# Mass prediction for the last discovered member of the axial-vector nonet with quantum numbers $\mathbf{J}^{P C}=1^{+-*}$ 

M.V. Chizhov ${ }^{1}$ and M.N. Naydenov ${ }^{1}$<br>${ }^{1}$ Department of Atomic Physics, Faculty of Physics, Sofia University, 1164 Sofia, Bulgaria

In this paper we have shown that the novel mass relation among the vector states, $\phi(1020)$ and $\phi(1680)$, with quantum numbers $\mathrm{J}^{P C}=1^{--}$and axial-vector strangeonium state $h_{1}(s \bar{s})$ with quantum numbers $1^{+-}$is also valid for nonzero current quark mass. This relation predicts the mass of recently discovered $h_{1}(s \bar{s})$ state by the Collaboration BESIII within experimental accuracy.

Keywords: Nambu-Jona-Lasinio model, mass relation

[^0]
## I. INTRODUCTION

It is known that there exist the two lowest-lying axial-vector nonets of meson states with quantum numbers for their neutral components $\mathrm{J}^{P C}=1^{++}$and $1^{+-}$. The first nonet, " $A$ ", includes isotriplet of $a_{1}$ mesons, two isodoublets of $K_{1 A}$ strange mesons and two isosinglet states $f_{1}$. The second nonet, " $B$ ", consists of isotriplet of $b_{1}$ mesons $^{1}$, two isodoublets of $K_{1 B}$ strange mesons and two isosinglet states $h_{1}$.

The two isosinglets of spin- 1 states have nearly pure $u \bar{u}+d \bar{d}$ and $s \bar{s}$ structures. There is still discussion about identification of the two $f_{1}$ states among three observed resonances $f_{1}(1285), f_{1}(1420)$ and $f_{1}(1510)$. While identification of the last from two $h_{1}(1170)$ and $h_{1}(1415)$ states has been established in last two years. The Collaboration BESIII discovered axial-vector strangeonium state $h_{1}(s \bar{s})$ [1, 2] and confirmed its previous observations by two collaborations LASS [3] and Crystal Barrel [4].

There is interesting situation with the measured and the predicted mass of the axialvector strangeonium state with quantum numbers $1^{+-}$. For the first time this state has been observed by the Collaboration LASS in 1988 with mass $m_{h_{1}(s \bar{s})}^{\text {LASS }}=(1380 \pm 20) \mathrm{MeV}$. Therefore, this state got the name $h_{1}(1380)$. The latest measurements by the Collaboration BESIII $m_{h_{1}(s \bar{s})}^{\mathrm{BESIII}}=(1423.2 \pm 2.1 \pm 7.3) \mathrm{MeV}$ and PDG average $m_{h_{1}(s \bar{s})}^{\mathrm{PDG}}=(1416 \pm 8) \mathrm{MeV}$ [5] required changing the name of this resonance to $h_{1}(1415)$ in the last year. However, there was no accurate prediction of the mass of this state among cited theoretical papers in the first version of BESIII publication [1]. The precise prediction of $h_{1}(s \bar{s})$ mass $m_{h_{1}(s \bar{s})}^{\text {theor }}=(1415 \pm 13) \mathrm{MeV}$ has been given in 2003 in the paper [6].

The detail consideration of this prediction and new investigation will be presented below.

## II. THE MODEL

Explanation of the spontaneous chiral symmetry breaking [7] and the introduction of quarks [8, 9] give us a principal possibility to describe the whole variety of the light hadron states, in particular the quark-antiquark meson states. The most theoretically and experimentally well studied is the nonet of pseudoscalar mesons, which arise as pseudo-Goldstone

[^1]bosons in result of spontaneous and explicit chiral symmetry breaking. The properties of pseudoscalar nonet can be accurately investigated using Nambu - Jona-Lasinio (NJL) model [10] or chiral perturbation theory [11]. Meanwhile, theoretical and experimental situation with identification and explaning properties of members of scalar nonet as quarkantiquark states is unsatisfactory.

In this paper we consider a model for spin- 1 nonets in the framework of paper [6]. It is well known, that besides the two considered lowest-lying axial-vector nonets, a nonet of vector mesons exists. The latest consists of isotriplet $\rho$ mesons, two isodoublets $K^{*}$ mesons and two isosinglets $\omega$ and $\phi$ with quantum numbers $1^{--}$, which have nearly pure $u \bar{u}+d \bar{d}$ and $s \bar{s}$ structures, correspondingly. So, there is an obvious asymmetry between the numbers of axial-vector and vector nonets.

