RECONSTRUCTING ÉTALE GROUPOIDS FROM SEMIGROUPS

TRISTAN BICE, LISA ORLOFF CLARK AND ASTRID AN HUEF

Abstract. We reconstruct étale groupoids from semigroups of functions defined upon them, thus unifying reconstruction theorems such as

Kumjian-Renault’s reconstruction from a groupoid C*-algebra.

Exel’s reconstruction from an ample inverse semigroup.

Steinberg’s reconstruction from a groupoid ring.

Choi-Gardella-Thiel’s reconstruction from a groupoid $L^p$-algebra.

1. Introduction

1.1. Motivation. Continuous functions on étale groupoids provide a rich array of non-commutative structures like C*-algebras, $L^p$-algebras, Steinberg algebras and inverse semigroups. Under suitable conditions, the groupoid can be even reconstructed from the corresponding algebraic structure, as seen in [Kum86], [Ren08], [Exe10], [Ste19] and [CGT19]. While the algebraic structures involved differ, what they do share is a product defined in essentially the same way. This hints at the possibility of unifying these reconstruction theorems by focusing just on the product structure. Indeed, in the commutative case this was essentially already done in [Mil49] – what we demonstrate is that [Mil49] admits a non-commutative extension which unifies all the above mentioned reconstruction theorems.

1.2. Outline. We start with some general notational conventions in §2. We also observe that semigroup-valued (partial) functions admit a well-defined product given in (2.1), so long as the domain of at least one of the functions is a bisection. This allows us more freedom than the ring or field-valued (total) functions usually considered elsewhere, and also avoids the need to consider the infinite sums that can arise when dealing with the convolution product.

In §3, we introduce the central concept of a bumpy semigroup. These are semigroups of functions defined on open bisections satisfying 3 basic properties needed to recover the underlying groupoid. We then show that bumpy semigroups exist precisely on locally compact étale groupoids, at least when the unit space is Hausdorff, and that even stronger compact-bumpy semigroups encompass a wide range of examples, including those arising in the reconstruction theorems in the literature mentioned above.

We next introduce the domination relation in §4, a transitive relation which can be defined on any abstract semigroup $S$ with a distinguished subsemigroup $D$. We then characterise the domination relation on compact-bumpy semigroups via the compact containment relation in (4.1).

2010 Mathematics Subject Classification. 06F05, 18B40, 20M18, 20M25, 22A22, 46L05, 47D03.

Key words and phrases. étale, groupoid, semigroup, continuous function, ring, C*-algebra.

The first author is supported by the Institute of Mathematics of the Czech Academy of Sciences. The second and third authors are supported by Victoria University of Wellington.
Next we consider ultrafilters with respect to the domination relation, using them to recover the étale groupoid in Theorem 5.3. This result, and its more categorical reformulation in Corollary 5.4, is the crux of the paper, from which we derive all our reconstruction theorems. As noted after Corollary 5.4, Exel’s reconstruction theorem follows immediately when the functions take values in the trivial 1-element semigroup.

The next task is to isolate a bumpy semigroup from a given semigroup (or algebra) of functions defined on arbitrary open subsets. In Theorem 6.5 and Proposition 6.6, we show how this can be achieved with a purely multiplicative notion of normaliser. This yields another reconstruction result in Corollary 6.10, which encompasses the original C*-algebraic reconstruction theorems of Kumjian and Renault, as well as the more recent $L^p$-algebraic reconstruction theorem of Choi-Gardella-Thiel.

In the penultimate section, we deal with more general semigroupoid-valued functions. By utilising the abundance of $\mathbb{Z}$-regular elements in compact-bumpy semigroups on ample groupoids, we obtain another reconstruction theorem in Corollary 7.5. We finish this section by noting how this generalises Steinberg’s reconstruction theorem and how this applies to groupoids where the fibres of the isotropy group bundle have no non-trivial units.

In the last section, we show how to extend all our results to the graded context.

2. Notation

First let us set out some general notation.

Given $a \subseteq Y \times X$, denote the image of $V \subseteq X$ and preimage of $W \subseteq Y$ by

- $a[V] = \{ y \in Y : \exists v \in V \ ((y,v) \in a) \}$
- $[W]a = \{ x \in X : \exists w \in W \ ((w,x) \in a) \}$

Denote the domain and range of $a \subseteq Y \times X$ by

- $\text{ran}(a) = a[X]$ and $\text{dom}(a) = [Y]a$.

The (partial) functions are those $a \subseteq Y \times X$ such that $a[x]$ contains at most one element, for all $x \in X$, which is then denoted by $a(x)$ as usual, i.e. $a[x] = \{ a(x) \}$.

The set of all $Y$-valued functions with domains in a family $\mathcal{X}$ is denoted by

- $\gamma \mathcal{X} = \{ a \subseteq Y \times X : \text{dom}(a) \in \mathcal{X} \ \text{and} \ \forall x \in \text{dom}(a) \ (a[x] \ \text{is a singleton}) \}$.

Given a groupoid $G$, we denote the source and range of any $g \in G$ by

- $s(g) = g^{-1}g$ and $r(g) = gg^{-1}$

We denote the units of $G$ by $G^0$ and the composable pairs by $G^2$, i.e.

- $G^0 = \{ s(g) : g \in G \} = \{ r(g) : g \in G \}$
- $G^2 = \{ (g,h) \in G \times G : s(g) = r(h) \}$.

We denote the bisections of $G$ by

- $\mathcal{B}(G) = \{ B \subseteq G : BB^{-1} \cup B^{-1}B \subseteq G^0 \}$.

Equivalently, $B \subseteq G$ is a bisection precisely when, for all $g, h \in G$,

- $r(g) = r(h)$ or $s(g) = s(h) \ \Rightarrow \ g = h$.

Arbitrary subsets of $G$ are denoted by $\mathcal{P}(G) = \{ X : X \subseteq G \}$. 
Proposition 2.1. For any groupoid $G$, semigroup $Y$ and $a, b \in \gamma \mathcal{P}(G)$ where either $\text{dom}(a)$ or $\text{dom}(b)$ is a bisection, we can define $ab \in \gamma \{\text{dom}(a)\text{dom}(b)\}$ by
\[
(2.1) \quad ab(gh) = a(g)b(h), \quad \text{for all } (g, h) \in G^2 \cap \text{dom}(a) \times \text{dom}(b).
\]
In particular, this yields a semigroup operation on $\gamma \mathcal{B}(G)$.

Proof. Note that when $B$ is a bisection and either $g, g' \in B$ or $h, h' \in B$ then
\[
gh = g'h' \implies g = g' \quad \text{and} \quad h = h'.
\]
(e.g. if $g, g' \in B$ then $gh = g'h'$ implies $r(g) = r(gh) = r(g'h') = r(g')$ so $g = g'$ and hence $h = g^*gh = g'^*g'h' = h'$). Thus $ab$ is well-defined by (2.1) whenever $\text{dom}(a)$ or $\text{dom}(b)$ is a bisection. If both $\text{dom}(a)$ and $\text{dom}(b)$ are bisections then so is $\text{dom}(ab) = \text{dom}(a)\text{dom}(b)$ and hence this yields a binary operation on $\gamma \mathcal{B}(G)$, which is associative because $Y$ is a semigroup. \hfill \Box

Remark 2.2. Note that $\gamma \mathcal{B}(G)$ always has a zero/absorbing element (namely the empty function $\emptyset$) even when $Y$ itself does not. Indeed, we are primarily interested in $Y$ satisfying (1-Cancellative) below, which means $Y$ can not have a zero if $Y$ has at least 2 elements. When dealing with a field like $\mathbb{C}$ or, more generally, a domain $R$, we prefer to consider $R \setminus \{0\}$-valued partial functions rather than $R$-valued total functions – see the remark below.

Remark 2.3. When $R$ is a ring, it is more common to consider $R$-valued functions $R\{G\}$ defined on the entirety of $G$ under the convolution product
\[
ab(f) = \sum_{f=gh} a(g)b(h),
\]
at least with some conditions on the functions to ensure the sum above makes sense. For example, when $\text{supp}(a) = [R \setminus \{0\}]a$ is a bisection, the sum always makes sense because it contains at most one non-zero term, in which case $ab(gh) = a(g)b(h)$ whenever $g \in \text{supp}(a)$, $h \in \text{supp}(b)$ and $s(g) = r(h)$. We thus get a semigroup of (total) $R$-valued functions $a$ on $G$ with bisection supports, which we can identify with their restrictions $a|_{\text{supp}(a)}$. As long as $R$ is a domain, i.e. as long as $R \setminus \{0\}$ is a subsemigroup of $Y$, this restriction map yields an isomorphism with the semigroup of (partial) $(R \setminus \{0\})$-valued functions defined on bisections of $G$.

Given a topology $\mathcal{O}(G)$ on $G$, we denote the open bisections by
\[
\mathcal{B}^o(G) = \mathcal{B}(G) \cap \mathcal{O}(G).
\]
We call $G$ étale if we have a basic inverse semigroup $\mathcal{B} \subseteq \mathcal{B}^o(G)$, meaning $\mathcal{B}$ is both a basis for the topology and an inverse semigroup with the usual operations, i.e.
\[
O, N \in \mathcal{B} \quad \Rightarrow \quad ON \in \mathcal{B} \quad \text{and} \quad O^{-1} \in \mathcal{B}.
\]
Equivalently, $G$ is étale if the involution $g \mapsto g^{-1}$ and product $(g, h) \mapsto gh$ are continuous on $G$ and $G^2$ respectively and the source (or, equivalently, the range) is an open map on $G$, i.e. $s(O) \in \mathcal{O}(G)$, for all $O \in \mathcal{O}(G)$.

