2 + \frac{1}{2p^m + 1} \frac{d}{dt} W_p(u). \]

This completes the proof of Theorem 7.3. \(\square\)

**Remark 7.4** In particular, taking limit \(p \to 1\) in Theorem 7.3, we recover the NIW formula \(\text{(7.3)}\) with \(m = n\) in Theorem 7.1 for the Shannon entropy power \(N(u)\), the Fisher information \(I(u)\) and the \(W\)-entropy associated with the heat equation \(\partial_t u = \Delta u\) on Riemannian manifold, i.e.,

\[ \frac{d^2 N(u)}{dt^2} = \frac{2}{n} N(u) \left[ \frac{2}{n} \left| I(u) - \frac{n}{2t} \right|^2 + \frac{1}{t} \frac{d}{dt} W(u) \right]. \]

Under the condition \(\text{Ric} \geq 0\), we have

\[ \frac{dW(u)}{dt} \leq -\frac{2t}{n} \left| I(u) - \frac{n}{2t} \right|^2. \]

In particular, under the condition \(\text{Ric} \geq 0\), the equality in the above inequality holds if and only if \(\frac{d^2 N}{dt^2} = 0\), which is equivalent to say that \((M, g)\) is Ricci flat, i.e., \(\text{Ric} = 0\), and \(v = \log u\) satisfies \(\nabla^2 v = -\frac{I(u)}{n} g\), where \(I(u)\) is a solution to the differential equation

\[ I'_p(u) + \frac{2}{n} I_p^2(u) = 0. \]

**7.2 Aronson-Benilan estimates for NLDE for Witten Laplacian**

Let \(u\) be a positive and smooth solution to the nonlinear diffusion equation \(\text{(2.4)}\) associated with the Witten Laplacian on \((M, g, \mu)\), i.e.,

\[ \partial_t u = Lu^p, \quad (7.18) \]

where \(p > 1 - \frac{1}{m}\). Let \(v = \frac{p}{p-1} u^{p-1}\). Then

\[ \partial_t v = (p - 1)vLv + |\nabla v|^2. \]

For any \(\alpha \geq 1\), let

\[ F_\alpha = (p - 1)Lv + (\alpha - 1)\frac{\partial_v v}{v} = \alpha(p - 1)Lv + (\alpha - 1)\frac{|\nabla v|^2}{v}. \]

In particular, \(F_1 = (p - 1)Lv\).

**Proposition 7.5** Let \(\mathcal{L} = \partial_t - (p - 1)vL\). Then

\[ \mathcal{L}F_\alpha = 2(p - 1) \left( |\nabla^2 v|^2 + \text{Ric}(L)(\nabla v, \nabla v) \right) + 2p(\nabla F_\alpha, \nabla v) + (\alpha - 1) \left( \frac{\partial_v v}{v} \right)^2 + F_1^2. \]

In particular, for \(\alpha = 1\), it holds

\[ \mathcal{L}F_1 = 2(p - 1) \left[ |\nabla^2 v|^2 + \text{Ric}(L)(\nabla v, \nabla v) \right] + 2p(\nabla F_1, \nabla v) + F_1^2. \quad (7.19) \]
Proof. The proof is similar to the one of Proposition 3.2 in [34] and uses the generalized Bochner formula. To save the length of the paper, we omit the detail.

We have the following Aronson-Benilan estimate for the nonlinear diffusion equation (2.4) associated with the Witten Laplacian for $p > 1 - \frac{2}{m}$ and $p \neq 1$, which extends the corresponding result due to Lu-Ni-Vazquez-Villani [34]. When $p = 1$, it corresponds the Li-Yau differential Harnack inequality for the heat equation $\partial_t u = Lu$ proved in [17, 19].

**Theorem 7.6** Let $u$ be a positive and smooth solution to the nonlinear diffusion equation (2.4) for $p > 1 - \frac{2}{m}$ and $p \neq 1$. Suppose that $\text{Ric}_{m,n}(L) \geq 0$. Then the Aronson-Benilan Harnack inequality holds: when $p > 1$,

$$F_1 + \frac{(p-1)\kappa}{t} \geq 0,$$

and when $p \in (1 - \frac{2}{m}, 1)$,

$$F_1 + \frac{(p-1)\kappa}{t} \leq 0,$$

Equivalently, for all $p > 1 - \frac{2}{m}$, it holds

$$Lv + \frac{\kappa}{t} \geq 0,$$

where

$$\kappa = \frac{m}{m(p-1)+2}. $$

Proof. The proof is similar to the one of the Aronson-Benilan estimate (7.9) and (7.10) for the PME or FDE associated with the Laplacian on compact Riemannian manifolds with non-negative Ricci curvature [34]. Indeed, for any $m \geq n$, we have (cf. [1, 17])

$$|\nabla^2 v|^2 + \text{Ric}(L)(\nabla v, \nabla v) \geq \frac{|Lv|^2}{m} + \text{Ric}_{m,n}(L)(\nabla v, \nabla v).$$

Thus, as $\text{Ric}_{m,n}(L) \geq 0$, we have

$$|\nabla^2 v|^2 + \text{Ric}(L)(\nabla v, \nabla v) \geq \frac{|Lv|^2}{m}.$$

By (7.19), for $p > 1$, we have

$$\mathcal{L}F_1 \geq \frac{2(p-1)}{m}|Lv|^2 + 2p\langle \nabla F_1, \nabla v \rangle + F_1^2,$$

whence

$$\mathcal{L}F_1 \geq \left( \frac{2}{m(p-1)} + 1 \right) F_1^2 + 2p\langle \nabla F_1, \nabla v \rangle.$$  \hspace{0.5cm} (7.23)

Let $F = tF_1$. By calculation and (7.23), we have

$$\mathcal{L}F = t\mathcal{L}F_1 + F_1 \geq \left( \frac{2}{m(p-1)} + 1 \right) \frac{F^2}{t} + 2p\langle \nabla F, \nabla v \rangle + \frac{F}{t}. $$

23
from which and the maximum principle, we can prove
\[ F \geq -(p-1)\kappa. \]
Equivalently, (7.20) or (7.22) holds.

