DYNAMICAL ZETA FUNCTIONS FOR GEODESIC FLOWS AND THE HIGHER-DIMENSIONAL REIDEMEISTER TORSION FOR FUCHSIAN GROUPS

YOSHIKAZU YAMAGUCHI

Abstract. We show that the absolute value at zero of the Ruelle zeta function defined by the geodesic flow coincides with the higher-dimensional Reidemeister torsion for the unit tangent bundle over a 2-dimensional hyperbolic orbifold and a non-unitary representation of the fundamental group. Our proof is based on the integral expression of the Ruelle zeta function. This integral expression is derived from the functional equation of the Selberg zeta function for a discrete subgroup with elliptic elements in \( \text{PSL}_2(\mathbb{R}) \). We also show that the asymptotic behavior of the higher-dimensional Reidemeister torsion is determined by the contribution of the identity element to the integral expression of the Ruelle zeta function.

1. Introduction

We study the Ruelle zeta function defined for a dynamical system called the geodesic flow on the unit tangent bundle over a 2-dimensional hyperbolic orbifold and the relation to the Reidemeister torsion for the unit tangent bundle with non-unitary representations of the fundamental group. Here a 2-dimensional hyperbolic orbifold means the quotient of the hyperbolic plane by a discrete subgroup of the orientation preserving isometry group, which is called a Fuchsian group. The Ruelle zeta function is closely related to another zeta function called the Selberg zeta function defined for a discrete subgroup of \( \text{PSL}_2(\mathbb{R}) = \text{SL}_2(\mathbb{R})/\{+1, -1\} \). The values of the Ruelle zeta function have been studied by using the functional equation of the Selberg zeta function. In particular, it has been revealed that the (absolute) value at zero of the Ruelle zeta function determines the analytic torsion or the Reidemeister torsion of a manifold with an acyclic local system given by a unitary representation of the fundamental group. We refer the readers to the article [She18] by S. Shen and the references given there on those developments.

In this paper, we consider the Ruelle zeta functions and the Reidemeister torsions defined for the unit tangent bundle \( S(T\Sigma) \) over a 2-dimensional hyperbolic orbifold \( \Sigma \) and a sequence of \( \text{SL}_n(\mathbb{C}) \)-representations of the fundamental group \( \pi_1(S(T\Sigma)) \). This study is motivated by the work [Müll12] of W. Müller, which investigates the asymptotic behavior of the analytic torsion or the Reidemeister torsion for a closed oriented hyperbolic 3-manifold \( X \) and \( \text{SL}_n(\mathbb{C}) \)-representations \( \rho_n \) of \( \pi_1(X) \) induced from the hyperbolic structure of \( X \). It was shown in [Müll12] that the hyperbolic volume is derived from the limit of the leading coefficient in the logarithm of the analytic torsion or the Reidemeister torsion \( \text{Tor}(X; \rho_n) \) for a closed hyperbolic 3-manifold \( X \) with \( \text{SL}_n(\mathbb{C}) \)-representations \( \rho_n \) of \( \pi_1(X) \).

Key words and phrases. Ruelle zeta function, geodesic flow, Selberg zeta function, Selberg trace formula asymptotic behavior, Reidemeister torsion, Fuchsian group.
More precisely, the leading coefficient converges as
\[
\lim_{n \to \infty} \frac{\log |\text{Tor}(X; \rho_n)|}{n^2} = \frac{\text{Vol}(X)}{4\pi}.
\]
Note that the sign of the right hand side is different from that of [M ül12] since \(\text{Tor}(X; \rho_n)\) in our convention is the inverse of that in [M ül12]. These \(\text{SL}_n(\mathbb{C})\)-representations \(\rho_n\) are given by the symmetric power of the standard representation of \(\text{SL}_2(\mathbb{C})\) and its restriction to the subgroup \(\pi_1(X)\) when \(\pi_1(X)\) is regarded as a discrete subgroup in \(\text{PSL}_2(\mathbb{C}) \cong \text{Isom}^+ \mathbb{H}^3\) such that \(X = \pi_1(X) \backslash \mathbb{H}^3\). Here \(\mathbb{H}^3\) is the hyperbolic 3-space and \(\text{Isom}^+ \mathbb{H}^3\) denotes the orientation preserving isometry group of \(\mathbb{H}^3\). The key ingredients of Müller’s observation are the following:

- the absolute value at zero of the Ruelle zeta function equals to the square of the analytic torsion;
- the Ruelle zeta function has a factorization whose factors have useful functional equations and;
- the asymptotic behavior of the analytic torsion is analyzed by using the functional equations which the factors in the factorization of the Ruelle zeta function satisfy.

The functional equation of each factor in the Ruelle zeta function is derived from that of the Selberg zeta function. The functional equation of the Selberg zeta function includes the volume of the hyperbolic manifold. Thus we find the hyperbolic volume in the asymptotic behavior of the analytic torsion.

The author has studied the asymptotic behavior of the Reidemeister torsion for a Seifert fibered space and \(\text{SL}_2(\mathbb{C})\)-representations of the fundamental group in [Y am17]. The observations in [Y am17] are based on explicit computations of the Reidemeister torsion in terms of the decomposition of a Seifert fibered space along tori. The purpose of this paper is to study the relation between the Ruelle zeta function of a dynamical system and a sequence of the Reidemeister torsion for a Seifert fibered space \(M\) with \(\text{SL}_2(\mathbb{C})\)-representations of \(\pi_1(M)\). Throughout this paper, we consider a Seifert fibered space \(M\) given by the quotient \(\Gamma \backslash \text{PSL}_2(\mathbb{R})\) by a discrete subgroup \(\Gamma\) in \(\text{PSL}_2(\mathbb{R})\). It is known that the quotient \(\Gamma \backslash \text{PSL}_2(\mathbb{R})\) is regarded as the unit tangent bundle over the hyperbolic orbifold \(\Gamma \backslash \mathbb{H}^2\). Here \(\Gamma\) acts on \(\mathbb{H}^2\) as a subgroup of the isometry group \(\text{Isom}^+ \mathbb{H}^2 \cong \text{PSL}_2(\mathbb{R})\) by linear fractional transformations.

In the case of a hyperbolic 3-manifold \(X\), there exists an injective homomorphism \(\rho : \pi_1(X) \to \text{PSL}_2(\mathbb{C}) \cong \text{Isom}^+ \mathbb{H}^3\) with discrete image such that \(M = \rho(\pi_1(X)) \backslash \mathbb{H}^3\), which is called the holonomy representation. By taking a lift of \(\rho\) to a homomorphism \(\pi_1(X) \to \text{SL}_2(\mathbb{C})\) and the composition with the symmetric powers of the standard representation of \(\text{SL}_2(\mathbb{C})\), we have a sequence of the \(\text{SL}_n(\mathbb{C})\)-representations \(\rho_n\) of \(\pi_1(X)\). Then we can define the Ruelle zeta function and the analytic torsion or the Reidemeister torsion for \(X\) with \(\rho_n\).

We will deal with the unit tangent bundle \(\Gamma \backslash \text{PSL}_2(\mathbb{R})\) over a 2-dimensional hyperbolic orbifold \(\Gamma \backslash \mathbb{H}^2\) as a Seifert fibered space \(M\). Such a Seifert fibered space \(M\) is also regarded as the quotient of the universal cover \(\text{PSL}_2(\mathbb{R})\) of \(\text{PSL}_2(\mathbb{R})\) by \(\pi_1(M)\) embedded in \(\text{Isom} \text{PSL}_2(\mathbb{R})\). Actually the image of \(\pi_1(M)\) by the embedding is contained in the subgroup \(\text{PSL}_2(\mathbb{R})\) in \(\text{Isom} \text{PSL}_2(\mathbb{R})\). We can regard the Seifert fibered space as the quotient \(\pi_1(M) \backslash \text{PSL}_2(\mathbb{R})\) by the subgroup \(\pi_1(M) \subset \text{PSL}_2(\mathbb{R})\) and obtain the \(\text{PSL}_2(\mathbb{R})\)-representation of \(\pi_1(M)\) by the restriction of the projection \(\text{PSL}_2(\mathbb{R}) \to \text{SL}_2(\mathbb{R})\) to \(\pi_1(M)\). Similarly to the case of a hyperbolic 3-manifold, we can have a sequence of \(\text{SL}_n(\mathbb{C})\)-representations \(\rho_n\) of \(\pi_1(M)\) and define the Ruelle zeta functions \(R_{\rho_{2n}}(s)\) and the Reidemeister torsions \(\text{Tor}(M; \rho_{2n})\) for \(M\) with even dimensional representation \(\rho_{2N}\). We will show that
Theorem 1.1 (Theorem 3.15). \(|R_{\Gamma(2)}(0)| = \text{Tor}(M; \rho_{2N})\).

Here the left hand side is the absolute value of the Ruelle zeta function at zero. We show this equality as follows. We see that (the inverse of) the Ruelle zeta function at zero has the following integral expression (Proposition 3.8):

\[
R_{\Gamma(2)}(0)^{-1} = \exp \left( \mu(D) \sum_{j=1}^{m} \left( \log \prod_{k=1}^{N} (1 - e^{(2k-1)\theta(q_j)} \sqrt{-1})(1 - e^{-(2k-1)\theta(q_j)} \sqrt{-1}) - \frac{2N}{m(q_j)} \log 2 \right) \right)
\]

where \(\mu(D)\) denotes the area of the base orbifold \(\Gamma \setminus \mathbb{H}^2\), see Section 3.2 for the details. This integral expression of \(R_{\Gamma(2)}(0)^{-1}\) is derived by the functional equation of the Selberg zeta function in Theorem 2.7 for the discrete subgroup \(\Gamma\) of \(\text{PSL}_2(\mathbb{R})\). We allow \(\Gamma\) to have torsion elements. Then the absolute value \(|R_{\Gamma(2)}(0)|^{-1}\) is expressed as

Theorem 1.2 (Theorem 3.17).

\[
| R_{\Gamma(2)}(0) |^{-1} = \exp \left( \mu(D) \left( -\frac{N}{\pi} \log 2 \right) \right) \cdot \exp \left[ \sum_{j=1}^{m} \left( \log \prod_{k=1}^{N} \left(1 - e^{(2k-1)\theta(q_j)} \sqrt{-1})(1 - e^{-(2k-1)\theta(q_j)} \sqrt{-1}) - \frac{2N}{m(q_j)} \log 2 \right) \right] \]
\]

where \(\theta(q_j)\) and \(m(q_j)\) are determined by torsion elements \(q_j\) in the fundamental group of the base orbifold.

Comparing the result of \(|R_{\Gamma(2)}(0)|\) with the Reidemeister torsion as in Proposition 3.14, we have the equality \(|R_{\Gamma(2)}(0)| = \text{Tor}(M; \rho_{2N})\).

Furthermore we observe that the second factor in the right hand side of Theorem 1.2 does not affect in the limit of the leading coefficient in \(\log |R_{\Gamma(2)}(0)|\) as \(N\) goes to infinity. Hence only the first factor contributes the limit of the leading coefficient in \(\log |R_{\Gamma(2)}(0)|\).

