

Adaptive Finite Time Stability of Delayed Systems With Applications to Network Synchronization

Xiwei Liu, *Senior member, IEEE*

Abstract—The finite time stability (FnTSta) theory of delayed systems has not been set up until now. In this paper, we propose a two-phases-method (2PM), to achieve this object. In the first phase, we prove that the time for norm of system error evolving from initial values to 1 is finite; then in the second phase, we prove that the time for norm of the error evolving from 1 to 0 is also finite, thus FnTSta is obtained. Considering the cost and complexity of controller, we use only two simple terms to realize this aim. For the proposed 2PM, time delays can be the same or asynchronous, bounded or unbounded, etc; the norm can be 2-norm, 1-norm, ∞ -norm, which show that 2PM is powerful and has a wide scope of applications. Furthermore, we also prove the adaptive finite time stability (AFnTSta) theory of delayed systems using 2PM. As an application of the obtained FnTSta theory, we consider the finite time outer synchronization (FnTOSyn) for complex networks with asynchronous unbounded time delays, corresponding criteria are also obtained. Finally, two numerical examples are given to demonstrate the validity of our theories.

I. INTRODUCTION

Convergence rate is an important index for investigating the dynamics of system equilibrium. The most studied cases are exponential stability and asymptotic stability by using the negative feedback technique, where the state of controlled system will approach to the equilibrium as close as possible but never be equal to the equilibrium. Compared with this infinite process, finite time stability (FnTSta) is proposed [1]-[4], which means that the system will reach the equilibrium in FnT (called the settling time). Of course, enhancement of the final target requires the redesign of external control, i.e., linear feedback can realize exponential stability, while FnTSta must use nonlinear feedback, and the relationship between time and control energy was discussed in [5]. Especially, in [2], the authors used

$$\dot{V}(t) \leq -cV(t)^\alpha, \quad 0 < \alpha < 1 \quad (1)$$

to investigate the FnTSta, which now has been the standard method of most papers in this area. In FnTSta analysis, the settling time depends on initial values. If the settling time is independent of initial values, it is called the fixed time stability (FxFtSta) [6].

Synchronization/consensus for complex networks, including neural networks (NNs) and multi-agent systems (MAS), as a typical example of cooperation between coupled systems has attracted more and more attention, whose development process also evolves from exponential/asymptotic synchronization [7], [8] to FnTSyn/FxTSyn along with the development of stability theory. [9] considered FnTSta using the normalized and signed gradient and applied it to network consensus; [10] investigated FnT consensus using a monotonic function; [11] investigated FnTSyn with markovian topology and impulsive effects; [12] studied FnT fractional-order networks synchronization; [13]-[15] set up the general theory for FnTSyn/FxTSyn; [16] investigated FxTSyn with discontinuous neural networks; [17] studied FnT/FxT pinning synchronization for networks with stochastic disturbances; [18] presented a review of FxTSyn; [19] designed FnT/FxT parameter identification algorithms.

In the real world, time delay is an important factor for consideration. Firstly, it arises in many cases, such as the ability of information processing unit is limited, the long distance in information transmission exists, or the outbreak of the virus has a incubation period, etc. Secondly, there are many types of delays, such as constant delay [20], time-varying delay, bounded delay, unbounded delay [21], distributed delay, etc. Thirdly, the existence of delay may impact even change the dynamical behaviors of systems. Therefore, there have been various works investigating the FnTSta or FnTSyn for delayed systems. [22] investigated the robust FxTSyn for master-slave coupled delayed Cohen-Grossberg NNs by designing an external control with time delays (equation (13) in [22]); [23] studied the FnTSyn with aperiodically intermittent control (AIC) by designing a control with time delays (equation (10) in [23]); [24] and [25] investigated FnTSyn of inertial memristive delayed NNs by designing a control with time delays (equation (6) in [24] and equation (12) in [25]); [26] studied the FxT outer synchronization for networks with aperiodically semi-intermittent control by designing a control with time delays (equation (2.5) in [26]).

Therefore, based on above discussions, we would raise **Problem 1: “For delayed systems, can we design a simple controller without using the time delay to realize FnTSta? How to prove its validity?”**

On the other hand, adaptive technique is important in real applications. In many cases, the parameters cannot be obtained directly and parameters may also be varying, therefore, a constant control coefficient may be not enough, while adaptive technique can solve this trouble and has been widely used. For example, in [27], the authors realized the adaptive exponential synchronization for AIC. Therefore, if Problem 1 is solved, we would like to propose a more difficult **Problem 2: “For**

delayed systems, can we design a simple adaptive rule, such that FnTSta can be realized? How to prove its validity?"

Now, we introduce some excellent related works about the two problems. [28] studied FnTSyn via AIC, where the time delay was constant and the external control contained only two terms, by designing a Lyapunov function using this constant delay, the authors proved a useful FnT lemma for AIC. [29] considered the drive-response FnTSyn for complex-valued NNs with bounded and differentiable time-varying delays, and distributed delays, designed a new Lyapunov-Krasovskii function using 1-norm, and proved its derivative was less than a negative constant, thus the FnTSyn was proved. [30] investigated the FnTSyn for memristive NNs with proportional delay qt , by using Filippov solution and Lyapunov-Krasovskii functional method, FnTSyn was proved. It is worth mentioning that an adaptive rule was also designed in [30]. The limitation of these previous works is that time delays are required to be concrete in order to construct Lyapunov-Krasovskii functional, like constant [28], or bounded and differentiable [29], or proportional [30]; moreover, time delays are required to be the same for each node.

Motivated by the above analysis, in this paper, we will address the above two problems. The contributions and advantages of this paper can be summarised as follows:

(1): The time delay for FnTSta has a large allowable range. It can be bounded or unbounded, the same or asynchronous, differentiable or not differentiable, etc. To achieve this aim, we will use the maximum-value method [21], [20].

(2): Two-phases-method (2PM) is shown to be powerful in FnT problems. Two phases means that the proof process is divided into two phases. In the first phase, the norm of system error will be proved to evolve from initial values to 1 in FnT (of course, 1 can be replaced by any constant). In the second phase, the norm of system error will be proved to evolve from 1 to 0 in FnT. Related works about 2PM can be found in [31], [32], [33], where the external control are composed of three terms to realize FnT anti-synchronization, while in this paper the number of control terms is reduced to two.

(3): The FnTSta theory for delayed systems is set up using 2PM. Therefore, problem 1 has been completely solved. The corresponding theorems under 2-norm, 1-norm and ∞ -norm are presented respectively. Moreover, the FnTSta theory is applied to FnT network outer synchronization problem.

(4): The AFnTSta theory for delayed system is set up using 2PM. Therefore, problem 2 has been completely solved. The corresponding theorems and adaptive rules under three norm are given respectively. Moreover, AFnTSta theory is also applied to FnT network outer synchronization problem.

The rest of this paper is organized as follows. In Section II, the FnTSta theory and AFnTSta theory for a delayed simple system model using 2PM are set up under three different norms respectively. In Section III, we apply the obtained theory under 2-norm to the FnT network outer synchronization. Moreover, two adaptive schemes are also designed to realize FnTSyn. In Section IV, we present two numerical examples to illustrate the validity of our obtained theoretical results. Finally, we conclude this paper in Section V.

II. THEORIES OF FINITE TIME STABILITY WITH DELAY

A. A simple model

At first, we set up some theories about (adaptive) FnTSta with unbounded (including bounded) time-varying delays of a general model:

$$\begin{aligned} \dot{p}(t) = & c_1 p(t) + c_2 p(t, \Pi(t)) \\ & - \text{diag}(\text{sgn}(p(t)))(c_3 \mathbf{1} + c_4 |p(t)|) \end{aligned} \quad (2)$$

where $p(t) = (p_1(t), \dots, p_m(t))^T \in R^{m \times 1}$,

$$\begin{aligned} p(t, \Pi(t)) = & (p_1(t - \pi_1(t)), \dots, p_m(t - \pi_m(t)))^T, \\ \text{sgn}(p(t)) = & (\text{sign}(p_1(t)), \dots, \text{sign}(p_m(t)))^T, \\ |p(t)| = & (|p_1(t)|, \dots, |p_m(t)|)^T, \\ \mathbf{1} = & (1, \dots, 1)^T \in R^m. \end{aligned}$$

Assumption 1. As for the asynchronous unbounded time delay $\pi_i(t)$, suppose we can find a continuous function $\pi(t)$ such that

$$\pi_i(t) \leq \pi(t) \quad (3)$$

where $t - \pi(t) \rightarrow +\infty$ and $\pi(t) \rightarrow +\infty$ as $t \rightarrow +\infty$.

Assumption 2. For this $\pi(t)$, suppose we can find a nondecreasing function $\mu(t)$ such that $\lim_{t \rightarrow +\infty} \mu(t) = +\infty$, and

$$\overline{\lim}_{t \rightarrow +\infty} \frac{\dot{\mu}(t)}{\mu(t)} = \beta, \quad \overline{\lim}_{t \rightarrow +\infty} \frac{\mu(t)}{\mu(t - \pi(t))} = 1 + \eta \geq 1 \quad (4)$$

Remark 1. In fact, system (2) can be simply transformed as

$$\dot{p}(t) = (c_1 - c_4)p(t) + c_2 p(t - \pi(t)) - c_3 \text{diag}(\text{sgn}(p(t))) \cdot \mathbf{1}$$

which makes the equation more simple. However, we still take the form as (2). The reason is that the two terms in the first line of (2) can be regarded as the intrinsic/original function of the system, while the two terms in the second line of (2) can be regarded as the external control on the system.

Definition 1. (see [2]) The origin $p(t) = 0$ is said to be a finite time stable equilibrium if the finite time convergence condition and Lyapunov stability condition hold globally.

The main method in this paper is two-phases-method (2PM), which is explicitly called in [33], its validity will be shown by using 2-norm, 1-norm, and ∞ -norm respectively.

B. FnTSta under 2-norm by using 2PM

In this subsection, we firstly choose the 2-norm, due to the wide applications in the literature of synchronization for complex networks. Moreover, under 2-norm, one can use the property of coupling matrix to show that pinning control can realize the synchronization.

Theorem 1. If there exists a positive constant ε_1 , such that the following conditions hold:

$$\beta + 2(c_1 - c_4) + |c_2|\varepsilon_1 + |c_2|m\varepsilon_1^{-1}(1 + \eta) < 0 \quad (5)$$

$$|c_2| - c_3 < 0 \quad (6)$$

where β and η are defined in (4), then FnTSta with unbounded time delays for (2) will be realized, where the settling time will be defined later.