On the other hand, by (7.19), for \( p \in (1 - \frac{2}{m}, 1) \), we have
\[
L F_1 - 2p(\nabla F_1, \nabla v) \leq F_1^2 - \frac{2(1-p)}{m} |Lv|^2 = -\left( \frac{2}{m(1-p)} - 1 \right) F_1^2.
\] (7.24)

Let \( F = tF_1 \). By calculation and (7.24), we have
\[
L F = tLF_1 + F_1
\leq -\left( \frac{2}{m(1-p)} - 1 \right) \frac{F^2}{t} + 2p(\nabla F, \nabla v) + \frac{F}{t}.
\]
from which and the maximum principle, we can prove
\[ F \leq -(p-1)\kappa. \]
Equivalently, (7.21) or (7.22) holds. The proof of Theorem 7.6 is completed. \( \square \)

7.3 \( W \)-entropy formula for NLDE for Witten Laplacian

In this subsection we extend the \( W \)-entropy formula due to Lu-Ni-Vazquez-Villani [34] to nonlinear diffusion equation associated with the Witten Laplacian on compact Riemannian manifolds. See related work by Huang and Li [15].

Let \((M, g)\) be a compact Riemannian manifold, \( m \geq n, \kappa = \frac{m}{m(p-1)+2}, a = (p-1)\kappa, \) and \( b = m(p-1) \). Let \( u \) be a positive and smooth solution to the nonlinear diffusion equation (7.18) associated with the Witten Laplacian on \((M, g, \mu)\). Inspired by Lu-Ni-Vazquez-Villani [34], define
\[
N_u(t) = -t^{a+1} \int_M v u d\mu.
\]
Similarly to Lemma 5.1, Lemma 5.2 and (5.4) in [34], we have

**Lemma 7.7** Let \( p > 0 \), and let \( v \) and \( F_1 \) be as in Theorem 7.6. Then
\[
\frac{d}{dt} \int_M v u d\mu = \int_M F_1 v u d\mu = -p \int_M |\nabla v|^2 u d\mu,
\]
\[
\frac{d}{dt} \int_M F_1 v u d\mu = 2 \int_M ((p-1)(|\nabla^2 v|^2 + Ric(L)(\nabla v, \nabla v) + F_1^2) v u d\mu.
\]
Moreover
\[
\frac{d}{dt} N_u(t) = -t^a \int_M (F_1 + \frac{a}{t}) v u d\mu.
\]

**Proof.** The proof is similar to the one in [34]. \( \square \)

Following [34], we introduce the Perelman \( W \)-entropy associated with (7.6) as follows
\[
W_u(t) := t \frac{d}{dt} N_u(t) + N_u(t).
\] (7.25)
To emphasis the dependence on \( p \), we use the notation \( W_p(u) \) instead of \( W_u \). By [34], we have
\[
W_p(u) = t^{a+1} \int_M \left( p \frac{|\nabla v|^2}{v} - \frac{a+1}{t} \right) v u d\mu.
\]
Theorem 7.8  Let $m \geq n$, and let $u$ be a positive smooth solution to the nonlinear diffusion equation \((7.18)\) with $p > 0$. Let $v = \frac{p}{p-1}w^{p-1}$, $F_1 = (p-1)Lv$, $\kappa = \frac{m}{m(p-1)+2}$, $a = (p-1)\kappa$ and $b = m(p-1)$. Define the W-entropy by \((7.25)\). Then

\[
\frac{d}{dt} N_u(t) = -t^a \int_M \left( F_1 + \frac{a}{t} \right) v u d\mu. \tag{7.26}
\]

and

\[
\frac{d}{dt} W_p(u) = -2pt^{a+1} \int_M \left( \left\| \nabla^2 v + \frac{g}{(b+2)t} \right\|_{\text{HS}}^2 + \frac{1}{m-n} \left( \nabla \phi \cdot \nabla v - \frac{m-n}{(b+2)t} \right)^2 \right) u^p d\mu 
- 2pt^{a+1} \int_M \text{Ric}_{m,n}(L)(\nabla v, \nabla v) u^p d\mu 
- 2p(\frac{p}{p-1}) t^{a+1} \int_M \left( L v + \frac{\kappa}{t} \right)^2 u^p d\mu. \tag{7.27}
\]

Proof. We can combine the argument used in the proof of the W-entropy formula for $\partial_t u = \Delta u^p$ in Theorem 5.5 in Lu-Ni-Vazquez-Villani \[34\] and the argument used in the proof of the W-entropy formula for $\partial_t u = Lu$ in Theorem 2.3 in \[19\] to give a proof of Theorem 7.8. To save the length of the paper, we omit the detail here. \[\]

Note that, there are two terms in the integrant in the right hand side of the first line of the W-entropy formula \((7.27)\). To better understand the geometric meaning of the sum of these two terms, we would like to give an alternative proof of the W-entropy formula \((7.27)\) for the case $m \in \mathbb{N}$ with $m \geq n$. In this case, let $(N, g_N)$ be a $(m-n)$ dimensional compact Riemannian manifold with volume $v_N(N) = 1$, and let $\tilde{M} = M \times N$ be equipped with the warped product metric

\[
\tilde{g} = g \oplus e^{-\frac{2\phi}{m-n}} g_N.
\]