Since it was shown in [Yam17] that the growth order of \(\log |\text{Tor}(M; \rho_{2N})| = \log |R_{\Gamma(2)}(0)|\) equals to \(2N\), this means that

\[
\lim_{N \to \infty} \frac{1}{2N} \sum_{j=1}^{m} \left( \log \prod_{k=1}^{N} \left(1 - e^{(2k-1)\theta(q_j)} \sqrt{-1})(1 - e^{-(2k-1)\theta(q_j)} \sqrt{-1}) - \frac{2N}{m(q_j)} \log 2 \right) \right) \xrightarrow{N \to \infty} 0
\]

and

\[
\lim_{N \to \infty} \frac{\log |\text{Tor}(M; \rho_{2N})|}{2N} = \lim_{N \to \infty} \frac{\log |R_{\Gamma(2)}(0)|}{2N} = \frac{\mu(D)}{2\pi} \log 2.
\]

We will discuss the above limits in Subsection 3.4. By the Gauss-Bonnet theorem \(\mu(D) = -2\pi \chi^\text{orb}\), the following equality also holds:

\[
\lim_{N \to \infty} \frac{\log |\text{Tor}(M; \rho_{2N})|}{2N} = \lim_{N \to \infty} \frac{\log |R_{\Gamma(2)}(0)|}{2N} = -\chi^\text{orb} \log 2.
\]

Here \(\chi^\text{orb}\) is the orbifold Euler characteristic of the base orbifold \(\Gamma \setminus \mathbb{H}^2\). It was also shown in the previous work [Yam17] that \(-\chi^\text{orb} \log 2\) gives an upper bound of the limits of the leading coefficients in the logarithm of the Reidemeister torsion for a Seifert fibered space among the sequences of \(\text{SL}_{2N}(\mathbb{C})\)-representations of its fundamental group. For \(M = \Gamma \setminus \text{PSL}_2(\mathbb{R})\), the sequence of \(\text{SL}_{2N}(\mathbb{C})\)-representations induced from the geometric description of \(M\) attains the upper bound in the limits of the leading coefficients in the logarithm of the Reidemeister torsion for \(M\) among sequences of \(\text{SL}_{2N}(\mathbb{C})\)-representations of \(\pi_1(M)\).

We note the differences from previous results on the Ruelle zeta function and the Reidemeister torsion. D. Fried observed the Ruelle zeta function and the Reidemeister torsion.
for the unit sphere bundles $S(TX)$ of a closed oriented hyperbolic manifold $X$ with orthogonal representations of $\pi_1(S(TX))$ in $\text{PSL}_2(\mathbb{R})$ and especially for a Seifert fibered space $M = \Gamma \backslash \text{PSL}_2(\mathbb{R})$ with unitary representations of $\pi_1(M)$ in $\text{PSL}_2(\mathbb{R})$. We deal with the Ruelle zeta function and the Reidemeister torsion for non-unitary representations of $\pi_1(M)$. Fried derived the equality between the Ruelle zeta function and the Reidemeister torsion by using the function equation of the Selberg zeta function. We also derive the relation between the Ruelle zeta function and the Reidemeister torsion by a functional equation of the Selberg zeta function. Our functional equation is a different version from those in [Fri86a, Fri86b].

One can also find a number of developments on Müller’s work in the both sides of the analytic torsion and the Reidemeister torsion. We will touch several developments on the asymptotic behaviour of the analytic or Reidemeister torsion for hyperbolic manifolds briefly. P. Menal-Ferrer and J. Porti showed the asymptotic behavior of the Reidemeister torsion for non-compact hyperbolic 3-manifolds of finite volume with cusps in [MFP14]. Wüller and J. Pfaff developed the study of the asymptotic behavior of the analytic torsion for odd dimensional hyperbolic manifolds of finite volume in [MP12, MP13]. Pfaff also introduced in [Pfa13] the normalized analytic torsion corresponding to the higher-dimensional Reidemeister torsion invariant introduced by Menal-Ferrer and Porti in [MFP14] and compared them in detail. H. Goda and L. Bénard, J. Dubois, M. Heusener and J. Porti provided the asymptotic behavior of the higher-dimensional Reidemeister invariants with the descriptions in terms of the twisted Alexander invariants. These descriptions are given for hyperbolic knot complements in [God17] and cusped hyperbolic 3-manifolds in [BDHPT9].

**Organization.** Section 2 is devoted to reviews of the materials which we need in this paper. Subsections 2.1 and 2.2 review the unit tangent bundle over a 2-dimensional hyperbolic orbifold as a Seifert fibered space and a dynamical system on the Seifert fibered space, called the geodesic flow. The Subsections 2.3, 2.4, 2.5 and 2.6 provide brief summaries on the Ruelle zeta function, the Selberg zeta function, the Selberg trace formula and the functional equation obtained as an application of the Selberg trace formula. Section 3 contains our main results. Subsection 3.1 discusses the $\text{SL}_2(\mathbb{C})$-representations given by the geometric description of our Seifert manifold. We will see the explicit value of $|R_{p_{2N}}(0)|$ in Subsection 3.2 and the equality between $|R_{p_{2N}}(0)|$ and the Reidemeister torsion in Subsection 3.3. Finally Subsection 3.4 presents the relation of $|R_{p_{2N}}(0)|$ to the asymptotic behavior of the Reidemeister torsion for a sequence of $2N$-dimensional representations as $N$ goes to infinity.

2. Preliminaries

Let $\Gamma \subset \text{PSL}_2(\mathbb{R}) = \text{SL}_2(\mathbb{R})/\{\pm 1\}$ be a discrete subgroup without parabolic elements. We denote by $\mathbb{H}^2$ the upper half plane which has the metric $(dx^2 + dy^2)/y^2$ with constant negative curvature $-1$. We identify $\text{PSL}_2(\mathbb{R})$ with the orientation preserving isometry group of $\mathbb{H}^2$ by linear fractional transformations. The assumption on parabolic elements means that both of the manifold $M = \Gamma \backslash \text{PSL}_2(\mathbb{R})$ and the orbifold $\Sigma = \Gamma \backslash \mathbb{H}^2$ are compact without boundary.

Throughout this paper, a nontrivial element $g \in \text{PSL}_2(\mathbb{R})$ is called hyperbolic, elliptic and parabolic if a representative $A \in \text{SL}_2(\mathbb{R})$ of $g$ has the trace $|\text{tr} A| > 2$, $|\text{tr} A| < 2$ and $|\text{tr} A| = 2$ respectively. Hence a representative of $g \in \text{PSL}_2(\mathbb{R})$ is conjugate to one of the
following matrices in $\text{SL}_2(\mathbb{R})$:

$$
\pm \begin{pmatrix} e^{i\ell/2} & 0 \\ 0 & e^{-i\ell/2} \end{pmatrix}, \quad \pm \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}, \quad \begin{pmatrix} \pm 1 & * \\ 0 & \pm 1 \end{pmatrix}
$$

where $\ell$ is the translation length along the axis of a hyperbolic element $g$. We often identify an element $g \in \text{PSL}_2(\mathbb{R})$ with its representative in $\text{SL}_2(\mathbb{R})$.

We will give brief reviews on 3-dimensional manifolds $\Gamma \backslash \text{PSL}_2(\mathbb{R})$ in Subsection 2.1 and the Ruelle and Selberg zeta functions associated with a dynamical flow on $\Gamma \backslash \text{PSL}_2(\mathbb{R})$ in Subsections 2.2 and 2.3. Subsections 2.4, 2.5 and 2.6 give reviews on the Selberg trace formula and the functional equation of the Selberg zeta function in the case that a discrete subgroup $\Gamma$ has elliptic elements.

### 2.1. Seifert Fibered space $\Gamma \backslash \text{PSL}_2(\mathbb{R})$

It is known that the quotient of $\text{PSL}_2(\mathbb{R})$ by a discrete subgroup $\Gamma$ is a Seifert fibered space. We review a 3-dimensional manifold $\Gamma \backslash \text{PSL}_2(\mathbb{R})$ as a Seifert fibered space. We refer readers to [Sc83, NJ81] for the details.

Since every element $g$ of $\text{PSL}_2(\mathbb{R})$ acts on $\mathbb{H}^2$ as an orientation preserving isometry, each $g$ also acts on the tangent bundle $T\mathbb{H}^2$ of $\mathbb{H}^2$ as an isometry with metric induced from $\mathbb{H}^2$. Denote by $S(T\mathbb{H}^2)$ the unit tangent bundle of $\mathbb{H}^2$. Actually the action of $\text{PSL}_2(\mathbb{R})$ on $S(T\mathbb{H}^2)$ is free, i.e., every stabiliser is trivial, and transitive (for example, the orbit of $z = \sqrt{-1}$ by $\text{PSL}_2(\mathbb{R})$ is $\mathbb{H}^2$ and the stabiliser of $z$ is given by $\text{SO}(2)$ which rotates unit tangent vectors in $S(T\mathbb{H}^2)$). Thus we can regard $S(T\mathbb{H}^2)$ as the homogeneous space $\text{PSL}_2(\mathbb{R})$. The actions of a discrete subgroup $\Gamma$ in $\text{PSL}_2(\mathbb{R})$ on $S(T\mathbb{H}^2) = \text{PSL}_2(\mathbb{R})$ and $\mathbb{H}^2$ give the unit tangent bundle $\Gamma \backslash \text{PSL}_2(\mathbb{R})$ over the orbifold $\Sigma = \Gamma \backslash \mathbb{H}^2$. Since $S(T\Sigma) = \Gamma \backslash \text{PSL}_2(\mathbb{R})$ is a circle bundle over $\Sigma$, we think of $\Gamma \backslash \text{PSL}_2(\mathbb{R})$ as a Seifert fibered space with the base orbifold $\Sigma$.

Under our assumption that $\Gamma$ has no parabolic elements, the singularities of the orbifold $\Sigma$ are only cone points. If the orbifold $\Sigma$ has $m$ cone points with angle $2\pi/\alpha_j$ ($1 \leq j \leq m$, $\alpha_j \in \mathbb{Z}$, $\alpha_j \geq 2$) and the underlying closed surface with genus $g$, then $\Gamma = \pi_1(\Sigma)$ has the following presentation:

1. $\Gamma = \langle a_1, b_1, \ldots, a_g, b_g, q_1, \ldots, q_m \mid q_j^{a_j} = 1, \prod_{j=1}^{m} q_j \prod_{i=1}^{2} [a_i, b_i] = 1 \rangle$

where $a_i$ and $b_i$ are generators of the fundamental group of the underlying closed surface and $q_j$ is the homotopy class of a closed loop around the $j$-th cone point. The fundamental group of $\Gamma \backslash \text{PSL}_2(\mathbb{R})$ has the following presentation:

2. $\pi_1(\Gamma \backslash \text{PSL}_2(\mathbb{R}))$

$$\langle a_1, b_1, \ldots, a_g, b_g, q_1, \ldots, q_m, h \mid h : \text{central}, q_j^{a_j} h^{\alpha_j - 1} = 1, \prod_{j=1}^{m} q_j \prod_{i=1}^{\alpha_j} [a_i, b_i] = h^{2-2g} \rangle.$$

Here $h$ denotes the homotopy class of a regular fiber in the Seifert fibration of $\Gamma \backslash \text{PSL}_2(\mathbb{R})$, in other words, $h$ is the homotopy class of a fiber in $S(T\Sigma)$ on a smooth point of $\Sigma$.

It is also known that the exceptional fiber $\ell_j$ on the $j$-th cone point is expressed as

3. $\ell_j = q_j^{-1} h^{-1}$.

