N-POINT SPHERICAL FUNCTIONS AND ASYMPTOTIC BOUNDARY KZB EQUATIONS

J.V. STOKMAN & N. RESHETIKHIN

Abstract. Let $G$ be a split real connected Lie group with finite center. In the first part of the paper we define and study formal elementary spherical functions. They are formal power series analogues of elementary spherical functions on $G$ in which the role of the quasi-simple admissible $G$-representations is replaced by Verma modules. For generic highest weight we express the formal elementary spherical functions in terms of Harish-Chandra series and integrate them to spherical functions on the regular part of $G$. We show that they produce eigenstates for spin versions of quantum hyperbolic Calogero-Moser systems.

In the second part of the paper we define and study special subclasses of global and formal elementary spherical functions, which we call global and formal $N$-point spherical functions. Formal $N$-point spherical functions arise as limits of correlation functions for boundary Wess-Zumino-Witten conformal field theory on the cylinder when the position variables tend to infinity. We construct global $N$-point spherical functions in terms of compositions of equivariant differential intertwiners associated with principal series representations, and express them in terms of Eisenstein integrals. We show that the eigenstates of the spin quantum Calogero-Moser system associated to $N$-point spherical functions are also common eigenfunctions of a commuting family of first-order differential operators, which we call asymptotic boundary Knizhnik-Zamolodchikov-Bernard operators. These operators are explicitly given in terms of folded classical dynamical $r$-matrices and associated dynamical $k$-matrices.

1. Introduction

1.1. Preliminaries on \( \sigma \)-spherical functions. Let \( \mathfrak{g} \) be a complex semisimple Lie algebra, \( \theta \in \text{Aut}(\mathfrak{g}) \) a Chevalley involution, \( \mathfrak{k} = \mathfrak{g}^\theta \) its fix-point subalgebra, \( \mathfrak{h} \) a Cartan subalgebra contained in the \(-1\)-eigenspace of \( \theta \), \( \mathfrak{b} \) a Borel subalgebra containing \( \mathfrak{h} \), and \( n = [\mathfrak{b}, \mathfrak{b}] \). Let \( R \) and \( R^+ \) be the associated set of roots and positive roots respectively, and \( \mathfrak{g}_0 \) a split real form of \( \mathfrak{g} \) compatible with \( \mathfrak{h} \) and \( \theta \). Then \( \theta_0 := \theta|_{\mathfrak{g}_0} \) is a Cartan involution, \( \mathfrak{h}_0 := \mathfrak{h} \cap \mathfrak{g}_0 \) is a split real form of \( \mathfrak{h} \), and \( \mathfrak{k}_0 := \mathfrak{k} \cap \mathfrak{g}_0, \mathfrak{n}_0 := \mathfrak{n} \cap \mathfrak{g}_0 \) are real forms of \( \mathfrak{k} \) and \( \mathfrak{n} \) respectively. Let \( G \) be a connected Lie group with finite center and Lie algebra \( \mathfrak{g}_0 \), and \( K \subset G \) the connected Lie subgroup with Lie algebra \( \mathfrak{k}_0 \). Let \( N := \exp(\mathfrak{n}_0), A := \exp(\mathfrak{h}_0) \) and denote by \( A_+ \) its positive Weyl chamber. By the Iwasawa decomposition, each \( g \in G \) admits a unique decomposition \( g = kn \) with the elements \( k \in K, a \in A \) and \( n \in N \) depending smoothly on \( g \in G \).

Let \( (\sigma, V_\ell) \) and \( (\sigma_r, V_r) \) be finite dimensional \( \mathfrak{k} \)-representations and denote by \( \sigma := \sigma_\ell \otimes \sigma_r \) the representation map of the resulting \( \mathfrak{k} \oplus \mathfrak{k} \)-module \( V_\ell \otimes V_r^* \simeq \text{Hom}(V_r, V_\ell) \). If it integrates to a \( K \times K \)-representation, then the corresponding representation map will still be denoted by \( \sigma \). If this is the case, denote by \( C^\infty_\sigma(G) \) the space of \( \sigma \)-spherical functions on \( G \), which consists of the smooth functions \( f : G \to V_\ell \otimes V_r^* \) satisfying

\[
  f(k_\ell g k_\ell^{-1}) = \sigma(k_\ell, k_r) f(g) \quad (k_\ell, k_r \in K, g \in G).
\]

Then \( f \in C^\infty_\sigma(G) \) is called an elementary \( \sigma \)-spherical function if it is of the form

\[
  f^{\phi_\ell, \phi_r}(g) := \phi_\ell \circ \pi(g) \circ \phi_r
\]

for some quasi-simple admissible representation \((\pi, \mathcal{H})\) of \( G \), where \( \phi_\ell \in \text{Hom}_K(\mathcal{H}, V_\ell) \) and \( \phi_r \in \text{Hom}_K(V_r, \mathcal{H}) \) are two \( K \)-intertwiners. The elementary \( \sigma \)-spherical functions \( f^{\phi_\ell, \phi_r} \) are common eigenfunctions for the action of the center \( Z(g) \) of \( U(g) \) as bi-invariant differential operators on \( G \), with the eigenvalues given by the central character of \( \mathcal{H} \) (see, e.g., [26], [5], [61], as well as Section 3).

For \( \lambda \in \mathfrak{h}^* \) let \( \pi_\lambda : G \to \text{GL}(\mathcal{H}_\lambda) \) be the quasi-simple, admissible representation of \( G \) obtained by normalised induction from the multiplicative character \( \eta_\lambda : AN \to \mathbb{C}^*, \eta_\lambda(ann) := e^{\lambda \log(a)} \) of
the closed subgroup $AN \subset G$ ($a \in A$, $n \in N$). It is isomorphic to a finite direct sum of principal series representations. The associated elementary $\sigma$-spherical functions $f_{M_\lambda}^{\phi_\ell, \phi_r}$ admits an integral representation

$$f_{M_\lambda}^{\phi_\ell, \phi_r}(g) = E_{\lambda}^\sigma(g)T_{\lambda}^\phi$$

with $T_{\lambda}^\phi \in \text{Hom}(V_\ell, V_r)$ an explicit rank one operator and $E_{\lambda}^\sigma(g)$ the Eisenstein integral

$$E_{\lambda}^\sigma(g) = \int_K a(g^{-1}x)^{-\lambda - \rho} \sigma(x, k(g^{-1}x))dx,$$

where $dx$ is the normalised Haar measure on $K$, $\rho = \frac{1}{2} \sum_{\alpha \in R^+} \alpha$, and $a^\mu := e^{\mu(\log a)}$ for $\mu \in \mathfrak{h}^*$ and $a \in A$ (see Proposition [4.1]). Eisenstein integrals play an important role in Harish-Chandra’s theory of harmonic analysis on $G$ (see, e.g., [27, 28, 29, 61]).

1.2. Global description of the main results. In the first part of the paper we study formal elementary $\sigma$-spherical functions, which are formal analogues of $f_{M_\lambda}^{\phi_\ell, \phi_r}|_{A_+}$ in which the role of $H_\lambda$ is taken over by the Verma module $M_\lambda$ of highest weight $\lambda \in \mathfrak{h}^*$ with respect to the Borel subalgebra $b$ or better yet, by $M_{\lambda - \rho}$, in order to have matching central characters. Their construction is as follows.