Then the volume measure on $\tilde{M}$ is

\[
d\text{vol}_{\tilde{M}} = d\mu \otimes dv_N.
\]

Recall the following

Proposition 7.9 \((27)\) Let $\Delta_{\tilde{M}}$ be the Laplace-Beltrami operator on $(\tilde{M}, \tilde{g})$. Then

\[
\Delta_{\tilde{M}} = L + e^{-\frac{2\phi}{m-n}} \Delta_N,
\]

where $\Delta_N$ is the Laplace-Beltrami operator on $(N, g_N)$. In particular, for $f \in C^2(M)$,

\[
\Delta_{\tilde{M}} f = L f.
\]

Moreover, for $f \in C^2(M)$, we have

\[
\tilde{\nabla}_i f = \nabla_i f, \quad \tilde{\nabla}_\alpha f = 0,
\]

and

\[
\tilde{\nabla}_i^2 f = \nabla_i^2 f, \quad \tilde{\nabla}_i^2 f = 0, \quad \tilde{\nabla}_\alpha^2 f = -\frac{\nabla \phi \cdot \nabla f}{m-n} g_{\alpha\beta}.
\]

where $\tilde{\nabla}$ and $\tilde{\nabla}^2$ denote the gradient and the Hessian on $(\tilde{M}, \tilde{g})$, $i, j = 1, \ldots, n$ denotes the direction of local coordinates along $M$, and $\alpha, \beta = n+1, \ldots, m$ denotes the direction of local coordinates along $N$. 

25
In view of Proposition 7.9, the nonlinear diffusion equation (7.18) associated with the Witten Laplacian is equivalent to the nonlinear diffusion equation associated with the Laplace-Beltrami operator on $\Delta \tilde{M}$ on $(\tilde{M}, \tilde{g})$, i.e.,

$$\partial_t u = \Delta_M u^p,$$  \hfill (7.28)

By the $W$-entropy formula (7.13) due to Lu-Ni-Vazquez-Villani [34] for the nonlinear diffusion equation (7.28) associated with the Laplace-Beltrami operator on $(\tilde{M}, \tilde{g})$, we have

$$\frac{d}{dt} W_p(u) = -2(p-1)t^{a+1} \int_M \left( \left\| D^2 v + \frac{\bar{g}}{(b+2)t} \right\|_{HS}^2 + \tilde{Ric}(\nabla v, \nabla v) \right) v u d\mu$$

$$-2t^{a+1} \int_M \left( F_1 + \frac{a}{t} \right)^2 v u d\mu,$$  \hfill (7.29)

where $\tilde{Ric}$ denotes the Ricci curvature on $(\tilde{M}, \tilde{g})$. By [5, 32, 17, 21], we have

$$\tilde{Ric}(\nabla v, \nabla v) = \text{Ric}_{m,n}(L)(\nabla v, \nabla v).$$

On the other hand, by Proposition 7.9, we have

$$\left\| \nabla^2 v + \frac{\bar{g}}{(b+2)t} \right\|_{HS}^2 = \left\| \nabla^2 v + \frac{g}{(b+2)t} \right\|_{HS}^2 + \frac{1}{m-n} \left( \nabla \phi \cdot \nabla v - \frac{m-n}{(b+2)t} \right)^2.$$  \hfill (7.30)

Therefore, we reprove the $W$-entropy formula for the nonlinear diffusion equation (7.18) associated with the Witten Laplacian on $(M, g, \mu)$ for the case $m \in \mathbb{N}$ and $m \geq n$.

**Remark 7.10** The above proof is an analogue of the one in our previous paper [21] for the $W$-entropy formula for the linear heat equation $\partial_t u = L u$ associated with the Witten Laplacian on $(M, g, \mu)$ for $m \in \mathbb{N}$ with $m \geq n$. The advantage of this proof is that it gives a geometric interpretation of the integrant in the first line of the right-hand side of the $W$-entropy formula. Namely, by (7.30), the quantity $\left\| \nabla^2 v + \frac{g}{(b+2)t} \right\|_{HS}^2 + \frac{1}{m-n} \left( \nabla \phi \cdot \nabla v - \frac{m-n}{(b+2)t} \right)^2$ equal to $\left\| \nabla^2 v + \frac{\bar{g}}{(b+2)t} \right\|_{HS}^2$ which appear in the first integrant in the right-hand side of Lu-Ni-Vazquez-Villani’s $W$-entropy formula (7.29) for the nonlinear diffusion equation (7.28) on the warped product space $(\tilde{M}, \tilde{g})$.

**Corollary 7.11** Let $(M, g)$ be a compact Riemannian manifold with $CD(0, m)$-condition (i.e., $\text{Ric}_{m,n}(L) \geq 0$). Let $u$ be a positive and smooth solution to the nonlinear diffusion equation (7.18). Then,

(i) For $p > 1 - \frac{2}{m}$, $\frac{d}{dt} N_u(t) \leq 0$, and any ancient positive smooth solution to (7.18) must be a constant.

(ii) For $p \geq 1 - \frac{1}{m}$, $\frac{d}{dt} W_p(t) \leq 0$. In particular, $N_u(t)$ is a monotone non-decreasing concave function in $\frac{1}{t}$.

**Proof.** The proof is similar to the one in [34] for the nonlinear diffusion equation $\partial_t u = \Delta u^p$ on compact Riemannian manifold with negative Ricci curvature. $\square$

### 7.4 NIW formula for NLDE for Witten Laplacian

In this subsection we prove the NIW formula for nonlinear diffusion equation associated with the Witten Laplacian on compact Riemannian manifolds.
Theorem 7.12 Let $m \geq n$, and $u$ be a positive and smooth solution to the nonlinear diffusion equation \( \frac{d^2 N_p(u)}{dt^2} = 2\sigma N_p(u) \left( \frac{1 + m(p-1)}{m} I_p(u) - \frac{\kappa}{t} \right)^2 + \frac{1}{2p\|u\|_p^{p-1}} \frac{1}{dt} W_p(u) \).  