Proof: From (5) and Assumption 2, we can get a time T , such that for $t \geq T$,

$$\frac{\dot{\mu}(t)}{\mu(t)} + 2(c_1 - c_4) + |c_2|\varepsilon_1 + |c_2|m\varepsilon_1^{-1} \frac{\mu(t)}{\mu(t - \pi(t))} < 0 \quad (7)$$

In the following, we will always discuss from T . 2PM will be shown carefully in the next proof procedure. If $\sup_{T - \pi(T) \leq s \leq T} \|p(s)\|_2 \leq 1$, then we will switch to Phase II directly; else, we will start from Phase I.

Phase I: At first, we will prove that the norm of $p(t)$ will decrease from initial values to 1 in FnT.

Define a Lyapunov function

$$V_1(t) = \mu(t)p(t)^T p(t) \quad (8)$$

and a maximum-value function

$$W_1(t) = \sup_{t - \pi(t) \leq s \leq t} V_1(s) \quad (9)$$

Obviously, $V_1(t) \leq W_1(t)$, $t \geq T$.

If $V_1(t) < W_1(t)$. Then there must exist a constant $\delta_1 > 0$ such that $V_1(s) \leq W_1(t)$ for $s \in (t, t + \delta_1)$, i.e., $W_1(s) = W_1(t)$ for $s \in (t, t + \delta_1)$.

Else if there exists a point $t_1 \geq T$, $V_1(t_1) = W_1(t_1)$, then

$$\begin{aligned} & \left. \frac{dV_1(t)}{dt} \right|_{t=t_1} = \dot{\mu}(t)p(t)^T p(t) + 2\mu(t)p(t)^T \dot{p}(t) \\ &= \frac{\dot{\mu}(t)}{\mu(t)} \mu(t)p^T(t)p(t) + 2\mu(t)p^T(t)[c_1 p(t) + c_2 p(t - \Pi(t)) \\ & \quad - \text{diag}(\text{sgn}(p(t)))(c_3 \mathbf{1} + c_4 |p(t)|)] \\ & \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2c_1 \right] V_1(t) + |c_2| [\varepsilon_1 \mu(t)p^T(t)p(t) \\ & \quad + \varepsilon_1^{-1} \mu(t) \sum_{i=1}^m p_i(t - \pi_i(t))^2] \\ & \quad - 2\mu(t)[c_3 |p(t)|^T \cdot \mathbf{1} + c_4 p(t)^T p(t)] \\ & \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2(c_1 - c_4) + |c_2|\varepsilon_1 \right] V_1(t) + |c_2|\varepsilon_1^{-1} \frac{\mu(t)}{\mu(t - \pi(t))} \\ & \quad \cdot \sum_{i=1}^m \frac{\mu(t - \pi_i(t))}{\mu(t - \pi_i(t))} \mu(t - \pi_i(t)) p_i(t - \pi_i(t))^2 \quad (10) \\ & \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2(c_1 - c_4) + |c_2|\varepsilon_1 \right] V_1(t) + |c_2|\varepsilon_1^{-1} \frac{\mu(t)}{\mu(t - \pi(t))} \\ & \quad \cdot \sum_{i=1}^m \mu(t - \pi_i(t)) \sum_{k=1}^m p_k(t - \pi_i(t))^2 \\ & \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2(c_1 - c_4) + |c_2|\varepsilon_1 \right] V_1(t) \\ & \quad + |c_2|\varepsilon_1^{-1} \frac{\mu(t)}{\mu(t - \pi(t))} \sum_{i=1}^m V_1(t - \pi_i(t)) \\ & \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2(c_1 - c_4) + |c_2|\varepsilon_1 \right] V_1(t) \\ & \quad + |c_2|m\varepsilon_1^{-1} \frac{\mu(t)}{\mu(t - \pi(t))} V_1(t) \quad (11) \\ & \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2(c_1 - c_4) + |c_2|\varepsilon_1 + |c_2|m\varepsilon_1^{-1} \frac{\mu(t)}{\mu(t - \pi(t))} \right] V_1(t) \\ & < 0 \end{aligned}$$

Therefore,

$$\begin{aligned} W_1(T) & \geq W_1(t) = \sup_{t - \pi(t) \leq s \leq t} \mu(s)p(s)^T p(s) \\ & \geq \mu(t - \pi(t)) \sup_{t - \pi(t) \leq s \leq t} p(s)^T p(s), \quad t \geq T \end{aligned}$$

i.e.,

$$\sup_{t - \pi(t) \leq s \leq t} p(s)^T p(s) \leq \frac{W_1(T)}{\mu(t - \pi(t))}, \quad (12)$$

Since $\lim_{t \rightarrow +\infty} \mu(t - \pi(t)) = +\infty$, there exists $T_1 (\geq T)$,

$$\sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_2 \leq 1, \quad t \geq T_1 \quad (13)$$

i.e., system (2) with initial values would across the hyperplane with $\sup_{t - \pi(t) \leq s \leq t} p(s)^T p(s) = 1$ in T_1 .

Phase II: Next, we will prove that the norm of $p(t)$ will decrease from 1 to 0 in FnT.

From condition (6), we can find a sufficiently small constant $\varepsilon_2 > 0$, such that $|c_2| - c_3 + \varepsilon_2 < 0$. Using this ε_2 , we define another Lyapunov function

$$V_2(t) = (p(t)^T p(t))^{\frac{1}{2}} + \varepsilon_2 t, \quad t \geq T_1 \quad (14)$$

and the maximum-value function

$$W_2(t) = \sup_{t - \pi(t) \leq s \leq t} V_2(s), \quad t \geq T_1 \quad (15)$$

Similarly, $V_2(t) \leq W_2(t)$. If $V_2(t) < W_2(t)$, then there must exist a constant $\delta_2 > 0$ such that $V_2(s) \leq W_2(t)$ for $s \in (t, t + \delta_2)$, i.e., $W_2(s) = W_2(t)$ for $s \in (t, t + \delta_2)$.

Else if there exists a point $t_2 \geq T_1$, $V_2(t_2) = W_2(t_2)$. Differentiating $V_2(t)$ along (2),

$$\begin{aligned} & \left. \dot{V}_2(t) \right|_{t=t_2} = (p(t)^T p(t))^{-\frac{1}{2}} p^T(t)[c_1 p(t) + c_2 p(t - \Pi(t)) \\ & \quad - \text{diag}(\text{sgn}(p(t)))(c_3 \mathbf{1} + c_4 |p(t)|)] + \varepsilon_2 \\ &= (p(t)^T p(t))^{-\frac{1}{2}} [(c_1 - c_4)p(t)^T p(t) \\ & \quad + |c_2| \sum_{i=1}^m |p_i(t)| |p_i(t - \pi_i(t))| - c_3 \sum_{i=1}^m |p_i(t)|] + \varepsilon_2 \\ & \leq (p(t)^T p(t))^{-\frac{1}{2}} [(|c_2| - c_3) \sum_{i=1}^m |p_i(t)|] + \varepsilon_2 \\ & \leq (|c_2| - c_3)(p(t)^T p(t))^{-\frac{1}{2}} \left(\sum_{i=1}^m p_i(t)^2 \right)^{\frac{1}{2}} + \varepsilon_2 \quad (16) \\ &= |c_2| - c_3 + \varepsilon_2 < 0 \end{aligned}$$

where (16) is obtained due to $\|p(t)\|_2 \leq \|p(t)\|_1$.

Therefore, for all $t \geq T_1$

$$\begin{aligned} & (p(t)^T p(t))^{\frac{1}{2}} + \varepsilon_2 t = V_2(t) \leq W_2(t) \leq W_2(T_1) \\ &= \sup_{T_1 - \pi(T_1) \leq s \leq T_1} ((p(s)^T p(s))^{\frac{1}{2}} + \varepsilon_2 s) \\ & \leq \sup_{T_1 - \pi(T_1) \leq s \leq T_1} (p(s)^T p(s))^{\frac{1}{2}} + \varepsilon_2 T_1 = 1 + \varepsilon_2 T_1 \end{aligned}$$

i.e.,

$$(p(t)^T p(t))^{\frac{1}{2}} \leq 1 - \varepsilon_2(t - T_1) \quad (17)$$

According to the above inequality, norm of $p(t)$ will evolve from 1 to 0 in finite (fixed) time. Especially, $p(t) \equiv 0$ for any

$$t \geq T_2 = \frac{1}{\varepsilon_2} + T_1. \quad (18)$$

The proof is completed. \blacksquare

Remark 2. The advantage of the introduced maximum-value functions $W_1(t)$ in (9) and $W_2(t)$ in (15) is that it can relax the requirement of time delays, i.e., time delays can be asynchronous. When all time delays are the same, i.e., $\pi_i(t) = \pi(t)$, then the process from (10) to (11) can be improved with ‘ m ’ in (11) being replaced by ‘1’.

Remark 3. According to the form of external control, we can find that $|p(t)|^0, |p(t)|^1$ are both needed. In fact, $|p(t)|^\alpha, 0 < \alpha < 1$ can also be added, but it is not necessary. Related works using this term to realize FnT anti-synchronization can be found in [31]-[33]. If FxTSta is required, then the term $|p(t)|^\alpha$, where $\alpha > 1$ should be added, its proof is similar to the above, the first phase will use FxT, since the second phase is FxT, so the whole time will be FxT.

Remark 4. In fact, Phase II can be proved by using an alternative function as $V_2(t) = p(t)^T p(t)$ and differentiating it directly, interested reader can do this by yourself. In the proof, we do not adopt this function due to our proposed function (14) can be applied in other cases such as FnTSta under adaptive rule, which will be shown later.

Next, we consider some concrete forms of time delays.

Corollary 1. (FnTSta with proportional delay) For system (2), with $\pi_i(t) \leq qt$, if there exists a positive constant ε_1 , such that (6) and

$$2(c_1 - c_4) + |c_2|\varepsilon_1 + |c_2|m\varepsilon_1^{-1}(1 - q)^{-\varrho} < 0, \quad (19)$$

hold, where $\varrho > 0$ is a small positive constant, then FnTSta with proportional delay for (2) will be realized.

Proof: Since $\pi(t) = qt, 0 < q < 1$, we can choose $\mu(t) = t^\varrho, \varrho > 0$. Obviously, $\mu(t)$ is increasing,

$$\begin{aligned} \lim_{t \rightarrow +\infty} \frac{\dot{\mu}(t)}{\mu(t)} &= \lim_{t \rightarrow +\infty} \frac{\varrho t^{\varrho-1}}{t^\varrho} = \lim_{t \rightarrow +\infty} \frac{\varrho}{t} = 0 \\ \lim_{t \rightarrow +\infty} \frac{\mu(t)}{\mu(t - \pi(t))} &= \lim_{t \rightarrow +\infty} \frac{t^\varrho}{(t - qt)^\varrho} = (1 - q)^{-\varrho} \end{aligned}$$

According to Theorem 1, the proof is completed. \blacksquare

More types of unbounded time delays $\pi(t)$ and corresponding functions $\mu(t)$ can be found in pioneering work [21].