For $\mu \in \mathfrak{h}^*$ let $\xi_\mu$ be the multiplicative character $\xi_\mu(a) := a^\mu$ on $A$. For a weight $\mu$ of $M_\lambda$ (i.e., $\mu \leq \lambda$ with respect to the dominance order $\leq$ on $\mathfrak{h}^*$), write $M_\lambda[\mu]$ for the corresponding weight space in $M_\lambda$. Write $\overline{M_\lambda}$ for the $n^*$-completion of $M_\lambda$, with $n^- := \theta(n)$ the nilpotent subalgebra of $\mathfrak{g}$ opposite to $b$. Fix $\ell$-intertwiners $\phi_\ell \in \text{Hom}_\ell(M_\lambda, V_\ell)$ and $\phi_r \in \text{Hom}_r(V_r, M_\lambda)$. For $\mu \in \mathfrak{h}^*$ a weight of $M_\lambda$ let $\phi_\ell^{\mu} \in \text{Hom}(M_\lambda[\mu], V_\ell)$ and $\phi_r^{\mu} \in \text{Hom}(V_r, M_\lambda[\mu])$ be the weight components of $\phi_\ell$ and $\phi_r$. The corresponding formal elementary $\sigma$-spherical function associated with $M_\lambda$ is the formal series

$$F_{M_\lambda}^{\phi_\ell, \phi_r} := \sum_{\mu \leq \lambda} (\phi_\ell^{\mu} \circ \phi_r^{\mu}) \xi_\mu$$

on $A_+$. We show that formal elementary $\sigma$-spherical functions are common (formal) eigenfunctions of commuting differential operators on $A_+$. These differential operators are Harish-Chandra’s $\sigma$-radial components $\hat{\Pi}^\sigma(z)$ of $z \in Z(\mathfrak{g})$, viewed as biinvariant differential operators on $G$. The eigenvalues are given by the values $\zeta_\lambda(z)$ of the central character $\zeta_\lambda$ of $M_\lambda$ at $z \in Z(\mathfrak{g})$. As a consequence, for generic highest weight $\lambda \in h^*_\mathfrak{HC}$ [3.10], the formal elementary $\sigma$-spherical function $F_{M_\lambda}^{\phi_\ell, \phi_r}$ can be related to the $\sigma$-Harish-Chandra series, which is the unique asymptotically free $\text{End}(\text{Hom}(V_\ell, V_r))$-valued formal eigenfunction

$$\Phi_\lambda^\sigma = \sum_{\mu \leq \lambda} \Gamma_\mu^\sigma(\lambda) \xi_\mu$$

of the radial component $\hat{\Pi}^\sigma(\Omega)$ of the action of the quadratic Casimir $\Omega \in Z(\mathfrak{g})$ with eigenvalue $\zeta_\lambda(\Omega)$ and with leading coefficient $\Gamma_0^\sigma(\lambda) = \text{id}_{V_\ell \otimes V_r}$ (see Subsection [3.3]):

$$F_{M_\lambda}^{\phi_\ell, \phi_r} = \Phi_\lambda^\sigma(\phi_\ell^{\mu} \circ \phi_r^{\mu})$$
(see Theorem 5.3c). Formula (1.3) allows one to control the analytic properties of the formal elementary \(\sigma\)-spherical functions. In particular it implies that \(F_{M,\lambda}^{\phi_1,\phi_2}\) for \(\lambda \in \mathfrak{h}_{\text{HC}}^{*}\) defines a \(\text{Hom}(V_{\ell}, V_{\ell})\)-valued analytic function on \(A_+\) that extends to a \(\sigma\)-spherical function on the dense open subset \(G_{\text{reg}} := K A_+ K\) of regular elements in \(G\) if \(\sigma\) integrates to a \(K \times K\)-representation and \(\phi_1^\sigma \circ \phi_2^\sigma \in \text{Hom}_{\text{HC}}(V_{\ell}, V_{\ell})\), with \(M := Z_K(A)\) the centraliser of \(A\) in \(K\).

The \(\sigma\)-Harish-Chandra series plays an important role in the asymptotic analysis of \(\sigma\)-spherical functions through the explicit expansion of the Eisenstein integral in Harish-Chandra series, see, e.g., [25, 28, 29, 61]. Another interesting recent application of \(\sigma\)-Harish-Chandra series is in the description of four-point spin conformal blocks in Euclidean conformal field theories within the conformal bootstrap program (see [55, 58, 67] and references therein).

For \(g = \mathfrak{sl}_2(C)\) the weight components of \(\ell\)-intertwiners \(\phi_\ell\) and \(\phi_r\) are Meixner-Pollaczek polynomials, and the \(\sigma\)-Harish-Chandra series can be expressed in terms of Gauss’ hypergeometric series \(2F_1\) (see Subsection 5.5).

Gauged versions of the \(\sigma\)-radial components of the biinvariant differential operators on \(G\) give rise to quantum Hamiltonians of \(\sigma\)-versions of quantum hyperbolic Calogero-Moser systems. Formula (1.3) then gives the representation theoretic interpretation of the corresponding asymptotically free eigenstates. The theory for the compact symmetric space associated to \(G/K\) yields spin versions of the quantum trigonometric Calogero-Moser system, with eigenstates described by vector-valued multivariable orthogonal polynomials. We will discuss this case in a separate paper.

In the second part of the paper we define and study \(N\)-point spherical functions and their formal analogues. The construction of \(N\)-point spherical functions is as follows. Let \((\tau_i, U_i)\) be finite dimensional \(G\)-representations \((1 \leq i \leq N)\) and write \(U := U_1 \otimes \cdots \otimes U_N\) for the associated tensor product \(G\)-representation with diagonal \(G\)-action. Let \(V_{\ell}\) and \(V_r\) be finite dimensional \(K\)-representations and denote the representation map of the \(K \times K\)-representation \((V_{\ell} \otimes U) \otimes V_r^*\) by \(\sigma^{(N)}\), where \(V_{\ell} \otimes U\) is regarded as \(K\)-representation with respect to the diagonal \(K\)-action.

\(N\)-point spherical functions are elementary \(\sigma^{(N)}\)-spherical functions on \(G\) of the form

\[ f_{\mathcal{H}_\Lambda}^{\phi_r, D, \phi_r} := f_{\mathcal{H}_\Lambda}^{(\phi_r \otimes \text{id}_U)}D, \phi_r \]

for

1. \(\mathcal{H}_\Lambda := (\mathcal{H}_{\lambda_0}, \ldots, \mathcal{H}_{\lambda_N})\),
2. \(D : \mathcal{H}_{\lambda_N}^\sigma \to \mathcal{H}_{\lambda_0}^\sigma \otimes U\) a \(G\)-equivariant differential operator given as the composition

\[ D = (D_1 \otimes \text{id}_U \otimes \cdots \otimes U_{N-1} \otimes \text{id}_U)D_N \]

of \(G\)-equivariant differential operators \(D_i : \mathcal{H}_{\lambda_i}^\sigma \to \mathcal{H}_{\lambda_{i+1}}^\sigma \otimes U_i\) \((i = 1, \ldots, N)\),
3. \(K\)-intertwiners \(\phi_r \in \text{Hom}_K(\mathcal{H}_{\lambda_0}, V_{\ell})\) and \(\phi_r \in \text{Hom}_K(V_{r}, \mathcal{H}_{\lambda_N})\).