The following observation will be useful later on.

Proposition 2.4. If $G$ is an étale groupoid, $O \in \mathcal{B}^o(G)$ and $C \subseteq G$ then
\[
r[C] \subseteq s(O) \quad \text{and} \quad C \text{ is compact} \quad \Rightarrow \quad OC \text{ is compact}.
\]
Proof. Take any net \((gₙ,λₙ)\) \(\subseteq OC\). As \(C\) is compact, \((cₙ)\) has a subnet \((c_{f(γ)})\) converging to \(c \in C\). Thus \(s(g_{f(γ)}) = r(c_{f(γ)}) \to r(c) = s(g)\), for some \(g \in O\). As \(s\) is a homeomorphism on \(O\), \(g_{f(γ)} \to g\) and hence \(g_{f(γ)}c_{f(γ)} \to gc \in OC\). □

Denote the compact and compact open bisections of \(G\) by \(B_c(G)\) and \(B^0_c(G)\) respectively. We call \(G\) ample if it has a basic inverse semigroup \(B \subseteq B^0_c(G)\). As \(ON = O \cap N\) for any \(O, N \in O(G^0)\), it follows that \(G^0\) is coherent and locally compact whenever \(G\) is ample. Standard results in non-Hausdorff topology (see [GL13]) then show that, if \(G\) is ample,

\(G^0\) is sober and \(T_1 \iff G^0\) is Hausdorff \(\iff G\) is locally Hausdorff.

3. Bumpy Semigroups

In §5, we will show how to reconstruct an étale groupoid \(G\) from a semigroup \(S\) of ‘bump’ functions on bisections of \(G\). For our reconstruction to work, we need some general conditions on \(S\) which we introduce in the present section.

We start with some basic standing assumptions.

**Assumption 1.** \(G\) is both a groupoid and a topological space.

**Assumption 2.** \(Y\) is a unital semigroup.

We denote the invertible elements of \(Y\) by

\[ Y^\times = \{y \in Y : \exists y^{-1} \in Y \ (yy^{-1} = 1 = y^{-1}y)\}. \]

The interior of \(X \subseteq G\) is denoted by \(\text{int}(X) = \bigcup\{V \in O(G) : V \subseteq X\}\).

**Definition 3.1.** We call \(S \subseteq \gamma B^0(G)\) bumpy if it satisfies all of the following.

- (1-Proper) \([1]\) is compact, for all \(a \in S\).
- (Urysohn) For any \(O \in O(G)\), we have \(a \in S\) with \(\text{dom}(a) \subseteq O\).
  - For any \(g \in O\), we can further require that \(g \in \text{int}(\{Y^\times\}{a})\).
- (Involutive) Whenever \(a \in S\) and \(g \in \text{int}(\{Y^\times\}{a})\), we have \(b \in S\) such that
  \[ g^{-1} \in \text{int}(\{h \in G : a(h^{-1}) = b(h)^{-1}\}) \]

In other words, (Urysohn) is saying that the empty function \(\emptyset\) is in \(S\) and, whenever we have an open neighbourhood \(O\) of any \(g \in G\), we can find some \(a \in S\) whose domain is contained in \(O\) and which takes invertible values on some neighbourhood of \(g\). On the other hand, (Involutive) says that, whenever \(a \in S\) takes invertible values on a neighbourhood of \(g\), we have \(b \in S\) which realises these inverses on a neighbourhood of \(g^{-1}\).

**Remark 3.2.** Say \(S \subseteq \gamma B^0(G)\) and, whenever \(g \in O \in O(G)\), we have \(a \in S\) with

- \((\text{Urysohn}')\) \(\text{dom}(a) \subseteq O\) and \(g \in \text{int}(\{Y^\times\}{a})\).

If \(G^0\) is open, Hausdorff and contains at least two distinct points \(g, h \in G^0\) then (Urysohn') yields \(a, b \in S\) with disjoint domains in \(G^0\). If \(S\) is also a semigroup then \(\emptyset = ab \in S\), so in this case (Urysohn') implies (Urysohn).

We are primarily interested in the case when \(G\) is both locally compact and étale — otherwise there will be no bumpy semigroups on \(G\).

**Proposition 3.3.** If \(S \subseteq \gamma B^0(G)\) is a bumpy semigroup, \(G\) is locally compact étale.
Proof: First note that $G$ has a basis of open bisections, namely $\{\text{dom}(a) : a \in S\}$. Indeed, if $g \in O \in \mathcal{O}(G)$ then (Urysohn) yields $a \in S$ with $\text{dom}(a) \subseteq O$ and $g \in \text{int}(\{Y^\times|a\})$ so, in particular, $g \in \text{dom}(a) \in \mathcal{B}^0(G)$. It follows that the product is an open map on $G$, as $S$ is a semigroup and $\text{dom}(a)\text{dom}(b) = \text{dom}(ab) \in \mathcal{B}^0(G)$.

Next note that the involution $g \mapsto g^{-1}$ is an open map. To see this, take any $g \in O \in \mathcal{O}(G)$, so (Urysohn) yields $a \in S$ with $\text{dom}(a) \subseteq O$ and $g \in \text{int}(\{Y^\times|a\})$. Then (Involutive) yields $b \in S$ with $g^{-1} \in \text{int}(\{h \in G : ah^{-1} = bh^{-1}\}) \subseteq \{Y^\times|a\}^{-1} \subseteq \text{dom}(a)^{-1} \subseteq O^{-1}$, showing $O^{-1}$ is open. Thus $\mathcal{B}^0(G)$ is a basic inverse semigroup, i.e. $G$ is étale.

To show $G$ is locally compact, it thus suffices to show that $G^0$ is locally compact. Accordingly, take $g \in O \in \mathcal{O}(G^0)$. As above, (Urysohn) and (Involutive) yield $a, b \in S$ with $\text{dom}(a) \subseteq O$ and $g = gg^{-1} \in \text{int}(\{1\}|ab)$. As $C = \{1\}|ab$ is compact and $r$ is continuous, $r[C]$ is also compact. As $r$ is an open map, $r[\text{int}(C)]$ is an open subset containing $g$, i.e. $r[C]$ is a compact neighbourhood of $g$ in $G^0$. Moreover, $r[C] \subseteq r[\text{dom}(a)\text{dom}(b)] \subseteq r[\text{dom}(a)] \subseteq O$, showing that $G^0$ is locally compact. □

In the examples we have in mind, we can actually replace $g$ above in Definition 3.1 with a compact subset. Accordingly, we strengthen bumpy semigroups as follows.

**Definition 3.4.** We call bumpy $S \subseteq \gamma\mathcal{B}^0(G)$ compact-bumpy if

- (Compact-Urysohn) For any $C \in \mathcal{B}^0(G)$ and $O \in \mathcal{B}^0(G)$ with $C \subseteq O$, we have $a \in S$ such that $\text{dom}(a) \subseteq O$ and $C \subseteq \{Y^\times|a\}$.

- (Compact-Involutive) If $a \in S$ and $C \subseteq \{Y^\times|a\}$ is compact, we have $b \in S$ such that, for all $g \in C$, $a(g)^{-1} = b(g^{-1})$.

If we already know that $G$ is locally compact then (Compact-Involutive) implies (Involutive), as each neighbourhood contains a compact neighbourhood. If we also already know that $G$ is étale then (Compact-Urysohn) implies (Urysohn), as each neighbourhood contains a bisection neighbourhood, which itself contains a compact neighbourhood. If $G^0$ is Hausdorff then (Compact-Urysohn) applies not just to $O \in \mathcal{B}^0(G)$ but even to arbitrary $O \in \mathcal{O}(G)$, as each compact bisection is contained in an open bisection (see [BS19, Proposition 6.3]). When $G^0$ is Hausdorff, the converse of Proposition 3.3 also holds, i.e. if $G$ is locally compact étale then there are bumpy semigroups on $G$, as shown in Example 3.7 and Example 3.8 below.

**Example 3.5.** Say $Y = \{1\}$ is the trivial unital semigroup and $G$ is ample, so we have a basic inverse semigroup $\mathcal{B} \subseteq \mathcal{B}^0(G)$. Identifying subsets with their characteristic functions, we can identify $\mathcal{B}$ with

$$S = \{1\}\mathcal{B} = \{\{1\} \times B : B \in \mathcal{B}\}.$$  

So $S$ is a subsemigroup of $\gamma\mathcal{P}(G)$, as $\mathcal{B}$ is a subsemigroup of $\mathcal{B}(G)$. Moreover,

- (1-Proper) holds because each $B \in \mathcal{B}$ is compact.
- (Urysohn) holds because $\mathcal{B}$ is a basis.
- (Compact-Involutive) holds because $O^{-1} \in \mathcal{B}$ whenever $O \in \mathcal{B}$.

So $S$ is a bumpy semigroup.

If $\mathcal{B} = \mathcal{B}^0(G)$ then (Compact-Urysohn) also holds so $S$ is compact-bumpy.
Example 3.6. Replace $Y$ above with any discrete group and let $S$ be the inverse semigroup of continuous/locally constant $Y$-valued functions with domains in $B$. We again immediately see that $S$ is a (compact-)bumpy semigroup.