**Remark 2.1.** The Seifert index of $\Gamma \backslash \text{PSL}_2(\mathbb{R})$ is $(g; (1, 2g - 2), (\alpha_1, \alpha_1 - 1), \ldots, (\alpha_m, \alpha_m - 1))$. We follow the convention that the fundamental group $\pi_1(\Gamma \backslash \text{PSL}_2(\mathbb{R}))$ of a Seifert fibered
space with index \((g; (1, b), (α_1, β_1), \ldots, (α_m, β_m))\) has the presentation:

\[
\langle a_1, b_1, \ldots, a_g, b_g, q_1, \ldots, q_m, h \mid h : \text{central}, q_j^{α_j} h^{β_j} = 1, \prod_{j=1}^m q_j \prod_{i=1}^g [α_i, β_i] = h^{-b} \rangle
\]

and the exceptional fiber \(ℓ_j\) is expressed as \(ℓ_j = q_j^{α_j} h^{β_j}\) for \(μ_j\) and \(ν_j \in \mathbb{Z}\) such that \(α_j ν_j − β_j μ_j = −1\).

### 2.2. Review on geodesic flows and the Ruelle zeta function.

We denote by \(TX\) the tangent bundle over a closed Riemannian manifold \((X, g)\) and by \(S(TX)\) the unit tangent bundle. Let \(φ_t\) be the following dynamical system on the unit tangent bundle \(S(TX)\):

\[
φ_t : S(TX) × \mathbb{R} → S(TX)
\]

\[(x, v, t) ↦ (\exp_s(tv), \frac{d}{dt} \exp_s(tv)),\]

where \(\exp : TX → X\) is the exponential map given by the metric \(g\). This dynamical system is called the geodesic flow on \(S(TX)\).

We can also consider the geodesic flow for a hyperbolic orbifold \(Σ = Γ \backslash \mathbb{H}^2\) when \(Σ\) has cone points. There exists another definition of the geodesic flow on \(S(TΣ)\) by a one parameter group action. We adopt this alternative definition of the geodesic flow on \(S(TΣ)\) and use it to define the related dynamical zeta function.

When we regard the manifold \(Γ \backslash \text{PSL}_2(\mathbb{R})\) as the unit tangent bundle \(S(TΣ)\) of \(Σ\), the action of the one parameter group \(a_t\) is defined by the matrix:

\[
\begin{pmatrix}
  e^{t/2} & 0 \\
  0 & e^{-t/2}
\end{pmatrix}
\]

for \(t ∈ \mathbb{R}\) on \(\text{PSL}_2(\mathbb{R})\) from the right, that is

\[
\text{PSL}_2(\mathbb{R}) × \mathbb{R} → \text{PSL}_2(\mathbb{R})
\]

\[(A, t) ↦ A \begin{pmatrix} e^{t/2} & 0 \\ 0 & e^{-t/2} \end{pmatrix},\]

defines a dynamical system \(φ_t\) on \(\text{PSL}_2(\mathbb{R})\). The one parameter group \(a_t\) defines the flow on \(S(T \mathbb{H}^2) = \text{PSL}_2(\mathbb{R})\) of the left invariant vector field generated by the element \(\begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix}\) of the Lie algebra \(\text{sl}_2(\mathbb{R})\). The orbit \(ga_t\) for \(g ∈ \text{PSL}_2(\mathbb{R})\) projects to a geodesic through \(g \cdot \sqrt{-1}\) on \(\mathbb{H}^2\). This action of the one parameter group \(a_t\) also induces the geodesic flow on \(S(TΣ) = Γ \backslash \text{PSL}_2(\mathbb{R})\).

Set \(M = Γ \backslash \text{PSL}_2(\mathbb{R})\). Then we can define the Ruelle zeta function for the geodesic flow \(φ_t\) and a representation \(ρ : π_1(M) → \text{GL}_n(\mathbb{C})\) as follows.

### Definition 2.2.

For \(M = Γ \backslash \text{PSL}_2(\mathbb{R})\) and a representation \(ρ : π_1(M) → \text{GL}_n(\mathbb{C})\), the Ruelle zeta function \(R_ρ(s)\) is defined as

\[
R_ρ(s) = \prod_{γ \text{prime}} \text{det}(1 − ρ(γ)e^{-ℓ(γ)})
\]

where \(γ\) runs over the prime closed orbits of the geodesic flow \(φ_t\) and \(ℓ(γ)\) denotes the period of \(γ\).

A closed orbit \(γ\) of \(φ_t\) is called prime if \(γ\) is not expressed as \(γ = γ_0^m\) by any integer \(m\) with \(|m| > 1\) and other closed orbit \(γ_0\).

The Ruelle zeta function is defined for \(\text{Re}\ s > 0\) and it can be extended to the complex plane meromorphically by the meromorphic extension of the Selberg zeta function. We
will see the expression of the Ruelle zeta function in terms of the Selberg zeta functions in Subsections 2.3 and 3.2.

**Remark 2.3.** One can define the Ruelle zeta function for more general dynamical systems which are called the Anosov flows. For the details, we refer to [Fri86][She18] on the Anosov flow and the Ruelle zeta function concerning the Reidemeister torsion. The alternative definition of the geodesic flow on $S(T\Sigma)$ is referred to as an algebraic Anosov flow.

Actually the period of $\gamma$ is thought of as the length of the closed geodesic on $H^2$. This is due to that the closed orbits of $\phi_t$ arise from the (unoriented) closed geodesics on $\Sigma = \Gamma \backslash H^2$ by the definition of the geodesic flow. Moreover we can regard a closed orbit $\gamma$ of $\phi_t$ as the conjugacy class of a hyperbolic element in $\Gamma$. We review this correspondence shortly below.

Each closed orbit of the geodesic flow $\phi_t$ gives a closed geodesic on $\Sigma$. If we lift geodesics on $\Sigma$ to $H^2$, the lifts are given by lines or arcs perpendicular to the real line. Since such lines or arcs perpendicular to the real line are the axes of linear fractional transformations of hyperbolic elements in $\Gamma$, each closed geodesic on $\Sigma$ represents a hyperbolic element of $\Gamma$. If we take a different starting point of a closed geodesic, then the corresponding hyperbolic element of $\Gamma$ is changed by conjugation. Hence there is a one–to–one correspondence between closed orbits of the geodesic flow $\phi_t$ and the conjugacy classes of hyperbolic elements in $\Gamma$.

Under correspondence between the closed orbits of the geodesic flow and the conjugacy classes of hyperbolic elements in $\Gamma$, we can relate the Ruelle zeta function to another zeta function called the Selberg zeta function.

### 2.3. The Selberg zeta function

We review the Selberg zeta function for a discrete subgroup $\Gamma$ of $\text{PSL}_2(\mathbb{R})$ and the relation to the Ruelle zeta function for the geodesic flow on the unit tangent bundle over $\Gamma \backslash H^2$. In what follows, $N(T)$ stands for the eigenvalue ratio $> 1$ of a representative matrix for a hyperbolic element $T \in \text{PSL}_2(\mathbb{R})$, which is referred to as the norm of $T$.

**Definition 2.4 (the Selberg zeta function).** The *Selberg zeta function* $Z(s)$ for a discrete subgroup $\Gamma$ of $\text{PSL}_2(\mathbb{R})$ is defined by

$$Z(s) = \prod_{\{T\text{ prime}\}} \prod_{k=0}^{\infty} (1 - N(T)^{-s-k})$$

for $\text{Re}(s) > 1$. Here $\{T\}$ runs over the conjugacy classes of nontrivial prime hyperbolic elements $T$ in $\Gamma$. A nontrivial element $T$ in $\Gamma$ is called *prime* if $T$ is not expressed as $T = T_0^m$ by any integer $m$ with $|m| > 1$ and other element $T_0$.

The right hand side of (4) converges absolutely for $\text{Re}(s) > 1$. It is also known that $Z(s)$ can be extended to the complex plane meromorphically. If $\gamma$ is the axis of the linear fractional transformation by a hyperbolic element $T$ in $\Gamma$, then $\gamma$ is a closed geodesic and the hyperbolic element $T$ is conjugate to the diagonal matrix

$$\begin{pmatrix} e^{(\gamma)/2} & 0 \\ 0 & e^{-(\gamma)/2} \end{pmatrix}$$

under the correspondence between the conjugacy class $\{T\}$ and the closed geodesic $\gamma$ in $\Gamma \backslash H^2$. Thus the norm $N(T)$ for the conjugacy class $\{T\}$ satisfies

$$N(T) = e^{(\gamma)}.$$
When we take the 1-dimensional trivial representation $\rho : \pi_1(M) \to \text{GL}_1(\mathbb{C})$, we denote the Ruelle zeta function by $R(s)$. This classical Ruelle zeta function $R(s)$ is expressed as

\[ R(s) = \prod_{\gamma \text{ prime}} \det(1 - e^{-s\gamma}) = \prod_{T \text{ prime}} \det(1 - N(T)^{-s}) = \frac{Z(s)}{Z(s + 1)}. \]  

(5)

We will see a similar expression of the Ruelle zeta function for an $\text{SL}_m(\mathbb{C})$-representation of $\pi_1(\mathbb{H}^2 \backslash \mathbb{H}^2)$ in Section 2.

2.4. Selberg Trace formula for a discrete subgroup with elliptic elements. We will need the functional equation of the Selberg zeta function for a discrete subgroup with elliptic elements in $\text{PSL}_2(\mathbb{R})$. The functional equation is derived from an application of the Selberg trace formula. We review the Selberg trace formula for a discrete subgroup with elliptic elements throughout the paper, we do not consider orbifolds $\mathbb{H}^2 \backslash \mathbb{H}^2$ with cusps.

The Selberg trace formula gives a method of finding the trace of some linear operator on the space of complex valued functions on $\Sigma = \Gamma \backslash \mathbb{H}^2$. Here we identify functions on $\Sigma$ with functions $f(z)$ on $\mathbb{H}^2$ such that $f(\sigma z) = f(z)$ for all $\sigma \in \Gamma$, which are called automorphic functions on $\mathbb{H}^2$ with respect to $\Gamma$.

We consider linear operators $L$ commuting with the action of $\text{PSL}_2(\mathbb{R})$ on functions $f(z)$ ($z \in \mathbb{H}^2$), that is, $L(f(\sigma z)) = (Lf)(\sigma z)$. These linear operators are called invariant operators. Each invariant operator acts on the space of automorphic functions with respect to $\Gamma$. It is known that the Laplacian $D = y^2(\partial^2/\partial x^2 + \partial^2/\partial y^2)$ on $\mathbb{H}^2$ is also an invariant operator. Under the assumption that $\Sigma$ has no cusps, the space $L^2(\Gamma \backslash \mathbb{H}^2)$ of square integrable automorphic functions is a countably infinite dimensional vector space over $\mathbb{C}$ and has a basis consisting of the eigenfunctions of the Laplacian $D$. We restrict our attention to integral operators $L$, which are defined for a function $f(z)$ on $\mathbb{H}^2$ as

\[(Lf)(z) = \int_{\mathbb{H}^2} k(z, w)f(w) \, dw\]

with a kernel function $k(z, w) : \mathbb{H}^2 \times \mathbb{H}^2 \to \mathbb{C}$. A kernel function $k(z, w)$ defines an invariant integral operator $L$ if and only if $k(z, w)$ satisfies $k(\sigma z, \sigma w) = k(z, w)$ for any $\sigma \in \text{PSL}_2(\mathbb{R})$. Such a kernel function is called a point pair invariant.