The Eisenstein integral representation of \(f_{\mathcal{H}_\Lambda}^{\phi_r, D, \phi_r}\) is

\[ f_{\mathcal{H}_\Lambda}^{\phi_r, D, \phi_r}(g) = \int_K dx a(g^{-1}x)^{-\lambda_N - \rho} \left( \sigma_1(x) \otimes \tau_1(x) \otimes \cdots \otimes \tau_N(x) \otimes \sigma_r^*(k(g^{-1}x)) \right) T_{\lambda}^{(\phi_r \otimes \text{id}_U)}D, \phi_r. \]
Similarly, formal \( N \)-point spherical functions \( F^{\phi_{\ell}, \Psi}_{\sigma_{\lambda}} \) are formal elementary \( \sigma^{(N)} \)-spherical functions of the form

\[
F^{\phi_{\ell}, \Psi}_{\sigma_{\lambda}} := F^{(\phi_{\ell} \otimes \text{id}_U)}_{\sigma_{\lambda}} \Psi
\]

with

1. \( M_{\sigma} = (M_{\lambda_0}, \ldots, M_{\lambda_N}) \).
2. \( \Psi : M_{\lambda_N} \to M_{\lambda_0} \otimes U \) a \( \mathfrak{g} \)-intertwiner given as the composition

\[
\Psi = (\Psi_1 \otimes \text{id}_{U_2} \otimes \cdots \otimes \text{id}_{U_N}) \cdots (\Psi_{N-1} \otimes \text{id}_{U_N}) \Psi_N
\]

of \( N \) \( \mathfrak{g} \)-intertwiners \( \Psi_i : M_{\lambda_i} \to M_{\lambda_{i-1}} \otimes U_i \),
3. \( \mathfrak{h} \)-intertwiners \( \phi_{\ell} \in \text{Hom}(M_{\lambda_{i-1}}, V_{\ell}) \) and \( \phi_r \in \text{Hom}(V_r, M_{\lambda_N}) \).

In the formal setup, \((\sigma_{\ell}, V_{\ell})\) and \((\sigma_r, V_r)\) can be taken to be finite dimensional \( \mathfrak{h} \)-modules, and \((\tau_{\ell}, U_{\ell})\) finite dimensional \( \mathfrak{g} \)-modules (\( 1 \leq i \leq N \)). For generic \( \lambda_N \), the formal \( N \)-point spherical function admits an expression in terms of the \( \sigma^{(N)} \)-Harish-Chandra series \( \Phi_{\sigma_{\lambda_N}}^{(N)} \) and the highest weight components of the \( \mathfrak{h} \)-intertwiners \( (\phi_r \otimes \text{id}_U) \Psi \) and \( \phi_r \) the analogues of boundary vertex operators.

The analogous construction of formal \( N \)-point spherical functions in the affine setup is expected to give correlation functions for boundary Wess-Zumino-Witten (WZW) conformal field theory on an elliptic curve with conformally invariant boundary conditions. From this perspective, the \( \mathfrak{g} \)-intertwiners \( \Psi_i \) are the analogues of vertex operators, and the \( \mathfrak{h} \)-intertwiners \( \phi_{\ell} \) and \( \phi_r \) the analogues of boundary vertex operators.

This analogy with WZW conformal field theory predicts that the \( N \)-point spherical functions satisfy additional first order differential equations, obtained from trigonometric Knizhnik-Zamolodchikov-Bernard (KZB) type equations in the limit when the points are escaping to infinity and only the differential equations in the dynamical variables remain. We will derive such first order differential equations for the \( N \)-point spherical functions directly, and call them asymptotic boundary Knizhnik-Zamolodchikov-Bernard (KZB) equations. They are explicitly given in terms of \( \theta \)-folded classical dynamical trigonometric \( \tau \)-matrices and associated classical dynamical trigonometric \( k \)-matrices. Boundary KZB equations with spectral parameters will be discussed in a separate paper (for affine \( sl_2 \) Kolb \cite{Kolb} has already derived the associated KZB-heat equation).

Gauging to the context of the spin versions of quantum Calogero-Moser systems, the first order differential equations will be rewritten as eigenvalue equations for commuting first order differential operators \( D_1, \ldots, D_N \) called asymptotic boundary KZB operators. We show that the asymptotic boundary KZB operators also commute with the quantum Hamiltonians of the spin quantum Calogero-Moser system, leading to the interpretation of the quantum Calogero-Moser system as a quantum spin Calogero-Moser chain with \( N + 1 \) quadratic quantum Hamiltonians\footnote{Define for a \( \sigma^{(N)} \)-spherical functions \( f \),

\[
f(g_0, \ldots, g_N) := (\tau_1(g_0^{-1}) \otimes \tau_2(g_1^{-1} g_0^{-1}) \otimes \cdots \otimes \tau_N(g_{N-1}^{-1} \cdots g_1^{-1} g_0^{-1}) f(g_0 \cdots g_N).
\]

It satisfies \( f(kz_0, h_1, h_2, \ldots, h_N g_N k^{-1}) = (\sigma(k_1) \otimes \tau_1(h_1) \otimes \cdots \otimes \tau_N(h_N) \otimes \sigma(k_N)) f(g_0, \ldots, g_N) \) for \( (k_1, h_1, \ldots, h_N, k_N) \in K \times G^{\times N} \times K \). The action of \( Z(q) \) by biinvariant differential operators on the \( j \)th argument of \( f \) gives, through the restriction map \( f \to f|_A \), commuting differential operators \( \Pi_j(z) (z \in Z(q), 0 \leq j \leq N) \) on \( A \). Up to an appropriate gauge, the quadratic quantum Hamiltonians then are \( -\frac{1}{2} \Pi_j(\omega) (0 \leq j \leq N) \), and the asymptotic boundary KZB operators \( D_j \) are \( \frac{1}{2} (\Pi_j(\omega) - \Pi_{j-1}(\omega)) (1 \leq i \leq N) \). We will show this in a separate paper.}.

1.3. Spin quantum Calogero-Moser systems. The construction of the spin quantum Calogero-Moser systems can be done "universally", with \( U(\mathfrak{g})^{\otimes 2} \) taking over the role of the internal spin space \( V_{\ell} \otimes V_r^* \). The key point is the fact that Harish-Chandra’s radial component map is
universal, i.e., it produces for $z \in Z(\mathfrak{g})$ mutually commuting $U(\mathfrak{t})^\otimes 2$-valued commuting differential operators $\hat{\Pi}(z)$ on $A$ such that $\sigma(\hat{\Pi}(z)) = \hat{\Pi}^\sigma(z)$ for all $\mathfrak{t} \oplus \mathfrak{t}$-representations $\sigma$. In order to describe the resulting universal Schrödinger operator explicitly we need a bit more notations.

The Killing form $K_{\mathfrak{g}_0}$ on $\mathfrak{g}_0$ restricts to a scalar product on $\mathfrak{h}_0$, giving $A = \exp(\mathfrak{h}_0)$ the structure of a Riemannian manifold. Let $\Delta$ be the corresponding Laplace-Beltrami operator on $A$. Denote by $\mathfrak{g}_{0,0}$ the root space in $\mathfrak{g}_0$ associated to the root $\alpha \in R$. Let $e_\alpha \in \mathfrak{g}_{0,0}$ ($\alpha \in R$) such that $\theta_0(e_\alpha) = -e_\alpha$ and $[e_\alpha, e_{-\alpha}] = t_\alpha$, where $t_\alpha \in \mathfrak{h}_0$ is the unique element such that $K_{\mathfrak{g}_0}(t_\alpha, h) = \alpha(h)$ for all $h \in \mathfrak{h}_0$. The dual space $\mathfrak{h}_0^*$ inherits the scalar product of $\mathfrak{h}_0$ via the Killing form. We extend it to a complex bilinear form $(\cdot, \cdot)$ on $\mathfrak{h}$. Consider the elements $y_\alpha := e_\alpha - e_{-\alpha} \in \mathfrak{f}_0$ for $\alpha \in R$. Note that $\{y_\alpha\}_{\alpha \in R^+}$ is a linear basis of $\mathfrak{f}_0$, and $y_{-\alpha} = -y_\alpha$.