Recall that a $Y$-valued map $a$ is proper if $[C]a$ is compact whenever $C \subseteq Y$ is, i.e. preimages of compact subsets of the given codomain are again compact.

Example 3.7. Say $Y$ is the half-open interval $(0,1]$ with its usual topology and product. If $G$ is étale, products of open subsets are open. If $G^0$ is Hausdorff, products of compact subsets are also compact. It follows that products of proper continuous maps from open bisections to $U$ are again proper and continuous and hence form a semigroup $S$. Moreover,

(1-Proper) holds because each $a \in S$ is proper.

(Compact-Urysohn) holds if $G$ is locally compact, by Urysohn’s lemma.

(Compact-Involutive) holds because $a^* \in S$ whenever $a \in S$ (where $a^*(y) = a(y^{-1})$, which is proper and continuous because $a$ is and $g \mapsto g^{-1}$ is a homeomorphism).

So again $S$ is a compact-bumpy semigroup.

Example 3.8. Say $Y = A^X$, where $A$ is a unital Banach algebra. For any $Y$-valued map $a$, define a real-valued map $\|a\|$ by $\|a\|(g) = \|a(g)\|$. If again $G$ is locally compact étale and $G^0$ is Hausdorff, we can let $S$ be the semigroup of continuous maps $a$ from open bisections to $Y$ such that $\|a\|$ is proper with respect to the codomain $(0, \infty]$. Again (1-Proper) holds because each $\|a\|$ is proper, while (Compact-Urysohn) and (Compact-Involutive) also hold thanks to Urysohn’s lemma (and the fact that $y \mapsto y^{-1}$ is continuous on the open subset of all invertible elements in any unital Banach algebra). So yet again $S$ is a very bumpy semigroup.

Note that Example 3.5 corresponds to [Exe10]. Also Example 3.6 corresponds to [Ste19] (see the comments after Corollary 7.5), while Example 3.8 with $Y = \mathbb{C}$ corresponds to [Kum86], [Ren08] and [CGT19] (see the comments after Corollary 6.10).

4. Domination

The diagonal of any $A \subseteq \gamma P(G)$ consists of those $a \in S$ with domains in $G^0$, i.e.

$$D(A) = A \cap \gamma P(G^0) = \{d \in A : \text{dom}(d) \subseteq G^0\}.$$ 

Our goal in next section will be to recover $G$ from a bumpy semigroup $S \subseteq \gamma B^0(G)$ together with its diagonal subsemigroup $D = D(S)$. To do this, we will consider ultrafilters with respect to the domination relation $\prec$.

Definition 4.1. Given a semigroup $S$ and $D \subseteq S$, we define relations

$$a \prec_b b \iff asb = a = bsa \quad \text{and} \quad as, sa \in D.$$ 

$$a \prec b \iff \exists s \in S \ (a \prec_s b).$$

As long as $D$ is a subsemigroup of $S$, $\prec$ will be transitive. We can also switch the subscript and the right argument by suitably modifying the left argument.

Proposition 4.2. If $D$ is a subsemigroup of $S$ then, for all $a, b, c, c', c \in S$,

(Transtive) \quad a \prec_b b \prec_{c'} c \quad \Rightarrow \quad a \prec_{c'} c.

(Switch) \quad a \prec_b c \quad \Rightarrow \quad bab \prec_b b.

If $0 \in D$ is an absorbing element of $S$ then $0 \prec_a b$, for all $a, b \in S$. 

Proof:

(Transitive) If \( a \prec b \prec c \) then \( ac' = ab'bc' \in DD \subseteq D \supseteq DD \ni c'bb'a = c'a \) and
\[
ac'c = ab'bc'c = ab'b = a = bb'a = cc'bb'a = cc'a.
\]

(Switch) If \( a \prec b \) then \( babc = ba \in E \ni ab = cbab \) and \( babcb = bab = bcbab \).

Lastly, if \( 0 \in D \) is an absorbing element of \( S \) then, for all \( a, b \in S \), we see that
\( 0a = 0b = 0 \in D \) and \( ba0 = 0 = 0ab \) i.e. \( 0 \prec_a b \).

From now on, we need a couple more basic standing assumptions.

**Assumption 3.** \( G^0 \) is Hausdorff.

**Assumption 4.** \( Y \) is 1-cancellative, i.e. for all \( x, y \in Y \),

(1-Cancellative) \( xy = x \iff y = 1 \iff yx = x \).

Under these assumptions, \( \prec \) can be characterised via the compact containment relation \( \subseteq \) on compact-bumpy semigroups. Specifically, for any \( V, W \subseteq G \) define
\[
V \subseteq W \iff \exists \text{ compact } C \subseteq G \ (V \subseteq C \subseteq W).
\]

**Proposition 4.3.** If \( S \subseteq \gamma B^0(G) \) is a compact-bumpy semigroup and \( D = D(S) \),

(4.1) \( a \prec b \iff \text{dom}(a) \subseteq [Y^\times]b \).

Proof. Say \( a \prec b \) and \( g \in \text{dom}(a) \), so \( a(g) = ab'g = a(h)b'(i)g(j) \), for some \( h, i, j \in G \) with \( g = hi j \). As \( \text{dom}(a) \) is a bisection and \( r(g) = r(h) \), we must have \( h = g \) so \( a(g) = a(h)b'(i)j = a(g)b'(i)j \) and hence \( b'(i)j = 1 \), by (1-Cancellative).

As \( ab' \in E \), we must also have \( hi \in G^0 \) so \( i = h^{-1} = g^{-1} \) and \( g = hi j = j \in \text{dom}(b) \).

Thus \( 1 = b'(ij) = b'b(g^{-1}g) = b'(g^{-1})b(g) \) and, likewise, \( 1 = b(g)b'(g^{-1}) \) so
\[
\text{dom}(a) \subseteq \text{dom}(b')^{-1}([1]b' \cap ([1]bb')\text{dom}(b')^{-1}.
\]

Note \([1]bb'\) and \([1]b'b\) are compact, by (1- Proper), and hence so are \( \text{dom}(b')^{-1}([1]b' \cap ([1]bb')\text{dom}(b')^{-1} \) by Proposition 2.4. As these compact sets are contained in the Hausdorff subspace \( \text{dom}(b) \) (as \( G^0 \) is Hausdorff and \( G \) is étale – see Proposition 3.3), their intersection is also compact and certainly contained in \([Y^\times]b \) so
\[
\text{dom}(a) \subseteq [Y^\times]b.
\]

Conversely, if \( \text{dom}(a) \subseteq [Y^\times]b \) then (Compact-Involutive) yields \( b' \in S \) such that \( b(g)^{-1} = b'(g^{-1}) \), for every \( g \in \text{dom}(a) \). Thus
\[
\text{dom}(ab') = \text{dom}(a)\text{dom}(a)^{-1} \subseteq G^0 \supseteq \text{dom}(a)^{-1}\text{dom}(a) = \text{dom}(b'a),
\]
\( i.e. \ ab', b'a \in D \), and
\[
ab'b(g) = a(g)b'(g^{-1}g) = a(g) = bb'(gg^{-1})a(g) = bb'a(g),
\]
\( i.e. \ ab'b = a = bb'a \) and hence \( a \prec b \).

Note that if all elements of \( Y \) are invertible, e.g. if \( Y = \mathbb{F} \setminus \{0\} \) for a field \( \mathbb{F} \) like \( \mathbb{R} \) or \( \mathbb{C} \), then (4.1) reduces to compact containment of domains, i.e.
\[
a \prec b \iff \text{dom}(a) \subseteq \text{dom}(b).
\]

Also note \( \Rightarrow \) only required (1- Proper) so still applies bumpy semigroups. Conversely, \( \Leftarrow \) only required (Compact-Involutive) so still applies to Example 3.5 where \( B \subseteq B^0(G) \) is any basic inverse semigroup, in which case (4.1) becomes
\[
a \prec b \iff \text{dom}(a) \subseteq \text{dom}(b).
\]
5. Groupoid Reconstruction

**Definition 5.1.** Given a semigroup $S$ and $D \subseteq S$, we call $F \subseteq S$ a filter if

(\text{Filter}) \quad a, b \in F \iff \exists c \in F \ (a, b \succ c).

The maximal proper filters are called ultrafilters and are denoted by $\mathcal{U}(S)$.

Equivalently, a filter is a down-directed up-set, i.e.

(\text{Up-Set}) \quad F \supseteq F^\prec = \{a \in S : \exists f \in F \ (f \prec a)\}.

(\text{Down-Directed}) \quad a, b \in F \implies \exists c \in F \ (a, b \succ c).

If $0 \in D$ is an absorbing element of $S$ then $0$ is a $\prec$-minimum (see Proposition 4.2).

This means a filter $F$ is proper iff $0 \notin F$, so ultrafilters are maximal filters avoiding $0$. We consider the topology on $\mathcal{U}(S)$ generated by the basis $(\mathcal{U}_a)_{a \in S}$ where

$$\mathcal{U}_a = \{U \in \mathcal{U}(S) : a \in U\}.$$  

On subsets $T \subseteq S$, we also have a $^*$ operation given by

$$T^* = \{s \in S : \exists t \in T \ \exists r \in S \ (t \prec_s r)\}.$$  

**Remark 5.2.** A somewhat less general version of the next result can be found in [Bic19, Proposition 1.2]. The key difference is that we are not using any involution on $S$ – the involution on $G$ is recovered from the product on $S$ via this $^*$ operation.