In paper [6] in the framework of extended $\mathrm{U}(1)$ massless quark NJL model a new approach to restoring the symmetry has been suggested. In this way new mass relations among spin-1 mesons from different nonets have been derived, which are confirmed experimentally. The basic idea was in the consideration of all possible Lorentz invariant local Yukawa interactions between quark currents: $\bar{\psi} \psi, \bar{\psi} \gamma^{5} \psi, \bar{\psi} \gamma_{\mu} \psi, \bar{\psi} \gamma_{\mu} \gamma^{5} \psi, \bar{\psi} \sigma_{\mu \nu} \psi$ and the corresponding meson fields $S, P, V_{\mu}, A_{\mu}, T_{[\mu \nu]}^{2}$ with quantum numbers $0^{++}, 0^{-+}, 1^{--}, 1^{++},\left(1^{--}, 1^{+-}\right)$. The quark current $\bar{\psi} \sigma_{\mu \nu} \psi$ and the corresponding second-rank antisymmetric tensor field $T_{[\mu \nu]}$ possess two types of different quantum numbers: $1^{--}$and $1^{+-}$. On the mass-shell $T_{[\mu \nu]}$ can be decomposed into vector, $R_{\mu}$, and axial-vector, $B_{\mu}$, fields

$$
\begin{equation*}
T_{[\mu \nu]}=\left(\hat{\partial}_{\mu} R_{\nu}-\hat{\partial}_{\nu} R_{\mu}\right)-\frac{1}{2} \epsilon_{\mu \nu \alpha \beta}\left(\hat{\partial}^{\alpha} B^{\beta}-\hat{\partial}^{\beta} B^{\alpha}\right) \tag{1}
\end{equation*}
$$

with corresponding quantum numbers $1^{--}$and $1^{+-}$. Here we introduce the definition $\hat{\partial}_{\mu}=$ $\partial_{\mu} / \sqrt{-\partial^{2}}$. Vice versa the $R_{\mu}$ and $B_{\mu}$ fields can be expressed through $T_{[\mu \nu]}$ :

$$
\begin{equation*}
R_{\mu}=\hat{\partial}^{\nu} T_{[\mu \nu]}, \quad B_{\mu}=\frac{1}{2} \epsilon_{\mu \nu \alpha \beta} \hat{\partial}^{\nu} T^{[\alpha \beta]}, \tag{2}
\end{equation*}
$$

which due to antisymmetry of $T_{[\mu \nu]}$ obey the obvious identities

$$
\begin{equation*}
\partial^{\mu} R_{\mu} \equiv 0, \quad \partial^{\mu} B_{\mu} \equiv 0 \tag{3}
\end{equation*}
$$

Therefore, the existing $h_{1}(s \bar{s})$ meson with quantum numbers $1^{+-}$from axial-vector " $B$ " nonet can be described by axial-vector field $B_{\mu}$ and requires the inclusion in the model the

[^2]quark current $\bar{\psi} \sigma_{\mu \nu} \psi$ and the corresponding second-rank antisymmetric tensor field $T_{[\mu \nu]}$. Since the two vector fields $V_{\mu}$ and $R_{\mu}$ have the same quantum numbers $1^{--}$they could mix, which leads to the two physical states, $\phi$ and $\phi^{\prime}$ for $\mathrm{U}(1) s \bar{s}$ quark structure. So, extending this suggestion to $\mathrm{U}(3)$ model, it can be proposed that the lowest-lying vector nonet of physical states with quantum numbers $1^{--}$is produced from a mixing of vector and tensor nonets, similar to the two $K_{1}(1270)$ and $K_{1}(1400)$ physical states, which are superpositions of $K_{1 A}$ and $K_{1 B}$ states from the corresponding axial-vector nonets.

The new relation between the masses of $\phi(1020), \phi^{\prime}=\phi(1680)$ and $h_{1}(s \bar{s})$ physical states 6]

$$
\begin{equation*}
2 m_{\phi}^{2}-m_{\phi} m_{\phi^{\prime}}+2 m_{\phi^{\prime}}^{2}=3 m_{h_{1}(s \bar{s})}^{2} \tag{4}
\end{equation*}
$$

which predicts the mass of undiscovered then $h_{1}(s \bar{s})$ state, has been obtained in approximation of zero current quark mass. However, it can be rather applied to $\omega(782), \omega^{\prime}=\omega(1650)$ and $h_{1}(1170)$ physical states, which consist of the light $u$ and $d$ quarks. Therefore, to confirm the relation (4), here we investigate the case of nonzero current quark mass $m_{0}$.