The Killing form $K_{\mathfrak{g}_0}$ on $\mathfrak{g}_0$ restricts to a scalar product on $\mathfrak{h}_0$, giving $A = \exp(\mathfrak{h}_0)$ the structure of a Riemannian manifold. Let $\Delta$ be the corresponding Laplace-Beltrami operator on $A$. Denote by $\mathfrak{g}_{0,0}$ the root space in $\mathfrak{g}_0$ associated to the root $\alpha \in R$. Let $e_\alpha \in \mathfrak{g}_{0,0}$ ($\alpha \in R$) such that $\theta_0(e_\alpha) = -e_\alpha$ and $[e_\alpha, e_{-\alpha}] = t_\alpha$, where $t_\alpha \in \mathfrak{h}_0$ is the unique element such that $K_{\mathfrak{g}_0}(t_\alpha, h) = \alpha(h)$ for all $h \in \mathfrak{h}_0$. The dual space $\mathfrak{h}_0^*$ inherits the scalar product of $\mathfrak{h}_0$ via the Killing form. We extend it to a complex bilinear form $(\cdot, \cdot)$ on $\mathfrak{h}$. Consider the elements $y_\alpha := e_\alpha - e_{-\alpha} \in \mathfrak{f}_0$ for $\alpha \in R$. Note that $\{y_\alpha\}_{\alpha \in R^+}$ is a linear basis of $\mathfrak{f}_0$, and $y_{-\alpha} = -y_\alpha$.

Set $\delta := \xi_\rho \prod_{a \in R^+} (1 - \zeta - 2\alpha)^{\frac{1}{2}}$, considered as analytic function on $A_+$, and consider the gauged commuting differential operators

$$H_z := \delta \circ \hat{\Pi}(z) \circ \delta^{-1} \quad (z \in Z(\mathfrak{g})),$$

which provide the quantum Hamiltonians of the spin quantum hyperbolic Calogero-Moser system. The universal Schrödinger operator is defined to be

$$H := -\frac{1}{2} \Delta + V,$$

with the $U(\mathfrak{t})^\otimes 2$-valued potential $V$ given by

$$V = -\frac{1}{2} \sum_{\alpha \in R} \frac{1}{(\xi_\alpha - \xi_{-\alpha})^2} \left( \|\alpha\|^2 + \prod_{c \in \{\pm 1\}} (y_\alpha \otimes 1 + \zeta_\alpha (1 \otimes y_\alpha)) \right).$$

The results from the previous subsections now lead to the following eigenstates. Suppose that $\sigma_\ell$ and $\sigma_r$ integrate to $K$-representations. Define the $(V_\ell \otimes V_r^*)^M$-valued smooth function $f^{0,0}_{\lambda,\phi_{\lambda}}$ on $A_+$ by

$$f^{0,0}_{\lambda,\phi_{\lambda}}(a) := \delta(a) f^{0,0}_{\lambda,\phi_{\lambda}}(a) \quad (a \in A_+),$$

where $(V_\ell \otimes V_r^*)^M \simeq \text{Hom}_K(V_r, V_\ell)$ is the space of $M$-invariant vectors in $V_\ell \otimes V_r^*$ with respect to the diagonal $M$-action.

For arbitrary finite dimensional $\mathfrak{t}$-representations $\sigma_\ell$ and $\sigma_r$, define the formal $V_\ell \otimes V_r^*$-valued power series $F^{0,0}_{\lambda,\phi_{\lambda}}$ on $A_+$ by

$$F^{0,0}_{\lambda,\phi_{\lambda}} := \delta F^{0,0}_{\lambda,\phi_{\lambda}} \circ F^{0,0}_{\lambda,\phi_{\lambda}},$$

where $\delta$ is expanded as scalar valued power series on $A_+$ with leading exponent $\rho$ (in particular, $F^{0,0}_{\lambda,\phi_{\lambda}}$ has leading exponent $\lambda$). It defines a $V_\ell \otimes V_r^*$-valued analytic function on $A_+$ if $\lambda + \rho \in \mathfrak{h}_0^\dag$. If $V_\ell$ and $V_r$ integrate to $K$-representations, then $F^{0,0}_{\lambda,\phi_{\lambda}}$ is $(V_\ell \otimes V_r^*)^M$-valued iff $\phi_{\lambda}^{\lambda - \rho} \circ \phi_{\lambda}^{\lambda - \rho} \in \text{Hom}_M(V_r, V_\ell)$. The normalised global and formal elementary $\sigma$-spherical functions $f^{0,0}_{\lambda,\phi_{\lambda}}$ and $F^{0,0}_{\lambda,\phi_{\lambda}}$ are eigenfunctions of the quantum Hamiltonians of the quantum $\sigma$-spin Calogero-Moser system

$$H_z(f_\lambda) = \zeta_{\lambda - \rho}(z) f_\lambda \quad \forall z \in Z(\mathfrak{g}),$$

where $f_\lambda = F^{0,0}_{\lambda,\phi_{\lambda}}$ and $f_\lambda = F^{0,0}_{\lambda,\phi_{\lambda}}$. In particular, $H(f_\lambda) = - \frac{\langle \Lambda, \rho \rangle}{2} f_\lambda$.

The equations (1.4) for $f_\lambda = F^{0,0}_{\lambda,\phi_{\lambda}}$ should initially be viewed as eigenvalue equations for formal $V_\ell \otimes V_r^*$-valued power series on $A_+$ with leading exponent $\lambda$. If $\lambda + \rho \in \mathfrak{h}_0^\dag$ then the formal eigenfunction $F^{0,0}_{\lambda,\phi_{\lambda}}$ is a normalised $\sigma$-Harish-Chandra series, and the eigenvalue equations are valid as $V_\ell \otimes V_r^*$-valued analytic functions on $A_+$. 

The eigenstates $f_{\psi_\ell,\phi_\nu}$ serve as wave functions for the $\sigma$-spin quantum Calogero-Moser system, while $F_{\psi_\ell,\phi_\nu}$ ($\psi \in W$), with $W$ the Weyl group of $R$, play the role of the asymptotically free wave functions with respect to the fundamental Weyl chamber $A_+$. The celebrated Harish-Chandra $c$-function expansion of $f_{\psi_\ell,\phi_\nu}$ in $\sigma$-Harish-Chandra series provides the solution of the associated asymptotic Bethe ansatz.

Some special cases of this representation theoretic construction of spin quantum Calogero-Moser systems have been described before; see [54] for the case when $\sigma_\ell$ and $\sigma_r$ are the trivial representation, see [52] Chpt. 5) for the case when $g = sp(C)$ and $\sigma_\ell = \sigma_r$ is one-dimensional (other natural special cases will be discussed in Subsection 3.6). For certain non-split symmetric pairs, the theory of Etingof, Kirillov Jr. and Schiffmann [14] [15] on generalised weighted trace functions and Oblomkov’s [52] version for Grassmannians fit into this framework. In these cases one of the two boundary representations $\sigma_\ell$ or $\sigma_r$ is one-dimensional. The classical integrable systems underlying the $\sigma$-spin quantum trigonometric Calogero-Moser systems were considered in [17] [18] [19] [57].