**Theorem 5.3.** If $S \subseteq \gamma B^0(G)$ is a bumpy semigroup with diagonal $D = D(S)$ then

$$g \mapsto S_g = \{a \in S : g \in \text{int}(\langle Y \rangle^a)\}$$

is a homeomorphism from $G$ onto $\mathcal{U}(S)$. Moreover, for all $(g, h) \in G^2$,

$$S_{g^{-1}} = S_g^* \quad \text{and} \quad S_{gh} = (S_g S_h)^\prec.$$  

**Proof.** Say $g \in G$ and $a, b \in S_g$. By (Involutive), we have $a', b' \in S$ with

$$g \in O = \{h \in G : a(h)^{-1} = a'(h^{-1})\}^* \cap \{h \in G : b(h)^{-1} = b'(h^{-1})\}^*,$$

By (Urysohn), we have $c \in S_g$ with $\text{dom}(c) \subseteq O$ and hence $c \prec_a a'$ and $c \prec_{b'} b$. We also see that if $S_g \ni a \prec_d d$ then $g \in \text{int}(\langle Y \rangle^a) \subseteq \text{dom}(a) \subseteq \text{int}(\langle Y \rangle^d)$ (see the proof of (4.1)) so $d \in S_g$ too and hence $S_g$ is a filter.

For maximality, say we had a filter $F \supseteq S_g$. Take $a, b \in S_g$ and $F \ni a \prec_d d$ then $g \in \text{int}(\langle Y \rangle^a) \subseteq \text{dom}(a) \subseteq \text{int}(\langle Y \rangle^d)$. As $F$ is a filter, we have $c, c', d \in S$ with $F \ni c \prec_{c'} c' \prec a, b$. Taking $C = [1]cc'\text{dom}(c')^{-1}$ or $C = \text{dom}(c')^{-1}[1]c'c$, note

$$\text{dom}(d) \subseteq C \subseteq \text{dom}(c) \subseteq \text{int}(\langle Y \rangle^b) \ni g.$$  

By (1-Proper), $C$ is compact and hence closed in $\text{dom}(a)$ so $g \in \text{dom}(a) \setminus C \in \mathcal{O}(G)$.

By (Urysohn), we have $c \in S_g$ with $\text{dom}(c) \subseteq \text{dom}(a) \setminus C$. Then the only element of $S$ below both $d$ and $e$ is the empty function, so $\text{dom}(d) \cap \text{dom}(e) \subseteq C \cap \text{dom}(e) = \emptyset$. Thus $0 \in F$, as $F$ is a filter, so $F$ is not proper and $S_g$ must be an ultrafilter.

On the other hand, say we have an ultrafilter $U \subseteq S$ and fix $a \in U$. Whenever $u \prec_{a'} a$, we see that $\text{dom}(u) \cap \text{dom}(a) \subseteq [1]aa'\text{dom}(a')^{-1}$ is compact and hence

$$\bigcap_{u \in U} \text{int}(\langle Y \rangle^u) = \bigcap_{u \in U, u \prec a} \text{dom}(u) \cap \text{dom}(a) \neq \emptyset.$$
(as any directed intersection of non-empty compact subsets of a Hausdorff space is again non-empty). For any \( g \in \bigcap_{a \in U} \text{int}([Y^x]a) \), we have \( U \subseteq S_g \) and hence \( U = S_g \), by maximality. So \( g \mapsto S_g \) is indeed a bijection from \( G \) onto \( \mathcal{U}(S) \). As

\[
S_g \in \mathcal{U}_a \iff a \in S_g \iff g \in \text{int}([Y^x]a)
\]

and \( \text{int}([Y^x]a)_{a \in S} \) is a basis for \( G \), by (Urysohn), \( g \mapsto S_g \) is a homeomorphism.

We certainly have \( S_g^+ \subseteq S_g \). Conversely, take \( a \in S_g \). We already showed that \( S_g^{-1} \) is a filter, so we have \( b \in S_g^{-1} \) with \( b \prec_a a \) and hence \( a'ba' \prec_a a' \), by (Switch). As \( g^{-1} \in \text{int}([Y^x]b) \subseteq \text{dom}(b) \subseteq \text{int}([Y^x]a')^{-1} \),

\[
g = gg^{-1}g \in \text{int}([Y^x]a')\text{int}([Y^x]b)\text{int}([Y^x]a') \subseteq \text{int}([Y^x]a'ba')
\]

so \( a'ba' \in S_g \) and hence \( a \in S_g^+ \), showing that \( S_g^+ = S_g \).

Likewise, whenever \( (g, h) \in G^2 \), we immediately see that \( (S_gS_h)^\prec \subseteq S_{gh} \). Conversely, take \( a \in S_{gh} \) and then further take \( a', b', c', d \in S \) with \( S_{gh} \ni c \prec_{a'} a \) and \( S_{h^{-1}} \ni d \prec_{b'} b \). We claim that \( cdb' \prec_{a'} a \). Indeed, if \( a' \prec a \) and \( b \prec a \), then \( cdb' \prec_{a'} a \). Conversely, suppose \( cdb' \prec_{a'} a \).

Corollary 5.4. If \( S \subseteq \gamma \mathcal{B}^o(G) \) and \( S' \subseteq \gamma \mathcal{B}^o(G') \) are diagonally isomorphic bumpy semigroups then \( G \) and \( G' \) are isomorphic etale groupoids.

Proof. If \( \phi : S \mapsto S' \) is a diagonal-preserving semigroup isomorphism then \( U \mapsto \phi[U] \) is a homeomorphism from \( \mathcal{U}(S) \) onto \( \mathcal{U}(S') \) with \( \phi[U] = \phi[U] \) and \( \phi(UV) \times = (\phi[U] \phi[V]) \times \). Thus \( G \) and \( G' \) are isomorphic etale groupoids, by Theorem 5.3.

In particular, we can consider Theorem 5.3 and Corollary 5.4 when \( Y = \{1\} \), as in Example 3.5, which corresponds to the reconstruction in [Exe10, Theorem 4.8]. However, our method differs somewhat – our reconstruction of \( G \) via ultrafilters in \( S \) is more in line with [LL13], while [Exe10] instead uses ultrafilters in \( D = \mathcal{D}(S) \) to recover \( G^0 \) first and then uses germs to reconstruct the rest of \( G \).

6. Semigroup Reconstruction

With the exception of [Exe10], most groupoid reconstruction theorems start with functions that are defined (or supported – see Remark 2.3) on arbitrary open subsets, not just open bisections. To recover the groupoid in this case, we must first obtain a subsemigroup with bisection domains. To do this, we examine various subsets that can be defined algebraically from the diagonal.
Theorem 6.5.

Proof. Proposition 6.3. Either way, \( g, h \in S \) is that we will only be examining the normalisers/commutant/centre of subsets of \( G \), the product of pairs outside \( S \), for which the product of pairs outside \( S \), is exhaustive then

\[
G^{iso} = \{ g \in G : s(g) = r(g) \}.
\]

(Isosections) \( \mathcal{I}(G) = \{ I \subseteq G : II^{-1} \cup I^{-1}I \subseteq G^{iso} \} \).

Equivalently, \( I \subseteq G \) is an isosection if, for all \( g, h \in I \),

\[
s(g) = s(h) \iff r(g) = r(h).
\]

Assumption 6. We are given a semigroup \( A \subseteq \gamma \mathcal{O}(G) \) on which the product is given by (2.1) whenever \( \text{dom}(a) \) or \( \text{dom}(b) \) is a bisection. From \( A \) we define

\[
Z = A \cap \gamma Y \mathcal{P}(G^0) = \{ a \in A : \text{dom}(a) \subseteq G^0 \text{ and } \text{ran}(a) \subseteq Z(Y) \}.
\]

\[
D = A \cap \gamma \mathcal{P}(G^0) = \{ a \in A : \text{dom}(a) \subseteq G^0 \}.
\]

\[
S = A \cap \gamma \mathcal{B}(G) = \{ a \in A : \text{dom}(a) \in \mathcal{B}(G) \}.
\]

\[
C = A \cap \gamma \mathcal{P}(G^{iso}) = \{ a \in A : \text{dom}(a) \subseteq G^{iso} \}.
\]

\[
N = A \cap \gamma \mathcal{I}(G) = \{ a \in A : \text{dom}(a) \in \mathcal{I}(G) \}.
\]

\[
M = \{ n \in N : \exists s, t \in S (\text{stn} = n = nts, \text{tn}, nt \in C \text{ and } st, ts \in Z) \}.
\]

Note \( M \) consists of those \( n \in N \) that are ‘C-Z-dominated’ by elements of \( S \). These will be important below in Theorem 6.5 when we consider normalisers.

Remark 6.2. Apart from associativity, we are not making any assumptions on the product on \( A \setminus S \), although the example to keep in mind would be the convolution product when \( Y = R \setminus \{ 0 \} \) for some domain \( R \). The reason we have such freedom is that we will only be examining the normalisers/commutant/centre of subsets of \( S \), for which the product of pairs outside \( S \) is of no relevance.

We call \( D \) exhaustive if, for all \( g \in G^0 \) and \( y \in Y \), we have \( d \in D \) with \( d(g) = y \).