Corollary 2. (FnTSta with bounded time delay) For system (2), with $\pi_i(t) \leq \pi$, if there exists a positive constant ε_1 , such that (6) and

$$\varpi + 2(c_1 - c_4) + |c_2|\varepsilon_1 + |c_2|m\varepsilon_1^{-1}e^{\varpi\pi} < 0, \quad (20)$$

hold, where $\varpi > 0$ is sufficiently small, then the FnTSta with bounded delays for (2) will be realized. Especially, when $\pi = 0$, then it becomes the FnTSta problem without delays, condition (20) becomes $\varpi + 2(c_1 - c_4) < 0$.

Proof: Since $\pi(t) = \pi$ is a constant, so we can choose $\mu(t) = e^{\varpi t}, \varpi > 0$, which is increasing,

$$\begin{aligned} \lim_{t \rightarrow +\infty} \frac{\dot{\mu}(t)}{\mu(t)} &= \lim_{t \rightarrow +\infty} \frac{\varpi e^{\varpi t}}{e^{\varpi t}} = \varpi \\ \lim_{t \rightarrow +\infty} \frac{\mu(t)}{\mu(t - \pi(t))} &= \lim_{t \rightarrow +\infty} \frac{e^{\varpi t}}{e^{\varpi(t - \pi)}} = e^{\varpi\pi} \end{aligned}$$

According to Theorem 1, it is proved. \blacksquare

Remark 5. We are interested in the role of each term in the external control. From condition (5), one knows that c_4 should be larger than c_1 ; from condition (6), c_3 should be larger than $|c_2|$, and the fixed settling time from 1 to 0 is determined by $1/(c_3 - |c_2|)$, so larger c_3 means the shorter stabilization time. Therefore, one can conclude that the larger the control parameters c_3 and c_4 , the faster FnTSta can be achieved.

C. AFnTSta under 2-norm by using 2PM

In some cases or environments, parameters like c_1 and c_2 may not be obtained. Therefore, we will adapt the control parameters c_3 and c_4 as large as possible, the adaptive rule will be designed and its validity will also be proved.

Theorem 2. For the following system

$$\begin{aligned} \dot{p}(t) &= c_1 p(t) + c_2 p(t - \Pi(t)) \\ &\quad - \text{diag}(\text{sgn}(p(t)))(c_3(t)\mathbf{1} + c_4(t)|p(t)|) \end{aligned} \quad (21)$$

with the adaptive rule

$$\dot{c}_3(t) = \begin{cases} 0, & \text{if } \sup_{t-\pi(t) \leq s \leq t} p(s)^T p(s) > 1 \\ d_1, & \text{if } \sup_{t-\pi(t) \leq s \leq t} p(s)^T p(s) \leq 1 \\ 0, & \text{if } \sup_{t-\pi(t) \leq s \leq t} p(s)^T p(s) = 0 \end{cases} \quad (22)$$

and

$$\dot{c}_4(t) = \begin{cases} d_2 \mu(t) p(t)^T p(t), & \text{if } \sup_{t-\pi(t) \leq s \leq t} p(s)^T p(s) > 1 \\ d_3 \|p(t)\|_2, & \text{if } \sup_{t-\pi(t) \leq s \leq t} p(s)^T p(s) \leq 1 \end{cases} \quad (23)$$

where parameters d_1, d_2, d_3 are any positive scalars, and the initial values are set to be $c_3(0) = c_4(0) = 0$. Then FnTSta can be realized.

Proof: 2PM will also be applied. With the same argument with that in Theorem 1, the time is considered from time T .

Phase I: Prove that the norm of $p(t)$ will decrease from initial values to 1 in FnT.

Define a new Lyapunov function

$$V_3(t) = \mu(t) p(t)^T p(t) + \frac{1}{d_2} (c_4(t) - c_4^*)^2 \quad (24)$$

and the function $W_3(t) = \sup_{t-\pi(t) \leq s \leq t} V_3(s)$. $V_3(t) \leq W_3(t), t \geq T$.

If $V_3(t) < W_3(t)$. Then there must exist a constant $\delta_3 > 0$ such that $V_3(s) \leq W_3(t)$ for $s \in (t, t + \delta_3)$, i.e., $W_3(s) = W_3(t)$ for $s \in (t, t + \delta_3)$.

Else, there exists a point $t_3, V_3(t_3) = W_3(t_3)$. Before differentiating, we discuss the limit of $c_4(t)$.

Case 1: From the definition of $\dot{c}_4(t)$ in (23), we know that $c_4(t)$ is positive and monotonically increasing, if $c_4(t) > c_4^*$, $t > T^*$, where c_4^* is a constant such that $\beta + 2(c_1 - c_4^*) + |c_2|\varepsilon_1 + |c_2|m\varepsilon_1^{-1}(1 + \eta) < 0$, then FnTSta can be achieved according to the analysis in Theorem 1.

Case 2: The limit of $c_4(t)$ is always bounded by c_4^* , $(c_4(t) - c_4^*)^2$ would be a decreasing function, thus $\mu(t)p(t)^T p(t)$ must be the maximum value in $[t - \pi(t), t]$.

Now, based on the above discussions, differentiating $V_3(t)$,

$$\begin{aligned} & \dot{V}_3(t)|_{t=t_3} \\ &= \dot{\mu}(t)p(t)^T p(t) + 2\mu(t)p(t)^T \dot{p}(t) + 2d_2^{-1}(c_4(t) - c_4^*)\dot{c}_4(t) \\ &= \frac{\dot{\mu}(t)}{\mu(t)}\mu(t)p^T(t)p(t) + 2\mu(t)p^T(t)[c_1p(t) + c_2p(t - \Pi(t)) \\ & \quad - c_4(t)p(t)] + 2(c_4(t) - c_4^*)\mu(t)p(t)^T p(t) \\ &\leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2(c_1 - c_4^*) + |c_2|\varepsilon_1 + |c_2|\varepsilon_1^{-1} \frac{\mu(t)}{\mu(t - \pi(t))} \right] V_1(t) \\ &< 0 \end{aligned}$$

Therefore,

$$\begin{aligned} W_3(T) \geq W_3(t) &\geq \sup_{t - \pi(t) \leq s \leq t} \mu(s)p(s)^T p(s) \\ &\geq \mu(t - \pi(t)) \sup_{t - \pi(t) \leq s \leq t} p(s)^T p(s), \end{aligned}$$

i.e.,

$$\sup_{t - \pi(t) \leq s \leq t} p(s)^T p(s) \leq \frac{W_3(T)}{\mu(t - \pi(t))}. \quad (25)$$

So there is a FnT point $T_3(\geq T)$ such that

$$\sup_{t - \pi(t) \leq s \leq t} p(s)^T p(s) \leq 1, \quad t \geq T_3 \quad (26)$$

Phase II: Prove that the norm of $p(t)$ will decrease from 1 to 0 in FnT.

From condition (6), one can find a sufficiently large constant $c_3^* > 0$ and sufficiently small constant $\varepsilon_2^* > 0$, such that $\sqrt{m}|c_2| - c_3^* + \varepsilon_2^* < 0$. Using this ε_2^* , we define

$$\begin{aligned} V_4(t) &= (p(t)^T p(t))^{\frac{1}{2}} + \frac{1}{2d_1}(c_3(t) - c_3^*)^2 \\ & \quad + \frac{1}{2d_3}(c_4(t) - c_4^*)^2 + \varepsilon_2^* t, \quad t \geq T_3 \end{aligned} \quad (27)$$

and $W_4(t) = \sup_{t - \pi(t) \leq s \leq t} V_4(s)$, $t \geq T_3$. Similarly, $V_4(t) \leq W_4(t)$. If $V_4(t) < W_4(t)$, then there must exist a constant $\delta_4 > 0$ such that $V_4(s) \leq W_4(t)$ for $s \in (t, t + \delta_4)$, i.e., $W_4(s) = W_4(t)$ for $s \in (t, t + \delta_4)$.

Else, there exists a time point $t_4 \geq T_3$ such that $V_4(t_4) = W_4(t_4)$. Similar discussions can be applied for $c_3(t)$ as before, here we omit them. Differentiating $V_4(t)$, we have

$$\begin{aligned} & \dot{V}_4(t)|_{t=t_4} = (p(t)^T p(t))^{-\frac{1}{2}} p^T(t)[c_1p(t) + c_2p(t - \Pi(t)) \\ & \quad - \text{diag}(\text{sgn}(p(t)))(c_3(t)\mathbf{1} + c_4(t)|p(t)|)] + \varepsilon_2^* \\ & \quad + (c_3(t) - c_3^*) + (c_4(t) - c_4^*)\|p(t)\|_2 \\ &= (p(t)^T p(t))^{-\frac{1}{2}} [(c_1 - c_4^*)p(t)^T p(t) \\ & \quad + |c_2| \sum_{i=1}^m |p_i(t)||p_i(t - \pi_i(t))| - c_3(t) \sum_{i=1}^m |p_i(t)|] \end{aligned}$$

$$\begin{aligned} & + (c_3(t) - c_3^*) + \varepsilon_2^* \\ &\leq |c_2| \frac{\|p(t)\|_1}{\|p(t)\|_2} - c_3(t) \frac{\|p(t)\|_1}{\|p(t)\|_2} + (c_3(t) - c_3^*) + \varepsilon_2^* \\ &\leq \sqrt{m}|c_2| - c_3^* + \varepsilon_2^* < 0 \end{aligned}$$

where the last inequality is obtained due to the norm equivalence $\|p(t)\|_2 \leq \|p(t)\|_1 \leq \sqrt{m}\|p(t)\|_2$.