1.4. Asymptotic boundary KZB operators. Set $\lambda - \rho := (\lambda_0 - \rho, \ldots, \lambda_N - \rho)$. By the previous subsection, the normalised global and formal $N$-point spherical functions

$$f_{\Delta,\phi_\nu,\nu} := \delta f_{\phi_\nu,\phi_\nu}, \quad F_{\Delta,\psi_\nu,\phi_\nu} := \delta F_{\psi_\nu,\phi_\nu}$$
on on $A_+$ of weight $\lambda$ are common eigenfunctions of the quantum Hamiltonians of the $\sigma^{(N)}$-spin quantum hyperbolic Calogero-Moser system. In particular we have for both $f_{\Delta} := f_{\Delta,\phi_\nu,\nu}$ and $f_{\Delta} := F_{\Delta,\phi_\nu,\nu}$,

$$H^{(N)}(f_{\Delta}) = -\frac{(\lambda_0, \lambda_N)}{2} f_{\Delta}$$
on on $A_+$, where

$$H^{(N)} = -\frac{1}{2} \Delta + V^{(N)}$$

and $V^{(N)}$ is the $U(\mathfrak{t}) \otimes U(\mathfrak{t}) \otimes (N-1) \otimes U(\mathfrak{t})$-valued potential

$$V^{(N)} = -\frac{1}{2} \sum_{\alpha \in R} \left( \frac{1}{\xi_\alpha - \xi_{-\alpha}} \right)^2 \left( \frac{||\alpha||^2}{2} + \prod_{e \in \{ \pm 1 \}} (y_\alpha \otimes 1 \otimes N \otimes 1 + 1 \otimes \Delta^{(N-1)}(y_\alpha) \otimes 1 + \xi_\alpha (1 \otimes 1 \otimes N \otimes y_\alpha) \right)$$
on with $\Delta^{(N-1)}: U(\mathfrak{t}) \rightarrow U(\mathfrak{t}) \otimes (N-1)$ the $(N-1)$-fold iterated comultiplication of $U(\mathfrak{t})$ (concretely, $\Delta^{(N-1)}(y_\alpha) = \sum_{i=1}^N (y_\alpha)_i$, with $(y_\alpha)_i$ the tensor $1 \otimes \cdots \otimes 1 \otimes y_\alpha \otimes 1 \otimes \cdots \otimes 1$ with $y_\alpha$ placed in the $i$th tensor component). We now explicitly describe the additional first order differential equations satisfied by $f_{\Delta}$.

Let $\{x_s\}_{s=1}^r$ be an orthonormal basis of $\mathfrak{h}_0$ and $\partial_{x_s}$ the associated first order differential operator on $A$ (then $\Delta = \sum_{s=1}^r \partial^{2}_{x_s}$). Write $E$ for the $U(\mathfrak{g})$-valued first order differential operator

$$E := \sum_{s=1}^r \partial_{x_s} \otimes x_s$$
on on $A$. Write $A_{reg} := G_{reg} \cap A$ for the dense open set of regular elements in $A$. Define $\mathfrak{g}^{\otimes 2}$-valued functions $r^\pm$ on $A_{reg}$ by

$$r^+ = \sum_{\alpha \in R} \frac{y_\alpha \otimes e_\alpha}{1 - \xi - 2\alpha}, \quad r^- = \sum_{s=1}^r x_s \otimes x_s + \sum_{\alpha \in R} \frac{(e_\alpha + e_{-\alpha}) \otimes e_\alpha}{1 - \xi - 2\alpha}$$

(1.6)
We will call the first-order $U(t) \otimes U(g)^{\otimes N} \otimes U(t)$-valued differential operators

$$D_i := E_i - \sum_{j=1}^{i-1} r^{+}_{ij} - \kappa_i - \sum_{j=i+1}^{N} r^{-}_{ij} \quad (i = 1, \ldots, N)$$

on $A_{\text{reg}}$ the asymptotic boundary Knizhnik-Zamolodchikov-Bernard (KZB) operators.

Here the indices $i,j$ on the right hand side of (1.7) indicate in which tensor components of $U(g)^{\otimes N}$ the $U(g)$-components of $E$, $r^\pm$ and $\kappa$ are placed (note that the only nontrivial contributions to the left and right $U(t)$-tensor components arise from $\kappa_i - \kappa_i^\text{core}$).

Note that $r^\pm$ and $\kappa_i^\text{core}$ can be also written as

$$r^\pm = \pm r + (1 \otimes \theta)r_{21}, \quad \kappa_i^\text{core} = m((1 \otimes \theta)r_{21}),$$

with $m$ being the multiplication map of $U(g)$, and

$$r := -\frac{1}{2} \sum_{s=1}^{r} x_s \otimes x_s - \sum_{a \in R} e_a \otimes e_a$$

being the Felder’s [20], [15, §2] trigonometric dynamical $r$-matrix. More generally, for $a \in A_{\text{reg}},$

$$\kappa(a) = r^+(a) \otimes 1 + 1 \otimes \kappa_{\text{core}}(a) \otimes 1 + 1 \otimes ((\text{Ad}_{-1} \otimes \text{id})r^+_{21}(a)).$$

In this paper we prove that the normalised $N$-point spherical functions $\Gamma^\text{reg,D,\phi}_i$ satisfy the first order differential equations

$$D_i(\Gamma^\text{reg,D,\phi}_i) = \left(\frac{\lambda_i}{2} - \frac{\lambda_{i-1} + \lambda_{i-1}}{2}\right) \Gamma^\text{reg,D,\phi}_i, \quad i = 1, \ldots, N$$

on $A_+ \ (\text{Theorem 6.19}).$ We will present two proofs (a third proof follows from generalised radial component considerations, see footnote 3, and will appear elsewhere). The starting point for both proofs is writing $(\lambda_i, \lambda_i) - (\lambda_{i-1}, \lambda_{i-1}) = \zeta_i(\Omega) = \zeta_{i-1}(\Omega)$ and replacing $\zeta_i(\Omega)$ and $\zeta_{i-1}(\Omega)$ in the right hand side of (1.9) with the actions of the Casimir $\Omega$ on $\mathcal{H}_{\Lambda_i}^\infty$ and $\mathcal{H}_{\Lambda_{i-1}}^\infty$, placed to the left and right of the $i$th intertwiner $D_i$ in the expression of the normalised $N$-point spherical function $\Gamma^\text{reg,D,\phi}_i$.

For the first proof we then substitute an explicit Cartan-type factorisation of the Casimir $\Omega$ (see [13,16]), which is in essence equivalent to Harish-Chandra’s explicit formula for the differential operator $\hat{\Pi}(\Omega)$ obtained as the radial component of the action of $\Omega$ as biinvariant differential operator on spherical functions. Pushing the left-and right factors from this factorisation through the intertwiners $D_j$ to the far left and right, is creating the $r^\pm$ contributions to the asymptotic boundary KZB equations (1.9). The remaining factors are then absorbed by the $K$-intertwiners $\phi_\ell$ and $\phi_r$, producing the contribution $\kappa_i - \kappa_i^\text{core}$ to $D_i$. In this proof the core $\kappa_i^\text{core}$ of $\kappa_i$ is already part of the initial factorisation of the Casimir element and stays put at its initial spot throughout this procedure. The terms $r^{+}_{ji} (j < i)$ and $r^{+}_{ij} (j > i)$ appear in this proof as the expressions (1.6), not as combinations of dynamical $r$-matrices.
In the second proof we substitute the factorisation
\begin{equation}
\Omega = \sum_{k=1}^{r} x_{k}^{2} + \frac{1}{2} \sum_{\alpha \in R} \left( \frac{1 + a^{-2\alpha}}{1 - a^{-2\alpha}} \right) t_{\alpha} + 2 \sum_{\alpha \in R} \frac{e_{\alpha}e_{\alpha}}{1 - a^{-2\alpha}}
\end{equation}
of the quadratic Casimir element \( \Omega \) for \( a \in A_{\text{reg}} \), push the left and right root vectors through the intertwiners \( D_{j} \) to the far left and right, reflect against the \( K \)-intertwiners \( \phi_{r} \) and \( \phi_{v} \), and push the reflected factors back to their original position, where they merge and create the core \( \kappa_{i}^{\text{core}} \) of \( \kappa_{i} \). When we move components of \( \Omega \) to the boundaries (to the left and to the right) the terms \( r_{ji} \) or \( r_{ij} \) are created by commuting with the intertwiners \( D_{j} \). On the way back they are producing similar terms, but now involving the \( \theta \)-twisted \( r \)-matrix \( (1 \otimes \theta)r_{21} \). This proof naturally leads to the expressions \( (1.8) \) for \( r^{\pm} \) and \( \kappa_{i}^{\text{core}} \) in terms of Felder’s \( r \)-matrix. We also prove that the normalised formal \( N \)-point spherical functions \( F_{\Delta}^{\phi_{r},\Psi,\phi_{v}} \) are formal power series eigenfunctions of the asymptotic boundary KZB operators,
\begin{equation}
D_{i}(F_{\Delta}^{\phi_{r},\Psi,\phi_{v}}) = \left( \frac{(\lambda_{i},\lambda_{i})}{2} - \frac{(\lambda_{i-1},\lambda_{i-1})}{2} \right) F_{\Delta}^{\phi_{r},\Psi,\phi_{v}}, \quad i = 1, \ldots, N.
\end{equation}
Some additional care is needed here, since it involves manipulations with formal power series.