Proposition 6.3. If \( D \) is exhaustive then \( Z = Z(D) \).

Proof. Take any \( e \in D \). If \( \text{ran}(e) \subseteq Z(Y) \) then certainly \( e \in Z(D) \). Conversely, if \( \text{ran}(e) \not\subseteq Z(Y) \) then we have \( g \in G^0 \) with \( e(g) \not\in Z(Y) \), which means we have \( y \in Y \) with \( e(g)y \neq ye(g) \). As \( D \) is exhaustive, we have \( d \in D \) with \( d(g) = y \) so \( e(g)d(g) \neq d(g)e(g) \) and hence \( ed \neq de \), showing that \( e \notin Z(D) \). \( \square \)

We say that \( Z \) is \( T_0 \) if \( \text{dom}[Z] = \{ \text{dom}(z) : z \in Z \} \) is \( T_0 \) in the usual sense, i.e. for all distinct \( g, h \in G^0 \), we have \( z \in Z \) with either \( g \in \text{dom}(z) \neq h \) or \( g \notin \text{dom}(z) \neq h \).

Proposition 6.4. If \( Z \) is \( T_0 \) then \( C = C(Z) \).

Proof. Take any \( a \in A \). If \( \text{dom}(a) \subseteq G^{iso} \) then certainly \( a \in C(Z) \). Conversely, if \( \text{dom}(a) \not\subseteq G^{iso} \), we have \( g \in \text{dom}(a) \) with \( s(g) \neq r(g) \). As \( Z \) is \( T_0 \), we have \( z \in Z \) such that \( s(g) \in \text{dom}(z) \neq r(g) \) and hence \( g \in \text{dom}(az) \setminus \text{dom}(za) \) or vice versa. Either way, \( az \neq za \) so \( a \notin C(Z) \). \( \square \)

Theorem 6.5. If \( Z \) is \( T_0 \) then \( M \subseteq N(Z) \subseteq N \).
Proof. Take $n \in \mathbb{N}(Z)$ and $g, h \in \text{dom}(n)$ with $s = s(g) = s(h)$. For all $z \in Z$, 
\[
\begin{align*}
s \in \text{dom}(z) & \Rightarrow \{g, h\} \subseteq \text{dom}(nz). \\
s \notin \text{dom}(z) & \Rightarrow \{g, h\} \cap \text{dom}(nz) = \emptyset.
\end{align*}
\]
If $r(g) \neq r(h)$ then, as $Z$ is $T_0$, we would have $z \in Z$ with $r(g) \in \text{dom}(z) \neq r(h)$ and hence $g \in \text{dom}(zn) \neq h$ or vice versa. Either way, $zn \notin nZ$, by the above implications, contradicting $n \in \mathbb{N}(Z)$. Likewise, $r(g) = r(h)$ implies $s(g) = s(h)$ so $\text{dom}(n) \in I(G)$, i.e. $n \in N$. This shows that $\mathbb{N}(Z) \subseteq N$.

On the other hand, take $n \in M$, so we have $s, s' \in S$ with $ss'n = n = ns's, s'n, ns' \in C$ and $s, s' \in Z$. For any $z \in Z$, we claim that 
\[
nz = ss's'n.
\]
To see this note that, whenever $g \in \text{dom}(ss's'n)$ or $g \in \text{dom}(nz)$, we have $h \in G$ with $s(g) = s(h), r(g) = r(h)$ and 
\[
ss's'n(g) = s(h)z(g^{-1}g)s'(g^{-1})n(g) = s(h)s'(g^{-1})n(g)z(g^{-1}g) = n(g)z(g^{-1}g) = nz(g),
\]
as $\text{dom}(ss'n) \subseteq G^\text{iso}$, $\text{dom}(z) \subseteq G^0$, ran$(z) \subseteq Z(Y)$ and $ss'n = n$. As $ss' \in Z$, we likewise see that, for any $e \in \text{dom}(ss')$, we have $g \in \text{dom}(s)$ with $e = gg^{-1}$ and 
\[
ss'(e) = s(g)z(g^{-1}g)s'(g^{-1}) = s(g)s'(g^{-1})z(g^{-1}g) = ss'(gg^{-1})z(g^{-1}g) \in Z(Y).
\]
Thus $ss' \in A \cap Z(Y)P(G^0) = Z$. Thus $nZ \subseteq Zn$ and, by a dual argument, $Zn \subseteq nZ$ so $n \in \mathbb{N}(Z)$, showing that $M \subseteq \mathbb{N}(Z)$.

Note that we always have 
\[
D \subseteq C \subseteq C(Z) \subseteq \mathbb{N}(Z).
\]
So while $\mathbb{N}(Z)$ may be smaller than $N$, it does at least have the same diagonal.

For the next result, we need to strengthen (Involutive) to require $ab, ba \in Z$, i.e. 
(Z-Involutite) Whenever $a \in S$ and $g \in \text{int}([Y^\times]|a)$, we have $b \in S$ with $ab, ba \in Z$ and 
\[
g^{-1} \in \text{int}(\{h \in G : a(h^{-1}) = b(h)^{-1}\}).
\]
Accordingly, we say $S$ is $Z$-bumpy if $S$ is bumpy and satisfies (Z-Involutite). Note that all the examples of bumpy semigroups in §3 are in fact $Z$-bumpy.

**Proposition 6.6.** If $S = N$ is $Z$-bumpy then so is $\mathbb{N}(Z)$.

**Proof.** Say $g \in O \in O(G^0)$. We claim that we have $z \in Z$ with $\text{dom}(z) \subseteq O$ and $g \in \text{int}([Y^\times]|a)$. To see this, note (Urysohn) yields $a \in S$ with $\text{dom}(a) \subseteq O$ and $g \in \text{int}([Y^\times]|a)$. Then (Z-Involutite) yields $b \in S$ with $ab, ba \in Z$ and 
\[
g^{-1} \in \text{int}(\{h \in G : a(h^{-1}) = b(h)^{-1}\}).
\]
Thus $g = gg^{-1} \in \text{int}([1]ab)$ and $\text{dom}(ab) \subseteq \text{dom}(a)\text{dom}(b) \cap G^0 \subseteq \text{dom}(a) \subseteq O$, as $O \subseteq G^0$. Thus $ab$ yields the required $z \in Z$, proving the claim. In particular, as $G^0$ is Hausdorff and hence $T_0$, this shows that $Z$ is also $T_0$. Then $M \subseteq \mathbb{N}(Z) \subseteq N = S$, by Theorem 6.5. As $S$ satisfies (1-Proper), it follows that $\mathbb{N}(Z)$ does too.

Now take any $a \in S = N$, so (Z-Involutite) yields $b \in S$ with $ab, ba \in Z$ and $g^{-1} \in O = \text{int}(\{h \in G : a(h^{-1}) = b(h)^{-1}\})$. Thus $gg^{-1} \in \text{int}([1]ab)$ and $g^{-1}g \in \text{int}([1]ba)$ so the claim yields $c, d \in Z$ with 
\[
\begin{align*}
dom(c) & \subseteq \text{int}([1]ab) \quad \text{and} \quad gg^{-1} \in \text{int}([1]c), \\
dom(d) & \subseteq \text{int}([1]ba) \quad \text{and} \quad g^{-1}g \in \text{int}([1]d).
\end{align*}
\]
Note that $a$ and $b$ witness $dbc \in M$, as $ab, ba \in Z$, $adbc, dbca \in Z \subseteq E \subseteq C$ and $badbc = dbc = dbcab$. Also,

$$g^{-1} \in \text{int}(|1|d)O(\text{int}(|1|c)) \subseteq \text{int}(\{h \in G : a(h^{-1}) = dbc(h)^{-1}\}),$$

showing that $M$ and hence $N(Z)$ satisfies (Z-Involutive).

Now take any $g \in O \in O(G)$, so (Urysohn) yields $a \in S$ with

$$\text{dom}(a) \subseteq O \quad \text{and} \quad g \in \text{int}(|Y^\times|a).$$

Taking $b, c, d \in S$ as above, we see that $a$ and $b$ also witness $cad \in M$, as $ab, ba \in Z$, $bcad, cadb \in Z \subseteq E \subseteq C$ and $abcd = cad = cadb$. Also,

$$g \in \text{int}(|1|c)O(\text{int}(|1|d)) \subseteq \text{int}(|Y^\times|cad)$$

and $\text{dom}(cad) \subseteq \text{dom}(a) \subseteq O$, showing that $M$ and hence $N(Z)$ satisfies (Urysohn).

Thus $N(Z)$ satisfies all the conditions needed to be $Z$-bumpy. \qed

Similarly, let us call $S$ compact-$Z$-bumpy if $S$ is compact-bumpy and

(Compact-$Z$-Involutive) If $a \in S$ and $B \subseteq |Y^\times|a$ is compact, we have $b \in S$ with $ab, ba \in Z$ and

$$a(g)^{-1} = b(g^{-1}), \quad \text{for all } g \in B.$$  

Again the examples in §3 are all compact-$Z$-bumpy.

When $S$ is compact-$Z$-bumpy, elements of $M$ can be characterised as follows.

**Proposition 6.7.** Assume $S$ is compact-$Z$-bumpy and we are given some $a \in A$. Then $a \in M$ if and only if we have some compact bisection $B \in \mathcal{B}_c(G)$ satisfying

(6.1) \quad $\text{s}[\text{dom}(a)] \subseteq \text{r}[B], \quad \text{r}[\text{dom}(a)] \subseteq \text{s}[B] \quad \text{and} \quad B\text{dom}(a) \cup \text{dom}(a)B \subseteq G^{\text{iso}}$.