Set $K(z, w) = \sum_{\sigma \in \Gamma} k(z, \sigma w)$. Then we regard the integral operator $L$ with a point pair invariant $k(z, w)$ on the space of automorphic functions as the integral operator with kernel $K(z, w)$ on the space of functions $f$ on $\Sigma$ by

\[ L(f)(z) = \int_{\mathbb{H}^2} k(z, w)f(w) \, d\mu(w) = \int_{\Sigma} \sum_{\sigma \in \Gamma} k(z, \sigma w)f(\sigma w) \, d\mu(w) = \int_{\mathcal{D}} K(z, w)f(w) \, d\mu(w) \]

where $\mathcal{D}$ is a fundamental region of $\Sigma$ in $\mathbb{H}^2$.

The integral $\int_{\mathcal{D}} K(z, z) \, dz$ defined from a point pair invariant $k(z, w)$ is called the trace of the above integral operator $L$ defined by $K(z, w)$. As in the finite dimensional case that a linear map $f$ on a finite dimensional vector space is diagonalizable if another linear map $g$ commuting with $f$ is diagonalizable, it is known that $L$ on $L^2(\Gamma \backslash \mathbb{H}^2)$ commutes with the Laplacian $D$ and then $L$ is diagonalized with respect to a basis consisting of eigenfunctions $\{\varphi_n\}$ of $D$ such that $D\varphi_n = \lambda_n \varphi_n$ ($0 = \lambda_0 > \lambda_1 \geq \lambda_2 \geq \ldots \to -\infty$). Each eigenfunction
Fourier transform of $g$ of Selberg transform

The first, second and third terms in the right hand side of (6) are the contributions of the $\Gamma$ identity, elliptic and hyperbolic elements in $\mathcal{R}$, respectively. We will review that the both sides can be expressed by using the Selberg transformation $h(r)$ in the next subsection.

2.5. The Selberg transformation. It is known that a kernel function $k(z, w)$ satisfies $k(\sigma z, \sigma w) = k(z, w)$ if and only if there exists a function $\Phi$ on $[0, \infty)$ such that

$$k(z, w) = \Phi \left( \frac{|z - w|^2}{\text{Im}(z) \text{Im}(w)} \right).$$

Let a point pair invariant $k(z, w)$ on $\mathbb{H} \times \mathbb{H}$ be

$$k(z, w) = \Phi \left( \frac{|z - w|^2}{\text{Im}(z) \text{Im}(w)} \right)$$

for a $C^\infty$-function $\Phi$ with compact support on the interval $[0, \infty)$. Set $Q(v)$ as

$$Q(v) = \int_v^\infty \Phi(t) \frac{dt}{\sqrt{t-v}}$$

and $g(u) := Q(e^u + e^{-u} - 2)$. Then we define the Selberg transform $h(r)$ of $k(z, w)$ as the Fourier transform of $g(u)$, i.e.,

$$h(r) := \int_{-\infty}^{\infty} g(u)e^{ru} \sqrt{-1} \, du.$$
The value of \( h(r_n) \) does not depend on the choice of \( r_n \) since it is known that \( h(r) \) is an even function. The sum of eigenvalues of the integral operator \( L \) defined by a point pair invariant \( k(z,w) \) turns into the sum of \( h(r_n) \) in which we take \( r_n \) as one of the complex numbers satisfying \( \lambda_n = -\frac{1}{4} - r_n^2 \) for the eigenvalue \( \lambda_n \) of the Laplacian \( D \) on \( L^2(\Gamma \backslash \mathbb{H}^2) \). We can rewrite each term in the equality (6) with the Selberg transformation \( h(r) \). The resulting equality is called the Selberg trace formula (we refer to [Sel56] and [Kub73, Appendix] for the details).

**Theorem 2.5** (The Selberg trace formula with elliptic elements). Suppose that \( L \) is the integral operator on \( L^2(\Gamma \backslash \mathbb{H}^2) \) defined by the kernel \( K(z,w) = \sum_{\sigma \in \Gamma} k(z, \sigma w) \) given by a point pair invariant \( k(z,w) \) on \( \mathbb{H}^2 \times \mathbb{H}^2 \). Let \( h(r) \) be the Selberg transform of \( k(z,w) \).

Then the equality (6) on the trace of \( L \) turns out to be

\[
\sum_{n=0}^{\infty} h(r_n) = \frac{\mu(D)}{4\pi} \int_{-\infty}^{\infty} r h(r) \tanh(\pi r) \, dr + \sum_{|R|: \text{elliptic}} \frac{1}{2m(R)} \sin \theta(R) \int_{-\infty}^{\infty} \frac{e^{-2\pi i R r}}{1 + e^{2\pi i r}} h(r) \, dr + \sum_{|T|: \text{hyperbolic}} \log N(T_0) N(T)^{1/2} - N(T)^{-1/2} g(\log N(T)) \]

where

- we take \( r_n \) as one of the complex numbers satisfying \( \lambda_n = -\frac{1}{4} - r_n^2 \) for the eigenvalue \( \lambda_n \) of the Laplacian \( D \);
- \( m(R) \) denotes the order of the centralizer \( Z(R) = \{ \sigma \in \Gamma | \sigma R \sigma^{-1} = R \} \);
- \( \theta(R) \in (0, \pi) \) is determined by \( \text{tr} R = 2 \cos \theta(R) \) and;
- \( T_0 \) is a prime hyperbolic element generating the centralizer

\[
Z(T) = \{ \sigma \in \Gamma | \sigma T \sigma^{-1} = T \}
\]

of \( T \) in \( \Gamma \).

The first, second and third terms in the right hand side are the contributions of the identity, elliptic and hyperbolic elements in \( \Gamma \) respectively. The function \( g(u) \) is also expressed as

\[
g(u) = \frac{1}{2\pi} \int_{-\infty}^{\infty} h(r) e^{-ur} \sqrt{-1} \, dr.
\]

Note that there exists a prime hyperbolic element \( T_0 \) for any hyperbolic element \( T \) in \( \Gamma \) such that \( Z(T) = (T_0^n | n \in \mathbb{Z}) \). This means that the centralizer \( Z(T) \) of a hyperbolic element \( T \) is conjugate to the cyclic group of infinite order

\[
\left\{ \left( \begin{array}{cc} e^{2\pi i n \gamma_0} & 0 \\ 0 & e^{-2\pi i n \gamma_0} \end{array} \right) \in \text{PSL}_2(\mathbb{C}) \bigg| n \in \mathbb{Z} \right\}
\]

where \( \gamma_0 \) is the closed geodesic corresponding to a prime element \( T_0 \).

**Remark 2.6.** The function \( \Phi(t) \) defining \( k(z,w) \) is recovered as

\[
\Phi(t) = -\frac{1}{\pi} \int_t^{\infty} \frac{dQ(v)}{\sqrt{v-1}}
\]

where

\[
Q(v) = g(u) \quad \text{for} \quad u = \log \frac{v + 2 + \sqrt{v^2 + 4v}}{2}.
\]
2.6. **The functional equation of the Selberg zeta function.** We can also use the Selberg trace formula in Theorem 2.3 if an appropriate function \( g(u) \) is given. The purpose of this subsection is to derive the functional equation of the Selberg trace formula for a discrete subgroup with elliptic elements along a way similar to that in [Hej76, § 1 – 4 in Chap. 2]. We will focus on how elliptic elements affect to the functional equation of the Selberg zeta function. For more details, we refer the reader to [Hej76, Chap. 2].

Set a function \( g(u) \) as

\[
g(u) = \frac{1}{2\alpha} e^{-|\alpha| u} - \frac{1}{2\beta} e^{-|\beta| u}
\]

for \( u \in \mathbb{R} \) and \( 1/2 < \text{Re}(\alpha) < \text{Re}(\beta) \). The Selberg transform \( h(r) \) is expressed as

\[
h(r) = \frac{1}{r^2 + \alpha^2} - \frac{1}{r^2 + \beta^2}.
\]

Then the Selberg trace formula (7) turns out to be

\[
\sum_{n=0}^{\infty} \left( \frac{1}{r_n^2 + \alpha^2} - \frac{1}{r_n^2 + \beta^2} \right) = \frac{\mu(D)}{4\pi} \int_{-\infty}^{\infty} r \left( \frac{1}{r^2 + \alpha^2} - \frac{1}{r^2 + \beta^2} \right) \tanh(\pi r) \, dr
\]

\[+ \sum_{[R] \text{ elliptic}} \frac{2m(R) \sin \theta(R)}{N(T_0)} \int_{-\infty}^{\infty} e^{-2|\theta|R} \left( \frac{1}{r^2 + \alpha^2} - \frac{1}{r^2 + \beta^2} \right) \, dr
\]

\[+ \frac{1}{2\alpha} \sum_{[T] \text{ hyperbolic}} \frac{\log N(T_0)}{N(T)^{1/2} - N(T)^{-1/2}} \frac{1}{N(T)^a}
\]

\[- \frac{1}{2\beta} \sum_{[T] \text{ hyperbolic}} \frac{\log N(T_0)}{N(T)^{1/2} - N(T)^{-1/2}} \frac{1}{N(T)^b}
\]

Here we replace the sums of terms for the conjugacy classes of hyperbolic elements \( T \) with the Selberg zeta functions as follows (see [Hej76, p. 66] for the details):

\[
\sum_{[T] \text{ hyperbolic}} \frac{\log N(T_0)}{N(T)^{1/2} - N(T)^{-1/2}} \frac{1}{N(T)^a} = \frac{Z'(\xi + 1/2)}{Z(\xi + 1/2)}
\]

Hence the Selberg trace formula (7) is expressed as

\[
\sum_{n=0}^{\infty} \left( \frac{1}{r_n^2 + \alpha^2} - \frac{1}{r_n^2 + \beta^2} \right)
\]

\[= \frac{\mu(D)}{4\pi} \int_{-\infty}^{\infty} r \left( \frac{1}{r^2 + \alpha^2} - \frac{1}{r^2 + \beta^2} \right) \tanh(\pi r) \, dr
\]

\[+ \sum_{[R] \text{ elliptic}} \frac{2m(R) \sin \theta(R)}{N(T_0)} \int_{-\infty}^{\infty} e^{-2|\theta|R} \left( \frac{1}{r^2 + \alpha^2} - \frac{1}{r^2 + \beta^2} \right) \, dr
\]

\[+ \frac{1}{2\alpha} \frac{Z'(\alpha + 1/2)}{Z(\alpha + 1/2)} - \frac{1}{2\beta} \frac{Z'(\beta + 1/2)}{Z(\beta + 1/2)}.
\]
Substituting $s - 1/2$ into $\alpha$ in the above equality, we can rewrite (9) as

\[
(9) \quad \frac{1}{2s - 1} \left( \frac{Z'(s)}{Z(s)} - \frac{1}{2} \frac{Z'(\beta + 1/2)}{Z(\beta + 1/2)} \right) = \sum_{k=0}^{\infty} \left( \frac{1}{r^2 + (s - 1/2)^2} - \frac{1}{r^2 + \beta^2} \right) 
\]

\[
+ \frac{\mu(D)}{4\pi} \int_{-\infty}^{\infty} \left( \frac{1}{r^2 + \beta^2} \right) \tanh(\pi r) \ dr 
\]

\[
(10) \quad + \sum_{|R| \text{ elliptic}} \frac{1}{2m(R) \sin \theta(R)} \int_{-\infty}^{\infty} \frac{1}{1 + e^{2\pi i r}} \left( \frac{1}{r^2 + \beta^2} - \frac{1}{r^2 + (s - 1/2)^2} \right) \ dr 
\]

\[
(11) \quad + \frac{\mu(D)}{2\pi} \int_{-\infty}^{\infty} \frac{1}{1 + e^{2\pi i r}} \left( \frac{1}{r^2 + \beta^2} - \frac{1}{r^2 + (s - 1/2)^2} \right) \ dr 
\]