The asymptotic boundary KZB equations \( (1.9) \) can be viewed as an analogue of the asymptotic KZB equations for generalised weighted trace functions \( [15, \text{Thm. 3.1}] \). The underlying symmetric space in \( [13] \) is \( G \times G / \text{diag}(G) \), while in our case it is \( G / K \).

Fix \( \Delta = (\lambda_{0}, \ldots, \lambda_{N}) \) with \( \lambda_{N} \in \mathfrak{h}_{\text{FC}} + \rho \). We show in Subsection \( 6.3 \) that the set of normalised formal \( N \)-point spherical functions \( F_{\Delta}^{\phi_{r},\Psi,\phi_{v}} \) of weight \( \Delta \) can be naturally parametrised by vectors \( v \otimes u \otimes f \) with \( v \in V_{l}, f \in V_{r}^{*} \) and \( u = u_{1} \otimes \cdots \otimes u_{N} \in U \) consisting of weight vectors \( u_{i} \in U_{i} \) of weight \( \lambda_{i} - \lambda_{i-1} \). The corresponding normalised formal \( N \)-point spherical function of weight \( \Delta \) then has leading coefficient \( J_{f}(\lambda_{N} - \rho)(v \otimes u) \otimes f \in V_{l} \otimes U \otimes V_{r}^{*} \), where \( J_{f}(\lambda_{N} - \rho) \) is a linear automorphism of \( V_{l} \otimes U \) that can be regarded as a left boundary version of the fusion operator \( g \)-intertwiners \( [12, 16] \). As a consequence we obtain sufficiently many common eigenfunctions of the spin quantum Calogero-Moser Hamiltonians and the asymptotic boundary KZB operators to ensure their commutativity (see Theorem \( 6.26 \)). In particular,
\begin{align*}
[D_{i}, D_{j}] &= 0 \quad (i, j = 1, \ldots, N), \\
[D_{i}, H^{(N)}] &= 0 \quad (i = 1, \ldots, N)
\end{align*}
as \( U(\mathfrak{t}) \otimes U(\mathfrak{g}) \otimes U(\mathfrak{t}) \)-valued differential operators on \( A_{\text{reg}} \). A different reasoning leading to the commutativity of the operators uses component-wise radial component maps (see footnote \( 3 \)). As a consequence of the commutativity of the asymptotic boundary KZB operators we will conclude that the \( r^{\pm} \) satisfy the mixed classical dynamical Yang-Baxter equations
\begin{align*}
\sum_{k=1}^{r} ((x_{k})_{1}1\partial_{x_{k}}(r_{23}^{r}) - (x_{k})_{2}2\partial_{x_{k}}(r_{13}^{r})) &= [r_{13}^{r}, r_{12}^{r}] + [r_{12}^{r}, r_{23}^{r}] + [r_{13}^{r}, r_{23}^{r}], \\
\sum_{k=1}^{r} ((x_{k})_{1}1\partial_{x_{k}}(r_{23}^{l}) - (x_{k})_{3}3\partial_{x_{k}}(r_{12}^{l})) &= [r_{12}^{l}, r_{13}^{l}] + [r_{12}^{l}, r_{23}^{l}] + [r_{13}^{l}, r_{23}^{l}], \\
\sum_{k=1}^{r} ((x_{k})_{2}2\partial_{x_{k}}(r_{13}^{r}) - (x_{k})_{3}3\partial_{x_{k}}(r_{12}^{r})) &= [r_{12}^{r}, r_{13}^{r}] + [r_{12}^{r}, r_{23}^{r}] + [r_{23}^{r}, r_{13}^{r}].
\end{align*}
as $U(g)^{\otimes 3}$-valued functions on $A_{\text{reg}}$, and $\kappa$ is a solution of the associated classical dynamical reflection type equation

$$
\sum_{k=1}^{r} (x_k)_2 \partial_{x_k} (\kappa_1 + r^-) - \sum_{k=1}^{r} (x_k)_1 \partial_{x_k} (\kappa_2 + r^+) = [\kappa_1 + r^-, \kappa_2 + r^+]
$$
as $U(t) \otimes U(g)^{\otimes 2} \otimes U(t)$-valued functions on $A_{\text{reg}}$. In the latter equation, $r^{\pm}(a)$ for $a \in A_{\text{reg}}$ is viewed as the element $1 \otimes r^{\pm}(a) \otimes 1$ in $U(t) \otimes U(g)^{\otimes 2} \otimes U(t)$.

1.5. Outlook. Harish-Chandra’s theory of harmonic analysis on $G$ has been developed for arbitrary real connected semisimple Lie groups $G$ with finite center (more generally, for reductive $G$ in Harish-Chandra’s class). We expect that the theory of global and formal $N$-point spherical functions and associated asymptotic boundary KZB equations extend to this more general setup. The role of the Cartan subalgebra $h_0$ will then be taken over by a maximal abelian subalgebra $a_0$ of the $-1$-eigenspace of the Cartan involution $\theta$ of the Lie algebra $g_0$ of $G$, and the role of the root system $R$ is taken over by the associated reduced root system in $a_0^\vee$.

Besides the earlier mentioned extension of the theory to the affine setting, which will appear in a separate paper, it is natural to generalise the theory to the context of quantum groups using the Letzter-Kolb [21, 44] theory of quantum (affine) symmetric pairs. An intriguing question is how the resulting $K$-matrices will relate with the Balagovic-Kolb [1] and Kolb-Yakimov [45] type universal $K$-matrices. This direction has many interesting applications in integrable models in statistical mechanics and quantum field theory with integrable boundary conditions, see, e.g., [8, 24, 39] and references therein.

1.6. Contents of the paper. In Section 2 we recall basic facts on irreducible split Riemannian pairs and establish the relevant notations. In Section 3 we recall, following [5, 61], Harish-Chandra’s radial component map and the explicit expression of the radial component of the quadratic Casimir element. We furthermore establish the link to spin quantum hyperbolic Calogero-Moser systems (Subsection 3.6) and highlight various important special cases, such as the case that $\sigma_f$ and $\sigma_r$ are one-dimensional and the case that $\sigma_f = \sigma_r$. The latter case is naturally related to the theory of matrix-valued orthogonal polynomials in the compact picture, see, e.g., [25, 81]. We recall the construction of the Harish-Chandra series in Subsection 5.7 and discuss how they give rise to eigenstates for the spin quantum hyperbolic Calogero-Moser systems. In the first two subsections of Section 4 we recall fundamental results of Harish-Chandra [24, 25, 29] on the principal series representations of $G$ and its associated matrix coefficients. In Subsection 4.3 we discuss the algebraic principal series representations, and the description of the associated spaces of $\ell$-intertwiners. Section 5 first discusses how the algebraic principal series representations can be identified with $\ell$-finite parts of weight completions of Verma modules, which leads to a detailed description of the $\ell$-intertwining spaces $\text{Hom}_\ell(M_\lambda, V_\ell)$ and $\text{Hom}_\ell(V_\ell, \overline{M}_\lambda)$. In the second half of the section we introduce formal elementary $\sigma$-spherical functions and prove their key properties (differential equations and relation to $\sigma$-Harish-Chandra series). In Section 6 we first derive asymptotic operator KZB equations for $g$-intertwiners and relate them to factorisations of the quadratic Casimir element $\Omega$. In Subsections 6.2 & 6.3 we describe the spaces of $G$-equivariant differential operators $\mathcal{H}_\lambda^\infty \to \mathcal{H}_\mu^\infty \otimes U$ for a finite dimensional $G$-representation $U$, and derive the asymptotic boundary KZB equations for the associated $N$-point spherical functions. In Subsection 6.4 we derive the asymptotic boundary KZB equations for the formal $N$-point spherical functions. Subsection 6.5 and subsection 6.6 introduce the boundary fusion operator and establishes the integrability of the asymptotic boundary KZB operators. Finally, in Subsection 6.7 we establish the resulting classical mixed dynamical Yang-Baxter and reflection equations for the terms $r^\pm$ and $\kappa$ in the asymptotic boundary KZB operators.
Acknowledgments. We thank Ivan Cherednik, Pavel Etingof, Giovanni Felder, Gert Heckman, Erik Koelink, Christian Korff, Tom Koornwinder, Eric Opdam, Maarten van Pruijssen, Taras Skrypnyk and Bart Vlaar for discussions and comments. We thank Sam van den Brink for carefully reading the first part of the paper and pointing out a number of typos. The work of N.R. was partially supported by NSF DMS-1601947. He also would like to thank ETH-ITS for the hospitality during the final stages of the work.