**Proof.** If $a \in M$ then we have $b, c \in S$ with $ab, ba \in C$, $bc, cb \in Z$ and $abc = a = cba$. Then $B = \text{dom}(c)^{-1}[1]cb \subseteq \text{dom}(b)$ satisfies (6.1) and is compact, by (1-Proper).

Conversely, say $a \in A$ and $B \in \mathcal{B}_c(G)$ satisfy (6.1). Note $\text{dom}(a)B \subseteq \text{dom}(B)B^{-1}$ is an isosection, as $\text{s}[\text{dom}(a)] \subseteq \text{r}[B]$ and both $\text{dom}(a)B$ and $B^{-1}$ are isosections, i.e. $a \in N$. By [BS19, Proposition 6.3], $B$ is contained in some $O \in \mathcal{B}^\circ(G)$ and then (Compact-Urysohn) yields $b \in S$ with $\text{dom}(b) \subseteq O$ and $B \subseteq |Y^\times|b$ and hence $ab, ba \in C$. Then (Compact-$Z$-Involutive) yields $c \in S$ with $bc, cb \in Z$ and $b(g)^{-1} = c(g^{-1})$, for all $g \in B$, so $abc = a = cba$ and hence $a \in M$. \qed

Recall that étale $G$ is effective if the interior of the isotropy consists of units, i.e.

(Effective) \quad $G^0 = \text{int}(G^{\text{iso}})$.

In this case, the characterisation of $M$ above can be further simplified. Specifically, $a \in M$ precisely when $a$ is supported on a compact bisection.

**Proposition 6.8.** If $S$ is compact-$Z$-bumpy and $G$ is effective then

$$M = \{a \in A : \exists B \in \mathcal{B}_c(G) \quad (\text{dom}(a) \subseteq B)\}$$

**Proof.** If $\text{dom}(a) \subseteq B \in \mathcal{B}_c(G)$ then $B^{-1}$ satisfies (6.1) so $a \in M$. Conversely, if $a \in M$ then we have $B \in \mathcal{B}_c(G)$ satisfying (6.1). By [BS19, Proposition 6.3], we can extend $B$ to some open bisection $O \in \mathcal{B}^\circ(G)$. Then

$$\text{dom}(a)B = \text{dom}(a)O \in \text{int}(G^{\text{iso}}) = G^0$$

and hence $\text{dom}(a) = \text{dom}(a)BB^{-1} \subseteq B^{-1} \in \mathcal{B}_c(G)$. \qed
In particular, if $G$ is also Hausdorff then
\[ M = \{ a \in A : \text{cl}(\text{dom}(a)) \in B_c(G) \}. \]

Here is an example of this situation where both inclusions in Theorem 6.5 are strict.

**Example 6.9.** Consider the principal groupoid/equivalence relation
\[ G = \{ (z, -z) : z \in \mathbb{Z} \} \cup \{ (z, z) : z \in \mathbb{Z} \}. \]

Declare $O \subseteq G$ to be open if $(0, 0) \notin O$ or $\{(n, n) : n \geq 0\} \setminus O$ is finite. Let $A \subseteq \gamma O(G)$ consist of all proper continuous maps from open $O$ to $Y = (0, 1]$. Define $a \in S = N$ and $d, u \in D = C = Z \subseteq N(Z)$ by
\[
\begin{align*}
\text{dom}(a) &= \{(n, -n) : n > 0\} \quad \text{and} \quad a((n, -n)) = 1/n. \\
\text{dom}(d) &= \{(-n, -n) : n > 0\} \quad \text{and} \quad d((-n, -n)) = 1/n. \\
\text{dom}(u) &= \{(n, n) : n \geq 0\} \quad \text{and} \quad u((n, n)) = 1.
\end{align*}
\]

Note $\text{dom}(d)$ (or even any subset of $G$ containing $\text{dom}(d)$) is not compact so $d \notin M$. Also $a \notin aZ$, for if we had $z \in Z$ with $a = az$ then $z((-n, -n)) = 1$, for all $n \in \mathbb{N}$, i.e. $1]z \supseteq \text{dom}(a)$ is not compact which means $z$ is not proper, a contradiction. Thus $a = ua \in Za \setminus aZ$ and hence $a \notin N(Z)$, showing that $M \subset N(Z) \subset N$.

**Assumption 7.** Assume $A' \subseteq \gamma O(G')$ satisfies the same assumptions as $A$ in Assumption 6, from which we likewise define $Z'$, $E'$, $S'$, $C'$, $N'$ and $M'$.

**Corollary 6.10.** $G$ and $G'$ are isomorphic étale groupoids whenever
\begin{enumerate}
\item $A$ and $A'$ are diagonally isomorphic semigroups,
\item $S = N$ is $Z$-bumpy and $S' = N'$ is $Z'$-bumpy, and
\item $D$ and $D'$ are exhaustive.
\end{enumerate}

**Proof.** If $\phi : A \rightarrow A'$ is a diagonal-preserving semigroup isomorphism, so its restriction to $N(Z) = N(Z(D))$ (see Proposition 6.3), which is thus diagonally isomorphic to $N(Z') = N(Z(D'))$. By Proposition 6.6, $N(Z)$ and $N(Z')$ are $Z$-bumpy. By Corollary 5.4, it follows that $G$ and $G'$ are isomorphic étale groupoids. \qed

Note that $G$ is effective iff every open isosection is an open bisection, i.e.
\[ B^e(G) = T^o(G), \]
in which case we automatically have $S = N$. This is the situation considered in many reconstruction theorems. For example, we can consider Corollary 6.10 when $A = C^*_r(G)$ and $A' = C^*_r(G')$ are the reduced groupoid $C^*$-algebras of effective locally compact $G$ and $G'$ (as in Remark 2.3, we identify each $a$ with $a|_{\text{supp}(a)}$, which is then a partial function to $Y = Z(Y) = \mathbb{C} \setminus \{0\}$). In this case, Corollary 6.10 corresponds to the reconstruction in [Ren08, Proposition 4.13]. We can also take $A = F_\lambda^p(G)$ and $A' = F_\lambda^p(G')$ to be the reduced $L^p$-algebras of $G$ and $G'$ (again identifying $a$ with $a|_{\text{supp}(a)}$) in which case Corollary 6.10 corresponds to the reconstruction in [CGT19, Corollary 5.6].

Again, the precise methods of reconstruction differ – instead of using ultrafilters to recover $G$, [Ren08] and [CGT19] first use characters to recover $G^0$ and then use germs to recover the rest of $G$. One advantage of ultrafilters over characters/germs is that they only depend on the product rather than the full algebra structure. Consequently, we only need a semigroup isomorphism between the $C^*$-algebras or $L^p$-algebras rather than an isometric algebra isomorphism.
7. Semigroupoids

As mentioned in Remark 2.2, given a domain $R$, we remove 0 to obtain a 1-cancellative semigroup $Y = R \setminus \{0\}$. However, if $R$ is just a ring then the product is only partially defined on $R \setminus \{0\}$. To deal with this, in this section we consider more general semigroupoid $Y$, i.e. we only have a partial associative product on $Y$. Here associativity means $x(yz)$ is defined iff $(xy)z$ is, in which case they are equal.

A unit $1 \in Y$ is an element such that, for any $y \in Y$, both $1y$ and $y1$ are defined and equal to $y$. We denote the invertible and regular elements of $Y$ by

- **(Invertible Elements)** $Y^\times = \{y \in Y : \exists y^{-1} \in Y \ (yy^{-1} = 1 = y^{-1}y)\}$.
- **(Regular Elements)** $Y^R = \{y \in Y : \exists y' \in Y \ (yy'y = y \text{ and } y'yy' = y')\}$

Note that products with invertible elements are always defined and hence $Y^\times$ is a group. Also note that $yy'y = y$ implies both $y'y'yy' = y'y$ and $yy'yy' = yy'$, i.e. both $y'y$ and $yy'$ are idempotents. Under (1-Cancellative), the only idempotent is the unit 1, from which it follows that $Y^R = Y^\times$.

We define the centre $Z(Y) = \{z \in Y : \forall y \in Y \ (yz = zy)\}$ as before, where $yz = zy$ means ‘$yz$ is defined iff $zy$ is defined, in which case they are equal’. We call unital $Y$ *indecomposable* if 1 is the only central idempotent. Given any $Z \subseteq Z(Y)$, we define the $Z$-regular elements by

$$Y^R_Z = \{y \in Y : \exists y' \in Y \ (yy', y'y \in Z, \ yy'y = y \text{ and } y'yy' = y')\}.$$  

As above, $yy'$ and $y'y$ here are both central idempotents so $Y^R_Z = Y^\times$ if $Y$ is indecomposable. Let us now make this a standing assumption, replacing the previous stronger (1-Cancellative) assumption.

**Assumption 1.** $Y$ is an indecomposable semigroupoid.

Our previous assumptions on $G$ remain.