In order to obtain relation (4) we consider only interactions of vector, $V_{\mu}$, tensor, $T_{[\mu \nu]}$, and scalar, $S$, fields with the field of strange quark, $\psi$. Linearized NJL Lagrangian with auxiliary (without kinetic terms) boson fields, has the form

$$
\begin{align*}
\mathcal{L}_{0}=\bar{\psi}\left(\not q-m_{0}\right) \psi & +g_{S} \bar{\psi} \psi S-\frac{\mu_{S}^{2}}{2} S^{2}+g_{V} \bar{\psi} \gamma^{\mu} \psi V_{\mu}+\frac{\mu_{V}^{2}}{2} V_{\mu}^{2} \\
& +\frac{g_{T}}{2} \bar{\psi} \sigma^{\mu \nu} \psi T_{[\mu \nu]}+\frac{\mu_{T}^{2}}{4}\left(4 \hat{\partial}^{\mu} T_{[\lambda \mu]} \hat{\partial}_{\nu} T^{[\lambda \nu]}-T_{[\mu \nu]} T^{[\mu \nu]}\right) \tag{5}
\end{align*}
$$

where $\mu_{S}^{2}, \mu_{V}^{2}$ and $\mu_{T}^{2}$ are bare mass terms ${ }^{3}$. Using relations (1]|2[3) the last line in eq. (5) can be rewritten as

$$
\begin{equation*}
g_{T} \bar{\psi} \sigma^{\mu \nu} \psi \hat{\partial}_{\mu} R_{\nu}+i g_{T} \bar{\psi} \sigma^{\mu \nu} \gamma^{5} \psi \hat{\partial}_{\mu} B_{\nu}+\frac{\mu_{T}^{2}}{2}\left(R_{\mu}^{2}+B_{\mu}^{2}\right) \tag{6}
\end{equation*}
$$

The corresponding Feynman diagrams are presented in Fig. 1 .

[^3]Figure 1: Feynman diagrams for Yukawa interactions. Here $\hat{q}_{\mu}=q_{\mu} / \sqrt{q^{2}}$, where $q_{\mu}$ is incoming four-momentum of $R_{\mu}$ and $B_{\mu}$ states.

## III. QUANTUM CORRECTIONS AND SYMMETRY BREAKING

Kinetic terms for the meson fields can be obtained through radiative quantum corrections. Let's calculate one-loop self-energy contributions for all the boson fields. For example, the contribution from the self-energy diagram of the scalar field (Fig. 2a) has the form

(a)

(b)

Figure 2: Quantum corrections to the self-energy part (a) and the self-interactions (b,c) of the scalar fields.

$$
\begin{align*}
\Pi^{S S}(q) & =i g_{S}^{2} N_{C} \int \frac{\mathrm{~d}^{4} p}{(2 \pi)^{4}} \operatorname{Tr}\left[\left(p-m_{0}\right)^{-1}\left(p-\not q-m_{0}\right)^{-1}\right] \\
& =4 i g_{S}^{2} N_{C} \int \frac{\mathrm{~d}^{4} p}{(2 \pi)^{4}} \frac{1}{p^{2}-m_{0}^{2}}-2 i g_{S}^{2} N_{C} \int \frac{\mathrm{~d}^{4} p}{(2 \pi)^{4}} \frac{q^{2}-4 m_{0}^{2}}{\left(p^{2}-m_{0}^{2}\right)^{2}}+\text { finite terms } \\
& =4 g_{S}^{2} N_{C} I_{2}-8 g_{S}^{2} N_{C} m_{0}^{2} I_{0}+2 g_{S}^{2} N_{C} I_{0} q^{2}+\text { finite terms }, \tag{7}
\end{align*}
$$

where

$$
\begin{equation*}
I_{2} \equiv i \int \frac{\mathrm{~d}^{4} p}{(2 \pi)^{4}} \frac{1}{p^{2}-m_{0}^{2}}=\int \frac{\mathrm{d}^{4} p_{E}}{(2 \pi)^{4}} \frac{1}{p_{E}^{2}+m_{0}^{2}}>0 \tag{8}
\end{equation*}
$$