Notations and conventions. We write $\text{ad}_L : L \to \mathfrak{gl}(L)$ for the adjoint representation of a Lie algebra $L$, and $K_L(\cdot, \cdot)$ for its Killing form. Real Lie algebras will be denoted with a subscript zero; The complexification of a real Lie algebra $\mathfrak{g}_0$ with be denoted by $\mathfrak{g} := \mathfrak{g}_0 \otimes \mathbb{C}$. The tensor product $\otimes_F$ of $F$-vector spaces is denoted by $\otimes$ in case $F = \mathbb{C}$. For complex vector spaces $U$ and $V$ we write $\text{Hom}(U,V)$ for the vector space of complex linear maps $U \to V$. Representations of Lie groups are complex, strongly continuous Hilbert space representations. If $U$ and $V$ are the representation spaces of two representations of a Lie group $G$, then $\text{Hom}_G(U,V)$ denotes the subspace of bounded linear $G$-intertwiners $U \to V$. If $U$ and $V$ are two $\mathfrak{g}$-modules for a complex Lie algebra $\mathfrak{g}$, then $\text{Hom}_\mathfrak{g}(U,V)$ denotes the subspace of $\mathfrak{g}$-intertwiners $U \to V$. The representation map of the infinitesimal $\mathfrak{g}$-representation associated to a smooth $G$-representation $(\tau, U)$ will be denoted by $\tau$ again, if no confusion can arise.

2. Irreducible split Riemannian symmetric pairs

This short section is to fix the basic notations for (split) real semisimple Lie algebras. For further reading consult, e.g., [42].

2.1. Real semisimple Lie algebras. Let $\mathfrak{g}_0$ be a real semisimple Lie algebra with Cartan subalgebra $\mathfrak{h}_0 \subset \mathfrak{g}_0$. Let

$$ \mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in \mathfrak{h}^*} \mathfrak{g}_\alpha $$

be the root space decomposition of the associated complex semisimple Lie algebra $\mathfrak{g}$ with root system $R = R(\mathfrak{g}, \mathfrak{h}) \subset \mathfrak{h}^*$ and associated root spaces

$$ \mathfrak{g}_{\alpha} := \{ x \in \mathfrak{g} \mid \text{ad}_{\mathfrak{h}}(h)x = \alpha(h)x \quad \forall h \in \mathfrak{h} \}. $$

We write $t_\lambda \in \mathfrak{h}$ for the unique element satisfying

$$ K_{\mathfrak{g}}(h, t_\lambda) = \lambda(h) \quad \forall h \in \mathfrak{h}. $$

Then $[x, y] = K_{\mathfrak{g}}(x, y)t_\alpha$ for $x \in \mathfrak{g}_\alpha$ and $y \in \mathfrak{g}_{-\alpha}$, see [40, Prop. 8.3].

Returning to the real semisimple Lie algebra $\mathfrak{g}_0$, recall that an involutive automorphism $\theta_0$ of the real semisimple Lie algebra $\mathfrak{g}_0$ is a Cartan involution if the bilinear form $(x, y) \mapsto -K_{\mathfrak{g}_0}(x, \theta_0(y))$ on $\mathfrak{g}_0$ is positive definite. Cartan involutions exist and are unique up to conjugation by an inner automorphism of $\mathfrak{g}_0$. The Cartan decomposition is the decomposition

$$ \mathfrak{g}_0 = \mathfrak{t}_0 \oplus \mathfrak{p}_0 $$

of $\mathfrak{g}_0$ in $\pm 1$-eigenspaces for the action of $\theta_0$. The $+1$-eigenspace $\mathfrak{t}_0 \subset \mathfrak{g}_0$ is a Lie subalgebra of $\mathfrak{g}_0$, and the $-1$-eigenspace $\mathfrak{p}_0$ is an ad$\mathfrak{g}_0(\mathfrak{t}_0)$-submodule of $\mathfrak{g}_0$.

Let $G$ be a connected real Lie group with Lie algebra $\mathfrak{g}_0$ and finite center. Denote $K \subset G$ for the connected Lie subgroup with Lie algebra $\mathfrak{t}_0$, which is maximal compact in $G$. The Cartan involution $\theta_0$ integrates to a global Cartan involution $\Theta_0 \in \text{Aut}(G)$, and $K$ is the subgroup of elements $g \in G$ fixed by $\Theta_0$. Hence $(G, K)$ is a Riemannian symmetric pair. The map $K \times \mathfrak{p}_0 \to G$, given by $(k, x) \mapsto k \exp(x)$, is a diffeomorphism, called the global Cartan decomposition of $G$. 

N-POINT SPHERICAL FUNCTIONS AND ASYMPOTIC BOUNDARY KZB EQUATIONS 11
Choose a maximally split Cartan subalgebra \( h_0 \subset g_0 \) with respect to the Cartan involution \( \theta_0 \), i.e., a \( \theta_0 \)-stable Cartan subalgebra \( h_0 \) such that \( a_0 := h_0 \cap p_0 \) is maximally abelian in \( p_0 \). Then \( h_0 = t_0 \oplus a_0 \) with \( t_0 = h_0 \cap t_0 \). With respect to the scalar product \((x, y) \mapsto -K_{g_0}(x, \theta_0(y))\) on \( g_0 \), the linear operator \( ad_{g_0}(h) \in \operatorname{End}(g_0) \) is skew-symmetric for \( h \in t_0 \) and symmetric for \( h \in a_0 \).

Note that the restriction of \( K_{g_0}(\cdot, \cdot) \) to \( a_0 \) is positive definite, turning \( a_0 \) in a Euclidean space. We write \((\cdot, \cdot) = K_{g_0}(\cdot, \cdot)|_{a_0 \times a_0} \) and \( \| \cdot \| \) for the resulting norm on \( a_0 \). We use the same notations for the induced scalar product and norm on \( a_0^* \). Furthermore, the complex bilinear extensions of \((\cdot, \cdot)\) to bilinear forms on \( a \) and \( a^* \) will also be denoted by \((\cdot, \cdot)\).

Let \( A \subset G \) be the connected Lie subgroup with Lie algebra \( a_0 \). It is a closed commutative Lie subgroup of \( G \), isomorphic to \( a_0 \) through the restriction of the exponential map \( \exp : \mathfrak{g} \to G \) to \( a_0 \). We write \( \log : A \to a_0 \) for its inverse. We furthermore write \( m_0 \) for the centralizer \( Z_{t_0}(a_0) \) of \( a_0 \) in \( t_0 \).