**Assumption 2.** $G$ is a groupoid and a topological space such that $G^0$ is Hausdorff.

Like before in (2.1), for any $a, b \in \gamma\mathcal{P}(G)$ such that either $\text{dom}(a)$ or $\text{dom}(b)$ is a bisection, we can define $ab \in \gamma\mathcal{P}(G)$ by

$$(7.1) \quad ab(gh) = a(gh)b(h)$$

whenever possible, i.e. whenever $g \in \text{dom}(a)$, $h \in \text{dom}(b)$, $gh$ is defined and $a(gh)b(h)$ is defined (the only thing to note is that $\text{dom}(ab)$ can now be a proper subset of $\text{dom}(a) \cap \text{dom}(b)$). So we can still take Assumption 6 to be in force, just with more general semigroupoid $Y$.

**Assumption 3.** As before in Assumption 6, we assume we are given a semigroupoid $A \subseteq \gamma\mathcal{O}(G)$ on which the product is given by (7.1) whenever $\text{dom}(a)$ or $\text{dom}(b)$ is a bisection and from which we define subsets $Z, D, S, C, N$ and $M$, as well as

$$R = A \cap \gamma\mathcal{B}_1(G) = \{a \in S : \text{dom}(a) \text{ is compact and } \text{ran}(a) \subseteq Y^\times\}.$$  

**Proposition 7.1.** If $S$ is compact-bumpy then $R = S^R_Z$.

*Proof.* If $a \in S^R_Z$ then we have $a' \in S$ such that, for all $g \in \text{dom}(a)$,

$$a(g)a'(g^{-1})a(g) = a(g), \quad a'(g^{-1})a(g)a'(g^{-1}) = a'(g^{-1})$$

This completes the proof.
and \(a(g)a'(g^{-1}), a'(g^{-1})a(g) \in \mathbb{Z}(Y)\) are idempotents. Thus \(a(g)^{-1} = a'(g^{-1})\), by Assumption 1, showing that \(\text{ran}(a) \subseteq Y^\times\) and \(\text{dom}(a) = \text{dom}(a)[1]a'a\) is compact, by (1-Prop), i.e. \(a \in R\), showing that \(S_Z^R \subseteq R\).

Conversely, if \(a \in R\) then \(\text{dom}(a)\) is compact and \(\text{ran}(a) \subseteq Y^\times\) so (Compact-Involutive) yields \(a' \in S\) such that \(a(g)^{-1} = a'(g^{-1})\), for all \(g \in \text{dom}(a)\). Thus \(aa'\) and \(a'a\) are the characteristic functions of \(\text{ran}(\text{dom}(a))\) and \(\text{dom}(a)\) respectively so \(aa', a'a \in Z\), \(aa' = a\) and \(a'a' = a'\), showing that \(a \in S_Z^R\).

\[\text{Corollary 7.4.}\] If \(G\) is étale and \(O, O' \in \mathcal{B}_c^i(G)\) then we have \(O'' \in \mathcal{B}_c^i(G)\) with
\[O'' \subseteq O' \quad \text{and} \quad s[O''] = s[O'] \setminus s[O] \quad \text{(or, equivalently, } r[O''] = r[O'] \setminus r[O]).\]

\[\text{Proof.}\] If \(G\) is étale and \(O, O' \in \mathcal{B}_c^i(G)\) then \(s[O'], s[O] \in \mathcal{O}_c(G^0)\). As \(G^0\) is Hausdorff, \(s[O'] \setminus s[O] \in \mathcal{O}_c(G^0)\) too so we can take \(O'' = O'(s[O'] \setminus s[O]) \in \mathcal{B}_c^i(G)\).

\[\text{Proposition 7.3.}\] If \(G\) is ample and \(S\) is compact-bumpy then
\[(7.2) \quad C_Z^R \subseteq D \quad \Rightarrow \quad N_Z^R \subseteq S.\]

\[\text{Proof.}\] Assume \(C_Z^R \subseteq D\) and take any \(a \in N_Z^R\), so we have \(a' \in N\) with \(aa'a = a, a'a' = a'\) and \(aa', a' \in Z\). Thus \(s[\text{dom}(a)] = s[\text{dom}(a')] = [1]a'a\), by Assumption 1, which is compact, by (1-Prop). As \(G\) is ample, each \(g \in \text{dom}(a)\) is contained in some \(O \in \mathcal{B}_c^i(G)\), which is itself contained in \(\text{dom}(a)\). As \(s[\text{dom}(a)]\) is compact, we can have a finite family of such \(O\) whose sources cover \(s[\text{dom}(a)]\). By Proposition 7.2, we can shrink these if necessary to ensure the sources of these sections are disjoint but still cover \(s[\text{dom}(a)]\). Taking the union of these we thus obtain \(O \in \mathcal{B}_c^i(G)\) such that
\[\text{dom}(a)O^{-1} \cup O^{-1}\text{dom}(a) \subseteq G^\text{iso} \quad \text{and} \quad \text{dom}(a)O^{-1}O = \text{dom}(a) = OO^{-1}\text{dom}(a).\]

Now (Compact-Urysohn) yields \(b \in S\) with \(\text{dom}(b) = O\) and \(\text{ran}(b) \subseteq Y^\times\). Then (Compact-Involutive) yields \(b' \in S\) with \(b(g)^{-1} = b'(g)^{-1}\), for all \(g \in O\). It follows that \(ab', ba' \in C\), \(ab'ba' = aa' \in Z\), \(a'a = ba'ab' \in Z\), \(ab'ba'ab' = aa'ab' = ab'\) and \(ba'ab'ba' = ba'aa' = ba'\), i.e. \(ab' \in \mathcal{R}_Z(C) \subseteq D\). In particular, \(ab', b \in S\) and hence \(a = ab'b \in S\), showing that \(N_Z^R \subseteq S\).

\[\text{Corollary 7.4.}\] If \(G\) is ample, \(S\) is compact-bumpy and \(D\) is exhaustive then
\[(7.3) \quad C_Z^R \subseteq D \quad \Rightarrow \quad R = N(\mathcal{Z}(D)^R R_{Z(D)})^R.\]

\[\text{Proof.}\] As \(D\) is exhaustive, we immediately see that \(Z = Z(D)\), just like in Proposition 6.3. As in Proposition 7.1, we see that
\[\mathcal{Z}(D)^R = A \cap \mathcal{Z}(Y) \times \mathcal{O}_c(G^0) = \{z \in Z: \text{dom}(z) \text{ is compact and } \text{ran}(z) \subseteq \mathbb{Z}(Y)^\times\}.\]

As in Theorem 6.5, \(N(\mathcal{Z}(D)^R \subseteq N \cap N(\mathcal{Z}(D)^R R_{Z(D)}^R) \subseteq N_Z^R\). By (7.2), \(N_Z^R \subseteq S\) and hence \(N_Z^R \subseteq S_Z^R = R\), by Proposition 7.1, showing \(N(\mathcal{Z}(D)^R R_{Z(D)}^R) \subseteq R\). On the other hand, if \(a \in R\) then \(B = \text{dom}(a)^{-1}\) satisfies (6.1) so \(a \in N(\mathcal{Z}(D)^R)\), as in Theorem 6.5, and hence \(a \in N(\mathcal{Z}(D)^R R_{Z(D)}^R)\), by (Compact-Involutive).

\[\text{Assumption' 4.}\] Again assume \(A' \subseteq \gamma \cdot O(G')\) satisfies the same assumptions as \(A\) in Assumption 3, from which we likewise define \(Z', D', S', C', N', M'\) and \(R'\).

\[\text{Corollary 7.5.}\] If \(G\) and \(G'\) are ample groupoids then they are isomorphic when
\[(1) \quad A \text{ and } A' \text{ are diagonally isomorphic semigroups},\]
\[(2) \quad S \text{ and } S' \text{ are compact-bumpy},\]
(3) $D$ and $D'$ are exhaustive, and
(4) $C^R_Z \subseteq D$ and $C^R_{Z'} \subseteq D'$.

Proof. If $\phi : A \to A'$ is a diagonal-preserving semigroup isomorphism then so its restriction to $R = N(Z(D)^R)_{Z(D)}^R$ (see (7.3)), which is thus diagonally isomorphic to $R' = N(Z(D')^R)_{Z(D')}^R$. As $G$ is ample and $S$ is compact-bumpy, so is $R$. Likewise, $R'$ is compact-bumpy so $G$ and $G'$ are isomorphic etale groupoids, by Corollary 5.4. □

In particular, we can consider Corollary 7.5 when $A$ and $A'$ are the Steinberg algebras of locally constant compactly supported functions taking values in indecomposable rings. This generalises [Ste19, Theorem 5.6] in several respects, namely

1. we only require a semigroup isomorphism, not a ring isomorphism,
2. the groupoids need not be Hausdorff (as long as their unit spaces are),
3. the coefficient rings can be non-commutative (and non-identical), and
4. Steinberg’s ‘local bisection hypothesis’ on the algebra is reduced to a regularity condition on the isotropy subalgebra (specifically $C^R_Z \subseteq D$).

Regarding the last point, Steinberg does obtain a similar reduction in [Ste19, Proposition 4.10]. In [Ste19, Theorem 5.5], Steinberg also shows this only needs to apply to one of the algebras, although the proof makes crucial use of the additive structure. If a purely multiplicative analog of [Ste19, Theorem 5.5] could be proved then we would likewise only need either $C^R_Z \subseteq D$ or $C^R_{Z'} \subseteq D'$ in Corollary 7.5. We will also extend Corollary 7.5 to the graded context in Corollary 8.6 below, just like in [Ste19, Theorem 5.6].