The integrals of (10) and (11) can be carried out by the residue theorem, for example, which follow from the integral along a rectangle with the vertices $X_1, X_1 + Y \sqrt{-1}, -X_2 + Y \sqrt{-1}, -X_2$ where $X_1, X_2 > 0$ and $Y \in \mathbb{N}$. According to [Hej76, pp. 69–71 and Proposition 4.9], the integral of (10) is expressed as

\[
\frac{\mu(D)}{4\pi} \int_{-\infty}^{\infty} \left( \frac{1}{r^2 + \beta^2} \right) \tanh(\pi r) \ dr = \frac{\mu(D)}{2\pi} \sum_{k=0}^{\infty} \left( \frac{1}{\beta + 1/2 + k} - \frac{1}{s + k} \right) 
\]

One can see that the integral of the third term (11) turns into

\[
(12) \quad \int_{-\infty}^{\infty} \frac{e^{-2\pi i R r}}{1 + e^{-2\pi i r}} \left( \frac{1}{r^2 + \beta^2} - \frac{1}{r^2 + (s - 1/2)^2} \right) \ dr 
\]

\[
= 2\pi \sqrt{-1} \left( \sum_{k=0}^{\infty} \frac{1}{2\pi} e^{-\pi i (2k + 1) \sqrt{-1}} \left( \frac{1}{(2k + 1) \sqrt{-1} + \beta} - \frac{1}{(2k + 1) \sqrt{-1} + (s - 1/2)} \right) \right) 
\]

\[
= 2\pi \sqrt{-1} \left( \frac{1}{2\sqrt{-1} \beta + e^{-2\pi i \sqrt{-1} \beta}} - \frac{1}{2\sqrt{-1} (s - 1/2) + e^{-2\pi i (s - 1/2) \sqrt{-1}}} \right) 
\]

by calculating the residues of the integrand. The sums (12) and (13) correspond to the residues of $e^{-2\pi i \beta r} / (1 + e^{-2\pi i r})$ and $1/(z^2 + \beta^2) - 1/(z^2 + (s - 1/2)^2)$ respectively.

If $\beta$ moves to $1/2 - s$, then the whole equality (9) turns out to be

\[
\frac{1}{2s - 1} \left( \frac{Z'(s)}{Z(s)} + \frac{Z'(1 - s)}{Z(1 - s)} \right) = \frac{\mu(D)}{2\pi} \sum_{k=0}^{\infty} \left( \frac{1}{1 - s + k} - \frac{1}{s + k} \right) 
\]

\[
+ \sum_{|R| \text{ elliptic}} \frac{\pi}{2m(R) \sin \theta(R)} \left( \frac{1}{1/2 - s} \frac{e^{-2\pi i (1/2 - s)}}{1 + e^{-2\pi i (1/2 - s)}} - \frac{1}{1 - 1/2} \frac{e^{-2\pi i (s - 1/2) \sqrt{-1}}}{1 + e^{-2\pi i (s - 1/2) \sqrt{-1}}} \right) 
\]

The first sum in the right hand side can be rewritten as

\[
\sum_{k=0}^{\infty} \left( \frac{1}{1 - s + k} - \frac{1}{s + k} \right) = -\pi \cot(\pi s) = \pi \tan(s - 1/2).
\]
Therefore we have
\begin{equation}
\frac{1}{2s-1} \left( \frac{Z'(s)}{Z(s)} + \frac{Z'(1-s)}{Z(1-s)} \right) = \frac{\mu(D)}{2} \tan \pi(s-1/2)
+ \sum_{[R]:\text{elliptic}} \frac{-\pi}{(2s-1)m(R) \sin \theta(R)} \frac{\cos((2\theta(R) - \pi)(s-1/2))}{\cos \pi(s-1/2)}.
\end{equation}

Finally we get the functional equation of $Z(s)$ from (14) as follows.

**Theorem 2.7** (The functional equation of the Selberg zeta function). Let $Z(s)$ be the Selberg zeta function for a discrete subgroup $\Gamma$ without parabolic elements in $\PSL_2(\mathbb{R})$. Then $Z(s)$ satisfies the following equality:
\begin{equation}
\frac{d}{ds} \log \frac{Z(s)}{Z(1-s)} = \mu(D)(s - 1/2) \tan \pi(s-1/2)
+ \sum_{[R]:\text{elliptic}} \frac{-\pi}{m(R) \sin \theta(R)} \frac{\cos((2\theta(R) - \pi)(s-1/2))}{\cos \pi(s-1/2)}
\end{equation}
where $[R]$ runs over the conjugacy classes of elliptic elements $R$ in $\Gamma$.

**Remark 2.8.** If $\Gamma$ has only hyperbolic elements, then the functional equation (15) can be written as
\[ Z(s) = Z(1-s) \exp \left( \mu(D) \int_0^{s-1/2} v \tan \pi v \, dv \right), \]
which coincides with the usual functional equation of $Z(s)$. For example, we refer to [Sel56, Equality (3.4)] and [Hej76, Theorem 4.2 in p. 73].

3. The higher-dimensional Reidemeister torsion and the dynamical zeta functions

We start with the construction of an $\SL_n(\mathbb{C})$-representation of $\pi_1(\Gamma \backslash \PSL_2(\mathbb{R}))$ and discuss its properties in Subsection 3.1. Subsection 3.2 gives the absolute value at zero of the Ruelle zeta function explicitly. We will show the equality between the absolute value at zero of the Ruelle zeta function and the Reidemeister torsion in Subsection 3.3 and discuss the asymptotic behavior of the Reidemeister torsion through the Ruelle zeta function in Subsection 3.4.

3.1. $\SL_n(\mathbb{C})$-representations for $\pi_1(\Gamma \backslash \PSL_2(\mathbb{R}))$. For $M = \Gamma \backslash \PSL_2(\mathbb{R})$, we will see that there exist some natural representations
\[ \rho_{2N} : \pi_1 M \to \SL_2(\mathbb{R})^\ast \to \SL_{2N}(\mathbb{C}) \]
such that $\rho_{2N}(h) = -1_{2N}$ for all $N \geq 1$ as follows.

We denote by $\widetilde{\PSL}_2(\mathbb{R})$ the universal cover of $\PSL_2(\mathbb{R})$. The covering projection from $\PSL_2(\mathbb{R})$ onto $\widetilde{\PSL}_2(\mathbb{R})$ induces the following exact sequence of groups:
\[ 0 \to \mathbb{Z} \to \widetilde{\PSL}_2(\mathbb{R}) \to \PSL_2(\mathbb{R}) \to 1. \]
This exact sequence is a central extension of $\PSL_2(\mathbb{R})$. Let $\Gamma$ be the preimage $p^{-1}(\Gamma)$ of a discrete subgroup $\Gamma$. We can regard $\Gamma$ as a subgroup of $\text{Isom}(\widetilde{\PSL}_2(\mathbb{R}))$ since $\PSL_2(\mathbb{R}) \subset \text{Isom}(\PSL_2(\mathbb{R}))$. Then $\Gamma$ acts on $\PSL_2(\mathbb{R})$ freely and the quotient $\Gamma \backslash \PSL_2(\mathbb{R})$ is a Seifert fibered space. It is known that $\Gamma \backslash \PSL_2(\mathbb{R})$ turns into the unit tangent bundle $\Gamma \backslash \PSL_2(\mathbb{R})$.
over $\Sigma = \Gamma \backslash \mathbb{H}^2$ (for the details, see [Scot83, §The geometry of $\tilde{\text{SL}}_2(\mathbb{R})$]). From the identification between $M = \Gamma \backslash \text{PSL}_2(\mathbb{R})$ and $\tilde{\Gamma} \backslash \text{PSL}_2(\mathbb{R})$, $\tilde{\Gamma}$ is the fundamental group $\pi_1(M)$ of $M = \Gamma \backslash \text{PSL}_2(\mathbb{R})$.

Since the 2-fold cover $\text{SL}_2(\mathbb{R})$ over $\text{PSL}_2(\mathbb{R})$ has the same universal cover $\text{PSL}_2(\mathbb{R})$, we can take an $\text{SL}_2(\mathbb{R})$-representation $\rho$ of $\pi_1(M)$ as the restriction of the projection from $\text{PSL}_2(\mathbb{R})$ onto $\text{SL}_2(\mathbb{R})$ to $\tilde{\Gamma} = \pi_1(M)$. The fundamental group $\tilde{\Gamma}$ is the central extension such that the following commutative diagram holds:

$$
\begin{array}{ccc}
0 & \longrightarrow & \mathbb{Z} & \longrightarrow & \tilde{\Gamma} & \longrightarrow & \Gamma & \longrightarrow & 1 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \text{PSL}_2(\mathbb{R}) & \longrightarrow & \text{PSL}_2(\mathbb{R}) & \longrightarrow & 1.
\end{array}
$$

According to [JN85, Proofs of Theorem 1 and 2], we can describe the image of the generators $h$ and $q_j$ in the presentation $\{2\}$ of $\tilde{\Gamma} = \pi_1(M)$ under the restriction of the projection from $\text{PSL}_2(\mathbb{R})$ onto $\text{SL}_2(\mathbb{R})$ as in the next proposition.

**Proposition 3.1.** Let the Seifert index of $M = \tilde{\Gamma} \backslash \text{PSL}_2(\mathbb{R})$ be $(g; (1, 2g - 2), (\alpha_1, \alpha_j - 1), \ldots, (\alpha_m, \alpha_m - 1))$ and $h$ denote the homotopy class of a regular fiber in the Seifert fibration of $M$. If $\rho$ is an $\text{SL}_2(\mathbb{R})$-representation of $\pi_1(M) = \tilde{\Gamma}$ given by the restriction of the projection from $\text{PSL}_2(\mathbb{R})$ onto $\text{SL}_2(\mathbb{R})$ to $\tilde{\Gamma}$, then the images of $h$ and $q_j$ in $\text{SL}_2(\mathbb{R})$ and a closed orbit $\gamma$ of the geodesic flow $\phi_t$ by $\rho$ satisfy that

$$
\begin{align*}
\rho(h) &= -1, \\
\rho(q_j) &\text{ is conjugate to } \begin{pmatrix} \cos(1 - \alpha_j) & \sin(1 - \alpha_j) \\ \sin(1 - \alpha_j) & \cos(1 - \alpha_j) \end{pmatrix}, \\
\rho(\gamma) &\text{ is conjugate to } \begin{pmatrix} e^{t(\gamma)/2} & 0 \\ 0 & e^{-t(\gamma)/2} \end{pmatrix}
\end{align*}
$$

where $t(\gamma)$ is the period of the closed orbit $\gamma$.

**Proof.** Every regular fiber in the Seifert fibration of $M$ gives a central element $h$ generating the center ($\simeq \mathbb{Z}$) of $\pi_1(M)$. It follows from the construction that the center $\langle h \rangle$ of $\pi_1(M)$ coincides with the center of $\text{PSL}_2(\mathbb{R})$. We can see that $\rho(h) = -1$.