is the quadratically divergent integral and

$$
\begin{equation*}
I_{0} \equiv-i \int \frac{\mathrm{~d}^{4} p}{(2 \pi)^{4}} \frac{1}{\left(p^{2}-m_{0}^{2}\right)^{2}}=\int \frac{\mathrm{d}^{4} p_{E}}{(2 \pi)^{4}} \frac{1}{\left(p_{E}^{2}+m_{0}^{2}\right)^{2}}>0 \tag{9}
\end{equation*}
$$

is the logarithmically divergent integral.
The first two terms in the last line of eq. (77) give contribution into the mass term of the scalar field $m_{S}^{2}=\mu_{S}^{2}+4 g_{S}^{2} N_{C}\left(2 m_{0}^{2} I_{0}-I_{2}\right)$. The third term indicates the appearance of the kinetic term. To normalize the scalar field wave function correctly, we must require fulfillment of the condition

$$
\begin{equation*}
2 g_{S}^{2} N_{C} I_{0}=1 \tag{10}
\end{equation*}
$$

Applying the similar procedure to all boson fields introduced in (5) and (6)

$$
\begin{gather*}
\Pi_{\mu \nu}^{V V}=\frac{4}{3} g_{V}^{2} N_{C} I_{0}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)-2 g_{V}^{2} N_{C}\left(m_{0}^{2} I_{0}+I_{2}\right) g_{\mu \nu}+\text { finite terms },  \tag{11}\\
\Pi_{\mu \nu}^{V R}=4 g_{V} g_{T} N_{C} I_{0} \frac{m_{0}}{\sqrt{q^{2}}}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+\text { finite terms }  \tag{12}\\
\Pi_{\mu \nu}^{R R}=\frac{2}{3} g_{T}^{2} N_{C} I_{0}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+4 g_{T}^{2} N_{C} I_{0} \frac{m_{0}^{2}}{q^{2}}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+\text { finite terms },  \tag{13}\\
\Pi_{\mu \nu}^{B B}=  \tag{14}\\
\frac{2}{3} g_{T}^{2} N_{C} I_{0}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)-4 g_{T}^{2} N_{C} I_{0} \frac{m_{0}^{2}}{q^{2}}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+\text { finite terms },
\end{gather*}
$$

the following useful relations among various Yukawa coupling constants from normalization of kinetic terms are obtained:

$$
\begin{equation*}
3 g_{S}^{2}=2 g_{V}^{2}=g_{T}^{2}=\frac{3}{2 N_{C} I_{0}} \tag{15}
\end{equation*}
$$

In other words, due to the dynamic origin of the kinetic terms, all interactions in the model are described by only one coupling constant, for example, $g=g_{S}$.

The self-interactions in Fig. 2(b,c) lead to the following effective potential for the scalar field

$$
\begin{equation*}
V_{\mathrm{eff}}=\frac{m_{S}^{2}}{2} S^{2}-2 g m_{0} S^{3}+\frac{g^{2}}{2} S^{4} \tag{16}
\end{equation*}
$$

The extremum condition

$$
\begin{equation*}
\left.\frac{\mathrm{d} V_{\mathrm{eff}}}{\mathrm{~d} S}\right|_{S=\langle S\rangle}=m_{S}^{2}\langle S\rangle-6 g m_{0}\langle S\rangle^{2}+2 g^{2}\langle S\rangle^{3}=0 \tag{17}
\end{equation*}
$$

at negative $m_{S}^{2}$ leads always to the absolute minimum of the effective potential with nontrivial solution $g\langle S\rangle=\left(3 m_{0}-\sqrt{9 m_{0}^{2}-2 m_{S}^{2}}\right) / 2<0$. It corresponds to the spontaneous symmetry breaking, which provides the strange quark with positive constituent mass

$$
\begin{equation*}
m_{s}=m_{0}-g\langle S\rangle>0 \tag{18}
\end{equation*}
$$

It also leads to additional contributions to mass terms and mixing between vector bosons (Fig. (3).

There are no additional contribution to the mass of the vector field $V_{\mu}, m_{V}^{2}=\mu_{V}^{2}-$ $2 g_{V}^{2} N_{C}\left(m_{0}^{2} I_{0}+I_{2}\right)$, while its mixing (12) with the vector field $R_{\mu}$ gets such contribution after symmetry breaking

$$
\begin{equation*}
\Delta \Pi_{\mu \nu}^{V R}=-4 g_{V} g_{T} N_{C} I_{0} \frac{g\langle S\rangle}{\sqrt{q^{2}}}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+\text { finite terms } \tag{19}
\end{equation*}
$$