For any $x \in G^0$, consider the interior isotropy group $G_x$ given by

$$G_x = \{ g \in \text{int}(G^{iso}) : s(g) = r(g) = x \}.$$ 

Let us assume that, for any $x \in G^0$ and $a, b \in C$, $(ab)|_{G_x}$ is uniquely determined by $a|_{G_x}$ and $b|_{G_x}$, which means we have a canonical semigroup operation on

$$C_x = \{ c|_{G_x} : c \in C \}.$$ 

If each $C_x$ has ‘no non-trivial units’ then every $Z$-regular element of $C$ is in $D$, i.e.

$$\forall x \in G^0 (C^\times_x \subseteq D_x) \Rightarrow C^R_Z \subseteq D,$$

where $D_x = \{ d|_{G_x} : d \in D \} (= \{ \emptyset \} \cup (Y \times \{ x \})$ when $D$ is exhaustive). As noted in [Ste19, §2.1], when $C_x$ is the convolution algebra of finitely supported functions, this condition is implied by various properties of $G_x$, e.g.

- $G_x$ is free or torsion-free and abelian
- $G_x$ is left or right orderable
- $G_x$ has the unique product property
- $C^\times_x \subseteq D_x$.

When dealing with Steinberg algebras, it even suffices to have $C^\times_x \subseteq D_x$ on some dense subset of $G^0$ (see [Ste19, Theorem 4.13]) so, as with [Ste19, Theorem 5.6], Corollary 7.5 also generalises [CR18, Theorem 3.1].

## 8. Gradings

In this section we generalise our results to graded groupoids and semigroups.

**Assumption” 1.** $\Gamma$ is a groupoid and $\Sigma$ is a semigroupoid.
Definition 8.1. We call \( c : \Sigma \to \Gamma \) a grading if, whenever \( xy \) is defined, 
\[
c(xy) = c(x)c(y).
\]
We call \( H \subseteq \Sigma \) homogeneous if \( c(x) = c(y) \), for all \( x, y \in H \).

In other words, a grading is a groupoid-valued cocycle/homomorphism/functor. Note any semigroupoid \( \Sigma \) is trivially graded by the one-element group \( \Gamma = \{1\} \).

Assumption\(^\prime\) 2. \( Y \) is a 1-cancellative semigroup and \( G \) is simultaneously a groupoid with grading \( c : G \to \Gamma \) and also a topological space with Hausdorff unit space \( G^0 \).

Let \( O_h(G) \) and \( B^o_h(G) \) denote the homogeneous open subsets and bisections. We define bumpy semigroups \( S \subseteq \gamma B^o_h(G) \) exactly like before in Definition 3.1. So the only extra requirement is that \( \text{dom}(a) \) is homogeneous, for all \( a \in S \). It follows that \( c \) yields a grading on \( S \setminus \{\emptyset\} \), which we also denote by \( c \), i.e. for all \( a \in S \setminus \{\emptyset\} \),
\[
c[\text{dom}(a)] = \{c(a)\}.
\]
Recall from Proposition 3.3 that the existence of a bumpy semigroup implies that \( G \) is locally compact and étale. It now also follows that the grading is locally constant, i.e. continuous with respect to the discrete topology on \( \Gamma \).

Proposition 8.2. If \( S \subseteq \gamma B^o_h(G) \) is bumpy then \( c \) is locally constant.

Proof. Whenever \( g \in O \in \mathcal{O}(G) \), (Urysohn) yields \( a \in S \) defined on a neighbourhood of \( g \). As \( \text{dom}(a) \) is homogeneous, \( c[\text{dom}(a)] = \{c(g)\} \), showing that \( c \) is constant on a neighbourhood of \( g \).

Recall from Theorem 5.3 that we can recover both the topology and groupoid structure of \( G \) from any bumpy semigroup. Now the grading on \( S \setminus \{\emptyset\} \) can also be used to recover the grading on \( G \).

Theorem 8.3. If \( S \subseteq \gamma B^o_h(G) \) is a bumpy semigroup with diagonal \( D = D(S) \) then 
\[
g \mapsto S_g = \{a \in S : g \in \text{int}([Y^x]a)\}
\]
is a homeomorphism from \( G \) onto \( \mathcal{U}(S) \). Moreover, for all \( (g, h) \in G^2 \),
\[
S_{g^{-1}} = S^*_g, \quad S_{gh} = (S_gS_h)^\prec \quad \text{and} \quad c[S_g] = \{c(g)\}.
\]

Proof. The proof is exactly like that of Theorem 5.3. The only extra thing to note is \( c[S_g] = \{c(g)\} \), which is immediate from the fact that \( g \in \text{dom}(a) \) implies \( c(a) = c(g) \), by the definition on \( c \) on \( S \setminus \{\emptyset\} \).

As in Corollary 5.4, the categorical import of Theorem 8.3 can be rephrased without reference to ultrafilters or the precise method of reconstruction.

Assumption\(^\prime\) 3. \( G' \), \( Y' \) and \( c' \) satisfy the same assumptions as \( G \), \( Y \) and \( c \).

So \( c' \) also yields a grading on any \( S' \subseteq \gamma B^o_h(G') \) or, more precisely, on \( S' \setminus \{\emptyset\} \). We call an isomorphism \( \phi : S \to S' \) graded if \( c(a) = c'(\phi(a)) \), for all \( a \in S \setminus \{\emptyset\} \).

Corollary 8.4. If \( S \subseteq \gamma B^o_h(G) \) and \( S' \subseteq \gamma B^o_h(G') \) are diagonally isomorphic graded bumpy semigroups then \( G \) and \( G' \) are isomorphic graded étale groupoids.

Proof. If \( \phi : S \to S' \) is a diagonal-preserving graded semigroup isomorphism then \( U \mapsto \phi[U] \) is a homeomorphism from \( \mathcal{U}(S) \) onto \( \mathcal{U}(S') \) with \( \phi[U^*] = \phi[U]^* \), \( \phi[(UV)^\prec] = (\phi[U]\phi[V])^\prec \) and \( c' [\phi[U]] = c[U] \). Thus \( G \) and \( G' \) are isomorphic graded étale groupoids, by Theorem 8.3. \( \square \)
Assumption 4. We are given a semigroups $A \subseteq \gamma \mathcal{O}_h(G)$ and $A' \subseteq \gamma \mathcal{O}_h(G')$ on which the product is given by (2.1) whenever $\text{dom}(a)$ or $\text{dom}(b)$ is a bisection. We define $Z, D, S, N, M \subseteq A$ and $Z', D', S', N', M' \subseteq A'$ as in Assumption 6.

Corollary 8.5. $G$ and $G'$ are isomorphic graded étale groupoids whenever

(1) $A$ and $A'$ are diagonally isomorphic graded semigroups,
(2) $S = N$ is $Z$-bumpy and $S' = N'$ is $Z'$-bumpy, and
(3) $D$ and $D'$ are exhaustive.

Proof. If $\phi : A \mapsto A'$ is a diagonal-preserving graded semigroup isomorphism, so its restriction to $R = N(\mathcal{Z}(D))$ (see Proposition 7.3), which is thus diagonally isomorphic to $N'(\mathcal{Z}(D'))$. By Proposition 6.6, $N(Z)$ and $N(Z')$ are $Z$-bumpy. By Corollary 8.4, $G$ and $G'$ are isomorphic graded étale groupoids.

Note if $O \in \mathcal{I}_h(G)$ is a homogeneous open isosection then, for some unit $\gamma \in \Gamma^0$, $O O^{-1} \cup O^{-1} O \subseteq \text{int}(G^\text{iso} \cap [\gamma]c)$. So if $[\gamma]c$ is effective, for all $\gamma \in \Gamma^0$, $\mathcal{I}_h(G) = \mathcal{E}_h(G)$ and hence $S = N$. This can be useful when we have a diagonal-preserving isomorphism $\phi : A \to A'$ even if $\phi$ does not respect the grading. Indeed, as long as $[\gamma]c$ and $[\gamma]'c'$ are effective, for all $\gamma \in \Gamma^0$, we can then still apply the ungraded reconstruction result in Corollary 6.10 to show that $G$ and $G'$ are isomorphic (ungraded) étale groupoids.

For our final graded result, we weaken our assumption on $Y$ and $Y'$ as in §7.

Assumption 5. $Y$ and $Y'$ are indecomposable unital semigroupoids.

Corollary 8.6. If $G$ and $G'$ are ample groupoids, they are graded isomorphic when

(1) $A$ and $A'$ are diagonally isomorphic graded semigroups,
(2) $S$ and $S'$ are compact-bumpy,
(3) $D$ and $D'$ are exhaustive, and
(4) $C_{RZ} \subseteq D$ and $C'_{RZ} \subseteq D'$.

Proof. If $\phi : A \mapsto A'$ is a diagonal-preserving graded semigroup isomorphism, so its restriction to $R = N(\mathcal{Z}(D))$ (see 7.3), which is thus diagonally graded isomorphic to $R' = N(\mathcal{Z}(D'))$. As $G$ is ample and $S$ is compact-bumpy, so is $R$. Likewise, $R'$ is compact-bumpy so $G$ and $G'$ are isomorphic graded étale groupoids, by Corollary 8.4.

Note Corollary 8.6 generalises [Ste19, Theorem 5.6] in that our gradings can take values in a groupoid rather than just a group (as well as in the other respects mentioned after Corollary 7.5).