Therefore,

$$\begin{aligned} & (p(t)^T p(t))^{\frac{1}{2}} + \varepsilon_2^* t \leq V_4(t) \leq W_4(t) \leq W_4(T_3) \\ &\leq 1 + \varepsilon_2^* T_3 \\ & \quad + \frac{(c_3(T_3 - \pi(T_3)) - c_3^*)^2}{2d_1} + \frac{(c_4(T_3 - \pi(T_3)) - c_4^*)^2}{2d_3} \\ &\leq 1 + \varepsilon_2^* T_3 + \frac{(c_3^*)^2}{2d_1} + \frac{(c_4^*)^2}{2d_3}, \end{aligned}$$

i.e.,

$$(p(t)^T p(t))^{\frac{1}{2}} \leq 1 + \frac{(c_3^*)^2}{2d_1} + \frac{(c_4^*)^2}{2d_3} - \varepsilon_2^*(t - T_3) \quad (28)$$

From the above inequality, norm of $p(t)$ will evolve from 1 to 0 in FnT. Especially, $p(t) \equiv 0$ for any

$$t \geq T_4 = (\varepsilon_2^*)^{-1} \left[1 + \frac{(c_3^*)^2}{2d_1} + \frac{(c_4^*)^2}{2d_3} \right] + T_3 \quad (29)$$

The proof is completed. \blacksquare

D. FnTSta under other norms by using 2PM

Besides 2-norm, there are other norms, such as 1-norm, ∞ -norm, etc. Next, we present the validity of proposed 2PM on FnTSta with 1-norm and ∞ -norm.

Theorem 3. *FnTSta with unbounded time delays for (2) will be realized, if condition (6) and the following condition hold:*

$$\beta + (c_1 - c_4) + |c_2|m(1 + \eta) < 0.$$

Theorem 4. *For (21) with the adaptive rules (22) and*

$$\dot{c}_4(t) = \begin{cases} d_2\mu(t)\|p(t)\|_1, & \text{if } \sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_1 > 1 \\ d_3\|p(t)\|_1, & \text{if } \sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_1 \leq 1 \end{cases}$$

FnTSta can be realized.

Theorem 5. *FnTSta with unbounded time delays for (2) will be realized, if condition (6) and the following condition hold:*

$$\beta + (c_1 - c_4) + |c_2|(1 + \eta) < 0.$$

Theorem 6. *For (21) with the adaptive rules (22) and*

$$\dot{c}_4(t) = \begin{cases} d_2\mu(t)\|p(t)\|_\infty, & \text{if } \sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_\infty > 1 \\ d_3\|p(t)\|_\infty, & \text{if } \sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_\infty \leq 1 \end{cases}$$

FnTSta can be realized.

All proofs can be found in the Appendixes.

III. FINITE TIME OUTER SYNCHRONIZATION OF COMPLEX NETWORKS WITH DELAYS

As an application of obtained FnTSta results, we will investigate FnTOSyn for delayed networks.

A. Model description

We adopt the simple drive-response coupled model, while the drive system with N nodes can be described as

$$\begin{aligned} \dot{x}_i(t) = & f(x_i(t)) + \theta_1 \sum_{j=1}^N a_{ij} x_j(t) \\ & + \theta_2 \sum_{j=1}^N b_{ij} g(x_j(t - \pi_{ij}(t))) \end{aligned} \quad (30)$$

where $x_i(t) = (x_{i1}(t), \dots, x_{in}(t))^T \in R^n, i = 1, \dots, N$, $f(x_i(t)) = (f_1(x_i(t)), \dots, f_n(x_i(t)))^T$, $g(x_j(t - \pi_{ij}(t))) = (g_1(x_j(t - \pi_{ij}(t))), \dots, g_n(x_j(t - \pi_{ij}(t))))^T$. Asynchronous time delay $0 \leq \pi_{ij}(t) \leq \pi(t)$ satisfies Assumption 1.

The response system can be defined as

$$\begin{aligned} \dot{y}_i(t) = & f(y_i(t)) + \theta_1 \sum_{j=1}^N a_{ij} y_j(t) \\ & + \theta_2 \sum_{j=1}^N b_{ij} g(y_j(t - \pi_{ij}(t))) + u_i(t) \end{aligned} \quad (31)$$

where $y_i(t) = (y_{i1}(t), \dots, y_{in}(t))^T$, $u_i(t)$ is external control.

Assumption 3. As for functions $f(\cdot)$ and $g(\cdot)$, suppose there exist positive constants L_f, L_g such that, for any $x_i, y_i \in R^n$,

$$\begin{aligned} \|f(y_i) - f(x_i)\|_2 & \leq L_f \|y_i - x_i\|_2, \\ \|g(y_i) - g(x_i)\|_2 & \leq L_g \|y_i - x_i\|_2. \end{aligned}$$

Assumption 4. As for the irreducible coupling matrix $A = (a_{ij})$, suppose it is a Metzler matrix with zero row sum.

Lemma 1. ([8]) If matrix A satisfies Assumption 4, then the new matrix $\tilde{A} = A - \text{diag}(\sigma, 0, \dots, 0)$ is Lyapunov stable, $\sigma > 0$. Denote $\xi = (\xi_1, \dots, \xi_N)^T$ is the left eigenvector corresponding to the zero eigenvalue of A , then $\xi_i > 0, i = 1, \dots, N$. In the following, we always suppose that $\sum_{i=1}^N \xi_i = 1$. Moreover, $\Xi \tilde{A} + \tilde{A} \Xi = 2\{\Xi \tilde{A}\}^s < 0$, where $\Xi = \text{diag}(\xi)$, i.e., its largest eigenvalue $\lambda_{\max}(\{\Xi \tilde{A}\}^s) < 0$.

Definition 2. Systems (30) and (31) are said to achieve the FnTOSyn, if for the synchronization error $e_i(t) = y_i(t) - x_i(t), i = 1, \dots, N$, there exists a time point T^* such that

$$\lim_{t \rightarrow T^*} \|e_i(t)\| = 0, \quad \text{and} \quad \|e_i(t)\| \equiv 0, \quad t \geq T^*.$$

Denote $\tilde{f}(e_i(t)) = f(y_i(t)) - f(x_i(t))$ and $\tilde{g}(e_i(t)) = g(y_i(t)) - g(x_i(t))$, then the dynamic model for error $e_i(t)$ can be described as:

$$\begin{aligned} \dot{e}_i(t) = & \tilde{f}(e_i(t)) + \theta_1 \sum_{j=1}^N a_{ij} e_j(t) \\ & + \theta_2 \sum_{j=1}^N b_{ij} \tilde{g}(e_j(t - \pi_{ij}(t))) + u_i \end{aligned} \quad (32)$$

Now, our aim is to design suitable external control $u_i(t)$ and prove its validity to realize FnTOSyn. Of course, the external control should be simple and easy to use. Under this standard, $u_i(t)$ should be only dependent on the current system state $e_i(t)$; moreover, pinning control strategy should also be considered in order to reduce control cost.

B. FnTOSyn using 2PM

In this subsection, we first design the form of $u_i(t)$ by the pinning control technique, then FnTOSyn under this control will also be proved using the proposed 2PM.

Design the controller $u_i(t)$ as

$$u_i(t) = \begin{cases} -\theta_1 \sigma e_1(t) - \theta_3 \text{sgn}(e_1(t)), & i = 1 \\ -\theta_3 \text{sgn}(e_i(t)), & \text{otherwise} \end{cases} \quad (33)$$

where $\sigma > 0$ and $\theta_3 > 0$.

Theorem 7. For the system (32) with control (33), if there exists a constant $\varepsilon_1 > 0$, such that following conditions hold:

$$\begin{aligned} \beta + 2L_f + \theta_2 \max_{i,j} |b_{ij}| N \varepsilon_1 + 2\theta_1 \lambda_{\max}(\{\Xi \tilde{A}\}^s) \\ + \theta_2 \max_{i,j} |b_{ij}| N^2 n L_g^2 \varepsilon_1^{-1} \frac{1}{\min_i \xi_i} (1 + \eta) < 0 \end{aligned} \quad (34)$$

and

$$\theta_2 \max_{i,j} |b_{ij}| N L_g - \theta_3 < 0, \quad (35)$$

then (32) will achieve FnTOSyn.

Proof: With the same argument as that in Theorem 1, the time is considered from time T , and according to condition (34), we have

$$\begin{aligned} \frac{\dot{\mu}(t)}{\mu(t)} + 2L_f + \theta_2 \max_{i,j} |b_{ij}| N \varepsilon_1 + 2\theta_1 \lambda_{\max}(\{\Xi \tilde{A}\}^s) \\ + \theta_2 \max_{i,j} |b_{ij}| N^2 n L_g^2 \varepsilon_1^{-1} \frac{1}{\min_i \xi_i} \frac{\mu(t)}{\mu(t - \pi(t))} < 0. \end{aligned}$$

If $\sup_{t - \pi(t) \leq s \leq t} \sum_{i=1}^N e_i^T(s) e_i(s) \leq 1, t \geq T$, then we will switch to Phase II directly; else, we will start from Phase I.

Phase I: Define

$$\bar{V}_1(t) = \mu(t) \sum_{i=1}^N \xi_i e_i(t)^T e_i(t), \quad t \geq T. \quad (36)$$

and

$$\bar{W}_1(t) = \sup_{t - \pi(t) \leq s \leq t} \bar{V}_1(s) \quad (37)$$

If at some time $t_1, \bar{V}_1(t_1) = \bar{W}_1(t_1)$, differentiating $\bar{V}_1(t)$ along (32),

$$\begin{aligned} \dot{\bar{V}}_1(t) = & \dot{\mu}(t) \sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \\ & + 2\mu(t) \sum_{i=1}^N \xi_i e_i(t)^T [\tilde{f}(e_i(t)) + \theta_1 \sum_{j=1}^N a_{ij} e_j(t) \\ & + \theta_2 \sum_{j=1}^N b_{ij} \tilde{g}(e_j(t - \pi_{ij}(t))) + u_i] \\ \leq & \frac{\dot{\mu}(t)}{\mu(t)} \bar{V}_1(t) + 2L_f \mu(t) \sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \\ & + 2\mu(t) \theta_1 E(t)^T (\{\Xi \tilde{A}\}^s \otimes I_n) E(t) \\ & + 2\mu(t) \theta_2 \sum_{i=1}^N \sum_{j=1}^N \xi_i e_i(t)^T b_{ij} \tilde{g}(e_j(t - \pi_{ij}(t))) \end{aligned}$$

$$\begin{aligned}
&\leq \left(\frac{\dot{\mu}(t)}{\mu(t)} + 2L_f + 2\theta_1 \lambda_{\max}(\{\Xi \tilde{A}\}^s) \right) \bar{V}_1(t) \\
&\quad + \mu(t) \theta_2 \max_{i,j} |b_{ij}| \sum_{i=1}^N \sum_{j=1}^N [\varepsilon_1 \xi_i e_i(t)^T e_i(t) \\
&\quad + \varepsilon_1^{-1} \xi_i \tilde{g}(e_j(t - \pi_{ij}(t)))^T \tilde{g}(e_j(t - \pi_{ij}(t)))] \\
&\leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2L_f + \theta_2 \max_{i,j} |b_{ij}| N \varepsilon_1 + 2\theta_1 \lambda_{\max}(\{\Xi \tilde{A}\}^s) \right] \bar{V}_1(t) \\
&\quad + \theta_2 \max_{i,j} |b_{ij}| N L_g^2 \varepsilon_1^{-1} \frac{1}{\min_i \xi_i} \mu(t) \sum_{i,j} \bar{V}_1(t - \pi_{ij}(t)) \\
&\leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2L_f + \theta_2 \max_{i,j} |b_{ij}| N \varepsilon_1 + 2\theta_1 \lambda_{\max}(\{\Xi \tilde{A}\}^s) \right. \\
&\quad \left. + \theta_2 \max_{i,j} |b_{ij}| N^2 n L_g^2 \varepsilon_1^{-1} \frac{1}{\min_i \xi_i} \frac{\mu(t)}{\mu(t - \pi(t))} \right] \bar{V}_1(t) \\
&< 0
\end{aligned}$$

where $E(t) = (e_1(t)^T, \dots, e_N(t)^T)^T$.