Figure 3: Quantum contributions to the mass terms and mixing between vector bosons after spontaneous symmetry breaking. Here the double lines correspond simultaneously to any of the $R_{\mu}$ or $B_{\mu}$ bosons.
in such a way that it depends only on physical constituent mass of the strange quark:

$$
\begin{equation*}
\Pi_{\mu \nu}^{V R}+\Delta \Pi_{\mu \nu}^{V R}=\sqrt{\frac{18 m_{s}^{2}}{q^{2}}}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+\text { finite terms } \tag{20}
\end{equation*}
$$

In its turn $R_{\mu}$ and $B_{\mu}$ fields get additional contributions

$$
\begin{align*}
\Delta \Pi_{\mu \nu}^{R R} & =4 g_{T}^{2} N_{C} I_{0} \frac{g^{2}\langle S\rangle^{2}-2 m_{0} g\langle S\rangle}{q^{2}}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+\text { finite terms }  \tag{21}\\
\Delta \Pi_{\mu \nu}^{B B} & =-4 g_{T}^{2} N_{C} I_{0} \frac{g^{2}\langle S\rangle^{2}-2 m_{0} g\langle S\rangle}{q^{2}}\left(q_{\mu} q_{\nu}-q^{2} g_{\mu \nu}\right)+\text { finite terms } \tag{22}
\end{align*}
$$

to their mass terms $m_{R}^{2}=\mu_{T}^{2}-4 g_{T}^{2} N_{C} I_{0}\left(m_{0}^{2}+g^{2}\langle S\rangle^{2}-2 m_{0} g\langle S\rangle\right)=\mu_{T}^{2}-6 m_{s}^{2}$ and $m_{B}^{2}=$ $\mu_{T}^{2}+4 g_{T}^{2} N_{C} I_{0}\left(m_{0}^{2}+g^{2}\langle S\rangle^{2}-2 m_{0} g\langle S\rangle\right)=\mu_{T}^{2}+6 m_{s}^{2}$, which also depend on the physical constituent mass of strange quark.

As a result the effective Lagrangian for the spin-1 bosons has the form

$$
\mathcal{L}_{\text {eff }}=-\frac{1}{2}\left(\begin{array}{ll}
V_{\mu} & R_{\mu}
\end{array}\right)\left(\begin{array}{cc}
q^{2}-m_{V}^{2} & \sqrt{18 m_{s}^{2} q^{2}}  \tag{23}\\
\sqrt{18 m_{s}^{2} q^{2}} & q^{2}-m_{B}^{2}+12 m_{s}^{2}
\end{array}\right)\binom{V^{\mu}}{R^{\mu}}-\frac{1}{2} B_{\mu}\left(q^{2}-m_{B}^{2}\right) B^{\mu}
$$

In paper [6] it has been shown that the masses of spin-1 isovector states $\rho, \rho^{\prime}=\rho(1450)$, $b_{1}$ and spin- 1 light isosinglets $\omega, \omega^{\prime}, h_{1}(1170)$ correspond to the hypothesis of the maximal mixing between $V_{\mu}$ and $R_{\mu}$ states. It leads to the additional constraint

$$
\begin{equation*}
m_{V}^{2}=m_{B}^{2}-12 m_{s}^{2} \tag{24}
\end{equation*}
$$

Zeros of determinant of the matrix between $\left(V_{\mu} R_{\mu}\right)^{T}$ doublets correspond to the masses for the physical $\phi$ and $\phi^{\prime}$ bosons, while $h_{1}(s \bar{s})$ meson has $m_{B}$ mass. Using Vieta's formulas

$$
\begin{equation*}
m_{\phi}^{2}+m_{\phi^{\prime}}^{2}=2\left(m_{V}^{2}+9 m_{s}^{2}\right), \quad m_{\phi} m_{\phi^{\prime}}=m_{V}^{2} \tag{25}
\end{equation*}
$$

for quadratic equation $\left(q^{2}\right)^{2}-2\left(m_{V}^{2}+9 m_{s}^{2}\right) q^{2}+m_{V}^{4}=0$ and relation (24) we have reproduced the mass formula (4) without the assumption of initial massless quarks.

## IV. CONCLUSION

In this paper we have shown that novel mass relation (4) for $U(1)$ case of the strange quark with nonzero current mass, $m_{0}$, has the same form as for initially massless quark. Therefore, the prediction of the mass of axial-vector strangeonium state $h_{1}(s \bar{s})$ with quantum numbers $1^{+-}$in [6] is valid. This is also confirmed experimentally by the Collaboration BESIII [2].