Under the condition $CD(0, m)$, we have  

$$
\frac{1}{2p\|u\|_p^{p-1}} \frac{1}{dt} W_p(u) \leq - \frac{1 + m(p-1)}{m} \left| I_p(u) - \frac{\kappa}{t} \right|^2 .
$$

In particular, under the condition $\text{Ric}_{m,n}(L) \geq 0$, the equality in the above inequality holds if and only if $\frac{d^2 N_p}{dt^2} = 0$, which is equivalent to say that $(M,g)$ is quasi-Ricci flat, i.e., $\text{Ric}_{m,n}(L) = 0$, and $\nabla^2 v = - I_p(u) g$, where $I_p(u) := \frac{d}{dt} H_p(u(t))$ is the $p$-th Fisher information and satisfies the differential equation  

$$
I_p(u) + \sigma I_p^2(u) = 0 .
$$

Proof. Note that $v = c'(u)$. By Theorem 7.8, we have  

$$
\frac{1}{2p\|u\|_p^{p-1}} \frac{d}{dt} W_p(u) = - \int_M \left[ \left\| \nabla^2 v + \frac{g}{(b+2)t} \right\|_{\text{HS}}^2 + \frac{1}{m-n} \left( \nabla \phi \cdot \nabla v - \frac{m-n}{(b+2)t} \nabla v \right)^2 \right] u^p d\mu
$$

$$
- \int_M \nabla \phi \cdot \nabla v u^p d\mu - (p-1) \int_M \left( L v + \frac{\kappa}{t} \right)^2 u^p d\mu ,
$$

and by Theorem 5.1 it holds  

$$
\frac{d^2 N_p}{dt^2} = - \left( p - 1 + \frac{1}{m} \right) \int_M \left( L v - \int_M L v d\gamma \right)^2 u^p d\mu
$$

$$
- \int_M \left( \frac{m-n}{mn} \left( L v + \frac{m-n}{m-n} \nabla \phi \cdot \nabla v \right)^2 + \left\| \nabla^2 v - \frac{\Delta v}{n} g \right\|_{\text{HS}}^2 \right] u^p d\mu ,
$$

where $d\gamma = \frac{u^p d\mu}{\int_M u^p d\mu} = \frac{v d\mu}{\int_M v d\mu}$. 

Let $I_1 = \frac{\|u\|_p^p}{2\sigma N_p(u)} \frac{d^2 N_p(u)}{dt^2}$, $I_2 = \frac{1}{2p\|u\|_p^{p-1}} \frac{d}{dt} W_p(u)$ and $I_3 = I_1 - I_2$. Then $I_3 = I_{31} + I_{32} + I_{33}$, where  

$$
I_{31} = \int_M \left[ \left\| \nabla^2 v + \frac{g}{(b+2)t} \right\|_{\text{HS}}^2 - \left\| \nabla^2 v - \frac{\Delta v}{n} g \right\|_{\text{HS}}^2 \right] u^p d\mu
$$

$$
= \int_M \left[ \frac{2}{(b+2)t} \Delta v + \frac{n}{(b+2)^2} \right] u^p d\mu
$$

$$
= \int_M \left[ \frac{2}{(b+2)t} \Delta v + \frac{n}{(b+2)^2} \left( L v + \nabla \phi \cdot \nabla v \right)^2 + \frac{n}{(b+2)^2} \right] u^p d\mu
$$

$$
= \int_M \left[ \frac{2}{(b+2)t} \Delta v + \frac{n}{(b+2)^2} \right] u^p d\mu
$$

$$
+ \int_M \left[ \frac{1}{m} \left| L v \right|^2 - \left| \nabla \phi \cdot \nabla v \right| + \frac{m-n}{mn} \left( L v + \frac{m-n}{m-n} \nabla \phi \cdot \nabla v \right)^2 \right] u^p d\mu ,
$$

where $\nabla \phi = \nabla g - \nabla v$.
$$I_{32} = \int_M (p-1) \left( Lv + \frac{\kappa}{t} \right)^2 u^p d\mu - \left( p-1 + \frac{1}{m} \right) \int_M \left| Lv - \int_M Lvd\gamma \right|^2 u^p d\mu$$

$$= \int_M \left[ -\frac{1}{m} \left| Lv \right|^2 + \frac{2a}{t} Lv + \frac{a^2}{(p-1)^2} \right] u^p d\mu + \left( p-1 + \frac{1}{m} \right) \left( \int_M Lvu^p d\mu \right)^2 \left( \int_M u^p d\mu \right)^{-1},$$

and

$$I_{33} = \int_M \left[ \frac{1}{m-n} \left( \nabla \phi \cdot \nabla v - \frac{m-n}{(b+2)t} \right)^2 - \frac{m-n}{mn} \left( Lv + \frac{m}{m-n} \nabla \phi \cdot \nabla v \right)^2 \right] u^p d\mu.$$
Theorem 8.1 Let \((M, g, \mu)\) be a complete Riemannian manifold with \(CD(0, m)\)-condition and the maximal volume growth condition
\[
\mu(B(x, r)) \geq C_m r^m, \quad \forall x \in M, r > 0.
\]
(8.1)