According to the same arguments in Theorem 1, system (32) would decrease and across the hyperplane with $\sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^N e_i(t)^T e_i(t) = 1$ in FnT $T_1 (\geq T)$.

Phase II: From condition (35), we can find a sufficiently small constant $\varepsilon_2 > 0$, such that $(\theta_2 \max_{i,j} |b_{ij}| N d_2 - \theta_3) + \varepsilon_2 < 0$. Using this ε_2 , we define another Lyapunov function

$$\bar{V}_2(t) = \left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{\frac{1}{2}} + \varepsilon_2 t, \quad t \geq T_1 \quad (38)$$

and the maximum-value function

$$\bar{W}_2(t) = \sup_{t-\pi(t) \leq s \leq t} \bar{V}_2(s), \quad t \geq T_1 \quad (39)$$

If at some time t_2 , $\bar{V}_2(t_2) = \bar{W}_2(t_2)$, differentiating $\bar{V}_2(t)$,

$$\begin{aligned}
\dot{\bar{V}}_2(t) &= \left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{-\frac{1}{2}} \sum_{i=1}^N \xi_i e_i(t)^T \dot{e}_i(t) + \varepsilon_2 \\
&\leq \varepsilon_2 + \left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{-\frac{1}{2}} \\
&\quad \left[(L_f + \theta_1 \lambda_{\max}(\{\Xi \tilde{A}\}^s)) \sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right. \\
&\quad + \theta_2 \sum_{i=1}^N \sum_{j=1}^N \xi_i e_i(t)^T b_{ij} \tilde{g}(e_j(t - \pi_{ij}(t))) \\
&\quad \left. - \theta_3 \sum_{i=1}^N \xi_i e_i(t)^T \text{sgn}(e_i(t)) \right] \\
&\leq \varepsilon_2 + \left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{-\frac{1}{2}} \\
&\quad (\theta_2 \max_{ij} |b_{ij}| N L_g - \theta_3) \sum_{i=1}^N \sqrt{\xi_i} |e_i(t)|^T \mathbf{1} \\
&\leq \varepsilon_2 + (\theta_2 \max_{ij} |b_{ij}| N L_g - \theta_3) < 0
\end{aligned}$$

With the similar arguments in Theorem 1, the error $(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t))^{\frac{1}{2}}$ will flow from 1 to 0 in FnT. Especially, $e_i(t) \equiv 0$ for any $t \geq T_2 = 1/\varepsilon_2 + T_1$. ■

Remark 6. From the above theorem, we can find that the enlargement of inequalities can be improved by discussing more carefully. For example, the property of matrix $B = (b_{ij})$ (Metzler or not), the type of time delays $\pi_{ij}(t)$ (synchronous or asynchronous, bounded or unbounded), the definition of function $g(\cdot)$ (linear or nonlinear), and even other different norms of $e_i(t)$ (1-norm or ∞ -norm), etc. All these can be done following our proposed 2PM, which has a wide scope of applications for FnT analysis of delayed systems.

Next, we design another controller added on each node,

$$u_i(t) = -\theta_3 \text{sgn}(e_i(t)) - \theta_4 e_i(t), \quad (40)$$

where $\theta_3 > 0$ and $\theta_4 > 0$, and $i = 1, 2, \dots, N$.

Theorem 8. For the system (32) with control (40), if there exists a constant $\varepsilon_1 > 0$, such that (35) and

$$\begin{aligned}
&\beta + 2L_f + \theta_2 \max_{i,j} |b_{ij}| N \varepsilon_1 + 2\lambda_{\max}(\{\Xi \hat{A}\}^s) \\
&\quad + \theta_2 \max_{i,j} |b_{ij}| N^2 n L_g^2 \varepsilon_1^{-1} \frac{1}{\min_i \xi_i} (1 + \eta) < 0, \quad (41)
\end{aligned}$$

hold, where $\hat{A} = \theta_1 A + \theta_4 I$, then (32) will achieve FnTOSyn.

Its proof is similar to that in Theorem 7.

Next, we discuss classical type of synchronization, i.e., states of each nodes in the network are the same, here we call it finite time inner synchronization (FnTISyn), which is also the FnTSyn in the introduction.

C. FnTISyn using 2PM

In this case, synchronization trajectory $\phi(t)$ is a solution of an isolated node of (30),

$$\dot{\phi}(t) = f(\phi(t)), \quad (42)$$

where $\phi(t)$ can be a fixed point, a chaotic orbit, or others.

If $x_1(t) = \dots = x_N(t) = \phi(t)$ is a solution for network (30), then the following condition should hold:

$$\sum_{i=1}^N b_{ij} g(\phi(t - \pi_{ij}(t))) = 0 \quad (43)$$

In the literature of classical synchronization, condition (43) generally means the coupling relationships between node i and its neighbours, so its form can be transformed as: $\sum_{i=1}^N b_{ij} g(x_j(t - \pi_{ij}(t))) = \sum_{i=1}^N b_{ij} [g(x_j(t - \pi_{ij}(t))) - g(x_i(t - \pi_{ij}(t)))]$. Moreover, if network (30) itself can realize FnTISyn, then the outer synchronization can also convert into inner synchronization. As for the FnTISyn for networks with delay and without control, we will address this problem in other papers, here we omit it.

Now, consider the network (31) with external control, and define the error as $e_i(t) = y_i(t) - \phi(t)$, then its dynamics can be described as

$$\dot{e}_i(t) = f(y_i(t)) - f(\phi(t)) + \theta_1 \sum_{j=1}^N a_{ij} e_j(t) \quad (44)$$

$$+ \theta_2 \sum_{j=1}^N b_{ij} [g(y_j(t - \pi_{ij}(t))) - g(\phi(t - \pi_{ij}(t)))] + u_i(t)$$

where $u_i(t)$ can be defined in (33) (or (40)). Then, as a direct result of Theorem 7 (or Theorem 8), we have

Corollary 3. *If conditions (34) and (35) hold, then FnTISyn can be achieved for network (31).*

D. AFnTOSyn using 2PM

According to (34) and (35), one can see that the larger θ_1 and θ_3 , the faster AFnTOSyn can be achieved. Moreover, since in some cases, we cannot obtain the important parameters, even the network configuration. Next, we will apply the adaptive strategy on them and prove the validity of designed adaptive rules.

Theorem 9. *For the error system,*

$$\begin{aligned} \dot{e}_i(t) = & \tilde{f}(e_i(t)) + \theta_1(t) \sum_{j=1}^N \tilde{a}_{ij} e_j(t) \\ & + \theta_2 \sum_{j=1}^N b_{ij} \tilde{g}(e_j(t - \pi_{ij}(t))) - \theta_3(t) \text{sgn}(e_i(t)) \end{aligned} \quad (45)$$

with the following adaptive rule

$$\dot{\theta}_1(t) = \begin{cases} d_1 \mu(t) \sum_{i=1}^N e_i(t)^T e_i(t), \\ \text{if } \sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^N e_i(s)^T e_i(s) > 1 \\ d_2 \left(\sum_{i=1}^N e_i(t)^T e_i(t) \right)^{\frac{1}{2}}, & \text{otherwise} \end{cases} \quad (46)$$

and

$$\dot{\theta}_3(t) = \begin{cases} 0, & \text{if } \sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^N e_i(s)^T e_i(s) > 1 \\ 0, & \text{if } \sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^N e_i(s)^T e_i(s) = 0 \\ d_3, & \text{otherwise} \end{cases} \quad (47)$$

where parameters d_1, d_2, d_3 are any positive scalars, and the initial values are set to be $\theta_1(0) = \theta_3(0) = 0$. Then FnTOSyn can be realized.

Proof: With the same argument as that in Theorem 1, the time is considered from time T .

Phase I: Define a new Lyapunov function

$$\begin{aligned} \bar{V}_3(t) = & \mu(t) \sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \\ & + \frac{|\lambda_{\max}(\{\Xi \tilde{A}\}^s)|}{d_1} (\theta_1(t) - \theta_1^*)^2 \end{aligned} \quad (48)$$

and the function $\bar{W}_3(t) = \sup_{t-\pi(t) \leq s \leq t} \bar{V}_3(s)$.

Obviously, $\bar{V}_3(t) \leq \bar{W}_3(t)$, $t \geq T$. If there exists a point t_3 , $\bar{V}_3(t_3) = \bar{W}_3(t_3)$. Before differentiating, we discuss the limit of $c_4(t)$.