The center $\mathbb{Z}$ of $\text{PSL}_2(\mathbb{R})$ is contained in the component $\mathbb{R}$ in $\text{PSL}_2(\mathbb{R}) \simeq \mathbb{H}^2 \times \mathbb{R}$ (homeomorphically, note that $\text{PSL}_2(\mathbb{R})$ is not isometric to $\mathbb{H}^2 \times \mathbb{R}$). The projection of $\text{PSL}_2(\mathbb{R})$ onto $\text{SL}_2(\mathbb{R})$ sends the central element $m \in \mathbb{Z}$ of $\text{PSL}_2(\mathbb{R})$ to $(-1)^m$ in $\text{SL}_2(\mathbb{R})$ and a rational number $m/n$ in $\mathbb{R}$ of $\text{PSL}_2(\mathbb{R})$ to an $\text{SL}_2(\mathbb{R})$-matrix conjugate to the rotation matrix with angle $m\pi/n$. Together with the relation $q_j^n h^{n-1} = 1$, we can also see that $\rho$ sends $q_j$ to an $\text{SL}_2(\mathbb{R})$-matrix conjugate to the rotation matrix with angle $(1 - \alpha_j)\pi/\alpha_j$.

Finally every closed orbit of the geodesic flow $\phi_t$ is induced by the action of the one parameter group:

$$
\left\{ \begin{pmatrix} e^{t/2} & 0 \\ 0 & e^{-t/2} \end{pmatrix} \mid t \in \mathbb{R} \right\}
$$

which gives the flow of the vector field generated by $\begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix}$ of $\text{sl}_2(\mathbb{R})$ on $\text{PSL}_2(\mathbb{R})$. There exist the lifts of the vector field to the covering spaces $\tilde{\text{PSL}}_2(\mathbb{R})$ and $\text{SL}_2(\mathbb{R})$. The image $\rho(\gamma)$ is given by the projection to the flow of the vector field generated by the same element of the Lie algebra on $\text{SL}_2(\mathbb{R})$. Hence the image $\rho(\gamma)$ is conjugate to a hyperbolic element with positive trace.
We also review the irreducible \( n \)-dimensional representation \( \sigma_n \) of \( \text{SL}_2(\mathbb{C}) \). It is known that every irreducible \( n \)-dimensional representation over \( \mathbb{C} \) is equivalent to the following action of \( \text{SL}_2(\mathbb{C}) \) on the space of homogeneous polynomials of degree \( n - 1 \). Let \( V_n \) be the vector space consisting of homogeneous polynomials with coefficient \( \mathbb{C} \) of degree \( n - 1 \) in \( x \) and \( y \), i.e.,
\[
V_n = \text{span}_\mathbb{C}\{x^{n-1}, x^{n-2}y, \ldots, xy^{n-2}, y^{n-1}\}.
\]
The Lie group \( \text{SL}_2(\mathbb{C}) \) acts on \( V_n \) as
\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \cdot p(x, y) = p\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1}x, \begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1}y\right) = p(dx - by, -cx + ay)
\]
for \( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{C}) \). This action defines an irreducible \( \text{SL}_n(\mathbb{C}) \)-representation of \( \text{SL}_2(\mathbb{C}) \) which is denoted by \( \sigma_n \).

**Remark 3.2.** We give several remarks on \( \sigma_n \) needed later.

- The vector space \( V_n \) is also referred to as the \( (n - 1) \)-th symmetric product of \( \mathbb{C}^2 \) with the standard action of \( \text{SL}_2(\mathbb{C}) \).
- If an \( \text{SL}_2(\mathbb{C}) \)-matrix \( A \) has the eigenvalues \( a^{\pm 1} \), then \( \sigma_n(A) \) has the eigenvalues \( a^{n-1}, a^{n-3}, \ldots, a^{-(n-3)}, a^{-(n-1)} \) (the exponents are decreasing by 2). In the case of \( n = 2N \), the eigenvalues of \( \sigma_{2N}(A) \) are given by \( \{a^{\pm(2N-1)}, a^{\pm(2N-3)}, \ldots, a^{\pm 1}\} \).

**Definition 3.3** \( (2N \text{-dimensional representation of } \pi_1(\Gamma \backslash \text{PSL}_2(\mathbb{R}))) \). We define the \( \text{SL}_{2N}(\mathbb{C}) \)-representation \( \rho_{2N} \) as the composition of \( \sigma_{2N} \) with the restriction of \( \text{PSL}_2(\mathbb{R}) \to \text{SL}_2(\mathbb{R}) \) to \( \pi_1(\Gamma \backslash \text{PSL}_2(\mathbb{R})) \), i.e.,
\[
\rho_{2N} : \pi_1(\Gamma \backslash \text{PSL}_2(\mathbb{R})) \xrightarrow{\pi} \text{SL}_2(\mathbb{R})(\subset \text{SL}_2(\mathbb{C})) \xrightarrow{\sigma_{2N}} \text{SL}_{2N}(\mathbb{C}).
\]

**Proposition 3.4.** The \( \text{SL}_{2N}(\mathbb{C}) \)-representation \( \rho_{2N} \) sends \( h \) to \(-1_{2N}\).

**Proof.** By Proposition 3.1 and Remark 3.2, \( \rho \) sends \( h \) to \(-1 \) and the irreducible representation \( \sigma_{2N} \) of \( \text{SL}_2(\mathbb{C}) \) sends \(-1 \) to \(-1_{2N} \). Hence the \( \text{SL}_{2N}(\mathbb{C}) \)-representation \( \rho_{2N} = \sigma_{2N} \circ \rho \) also sends \( h \) to \(-1_{2N} \).

It follows from Proposition 3.4 and [Yam17 Proposition 4.1] that our representations \( \rho_{2N} \) define the higher-dimensional Reidemeister torsion of \( M = \Gamma \backslash \text{PSL}_2(\mathbb{R}) \) discussed in [Yam17]. For the details on the higher-dimensional Reidemeister torsion, see [Yam17].

**Corollary 3.5.** Each representation \( \rho_{2N} \) of \( \pi_1(M) \) defines an acyclic local system of \( M \) with the coefficient \( V_{2N} \) and the higher-dimensional Reidemeister torsion \( \text{Tor}(M, \rho_{2N}) \) of \( M \).

### 3.2. The Ruelle zeta function for \( \text{SL}_{2N}(\mathbb{C}) \)-representations.

We consider the Ruelle zeta function with a non-unitary representation \( \rho_{2N} \) of \( \pi_1(\Gamma \backslash \text{PSL}_2(\mathbb{R})) \) for a discrete subgroup \( \Gamma \in \text{PSL}_2(\mathbb{R}) \). The Ruelle zeta function with the \( 2N \)-dimensional representation \( \rho_{2N} \) is also expressed as the ratio of the Selberg zeta function. Moreover, the value of our Ruelle zeta function at zero has an integral expression given by the functional equation of the Selberg zeta function. We will observe the resulting integral expression in detail.

Here and subsequently, we often regard the unit tangent bundle \( \Gamma \backslash \text{PSL}_2(\mathbb{R}) \) over a hyperbolic orbifold \( \Sigma = \Gamma \backslash \mathbb{H}^2 \) as \( \Gamma \backslash \text{PSL}_2(\mathbb{R}) \) where \( \tilde{\Gamma} = p^{-1}(\Gamma) \) by the projection \( p : \text{PSL}_2(\mathbb{R}) \to \text{PSL}_2(\mathbb{R}) \).

**Proposition 3.6.** Suppose that \( M = \Gamma \backslash \text{PSL}_2(\mathbb{R})(= \tilde{\Gamma} \backslash \text{PSL}_2(\mathbb{R})) \) and \( \rho \) denotes the \( \text{SL}_2(\mathbb{R}) \)-representation of \( \pi_1(M)(= \tilde{\Gamma}) \) given by the restriction of the projection from \( \text{PSL}_2(\mathbb{R}) \) onto
SL₂(ℝ) to Γ. Then the Ruelle zeta function for M with the non-unitary representation ρ₂N = σ₂N ◦ ρ satisfies

\[ R_{ρ₂N}(s) = \frac{Z(s - N + 1/2)}{Z(s + N + 1/2)}. \]

Moreover, when we set \( η(s) = Z(s)/Z(1 - s) \), the value of Ruelle zeta function at zero is expressed as

\[ R_{ρ₂N}(0) = \frac{Z(-N + 1/2)}{Z(N + 1/2)} = η(N + 1/2)^{-1}. \]

**Proof.** By Proposition 3.1 and Remark 3.2, the Ruelle zeta function \( R_{ρ₂N}(s) \) is expressed as

\[
R_{ρ₂N}(s) = \prod_{γ \text{ prime}} \det(1 - ρ₂N(γ)e^{-s(γ)})
\]

\[
= \prod_{γ \text{ prime}} \prod_{k=1}^{N} (1 - e^{-s(2k-1)/2(γ)}) \left(1 - e^{s(2k-1)/2(γ)} \right)
\]

\[
= \prod_{k=1}^{N} \prod_{γ \text{ prime}} (1 - e^{-s(2k-1)/2(γ)})(1 - e^{s(2k-1)/2(γ)})
\]

\[
= \prod_{k=1}^{N} R \left( s - \frac{2k-1}{2} \right) R \left( s + \frac{2k-1}{2} \right)
\]

\[
= \frac{Z(s - 1/2)}{Z(s + 1/2)} \cdots \frac{Z(s - (2N - 1)/2)}{Z(s + 1/2)} \frac{Z(s + 1/2)}{Z(s + 2N)} \cdots \frac{Z(s + 2N)}{Z(s + 1/2)}
\]

\[
= \frac{Z(s - N + 1/2)}{Z(s + N + 1/2)}. \]

The second equality from the last follows from the classical relation (5) between the Ruelle and Selberg zeta functions. □

We will examine the absolute value at zero of the Ruelle zeta function \( R_{ρ₂N}(s) \) more closely. By calculating the integral expression of \( η(N + 1/2) = R_{ρ₂N}(0)^{-1} \), we have the explicit formula of \( |R_{ρ₂N}(0)|^{-1} \).

**Theorem 3.7.** Under the same assumptions as Proposition 3.6, the absolute value at zero of the Ruelle zeta function is expressed as follows.

\[
|R_{ρ₂N}(0)|^{-1} = |η(N + 1/2)|
\]

\[
= \exp \left[ μ(Σ) \left( \frac{N}{\pi} \log 2 \right) \right]
\]

\[
\cdot \exp \left[ \sum_{j=1}^{m} \left( \log \prod_{k=1}^{N} \left( 1 - e^{(2k-1)\theta(q_j)^{-1}} \right) \left( 1 - e^{-(2k-1)\theta(q_j)^{-1}} \right) - \frac{2N}{m(q_j)} \log 2 \right) \right]
\]

(16)
To prove Theorem 3.7 we start with the integral expression of \( \eta(s) \). By \( \eta(1/2) = 1 \) and the functional equation (13) of the Selberg zeta function, we can express \( \eta(s) \) as follows.

\[
\eta(s) = \exp \left( \int_{1/2}^{s} \frac{d}{dz} \log \eta(z) \, dz \right)
\]

\[
= \exp \left( \mu(\mathcal{D}) \int_{1/2}^{s} (z - 1/2) \tan \pi(z - 1/2) \, dz \right)
\]

\[
+ \sum_{\{\mathcal{R}\} \text{elliptic}} \int_{1/2}^{s} \frac{-\pi}{m(R) \sin \theta(R)} \frac{\cos((2\theta(R) - \pi)(z - 1/2))}{\cos \pi(z - 1/2)} \, dz \right) .
\]

put \( \xi = z - 1/2 \),

\[
= \exp \left( \mu(\mathcal{D}) \int_{0}^{s-1/2} \xi \tan \pi \xi \, d\xi \right)
\]

\[
+ \sum_{\{\mathcal{R}\} \text{elliptic}} \int_{0}^{s-1/2} \frac{-\pi}{m(R) \sin \theta(R)} \frac{\cos((2\theta(R) - \pi)\xi)}{\cos \pi \xi} \, d\xi \right) .
\]

Summarizing, we have the following integral expression of \( \eta(N + 1/2) = R_{p=2}^{-1}(0) \).