Then the entropy isoperimetric inequality holds for the Shannon entropy power: for any smooth probability distribution \(fd\mu\) such that \(I(f)\) and \(H(f)\) are well-defined, we have
\[
I(f) N(f) \geq \gamma_m := 2\pi em\kappa_*^\frac{m}{2}.
\]
(8.2)

where \(H(f) = -\int_M f \log fd\mu, I(f) = \int_M |\nabla f|^2 d\mu,\) and
\[
\kappa_* := \lim_{r \to \infty} \inf_{x \in M} \frac{V(B(x, r))}{\omega_m r^m},
\]
here \(\omega_m\) denotes the volume of the unit ball in \(\mathbb{R}^m\) (In the case \(m = n\) and \(M = \mathbb{R}^n\) with the Lebesgue measure, \(\kappa_* = 1\)). Equivalently, the Stam type logarithmic Sobolev inequality holds: for any smooth function \(f\) such that \(\int_M f^2 d\mu = 1\) and \(\int_M |\nabla f|^2 d\mu < \infty\), we have
\[
\int_M f^2 \log f^2 d\mu \leq \frac{m}{2} \log \left( \frac{4}{\gamma_m} \int_M |\nabla f|^2 d\mu \right).
\]

In particular, the above result holds with \(m = n\) on complete Riemannian manifolds with non-negative Ricci curvature and with the maximal volume growth condition for the standard Riemannian volume measure, which extends the well known entropy isoperimetric inequality for the Shannon entropy power on Euclidean space \(\mathbb{R}^n\) with the optimal constant \(\gamma_n = 2\pi e n\).

The proof of Theorem 8.2 (even in the case \(M = n, L = \Delta\) and \(\mu = v\)) uses the concavity of the Shannon entropy power along the heat equation \(\partial_t u = Lu\), two sides heat kernel estimates on complete Riemannian manifolds with \(CD(0, m)\)-condition and the maximal volume growth condition. It would be an interesting question whether we can extend Theorem 8.1 to the Renyi entropy power on complete Riemannian manifolds. As far as we know, it seems to be unknown in the literature. We would like to point out that, even thought it would be possible to extend the concavity of the Renyi entropy power to the nonlinear diffusion equation \(\partial_t u = \Delta u^p\) on complete Riemannian manifolds with non-negative Ricci curvature and to the nonlinear diffusion equation \(\partial_t u = Lu^p\) on weighted complete Riemannian manifolds with non-negative \(m\)-dimensional Bakry-Emery Ricci curvature (i.e., \(Ric_{m,n}(L) \geq 0\) for general \(m > n\)), however it is still unknown whether we can have nice asymptotic behavior of the fundamental solution of the nonlinear diffusion equation \(\partial_t u = \Delta u^p\) or \(\partial_t u = Lu^p\) on complete non-compact Riemannian manifolds with non-negative Ricci curvature on non-negative \(m\)-dimensional Bakry-Emery Ricci curvature. Thus, it is not available for us to use the same idea as we used for the linear heat equation case in [29] to prove the entropy isoperimetric inequality for the Renyi entropy power on complete Riemannian manifolds with non-negative Ricci curvature or non-negative \(m\)-dimensional Bakry-Emery Ricci curvature and maximal volume growth condition.

On the other hand, for any \(n > 2\) and \(p > \frac{n}{n+2}\), Savaré and Toscani [39] proved that for any smooth, strictly positive and rapidly decreasing probability density \(f\) on \(\mathbb{R}^n\), the following entropy isoperimetric inequality holds
\[
N_p(f) I_p(f) \geq \gamma_{n,p}
\]
(8.3)
with the optimal constant
\[
\gamma_{n,p} = N_p(M_p) I_p(M_p),
\]
where $M_p$ is the so-called Barenblatt solution to the nonlinear diffusion equation $\partial_t u = \Delta u^p$ on $\mathbb{R}^n$. More precisely,

$$M_p(x, t) = \frac{1}{t^{n/\mu}} \bar{M}_p \left( \frac{x}{t^{\nu/\mu}} \right),$$

where $\nu = 2 + n(p - 1)$, and

$$\bar{M}_p(x) = \left( C - \frac{1}{2\mu} \frac{p - 1}{p} |x|^2 \right)^{\frac{1}{p-1}};$$

here $(s)_+ = \max\{s, 0\}$, and the constant $C$ can be chosen to fix the mass of the source-type Barenblatt solution equal to one. For explicit formulae of the best constants $\gamma_{n,p}$ for $p \in (n/n + 2, 1)$ and $p > 1$, see [39].

According to Toscani [43], the entropy isoperimetric inequality (8.3) on $\mathbb{R}^n$ is equivalent to the Gagliardo-Nirenberg-Sobolev inequality on $\mathbb{R}^n$ (see (8.8) below). When $p = 1 - \frac{1}{n}$, Savaré and Toscani [39] proved the equivalence between the entropy isoperimetric inequality (8.3) and the Sobolev inequality on $\mathbb{R}^n$ with the best Sobolev constant: for $n > 2$,

$$\int_{\mathbb{R}^n} |\nabla g|^2 dx \geq \left( \frac{n - 2}{2n - 2} \right)^2 \gamma_{n,1-\frac{1}{n}} \left( \int_{\mathbb{R}^n} g^{\frac{2p}{2-p}} dx \right)^{\frac{2-p}{2}}.$$

For the best constants and the extremal functions in the Gagliardo-Nirenberg-Sobolev inequality and the Sobolev inequality on $\mathbb{R}^n$, see [2, 8, 12, 39] and references therein.

The purpose of this section is to prove the entropy isoperimetric inequality for the Renyi entropy power and the Gagliardo-Nirenberg-Sobolev inequality on complete Riemannian manifolds with non-negative Ricci curvature or non-negative $m$-dimensional Bakry-Emery Ricci curvature and maximal volume growth condition. To do so, we need a new approach.