Similarly, with the same arguments in Theorem 2, if $\theta_1(t) > \theta_1^*$, $t > T^*$, where θ_1^* is a constant such that (34) holds, then FnTOSyn can be achieved from Theorem 7. Otherwise, if the limit of $\theta_1(t)$ is always bounded by θ_1^* , $(\theta_1(t) - \theta_1^*)^2$ would be a decreasing function, thus $\mu(t) \sum_{i=1}^N \xi_i e_i(t)^T e_i(t)$ must be the maximum value in the interval $[t - \pi(t), t]$. Now,

differentiating $\bar{V}_3(t)$, with the same process in Theorem 7, we have

$$\begin{aligned} & \dot{\bar{V}}_3(t) \\ & \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + 2L_f + \theta_2 \max_{i,j} |b_{ij}| N \varepsilon_1 + 2\theta_1^* \lambda_{\max}(\{\Xi \tilde{A}\}^s) \right. \\ & \quad \left. + \theta_2 \max_{i,j} |b_{ij}| N^2 n L_g^2 \varepsilon_1^{-1} \frac{1}{\min_i \xi_i} \frac{\mu(t)}{\mu(t - \pi(t))} \right] \bar{V}_1(t) \\ & < 0 \end{aligned}$$

Therefore,

$$\begin{aligned} \bar{W}_3(T) \geq \bar{W}_3(t) \geq & \sup_{t-\pi(t) \leq s \leq t} \mu(s) \sum_{i=1}^N \xi_i e_i(s)^T e_i(s) \\ & \geq \mu(t - \pi(t)) \sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^N \xi_i e_i(s)^T e_i(s), \end{aligned}$$

i.e., there is a time point $T_3 (\geq T)$ such that

$$\sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^N \xi_i e_i(s)^T e_i(s) \leq 1, \quad t \geq T_3 \quad (49)$$

Phase II: From (35), one can find a sufficiently large constant $\theta_3^* > 0$ and sufficiently small constant $\varepsilon_2^* > 0$, such that $\theta_2 \max_{i,j} |b_{ij}| N^{\frac{3}{2}} n^{\frac{1}{2}} d_2 - \theta_3^* + \varepsilon_2^* < 0$. Using this ε_2^* ,

$$\begin{aligned} \bar{V}_4(t) = & \left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{\frac{1}{2}} + \frac{|\lambda_{\max}(\{\Xi \tilde{A}\}^s)|}{2d_2} (\theta_1(t) - \theta_1^*)^2 \\ & + \frac{1}{2d_3} (\theta_3(t) - \theta_3^*)^2 + \varepsilon_2^* t, \quad t \geq T_3 \end{aligned} \quad (50)$$

and $\bar{W}_4(t) = \sup_{t-\pi(t) \leq s \leq t} \bar{V}_4(s)$, $t \geq T_3$. Similarly, $\bar{V}_4(t) \leq \bar{W}_4(t)$. If there exists a time point such that the equality holds. Similar discussions can be applied for $\theta_3(t)$ as that in $\theta_1(t)$, here we omit them. Differentiating $\bar{V}_4(t)$,

$$\begin{aligned} & \dot{\bar{V}}_4(t) \\ & \leq \varepsilon_2^* + \left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{-\frac{1}{2}} \\ & \quad \left[(L_f + \theta_1(t) \lambda_{\max}(\{\Xi \tilde{A}\}^s)) \sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right. \\ & \quad \left. + \theta_2 \sum_{i=1}^N \sum_{j=1}^N \xi_i e_i(t)^T b_{ij} \tilde{g}(e_j(t - \pi_{ij}(t))) \right. \\ & \quad \left. - \theta_3(t) \sum_{i=1}^N \xi_i e_i(t)^T \text{sgn}(e_i(t)) \right] \\ & \quad + (\theta_1(t) - \theta_1^*) |\lambda_{\max}(\{\Xi \tilde{A}\}^s)| \left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{\frac{1}{2}} \\ & \quad + (\theta_3(t) - \theta_3^*) \\ & \leq \varepsilon_2^* + (\theta_2 \max_{i,j} |b_{ij}| N^{\frac{3}{2}} n^{\frac{1}{2}} L_g - \theta_3^*) < 0 \end{aligned}$$

Therefore,

$$\left(\sum_{i=1}^N \xi_i e_i(t)^T e_i(t) \right)^{\frac{1}{2}} + \varepsilon_2^* t \leq \bar{V}_4(t) \leq \bar{W}_4(t) \leq \bar{W}_4(T_3)$$

$$\leq 1 + \varepsilon_2^* T_3 + \frac{|\lambda_{\max}(\{\Xi \tilde{A}\}^s)|(\theta_1^*)^2}{2d_2} + \frac{(\theta_3^*)^2}{2d_3},$$

i.e., $e_i(t) \equiv 0$ for any

$$t \geq T_4 = (\varepsilon_2^*)^{-1} \left[1 + \frac{|\lambda_{\max}(\{\Xi \tilde{A}\}^s)|(\theta_1^*)^2}{2d_2} + \frac{(\theta_3^*)^2}{2d_3} \right] + T_3$$

The proof is completed. \blacksquare

As a direct result of the above theorem, we have

Corollary 4. For the network (44) with control (33), under the adaptive rules (46) and (47), FnTISyn can be realized.

Remark 7. From the adaptive rule (46), one can see that the drive system (30) has been changed due to the change of θ_1 , therefore, if one requirement for outer synchronization is that the drive system cannot be changed, then one should use the other controller defined in (40).

Theorem 10. For the following error system under (40),

$$\dot{e}_i(t) = \tilde{f}(e_i(t)) + \theta_1 \sum_{j=1}^N a_{ij} e_j(t) \quad (51)$$

$$+ \theta_2 \sum_{j=1}^N b_{ij} \tilde{g}(e_j(t - \pi_{ij}(t))) - \theta_3(t) \text{sgn}(e_i(t)) - \theta_4(t) e_i(t)$$

with the following adaptive rules defined in (47) and

$$\dot{\theta}_4(t) = \begin{cases} d_1 \mu(t) \sum_{i=1}^N e_i(t)^T e_i(t), \\ \text{if } \sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^N e_i(s)^T e_i(s) > 1 \\ d_2 \left(\sum_{i=1}^N e_i(t)^T e_i(t) \right)^{\frac{1}{2}}, & \text{otherwise} \end{cases} \quad (52)$$

where parameters d_1, d_2, d_3 are any positive scalars, and the initial values are set to be $\theta_3(0) = \theta_4(0) = 0$. Then FnTOSyn can be realized.

This result can be proved similarly to that in Theorem 9.

IV. NUMERICAL SIMULATIONS

Next, we present two numerical examples to demonstrate the validity of our proposed 2PM.

A. FnTSta of system with delay

Example 1: Consider the simplest system:

$$\dot{p}(t) = p(t) + 2p(t - \pi(t)) - c_3 \text{sgn}(p(t)) - c_4 p(t) \quad (53)$$

where $p(t) \in \mathbb{R}$.

Let $\pi(t) = 0.5t$, then according to Corollary 1, $\mu(t) = t^\ell$, pick $\varrho = 0.1, \varepsilon_1 = 2^{0.05}$, then conditions (19) and (6) becomes

$$2(1 - c_4) + 4 \cdot 2^{0.05} < 0, \quad \text{and} \quad 2 - c_3 < 0 \quad (54)$$

so parameter c_4 should be larger than $1 + 2^{1.05} = 3.071$, and c_3 should be larger than 2.

Pick $c_3 = 2.1, c_4 = 3.5$, then Fig. 1 shows that FnTSta can be realized; Fig. 2 shows that under the same $c_3 = 2.1$, the larger c_4 , the smaller convergence time, and small c_4 may destroy its stability. Fig. 3 shows that under the same $c_4 = 3.5$, the larger c_3 , the smaller convergence time.

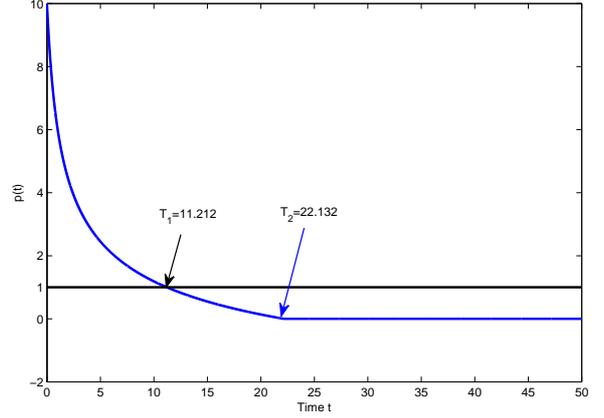

Fig. 1. FnTSta of system (53)

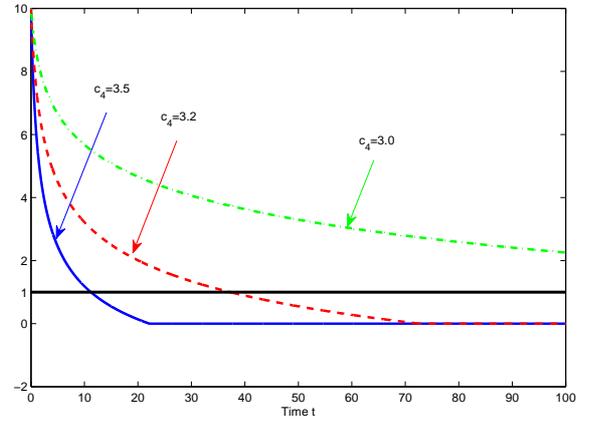

Fig. 2. FnTSta of system (53) under different c_4

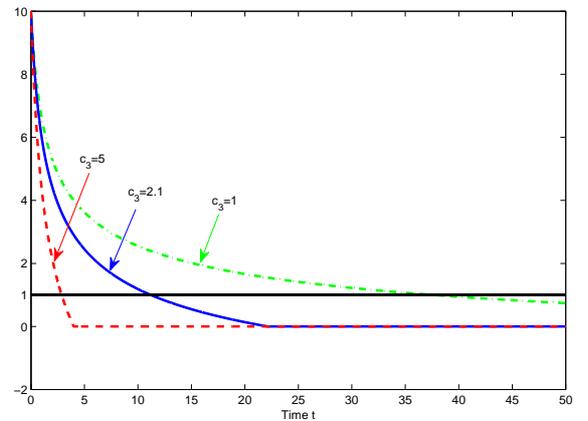

Fig. 3. FnTSta of system (53) under different c_3

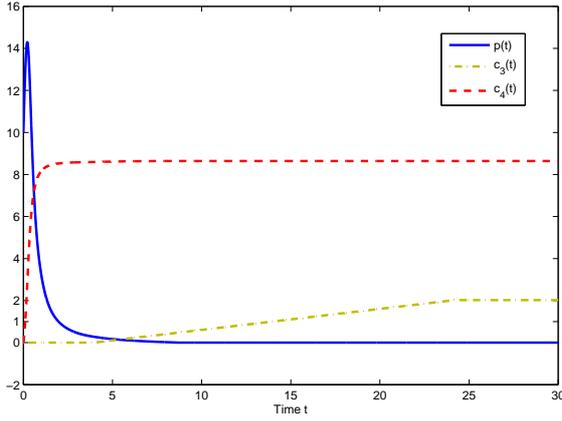

Fig. 4. The dynamics of $p(t)$, $c_3(t)$ and $c_4(t)$ for system (53) under adaptive rules (55) and (56)

Now, we apply the adaptive strategy to c_3 and c_4 in (53), where the adaptive rules are defined as

$$\dot{c}_3(t) = \begin{cases} 0, & \text{if } \sup_{0.5t \leq s \leq t} p(s)^2 > 1 \\ 0.1, & \text{if } \sup_{0.5t \leq s \leq t} p(s)^2 \leq 1 \\ 0, & \text{if } \sup_{0.5t \leq s \leq t} p(s)^2 = 0 \end{cases} \quad (55)$$

and

$$\dot{c}_4(t) = \begin{cases} 0.1t^{0.1}p(t)^2, & \text{if } \sup_{0.5t \leq s \leq t} p(s)^2 > 1 \\ 0.1|p(t)|, & \text{if } \sup_{0.5t \leq s \leq t} p(s)^2 \leq 1 \end{cases} \quad (56)$$

with $c_3(0) = c_4(0) = 0$, then according to Theorem 2, AFnTSta can be realized. Fig. 4 shows the dynamics of $p(t)$, $c_3(t)$ and $c_4(t)$, respectively. Moreover, since the time delay $\pi(t) = 0.5t$ is unbounded, and according to adaptive rules (55) and (56), the unchange of $c_3(t)$ and $c_4(t)$ has a long delay than the first time point t^* where $p(t^*) = 0$.