**Proposition 3.8.**

\[
R_{p=2}^{-1}(0) = \eta(N + 1/2)
\]

\[
= \exp \left( \mu(\mathcal{D}) \int_{0}^{N} \xi \tan \pi \xi \, d\xi + \sum_{\{\mathcal{R}\} \text{elliptic}} \int_{0}^{N} \frac{-\pi}{m(R) \sin \theta(R)} \frac{\cos((2\theta(R) - \pi)\xi)}{\cos \pi \xi} \, d\xi \right) .
\]

Then the absolute value \( |\eta(N + 1/2)| \) is determined by the real part of the exponent:

\[
\text{Re} \left( \mu(\mathcal{D}) \int_{0}^{N} \xi \tan \pi \xi \, d\xi + \sum_{\{\mathcal{R}\} \text{elliptic}} \int_{0}^{N} \frac{-\pi}{m(R) \sin \theta(R)} \frac{\cos((2\theta(R) - \pi)\xi)}{\cos \pi \xi} \, d\xi \right) .
\]

We calculate these integrals in Propositions 3.9 and 3.10 which arise from the identity element and elliptic elements in \( \Gamma \). Theorem 3.7 follows from Propositions 3.8, 3.9 and 3.10 together with the presentation (11) of \( \Gamma \).

**Proposition 3.9.** The contribution of the identity element to the exponent of \( |\eta(N + 1/2)| \) is expressed as

\[
\text{Re} \left( \mu(\mathcal{D}) \int_{0}^{N} \xi \tan \pi \xi \, d\xi \right) = \mu(\mathcal{D}) \left( -\frac{N}{\pi} \log 2 \right) .
\]

**Proof.** The real part of the path integral turns out to be

\[
\text{Re} \left( \int_{0}^{N} \xi \tan \pi \xi \, d\xi \right) = \text{Re} \left( \int_{0}^{N} \xi \tan \pi \xi \, d\xi \right)
\]

\[
= \left[ \frac{1}{\pi} \log |\cos \pi \xi| \right]_{0}^{N} + \frac{1}{\pi} \text{p.v.} \int_{0}^{N} \log |\cos \pi \xi| \, d\xi
\]

\[
= \frac{N}{\pi} \text{p.v.} \int_{0}^{1} \log |\cos \pi \xi| \, d\xi
\]

\[
= -\frac{N}{\pi} \log 2 .
\]
Next we proceed to the contribution of elliptic elements in $\Gamma$ to the exponent of $|\eta(N + 1/2)|$. The set of conjugacy classes of elliptic elements is divided into the subsets

$$\{[R_0], [R_0^2], \ldots, [R_0^{m_0-1}]\}$$

of conjugacy classes which have the representatives of the same order $m_0$.

**Proposition 3.10.** Suppose that an elliptic element $R_0$ satisfies $\text{tr} R_0 = 2 \cos \theta(R_0)$ with $\theta(R_0) = \pi/m_0 (m_0 \geq 2)$. Then the sum of

$$\text{Re} \left( \int_0^N \frac{-\pi}{m(R) \sin \theta(R)} \frac{\cos(2\theta(R) - \pi \xi)}{\cos \pi \xi} \, d\xi \right)$$

over $\{[R_0], [R_0^2], \ldots, [R_0^{m_0-1}]\}$ is given by

$$\log \prod_{k=1}^N \left( 1 - e^{(2k-1)\pi \sqrt{-1/m_0}} \right) \left( 1 - e^{-(2k-1)\pi \sqrt{-1/m_0}} \right) - \frac{2N}{m_0} \log 2.$$
we can express (17) as

\[
\text{Re} \int_1^{z_0} \frac{P(z)}{Q(z)} \, dz = \sum_{w^{m_0-1}} \frac{1}{m_0} \sum_{p=1}^{m_0-1} \left( \log \left| 1 - \frac{w^p - w^{-p}}{z_0^p - z_0^{-p}} \right| \right)
\]

since \(w/z_0^2\) also satisfies \((w/z_0^2)^{m_0} = -1\).

\[
= \frac{1}{m_0} \sum_{w^{m_0-1}} \left( \log \left| 1 - \frac{z_0 w^p - z_0 w^{-p}}{z_0^p - z_0^{-p}} \right| \right)
\]

as the sum of \((z_0 w)^p\) turns into \(m_0 - 1\) or \(-1\) if \(z_0 w = 1\) or not,

\[
= \frac{2}{m_0} \left( (m_0 - 1) \log |1 - z_0^{-1}| - \sum_{w^{m_0-1}} \log |1 - w| \right)
\]

by \(\prod_{w^{m_0-1}} (x - w) = x^{m_0} + 1\). This completes the proof. \(\Box\)

**Lemma 3.12.** The contribution of the elliptic elements \(R_0^p(1 \leq p \leq m_0 - 1)\) to the exponent of \(|\eta(N + 1/2)|\) over the \(k\)-th interval \([k-1, k]\) is expressed as

\[
\text{Re} \left( \int_{k-1}^k \sum_{p=1}^{m_0-1} \frac{-\pi}{m_0 \sin \frac{\pi}{m_0}} \frac{\cos \left( \frac{p\pi}{m_0} - \pi \right) \xi^p}{\cos \pi \xi^p} \, d\xi \right) = 2 \log |1 - e^{-(2k-1)\pi} \sqrt{m_0}| - \frac{2}{m_0} \log 2
\]

**Proof.** This follows in much the same way as in the proof of Lemma 3.11. We show the differences from the proof of Lemma 3.11 under the same notations. The integral of the
left hand side in (19) turns into
\[
\text{Re} \int_{x_0^2}^{x_0^1} \frac{P(z)}{\tilde{Q}(z)} \, dz
\]
\[
= \text{Re} \sum_{z_1 : \tilde{Q}(z_1) = 0} \frac{P(z_1)}{\tilde{Q}(z_1)} \log \frac{z_1 - z_1}{z_0 - z_0}
\]
by a similar argument in the proof of Lemma 3.11 and putting \(w = z_1 / z_0\),
\[
\sum_{w^{m_0} = -1} \frac{1}{m_0} \sum_{p=1}^{m_0-1} \frac{(z^{2k-1}w)^p - (z^{2k-1}w)^{-p}}{z_0^p - z_0^{-p}} \left( \log \left| 1 - \frac{w}{z_0^p} \right| - \log |1 - w| \right)
\]
\[
= \sum_{w^{m_0} = -1} \frac{1}{m_0} \log \left( 1 - \frac{w}{z_0^p} \right) \sum_{p=1}^{m_0-1} \frac{(z^{2k-1}w)^p - (z^{2k-1}w)^{-p}}{z_0^p - z_0^{-p}}
\]
\[
= \frac{1}{m_0} \sum_{w^{m_0} = -1} \left( \log \left| 1 - \frac{w}{z_0^p} \right| \sum_{p=1}^{m_0-1} (z^{2k-1}w)^p + (z^{2k-1}w)^{-p} \right)
\]
\[
= 2 \log |1 - z_0^{2k-1}| - \frac{2}{m_0} \log 2
\]
which proves our claim.

Finally we proceed to show Proposition 3.10.

**Proof of Proposition 3.10.** By Lemmas 3.11 and 3.12 our sum over the conjugacy classes \(\{R_0, R_0^2, \ldots, (R_0^{-m_0})^{-1}\}\) turns out to be
\[
\sum_{p=1}^{m_0-1} \text{Re} \left( \int_0^N \frac{-\pi}{m(R_0^p) \sin \theta(R_0^p)} \frac{\cos((2\theta(R_0^p) - \pi)\xi)}{\cos \pi \xi} \, d\xi \right)
\]
\[
= 2 \sum_{k=1}^N \log |1 - e^{-(2k-1)\pi \sqrt{-1}/m_0}| - \frac{2N}{m_0} \log 2
\]
\[
= \log \prod_{k=1}^N |1 - e^{-(2k-1)\pi \sqrt{-1}/m_0}|^2 - \frac{2N}{m_0} \log 2
\]
\[
= \log \prod_{k=1}^N (1 - e^{-(2k-1)\pi \sqrt{-1}/m_0})(1 - e^{-(2k-1)\pi \sqrt{-1}/m_0}) - \frac{2N}{m_0} \log 2.
\]
will show that the absolute value at zero of the Ruelle zeta function $R_{\rho_{2N}}(s)$ for the induced $\text{SL}_{2N}(\mathbb{C})$-representation $\rho_{2N}$ coincides with the higher-dimensional Reidemeister torsion $\text{Tor}(M; \rho_{2N})$ for $M = \Gamma \backslash \text{PSL}_{2}(\mathbb{R})$ with $\rho_{2N}$.

For this purpose, we find out the order of the $\text{SL}_{2}(\mathbb{R})$-matrix $\rho(\ell_j)$ corresponding to the exceptional fiber $\ell_j$ of $M$ in $\text{SL}_{2}(\mathbb{C})$.

**Lemma 3.13.** The $\text{SL}_{2}(\mathbb{R})$-matrix $\rho(\ell_j)$ for each exceptional fiber $\ell_j$ is conjugate to

$$\begin{pmatrix}
 e^{\pi \sqrt{-1}/\alpha_j} & 0 \\
 0 & e^{-\pi \sqrt{-1}/\alpha_j}
\end{pmatrix}$$

in $\text{SL}_{2}(\mathbb{C})$. In particular, the order of $\rho(\ell_j)$ is equal to $2\alpha_j$ in $\text{SL}_{2}(\mathbb{C})$.

**Proof.** By the relation (3), $\rho(\ell_j)$ is expressed as $\rho(\ell_j) = \rho(q_j)^{-1}\rho(h)^{-1}$. It follows from Proposition 3.1 that $\rho(q_j)^{-1}\rho(h)^{-1}$ is conjugate to $\begin{pmatrix}
 e^{\pi \sqrt{-1}/\alpha_j} & 0 \\
 0 & e^{-\pi \sqrt{-1}/\alpha_j}
\end{pmatrix}$ in $\text{SL}_{2}(\mathbb{C})$. 

It follows from Lemma 3.13 and Remark 3.2 that the $\text{SL}_{2N}(\mathbb{C})$-matrix $\rho_{2N}(\ell_j)$ has the eigenvalues $e^{\pi(2(2N-1)\pi \sqrt{-1}/\alpha_j), e^{\pi(2N-3)\pi \sqrt{-1}/\alpha_j}, \ldots, e^{\pi\pi \sqrt{-1}/\alpha_j}}$. By [Yam17] Proposition 4.8, the Reidemeister torsion for $\Gamma \backslash \text{PSL}_{2}(\mathbb{R})$ and $\rho_{2N}$ is given as follows.

**Proposition 3.14.** The higher-dimensional Reidemeister torsion for $M = \Gamma \backslash \text{PSL}_{2}(\mathbb{R})$ with $\rho_{2N}$ is expressed as

$$\text{Tor}(M; \rho_{2N}) = 2^{-2N(2-2g-m)} \prod_{j=1}^{m} \prod_{k=1}^{N} \left(2 \sin \frac{\pi(2k-1)}{2\alpha_j}\right)^{-2}$$

We are now in position to show the relation between the Ruelle zeta function and the Reidemeister torsion.