The idea of Toscani [43] and Savaré-Toscani [39] can go straightforward to (weighted) complete Riemannian manifolds. In fact, for $p > \frac{n}{m+2}$, the entropy isoperimetric inequality

$$N_p(f)I_p(f) \geq \gamma_{m,p},$$

holds on an $n$-dimensional weighted complete Riemannian manifold $(M, g, \mu)$ if and only if the following functional inequality: for any smooth and positive probability density $f$ on $M$,

$$\int_M \frac{\nabla f^p}{f} d\mu \geq \gamma_{m,p} \left( \int_M f^p d\mu \right)^{2 + \frac{2}{2m(p-1)}}.$$  

(8.5)

Let $f = g^{\frac{2p}{2-p}}$ with smooth $g > 0$ and $\int_M g^{\frac{2p}{2-p}} d\mu = 1$. Then (8.5) is equivalent to

$$\int_M |\nabla g|^2 d\mu \geq \gamma_{m,p} \left( \frac{2p - 1}{2p} \right)^2 \left( \int_M g^{\frac{2p}{2-p}} d\mu \right)^{2 + \frac{2}{2m(p-1)}}.$$

Equivalently, for smooth $g > 0$ with $\int_M g^{\frac{2p}{2-p}} d\mu = 1$,

$$\|\nabla g\|^2 \geq \gamma_{m,p} \left( \frac{2p - 1}{2p} \right)^2 \|g\|^{\frac{2p}{2-p}} \|g\|^{\frac{2 + 2m(p-1)}{2m(p-1)}}.$$  

(8.6)

By a simply scaling argument, (8.6) is equivalent to: for any smooth $g > 0$,

$$\|\nabla g\|^2 \|g\|^{\frac{2p}{2-p} - \frac{2 + 2m(p-1)}{2m(p-1)}} \geq \gamma_{m,p} \left( \frac{2p - 1}{2p} \right)^2 \|g\|^{\frac{2p}{2-p} - \frac{2 + 2m(p-1)}{2m(p-1)}}.$$  

(8.7)
The functional inequality (8.7) is indeed equivalent to the Gagliardo-Nirenberg-Sobolev inequality
\[ \|g\|_{q+1}^2 \leq A \|\nabla g\|_2^\theta \|g\|_{2q}^{1-\theta}, \] (8.8)
where \( q \in (0, 1) \) and \( \theta = \frac{m(1-q)}{(1+q)(m-(m-2)q)} \in (0, 1) \) satisfy
\[ \frac{1}{q+1} = \frac{\theta}{2^*} + \frac{1-\theta}{2q}, \] (8.9)
in which for \( m > 2 \),
\[ 2^* = \frac{2m}{m-2}. \]
Indeed, taking \( q = \frac{1}{2p-1} \), we can check that (8.7) is equivalent to (8.8) with
\[ A = \left( \frac{2p}{2p-1} \right)^{\theta - \frac{q}{m},p}. \] (8.10)
That is to say, the entropy isoperimetric inequality (8.4) with the optimal constant \( \gamma_{m,p} \) for \( p > \frac{m}{m+2} \) is equivalent to the optimal Gagliardo-Nirenberg-Sobolev inequality (8.8) with \( q = \frac{1}{2p-1} \), \( \theta \) in (8.9) and with the optimal constant \( A \) in (8.10).

In particular, when \( m > 2 \), for \( p = 1 - \frac{1}{m} \), we have \( \frac{2+2m(p-1)}{m(p-1)} = 0 \). The Gagliardo-Nirenberg-Sobolev inequality (8.7) becomes the Sobolev inequality
\[ \int_M |\nabla g|^2 d\mu \geq \left( \frac{m-2}{2m-2} \right)^2 \gamma_{m,1-\frac{1}{m}} \left( \int_M g^{\frac{2m}{m-2}} d\mu \right)^{\frac{m-2}{m}}. \]
That is to say, the entropy isoperimetric inequality (8.4) with the optimal constant \( \gamma_{m,p} \) for \( p = 1 - \frac{1}{m} \) for \( m > 2 \) is equivalent to the Sobolev inequality with the optimal Sobolev constant:
\[ \|g\|_{\frac{2m}{m-2}}^2 \leq \frac{1}{\gamma_{m,1-\frac{1}{m}}} \left( \frac{2m-2}{m-2} \right)^2 \|\nabla g\|_2^2. \] (8.11)
Moreover, it is well known that, by Proposition 6.2.3 in [2] and references therein, the Sobolev inequality (8.11) is equivalent to the Nash inequality
\[ \|f\|_2^{\frac{1+2/m}{2}} \leq C_m \|\nabla f\|_2 \|f\|_4^{2/m}. \]

Recall the following result which was proved by the second named author in [18].

**Theorem 8.2** Let \((M, g, \mu)\) be a complete Riemannian manifold with \( CD(0, m) \)-condition (i.e., \( \text{Ric}_{m,n}(L) \geq 0 \)) and the maximal volume growth condition
\[ \mu(B(x, r)) \geq C_m r^m, \quad \forall x \in M, r > 0. \] (8.12)
Then the Sobolev inequality holds for the measure \( \mu \): there exists a positive constant \( C_{\text{Sob}} \) depending on \( m \) and \( C_m \) such that
\[ \|f\|_2^{\frac{2}{m}} \leq C_{\text{Sob}} \|\nabla f\|_2^2, \quad \forall f \in C_0^\infty(M). \] (8.13)
The above result was proved in [18] using the upper bound heat kernel estimate of the Witten Laplacian obtained by the second named author in [17] on complete Riemannian manifolds and the well known criterion due to Carlen-Kusuoka-Stroock [4] on the equivalence between the validity of the Sobolev inequality and the ultracontractivity of the heat semigroup. More precisely, by Theorem 5.4 in [17], under the $CD(0,m)$-condition, for any $\varepsilon > 0$, $x, y \in M$ and $t > 0$, there is a constant $C_{1}(\varepsilon) > 0$ such that

$$p_{t}(x, y) \leq \frac{C_{1}(\varepsilon)}{\mu(B(x, \sqrt{t}))\mu(B(y, \sqrt{t}))}e^{-\frac{d^{2}(x, y)}{4(\varepsilon + 1)t}}.$$  \hspace{1cm} (8.14)