B. FnTOSyn of complex networks with delay

Example 2: Suppose the drive system is composed of three Lorenz oscillators,

$$\dot{x}_i(t) = f(x_i(t)) + 0.1 \sum_{j=1}^3 a_{ij}x_j(t) + \sum_{j=1}^3 b_{ij}g(x_j(t - \pi_{ij}(t))) \quad (57)$$

where $x_i(t) = (x_{i1}(t), x_{i2}(t), x_{i3}(t))^T$, the intrinsic function $f(x_i) : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ is described by:

$$\begin{pmatrix} 10(x_{i2}(t) - x_{i1}(t)) \\ 28x_{i1}(t) - x_{i2}(t) - x_{i1}(t)x_{i3}(t) \\ x_{i1}(t)x_{i2}(t) - 8x_{i3}(t)/3 \end{pmatrix},$$

the coupling matrix

$$A = (a_{ij}) = \begin{pmatrix} -5 & 2 & 3 \\ 1 & -4 & 3 \\ 1 & 2 & -3 \end{pmatrix},$$

$$B = (b_{ij}) = \begin{pmatrix} 1 & -1 & 1 \\ 1 & 1 & -1 \\ -1 & 1 & 1 \end{pmatrix},$$

the nonlinear function

$$g(x_i(t)) = \begin{pmatrix} \sin(x_{i1}(t)) + 2x_{i1}(t) \\ \sin(x_{i2}(t)) + 2x_{i2}(t) \\ \sin(x_{i3}(t)) + 2x_{i3}(t) \end{pmatrix},$$

and the asynchronous time delays are

$$\pi_{ij}(t) = 0.5(1 - 0.1 \cdot |\sin(i + 2j)|)t \leq \pi(t) = 0.5t,$$

and initial values are

$$\begin{aligned} x_1(0) &= (-1.5771, 0.5080, 0.2820)^T, \\ x_2(0) &= (0.0335, -1.3337, 1.1275)^T, \\ x_3(0) &= (0.3502, -0.2991, 0.0229)^T. \end{aligned}$$

The inner error among each node in the drive system (57) is measured by the following index:

$$\|E1(t)\| = \|x_2(t) - x_1(t)\|_2 + \|x_3(t) - x_1(t)\|_2 \quad (58)$$

Define the response system as:

$$\begin{aligned} \dot{y}_i(t) &= f(y_i(t)) + 0.1 \sum_{j=1}^3 a_{ij}y_j(t) + \sum_{j=1}^3 b_{ij}g(y_j(t - \tau_{ij}(t))) \\ &\quad + u_i(t) \end{aligned} \quad (59)$$

where $f(\cdot)$, A , B are defined as before. Its initial values are:

$$\begin{aligned} y_1(0) &= (-0.8479, -1.1201, 2.5260)^T, \\ y_2(0) &= (1.6555, 0.3075, -1.2571)^T, \\ y_3(0) &= (-0.8655, -0.1765, 0.7914)^T. \end{aligned}$$

The inner error among each node in the response system (59) is measured by the following index:

$$\|E2(t)\| = \|y_2(t) - y_1(t)\|_2 + \|y_3(t) - y_1(t)\|_2 \quad (60)$$

Moreover, as for the outer synchronization error between the drive system (57) and the response system (59), we use the following index:

$$\|E(t)\|_2 = \sqrt{\sum_{i=1}^3 [y_i(t) - x_i(t)]^T [y_i(t) - x_i(t)]} \quad (61)$$

When there is no controller, i.e., $u_i(t) = 0$, Fig. 5 (a) shows that nodes among the drive system are not synchronized, (b) shows that nodes among the response system are not synchronized, and (c) shows that outer synchronization is also not achieved.

Next, we apply the adaptive strategy to realize outer synchronization. The external controller $u_i(t)$ is defined by

$$u_i(t) = -\theta_3(t)\text{sgn}(e_i(t)) - \theta_4(t)e_i(t), \quad i = 1, 2, 3 \quad (62)$$

where $e_i(t) = y_i(t) - x_i(t)$, and the adaptive rules are

$$\dot{\theta}_3(t) = \begin{cases} 0.02, & \text{if } 0 < \sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^3 e_i(s)^T e_i(s) \leq 1 \\ 0, & \text{otherwise} \end{cases} \quad (63)$$

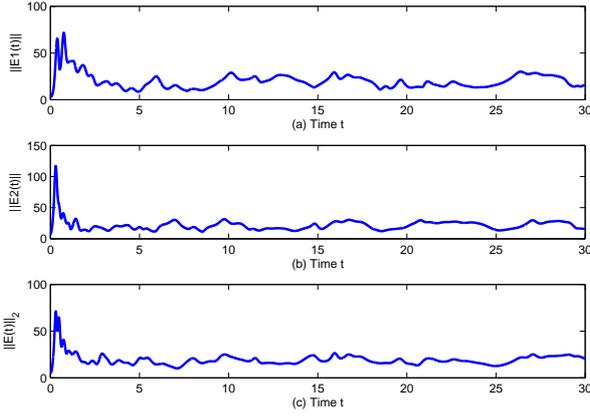

Fig. 5. The dynamics of $E_1(t)$, $E_2(t)$ and $\|E(t)\|_2$ under $u_i(t) = 0$

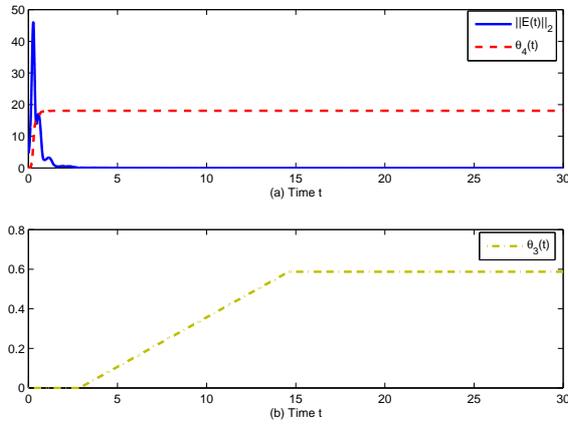

Fig. 6. The dynamics of $\|E(t)\|_2$, $\theta_3(t)$ and $\theta_4(t)$ under the controller (62) with adaptive rules (63) and (64)

and

$$\dot{\theta}_4(t) = \begin{cases} 0.05\mu(t) \sum_{i=1}^N e_i(t)^T e_i(t), \\ \text{if } \sup_{t-\pi(t) \leq s \leq t} \sum_{i=1}^3 e_i(s)^T e_i(s) > 1 \\ 0.05 \left(\sum_{i=1}^3 e_i(t)^T e_i(t) \right)^{\frac{1}{2}}, & \text{otherwise} \end{cases} \quad (64)$$

Fig. 6 shows that under the above defined adaptive controller, FnTOSyn can be finally realized.

V. CONCLUSION

In this paper, we concentrate our attention on FnTSta of delayed systems. Using our proposed 2PM, we design an external control with two terms, FnTSta is realized by using 2-norm, 1-norm, and ∞ -norm, respectively. The requirement of time delay is loose, which can be asynchronous and unbounded. Corresponding convergence rate is also defined using the function $\mu(t)$. AFnTSta is also proved using 2PM under our proposed adaptive rules. Moreover, we apply the obtained theoretical results on network outer synchronization, FnTOSyn and AFnTOSyn are also proved.

We hope this paper may shed some light on FnTSta for delayed systems. Further works include more applications of 2PM, such as FnTOSyn under intermittent control.

APPENDIX A: PROOF OF THEOREM 3

Proof: 2PM will be shown in the next proof procedure. If $\sup_{t-\pi(t) \leq s \leq t} \|p(s)\|_1 \leq 1, t \geq T$, then we will switch to Phase II directly; else, we will start from Phase I.

Phase I: Define a Lyapunov function

$$V_5(t) = \mu(t) \|p(t)\|_1 = \mu(t) \sum_{i=1}^m |p_i(t)| \quad (65)$$

and $W_5(t) = \sup_{t-\pi(t) \leq s \leq t} V_5(s)$. Obviously, $V_5(t) \leq W_5(t)$.

If $V_5(t) < W_5(t)$. Then there must exist a constant $\delta_5 > 0$ such that $V_5(s) \leq W_5(t)$ for $s \in (t, t + \delta_5)$, i.e., $W_5(s) = W_5(t)$ for $s \in (t, t + \delta_5)$.

Else if there exists a time $t_5 \geq T$, $V_5(t_5) = W_5(t_5)$, then

$$\begin{aligned} \dot{V}_5(t)|_{t=t_5} &= \dot{\mu}(t) \sum_{i=1}^m |p_i(t)| + \mu(t) \sum_{i=1}^m \text{sgn}(p_i(t)) \dot{p}_i(t) \\ &= \dot{\mu}(t) \sum_{i=1}^m |p_i(t)| + \mu(t) \sum_{i=1}^m \text{sgn}(p_i(t)) [c_1 p_i(t) \\ &\quad + c_2 p_i(t - \pi_i(t)) - c_3 \text{sgn}(p_i(t)) - c_4 p_i(t)] \\ &\leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + (c_1 - c_4) \right] V_5(t) + |c_2| \mu(t) \sum_{i=1}^m |p_i(t - \pi_i(t))| \\ &= \left[\frac{\dot{\mu}(t)}{\mu(t)} + (c_1 - c_4) \right] V_5(t) \\ &\quad + |c_2| \frac{\mu(t)}{\mu(t - \pi(t))} \sum_{i=1}^m \frac{\mu(t - \pi(t))}{\mu(t - \pi_i(t))} \mu(t - \pi_i(t)) |p_i(t - \pi_i(t))| \\ &\leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + (c_1 - c_4) + |c_2| m \frac{\mu(t)}{\mu(t - \pi(t))} \right] V_5(t) < 0 \end{aligned}$$

Therefore,

$$\begin{aligned} W_5(T) \geq W_5(t) &= \sup_{t-\pi(t) \leq s \leq t} \mu(s) \|p(s)\|_1 \\ &\geq \mu(t - \pi(t)) \sup_{t-\pi(t) \leq s \leq t} \|p(s)\|_1 \end{aligned}$$

i.e., there exists a point $T_5 (\geq T)$,

$$\sup_{t-\pi(t) \leq s \leq t} \|p(s)\|_1 \leq \frac{W_5(T)}{\mu(t - \pi(t))} \leq 1, \quad t \geq T_5$$

Phase II: From condition (6), we can find a sufficiently small constant $\varepsilon_2 > 0$, such that $m(|c_2| - c_3) + \varepsilon_2 < 0$. Using this ε_2 , we define another Lyapunov functional

$$V_6(t) = \|p(t)\|_1 + \varepsilon_2 t, \quad t \geq T_1 \quad (66)$$

and $W_6(t) = \sup_{t-\pi(t) \leq s \leq t} V_6(s), t \geq T_1$.