**Theorem 3.15.** $|R_{\rho_{2N}}(0)| = \text{Tor}(M; \rho_{2N})$

**Proof.** We have seen $|R_{\rho_{2N}}(0)|$ in Theorem 3.7. The angle $\theta(q_j)$ and the order $m(q_j)$ in the equality (16) satisfy $\theta(q_j) = \pi/\alpha_j$ and $m(q_j) = \alpha_j$ (note that $m(q_j)$ is the order of $\rho(q_j)$ in $\text{PSL}_{2}(\mathbb{R})$). By the Gauss–Bonnet theorem $\mu(D) = -2\pi \chi^{\text{orb}}(\Sigma)$, we can rewrite the equality (16) as

$$|R_{\rho_{2N}}(0)|^{-1} = \exp \left[ \mu(D) \left( -\frac{N}{\pi} \log 2 \right) \right]$$

$$\cdot \exp \left[ \sum_{j=1}^{m} \prod_{k=1}^{N} \left( 1 - e^{i(2k-1)\pi \sqrt{-1}/\alpha_j} \right) \left( 1 - e^{-i(2k-1)\pi \sqrt{-1}/\alpha_j} \right) - \frac{2N}{\alpha_j} \log 2 \right]$$

$$= \exp \left[ 2N \chi^{\text{orb}}(\Sigma) \log 2 \right]$$

$$\cdot \exp \left[ \sum_{j=1}^{m} \prod_{k=1}^{N} \left( 2 \sin \frac{\pi(2k-1)}{2\alpha_j} \right)^{-2} - \frac{2N}{\alpha_j} \log 2 \right].$$
replacing \( \chi^{orb}(\Sigma) \) with \( 2 - 2g - \sum_{j=1}^{m} (\alpha_j - 1)/\alpha_j \),

\[
= \exp \left[ 2N \left( 2 - 2g - m \frac{\alpha_j - 1}{\alpha_j} \right) \log 2 \right] \cdot \exp \left[ m \left( \log \prod_{k=1}^{N} \left( 2 \sin \frac{\pi (2k - 1)}{2\alpha_j} \right)^2 - \frac{2N}{\alpha_j} \log 2 \right) \right]
\]

\[
= \exp [2N(2 - 2g - m) \log 2] \exp \left[ \sum_{j=1}^{m} \left( \log \prod_{k=1}^{N} \left( 2 \sin \frac{\pi (2k - 1)}{2\alpha_j} \right)^2 \right) \right].
\]

comparing with (20),

\[
= \text{Tor}(M; \rho_{2N})^{-1}.
\]

\[\square\]

The Reidemeister torsion \( \text{Tor}(M; \rho_{2N}) \) in Proposition 3.14 is derived from the following equality:

(21) \[ \text{Tor}(M; \rho_{2N}) = \det(1 - \rho_{2N}(h))^{-(2-2g-m)} \prod_{j=1}^{m} \det(1 - \rho_{2N}(\ell_j))^{-1}. \]

Note that \( \det(1 - \rho_{2N}(h)) = 2^{2N} \). The contribution of the identity element to \( |R_{\rho_{2N}}(0)|^{-1} \) is also expressed as

(22) \[ \exp \left[ \mu(\mathcal{D}) \left( -\frac{N}{\pi} \log 2 \right) \right] = \exp \left[ 2N \chi^{orb}(\Sigma) \log 2 \right] = \det(1 - \rho_{2N}(h))^{2-2g-\sum_{j=1}^{m} (\alpha_j - 1)/\alpha_j}. \]

The contribution of elliptic elements to \( |R_{\rho_{2N}}(0)|^{-1} \) is expressed as

(23) \[ \exp \left[ \sum_{j=1}^{m} \left( \log \prod_{k=1}^{N} \left( e^{(2k - 1)\pi \sqrt{-1}/\alpha_j} - 1 \right) \left( e^{-(2k - 1)\pi \sqrt{-1}/\alpha_j} - 1 \right) - \frac{2N}{\alpha_j} \log 2 \right) \right]
\]

\[
= \prod_{j=1}^{m} \det(1 - \rho_{2N}(\ell_j)) \det(1 - \rho_{2N}(h))^{-1/\alpha_j}.
\]

One can find the common factors \( \prod_{j=1}^{m} \det(1 - \rho_{2N}(h))^{-1/\alpha_j} \) in the both of the contributions. The common factors cancel out in the product and the remain factors give the Reidemeister torsion as in (21). We will see the contribution of the identity element only affects the leading coefficient in the asymptotic behavior of \( \log |\text{Tor}(M; \rho_{2N})| \) as \( N \rightarrow \infty \) in the next Subsection.

Remark 3.16. Our manifold \( M = \Gamma \backslash \text{PSL}_2(\mathbb{R}) \) is regarded as \( \Gamma \backslash \overline{\text{PSL}}_2(\mathbb{R}) \) and \( \Gamma = p^{-1}(\Gamma') \subset \text{PSL}_2(\mathbb{R}) \) as a subgroup of \( \text{Isom} \text{PSL}_2(\mathbb{R}) \). Hence \( M \) is geometric and the representation \( \rho_{2N} = \sigma_{2N} \circ \rho \) is obtained from the geometric description of \( M \). However not all discrete subgroups \( G \subset \text{Isom} \text{PSL}_2(\mathbb{R}) \) with Seifert fibered spaces \( G \backslash \text{PSL}_2(\mathbb{R}) \rightarrow \Gamma \backslash \mathbb{H}^2 \) satisfy \( G = p^{-1}(\Gamma) \) under the projection \( p : \text{PSL}_2(\mathbb{R}) \rightarrow \text{PSL}_2(\mathbb{R}) \). See [Ste83, Theorem 4.15] for the details.
3.4. **Asymptotic behavior of the Reidemeister torsion via Ruelle zeta function.** In the previous section, we have seen that the Reidemeister torsion is expressed as the absolute value at zero of the Ruelle zeta function. We can also see the asymptotic behavior of the Reidemeister torsion for \(2N\)-dimensional representations from the viewpoint of the Ruelle zeta function as \(N\) goes to infinity.

First, we see that the contribution \( (23) \) of elliptic elements to the Ruelle zeta function vanishes in the asymptotic behavior of \( \log |R_{p_{2N}}(0)| \) when \(N\) goes to infinity.

**Lemma 3.17.** The contribution of elliptic elements to \( (\log |R_{p_{2N}}(0)|)/(2N) \) converges to zero as \(N \to \infty\), that is,

\[
\frac{1}{2N} \left( - \log \left( \prod_{j=1}^{m} \det(1 - \rho_{2N}(\ell_j)) \det(1 - \rho_{2N}(h))^{-1/\alpha_j} \right) \right) \xrightarrow{N \to \infty} 0.
\]

**Proof.** The contribution of elliptic elements to \( \log |R_{p_{2N}}(0)| \) is also given by

\[
- \log \left( \prod_{j=1}^{m} \det(1 - \rho_{2N}(\ell_j)) \det(1 - \rho_{2N}(h))^{-1/\alpha_j} \right)
= - \sum_{j=1}^{m} \log \det(1 - \rho_{2N}(\ell_j)) + \sum_{j=1}^{m} \frac{1}{\alpha_j} \log \det(1 - \rho_{2N}(h))
= - \sum_{j=1}^{m} \log \det(1 - \rho_{2N}(\ell_j)) + \sum_{j=1}^{m} \frac{2N}{\alpha_j} \log 2.
\]

By Lemma 3.13, our \( \text{SL}_2(\mathbb{C}) \)-representation \( \rho \) sends each exceptional fiber \( \ell_j \) to an \( \text{SL}_2(\mathbb{C}) \)-matrix of order \( 2\alpha_j \). Since \( \det(1 - \rho_{2N}(\ell_j)) \) is regarded as the Reidemeister torsion for the exceptional fiber \( \ell_j \) and the restriction of \( \rho_{2N} \), it follows from [Yam17, Proposition 3.8] that

\[
\lim_{N \to \infty} \frac{\log \det(1 - \rho_{2N}(\ell_j))^{-1}}{2N} = - \frac{\log 2}{\alpha_j}.
\]

The contribution of elliptic elements to the limit of \( (\log |R_{p_{2N}}(0)|)/(2N) \) is given by

\[
\lim_{N \to \infty} \frac{1}{2N} \left( - \sum_{j=1}^{m} \log \det(1 - \rho_{2N}(\ell_j)) + \sum_{j=1}^{m} \frac{2N}{\alpha_j} \log 2 \right)
= \sum_{j=1}^{m} \lim_{N \to \infty} \log \det(1 - \rho_{2N}(\ell_j))^{-1} \frac{1}{2N} + \sum_{j=1}^{m} \frac{1}{\alpha_j} \log 2
= 0.
\]

We can recover the limit of the leading coefficient in \( \log |\text{Tor}(M; \rho_{2N})| \) from the asymptotic behavior of \( |R_{p_{2N}}(0)| \).

**Proposition 3.18.** The leading coefficient of \( (\log |\text{Tor}(M; \rho_{2N})|)/(2N) \) is determined by the contribution \( (22) \) of the identity element to \( R_{p_{2N}}(0) \) as \( N \to \infty \). That is,

\[
\lim_{N \to \infty} \frac{\log |\text{Tor}(M; \rho_{2N})|}{2N} = \frac{\text{Area}(\Sigma)}{2\pi} \log 2.
\]

Therefore we can derive the area of the base orbifold \( \Sigma \) from the limit of the leading coefficient in \( \log |\text{Tor}(M; \rho_{2N})| \).
Proof. It follows from Theorem 3.15 and Lemma 3.17 that
\[
\lim_{N \to \infty} \frac{\log |\text{Tor}(M; \rho_{2N})|}{2N} = \lim_{N \to \infty} \frac{\log |R_{2N}(0)|}{2N} = \lim_{N \to \infty} \frac{1}{2N} \log \exp \left[ -\mu(D) \left( -\frac{N}{\pi} \log 2 \right) \right] = \frac{\mu(D)}{2\pi} \log 2.
\]

Together with the Gauss–Bonnet theorem \(\text{Area}(\Sigma) = \mu(D) = -2\pi\chi_{\text{orb}}\) for the hyperbolic orbifold \(\Sigma\), the equality (24) turns out to be
\[
\lim_{N \to \infty} \frac{\log |\text{Tor}(M; \rho_{2N})|}{2N} = -\chi_{\text{orb}} \log 2.
\]

It was showed in [Yam17] that there exist finitely many possibilities in the limits of the leading coefficient in \(\log |\text{Tor}(M; \rho_{2N})|\) for sequences of \(\text{SL}_2(\mathbb{C})\)-representations starting with \(\text{SL}_2(\mathbb{C})\)-representations sending \(h\) to \(-1\) and the maximum in those possibilities is given by \(-\chi_{\text{orb}} \log 2\).

Proposition 3.18 shows that the limit of the leading coefficient in \(\log |\text{Tor}(M; \rho_{2N})|\) for the sequence of \(\text{SL}_2(\mathbb{C})\)-representations \(\rho_{2N}\) induced from the geometric description \(M = \tilde{\Gamma} \backslash \text{PSL}_2(\mathbb{R})\) realizes the upper bound of limits of the leading coefficients in the logarithm of the Reidemeister torsion of \(M\).

**Corollary 3.19.** The limit of \((\log |\text{Tor}(M; \rho_{2N})|)/(2N)\) attains the maximum \(-\chi_{\text{orb}} \log 2\).