Now the maximal volume growth condition (8.12) yields

$$p_{t}(x, y) \leq \frac{C_{2}(\varepsilon)}{t^{m/2}}e^{-\frac{d^{2}(x, y)}{2(\varepsilon + 1)t}}.$$ \hspace{1cm} (8.15)

Hence $P_{t} = e^{tL}$ is ultracontractive in the sense that

$$\sup_{x, y \in M} p_{t}(x, y) \leq \frac{C_{2}(\varepsilon)}{t^{m/2}}.$$ \hspace{1cm} (8.16)

By the well known criterion due to Carlen-Kusuoka-Stroock [4], (8.16) is equivalent to say that the Sobolev inequality (8.13) holds.

We can use the entropy isoperimetric inequality (8.2) to give an alternative proof of Theorem 8.2. Indeed, by Theorem 8.1, under the condition of Theorem 8.2, the entropy isoperimetric inequality (8.2) holds. Equivalently, the entropy-energy inequality (in the sense of [2]) holds: for all $f \in C_{0}^{\infty}(M)$ with $\int_{M} f^{2}d\mu = 1$,

$$\text{Ent}(f^{2}) \leq \frac{m}{2}\log \left(\frac{4}{\gamma_{m}}\int_{M} |\nabla f|^{2}d\mu\right).$$ \hspace{1cm} (8.17)

By Proposition 6.2.3 in [2], the entropy-energy inequality (8.17) implies the Nash inequality

$$\|f\|_{2}^{1+2/m} \leq \frac{2}{\sqrt{\gamma_{m}}}\|\nabla f\|_{2}\|f\|_{2}^{2/m}, \quad \forall f \in C_{0}^{\infty}(M),$$ \hspace{1cm} (8.18)

which is equivalent to the Sobolev inequality (8.13) for some constant $C_{Sob}$ depending only on $m$ and $\gamma_{m}$. Indeed, all of (8.17), (8.18) and (8.13) are equivalent to the $L^{1}$ to $L^{\infty}$-ultracontractivity of the heat semigroup $P_{t} = e^{tL}$, i.e.,

$$\|P_{t}f\|_{\infty} \leq \frac{C_{1}}{t^{m/2}}\|f\|_{2}, \quad \forall t > 0,$$ \hspace{1cm} (8.19)

or the $L^{1}$ to $L^{\infty}$-ultracontractivity of the heat semigroup $P_{t} = e^{tL}$, i.e.,

$$\|P_{t}f\|_{1, \infty} \leq \frac{C_{1}}{t^{m/2}}\|f\|_{1}, \quad \forall t > 0.$$ \hspace{1cm} (8.20)

Moreover, by Proposition 6.10.2 in [2], the Sobolev inequality (8.13) is equivalent to the following Gagliardo-Nirenberg-Sobolev inequality

$$\|f\|_{q} \leq C_{Sob}^{\frac{s}{q}}\|\nabla f\|_{2}^{\frac{\theta}{s}}\|f\|_{s}^{1-\theta}, \quad \forall f \in C_{0}^{\infty}(M)$$ \hspace{1cm} (8.21)

for any $1 \leq s \leq q \leq 2^{*} = \frac{2m}{m-2}$, where $q$, $s$ and $\theta$ satisfy

$$\frac{1}{q} = \frac{\theta}{2^{*}} + \frac{1-\theta}{s}.$$ \hspace{1cm} (8.22)
In particular, when \( q = 2, \ s = 1 \) and \( \theta = \frac{m}{m-2} \), (8.24) becomes the Nash inequality

\[
\|f\|_2^{1+2/m} \leq \sqrt{C_{\text{Sob}}} \|\nabla f\|_2 \|f\|_1^{2/m}, \quad \forall f \in C_0^\infty(M)
\]

(8.23)

In view of this argument and Theorem 8.2, we have the following result which gives a reasonable condition for the validity of the entropy isoperimetric inequalities and the Gagliardo-Nirenberg-Sobolev inequality on complete Riemannian manifolds. As far as we know, it is new in the literature even in the case \( m = n, \ \phi = 0, \ \text{Ric}_{m,n}(L) = \text{Ric}, \) and \( \mu = \nu \).

**Theorem 8.3** Let \((M, g, \mu)\) be a complete Riemannian manifold with \( CD(0, m) \)-condition (i.e., \( \text{Ric}_{m,n}(L) \geq 0 \)) and the maximal volume growth condition (8.12), i.e.,

\[
\mu(B(x, r)) \geq C m r^m, \quad \forall x \in M, \ r > 0.
\]

Then
(i) the entropy isoperimetric inequality (8.2) holds, i.e.,

\[
I(f) N(f) \geq \gamma_m := 2 \pi e m \kappa^\frac{1}{m}.
\]

Moreover, there exists a positive constant \( C_{\text{Sob}} \) depending on \( m \) and \( \gamma_m \) such that
(ii) the Sobolev inequality (8.13) holds, i.e., for any \( f \in C_0^\infty(M) \),

\[
\|f\|_q^2 \leq C_{\text{Sob}} \|\nabla f\|_2^2, \quad \forall f \in C_0^\infty(M)
\]

for any \( 1 \leq s \leq q \leq 2^* = \frac{2m}{m-2} \), where \( q, s \) and \( \theta \in [0, 1] \) satisfy

\[
\frac{1}{q} = \frac{\theta}{2^*} + \frac{1-\theta}{s}.
\]