Obviously, $V_6(t) \leq W_6(t)$. If $V_6(t) < W_6(t)$, then there must exist a constant $\delta_6 > 0$ such that $V_6(s) \leq W_6(t)$ for $s \in (t, t + \delta_6)$, i.e., $W_6(s) = W_6(t)$ for $s \in (t, t + \delta_6)$.

Else if there exists a point $t_6 \geq T_5$, $V_6(t_6) = W_6(t_6)$. Differentiating $V_6(t)$ along (2), we have

$$\dot{V}_6(t)|_{t=t_6} = \sum_{i=1}^m \text{sgn}(p_i(t)) [c_1 p_i(t) + c_2 p_i(t - \pi_i(t))]$$

$$\begin{aligned}
& -c_3 \operatorname{sgn}(p_i(t)) - c_4 p_i(t) + \varepsilon_2 \\
\leq & (c_1 - c_4) \|p(t)\|_1 + |c_2| \sum_{i=1}^m |p_i(t - \pi_i(t))| - c_3 m + \varepsilon_2 \\
\leq & m(|c_2| - c_3) + \varepsilon_2 < 0
\end{aligned}$$

Therefore,

$$\begin{aligned}
& \|p(t)\|_1 + \varepsilon_2 t = V_6(t) \leq W_6(t) \leq W_6(T_5) \\
& = \sup_{T_5 - \pi(T_5) \leq s \leq T_5} \left(\|p(s)\|_1 + \varepsilon_2 s \right) \leq 1 + \varepsilon_2 T_5
\end{aligned}$$

so $\|p(t)\|_1 \leq 1 - \varepsilon_2(t - T_5)$, i.e., $p(t) \equiv 0$ for any $t \geq T_6 = T_5 + 1/\varepsilon_2$. ■

APPENDIX B: PROOF OF THEOREM 4

Because of page limit, here we just present corresponding functions, details can be added according to the procedure in Theorem 2 and calculations in Theorem 3.

Phase I: Choose

$$\bar{V}_5(t) = \mu(t) \|p(t)\|_1 + \frac{1}{2d_2} (c_4(t) - c_4^*)^2$$

whose derivative satisfies

$$\dot{\bar{V}}_5(t) \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + (c_1 - c_4^*) + |c_2| m \frac{\mu(t)}{\mu(t - \pi(t))} \right] V_5(t) < 0$$

Phase II: Choose

$$\begin{aligned}
& \bar{V}_6(t) \\
& = \|p(t)\|_1 + \frac{1}{2d_1} (c_3(t) - c_3^*)^2 + \frac{1}{2d_3} (c_4(t) - c_4^*)^2 + \varepsilon_2^* t
\end{aligned}$$

whose derivative satisfies

$$\dot{\bar{V}}_6(t) \leq (c_1 - c_4^*) \|p(t)\|_1 + m(|c_2| - c_3^*) + \varepsilon_2^* < 0.$$

APPENDIX C: PROOF OF THEOREM 5

Proof: 2PM will be shown in the next proof procedure.

If $\sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_1 \leq 1, t \geq T$, then we will switch to Phase II directly; else, we will start from Phase I.

Phase I: Define a Lyapunov function

$$V_7(t) = \mu(t) \|p(t)\|_\infty = \mu(t) \max_{i=1, \dots, m} |p_i(t)| \quad (67)$$

and $W_7(t) = \sup_{t - \pi(t) \leq s \leq t} V_7(s)$. $V_7(t) \leq W_7(t), t \geq T$.

If $V_7(t) < W_7(t)$. Then there must exist a constant $\delta_7 > 0$ such that $V_7(s) \leq W_7(t)$ for $s \in (t, t + \delta_7)$, i.e., $W_7(s) = W_7(t)$ for $s \in (t, t + \delta_7)$.

Else if there exists a point $t_7 \geq T$, $V_7(t_7) = W_7(t_7)$, for this time t_7 , we suppose that $|p_{i^\circ}(t_7)| = \max_{i=1, \dots, m} |p_i(t_7)|$. Then

$$\begin{aligned}
& \dot{V}_7(t)|_{t=t_7} = \dot{\mu}(t) |p_{i^\circ}(t)| + \mu(t) \operatorname{sgn}(p_{i^\circ}(t)) \dot{p}_{i^\circ}(t) \\
& = \dot{\mu}(t) |p_{i^\circ}(t)| + \mu(t) \operatorname{sgn}(p_{i^\circ}(t)) [c_1 p_{i^\circ}(t) \\
& \quad + c_2 p_{i^\circ}(t - \pi_{i^\circ}(t)) - c_3 \operatorname{sgn}(p_{i^\circ}(t)) - c_4 p_{i^\circ}(t)] \\
& \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + (c_1 - c_4) + |c_2| \frac{\mu(t)}{\mu(t - \tau(t))} \right] V_7(t) < 0
\end{aligned}$$

Therefore,

$$W_7(T) \geq W_7(t) = \sup_{t - \pi(t) \leq s \leq t} \mu(s) \|p(s)\|_\infty$$

$$\geq \mu(t - \pi(t)) \sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_\infty$$

i.e., there exists a point $T_7 (\geq T)$,

$$\sup_{t - \pi(t) \leq s \leq t} \|p(s)\|_\infty \leq \frac{W_7(T)}{\mu(t - \pi(t))} \leq 1, \quad t \geq T_7$$

Phase II: From condition (6), we can find a sufficiently small constant $\varepsilon_2 > 0$, such that $(|c_2| - c_3) + \varepsilon_2 < 0$. Using this ε_2 , we define another Lyapunov function

$$V_8(t) = \|p(t)\|_\infty + \varepsilon_2 t, \quad t \geq T_7 \quad (68)$$

and $W_8(t) = \sup_{t - \pi(t) \leq s \leq t} V_8(s), t \geq T_7$.

Similarly, $V_8(t) \leq W_8(t)$. If $V_8(t) < W_8(t)$, then there must exist a constant $\delta_8 > 0$ such that $V_8(s) \leq W_8(t)$ for $s \in (t, t + \delta_8)$, i.e., $W_8(s) = W_8(t)$ for $s \in (t, t + \delta_8)$.

Else if there exists a point $t_8 \geq T_7$, $V_8(t_8) = W_8(t_8)$, for this time t_8 , we suppose that $p_{i^\circ}(t_8) = \max_{i=1, \dots, m} p_i(t_8)$. Differentiating $V_8(t)$ along (2), we have

$$\begin{aligned}
& \dot{V}_8(t)|_{t=t_8} = \operatorname{sgn}(p_{i^\circ}(t)) [c_1 p_{i^\circ}(t) + c_2 p_{i^\circ}(t - \pi_{i^\circ}(t)) \\
& \quad - c_3 \operatorname{sgn}(p_{i^\circ}(t)) - c_4 p_{i^\circ}(t)] + \varepsilon_2 \leq (|c_2| - c_3) + \varepsilon_2 < 0
\end{aligned}$$

Therefore,

$$\begin{aligned}
& \|p(t)\|_\infty + \varepsilon_2 t = V_8(t) \leq W_8(t) \leq W_8(T_7) \\
& = \sup_{T_7 - \pi(T_7) \leq s \leq T_7} \left(\|p(s)\|_\infty + \varepsilon_2 s \right) \leq 1 + \varepsilon_2 T_7
\end{aligned}$$

so $\|p(t)\|_\infty \leq 1 - \varepsilon_2(t - T_7)$, i.e., $p(t) \equiv 0$ for any $t \geq T_8 = T_7 + 1/\varepsilon_2$. The proof is completed. ■

APPENDIX D: PROOF OF THEOREM 6

Because of page limit, here we just present corresponding functions, details can be added according to the procedure in Theorem 2 and calculations in Theorem 5.

Phase I: Choose

$$\bar{V}_7(t) = \mu(t) \|p(t)\|_\infty + \frac{1}{2d_2} (c_4(t) - c_4^*)^2$$

whose derivative satisfies

$$\dot{\bar{V}}_7(t) \leq \left[\frac{\dot{\mu}(t)}{\mu(t)} + (c_1 - c_4^*) + |c_2| \frac{\mu(t)}{\mu(t - \pi(t))} \right] V_7(t) < 0$$

Phase II: Choose

$$\begin{aligned}
& \bar{V}_8(t) \\
& = \|p(t)\|_\infty + \frac{1}{2d_1} (c_3(t) - c_3^*)^2 + \frac{1}{2d_3} (c_4(t) - c_4^*)^2 + \varepsilon_2^* t
\end{aligned}$$

whose derivative satisfies

$$\dot{\bar{V}}_8(t) \leq (c_1 - c_4^*) \|p(t)\|_\infty + (|c_2| - c_3^*) + \varepsilon_2^* < 0.$$

ACKNOWLEDGMENT

The author would give thanks to Han Zhang, Weijin Liu, Zihan Li and Hailian Ma for their beneficial discussions.

Xiwei Liu (M'14, SM'17) received the Ph.D. degree in applied mathematics from Fudan University, Shanghai, China, in 2008. He was a Post-Doctoral Researcher with the Department of Physics, Fudan University, from 2008 to 2010. Then, he joined the Department of Computer Science and Technology, Tongji University, Shanghai. He has been a Professor with the Department of Computer Science and Technology, Tongji University since Dec. 2016. His current research interests include nonlinear dynamical systems, complex networks, and neural networks.

He is a recipient of Natural Science Award from Ministry of Education of China in 2015.

He is currently an Associate Editor of *Neurocomputing*.