(iii) the Gagliardo-Nirenberg-Sobolev inequality holds: for any \( f \in C_0^\infty(M) \),

\[
\|f\|_q \leq C_{\text{Sob}}^\frac{\theta}{2^*} \|\nabla f\|_2 \|f\|_s^{1-\theta}, \quad \forall f \in C_0^\infty(M)
\]

for any \( 1 \leq s \leq q \leq 2^* = \frac{2m}{m-2} \), where \( q, s \) and \( \theta \in [0, 1] \) satisfy

\[
\frac{1}{q} = \frac{\theta}{2^*} + \frac{1-\theta}{s}.
\]

(iv) the Nash inequality holds, i.e., for any \( f \in C_0^\infty(M) \),

\[
\|f\|_2^{1+2/m} \leq \sqrt{C_{\text{Sob}}} \|\nabla f\|_2 \|f\|_1^{2/m}.
\]

(vi) the entropy isoperimetric inequality holds for the Renyi entropy: for any smooth probability distribution \( f \text{d}\mu \) such that \( I_p(f) \) and \( H_p(f) \) are well-defined, we have

\[
N_p(f) I_p(f) \geq C_{m,p}.
\]

where \( C_{m,p} \) is a constant depending on \( m, p \) and \( C_{\text{Sob}} \).

(vii) the ultracontractivity of the heat semigroup holds: there exists a constant \( C > 0 \) depending on \( m \) and \( C_{\text{Sob}} \) such that

\[
p_t(x, y) \leq C \frac{1}{t^{m/2}}, \quad \forall x, y \in M, t > 0.
\]

**Remark 8.4** In [9, 10, 11], Demange proved some Sobolev inequalities on complete Riemannian manifolds with Ricci curvature bounded below by zero, positive or negative constant. More precisely, let \( M \) be a \( d \)-dimensional complete Riemannian manifold with Ricci curvature bounded below by a negative constant \(-\rho\), where \( \rho > 0 \), and assume that there is a constant \( \beta \in \mathbb{R} \) such that the potential function \( T: M \to \mathbb{R} \) satisfies

\[
\nabla^2 T \geq \left( \frac{\rho}{d-1} T + \beta \right) g.
\]

33
Let \(v > 0\) be such that \((d - 1)v^{-1/d} = T\) and suppose that the following technical condition holds: there exists \(m \geq d\) such that

\[
\int (T^{-m} |\nabla T|^4 + T^{-d}) d\mu < \infty.
\]

Then for any smooth positive function \(f\) with \(\int_M f d\mu = \int v d\mu\) (where \(\mu\) denotes the volume measure) and \(f = v\) on the complementary of a compact set, the following Sobolev inequality holds

\[
2\beta E(f) + \frac{\rho}{d-1} J(f) \leq I(f),
\]

where \(I(f) = \int_M f |\nabla(-(d-1)f^{-1/d} + T)|^2 d\mu\), \(J(f) = \int_M \left[ \int_{v(x)}^f (-\frac{(d-1)\xi^{-1/d} + T(x)}{d-1})^2 ds \right] d\mu(x)\) and \(E(f) = \int_M \left[ \int_{v(x)}^f \frac{(d-1)\xi^{-1/d} + T(x)}{d-1} ds \right] d\mu(x)\). See [4]. On the other hand, assuming that \(M\) is a \(d\)-dimensional complete Riemannian manifold with nonnegative Ricci curvature and equipped with a potential function \(T = (d - 1)v^{-1/d}\) such that for a strictly positive constant \(\rho > 0\), \(\nabla^2 T \geq \rho g\). Then the following Sobolev inequality holds

\[
\int_M \left( d^{1-1/d} - f^{1-1/d} \frac{f - v}{d - 1} \right) d\mu \leq \frac{1}{2\rho} \int_M f |\nabla(f^{1-1/d} - v^{1-1/d})|^2 d\mu.
\]

See [11]. The case of compact Riemannian manifolds with positive Ricci curvature lower bound has been also studied. See [10].

Remark 8.5 As we have pointed out in Introduction and in the beginning of Section 4, we can use a similar argument as used in the first proof of the entropy power concavity inequalities (EPCI) in Theorem 2.1, Theorem 2.2 and Theorem 2.3 to prove the EPCI for the Renyi entropy power associated with nonlinear diffusion equation on RCD(K, N) metric measure spaces and on compact metric measure spaces equipped with a (K, N)-super Ricci flow in the sense of [42]. By the same argument as used in the proof of Theorem 8.3, we can further extend the entropy isoperimetric inequalities for the Shannon entropy power and the Renyi entropy power, the Gagliardo-Nirenberg-Sobolev inequality, the Sobolev inequality and the Nash inequality to RCD(0, N) spaces with the maximal volume growth condition. This will be developed in a forthcoming paper.

To end this paper, we would like to mention that Wang et al. [48, 49] proved the concavity of the Renyi entropy power for the \(p\)-Laplacian equation and the double nonlinear diffusion equations on compact Riemannian manifolds. Our work on the entropy power concavity inequalities in Theorem 2.1, Theorem 2.2 and Theorem 2.3 has been done in our 2017 preprint [24] and is independent of [48, 49].

Acknowledgement. The second author is very grateful to Prof. N. Mok for his suggestion to study the entropy power on manifolds and Prof. L. Ni for his suggestion to study nonlinear diffusion equations on manifolds. We would like to thank Prof. Guang-Yue Han and Prof. Feng-Yu Wang for helpful discussions in the earlier stage of this work. Finally, we would like to thank Dr. Yu-Zhao Wang for his interest, nice discussions and for his careful reading on the earlier versions of the manuscript of this work.