2.2. Split real semisimple Lie algebras. In this paper we restrict attention to split real semisimple Lie algebras.

**Definition 2.1.** A Cartan subalgebra \( h_0 \subset g_0 \) of a real semisimple Lie algebra \( g_0 \) is said to be split if \( \operatorname{ad}_{g_0}(h) \in \operatorname{End}(g_0) \) is diagonalizable for all \( h \in h_0 \). If \( g_0 \) admits a split Cartan subalgebra, then \( g_0 \) is called a split real semisimple Lie algebra.

Let \( g_0 \) be a split real semisimple Lie algebra with split Cartan subalgebra \( h_0 \). The root space decomposition (2.1) refines to

\[ g_0 = h_0 \oplus \bigoplus_{\alpha \in R} g_{0, \alpha} \]

with \( g_{0, \alpha} := g_0 \cap g_{0, \alpha} \), a one-dimensional real vector space for all \( \alpha \in R \). In particular, all roots \( \alpha \in R \) are real-valued on \( h_0 \) (conversely, a Cartan subalgebra \( h_0 \) of \( g_0 \) with the property that all the roots \( \alpha \in R \) are real-valued on \( h_0 \), is split). Let \( \{\alpha_1, \ldots, \alpha_r\} \) be a set of simple roots of \( R \) and write \( R^+ \) for the associated set of positive roots. For any choice of root vectors \( e_j \in g_{0, \alpha_j} \) and \( f_j \in g_{0, -\alpha_j} \), satisfying \([e_j, f_j] = t_{\alpha_j} \) (1 \( \leq j \leq \tau \)), there exists a unique involution \( \theta_0 \in \operatorname{Aut}(g_0) \) such that

\[ \theta_0(e_j) = -f_j, \quad 1 \leq j \leq \tau \]

and \( \theta_0|_{h_0} = -\operatorname{id}_{h_0} \), cf., e.g., [36, Prop. 14.3]. Furthermore, \( \theta_0 \in \operatorname{Aut}(g_0) \) is a Cartan involution and \( a_0 = h_0 \). Consequently \( h_0 \subset g_0 \) is a maximally split Cartan subalgebra with respect to \( \theta_0 \), and \( m_0 = \{0\} \). The complex linear extension \( \theta \in \operatorname{Aut}(g) \) of \( \theta_0 \) is a Chevalley involution of \( g \).

Conversely, let \( g_0 \) be a split real semisimple Lie algebra and \( \theta_0 \in \operatorname{Aut}(g_0) \) a Cartan involution. Choose a maximally split Cartan subalgebra \( h_0 \subset g_0 \) with respect to \( \theta_0 \). Then \( h_0 \subset g_0 \) is a split Cartan subalgebra, and \( h_0 \subset p_0 \). Furthermore, there exists a choice of root vectors \( e_j \in g_{0, \alpha_j} \) and \( f_j \in g_{0, -\alpha_j} \), satisfying \([e_j, f_j] = t_{\alpha_j} \) and \( \theta_0(e_j) = -f_j \) for \( j = 1, \ldots, \tau \).

Complexification \( g_0 \mapsto g \) defines a surjective map from the set of isomorphism classes of real semisimple Lie algebras to the set of isomorphism classes of complex semisimple Lie algebras. It restricts to a bijection from the set of isomorphism classes of split real semisimple Lie algebras onto the set of isomorphism classes of complex semisimple Lie algebras.

2.3. One-dimensional \( t \)-representations. We fix from now on a triple \((g_0, h_0, \theta_0)\) with \( g_0 \) a split real semisimple Lie algebra, \( h_0 \) a split Cartan subalgebra and \( \theta_0 \) a Cartan involution such that \( \theta_0|_{h_0} = -\operatorname{id}_{h_0} \). The associated pair \((G, K)\) is an irreducible split Riemannian symmetric pair. We fix from now on \( e_\alpha \in g_{0, \alpha} \) (\( \alpha \in R \)) such that \([e_\alpha, e_{-\alpha}] = t_\alpha \) and \( \theta_0(e_\alpha) = -e_{-\alpha} \) for all \( \alpha \in R \) (the fact that this is possible follows from, e.g., [36, §25.2]). Note that \( K_{g_0}(e_\alpha, e_{-\alpha}) = 1 \) for \( \alpha \in R \). Set

\[ y_\alpha := e_\alpha - e_{-\alpha} \in t_0, \quad \alpha \in R, \]
then $y_{-\alpha} = -y_\alpha$ ($\alpha \in R$) and

$$\mathfrak{t}_0 = \bigoplus_{\alpha \in R^+} \mathbb{R} y_\alpha,$$

$$\mathfrak{p}_0 = \mathfrak{h}_0 \oplus \bigoplus_{\alpha \in R^+} \mathbb{R}(e_\alpha + e_{-\alpha}).$$

Let $\text{ch}(\mathfrak{t}_0)$ be the space of one-dimensional real representations of $\mathfrak{t}_0$. If $\mathfrak{g}$ is simple but not of type $C_r$ ($r \geq 1$) then $\mathfrak{t}_0$ is semisimple (see, for instance, [60, §3.1]), hence $\text{ch}(\mathfrak{t}_0) = \{\chi_0\}$ with $\chi_0$ the trivial representation. If $\mathfrak{g}_0 \simeq \mathfrak{sp}(r; \mathbb{R})$ ($r \geq 1$) then $\mathfrak{t}_0 \simeq \mathfrak{gl}_r(\mathbb{R})$, hence $\text{ch}(\mathfrak{t}_0) = \mathbb{R}\chi$ is one-dimensional. Write in this case $\mathfrak{t}_0 = \mathfrak{k}_0 \oplus \mathfrak{n}_0$ with Lie algebra $\mathfrak{g}_0$ as vector spaces is the Iwasawa decomposition of $\mathfrak{g}$. The decomposition

$$\mathfrak{g}_0 = \mathfrak{k}_0 \oplus \mathfrak{n}_0$$

as vector spaces is the Iwasawa decomposition of $\mathfrak{g}_0$. Let $N \subset G$ be the connected Lie subgroup with Lie algebra $\mathfrak{n}_0$. Then $N$ is simply connected and closed in $G$, and the exponential map $\exp : \mathfrak{n}_0 \to N$ is a diffeomorphism. The multiplication map

$$(2.4) \quad K \times A \times N \to G, \quad (k, a, n) \mapsto kan$$

is a diffeomorphism onto $G$ (the global Iwasawa decomposition). We write

$$g = k(g)a(g)n(g)$$

for the Iwasawa decomposition of $g \in G$, with $k(g) \in K$, $a(g) \in A$ and $n(g) \in N$.

Since $\mathfrak{n}_0 = \{0\}$, the centralizer $M := Z_K(\mathfrak{a}_0)$ of $\mathfrak{a}_0$ in $K$ is a finite group. The minimal parabolic subgroup $P = MAN$ of $G$ is a closed Lie subgroup of $G$ with Lie algebra $\mathfrak{p}_0 := \mathfrak{h}_0 \oplus \mathfrak{n}_0$. Note that the complexification $\mathfrak{b}$ of $\mathfrak{b}_0$ is the Borel subalgebra of $\mathfrak{g}$ containing $\mathfrak{h}$.

3. Radial components of invariant differential operators

Throughout this section we fix a triple $(\mathfrak{g}_0, \mathfrak{h}_0, \mathfrak{b}_0)$ with $\mathfrak{g}_0$ a split real semisimple Lie algebra, $\mathfrak{h}_0$ a split Cartan subalgebra and $\mathfrak{b}_0$ a Cartan involution such that $\mathfrak{b}_0|_{\mathfrak{h}_0} = -\mathfrak{id}_{\mathfrak{h}_0}$. We write $\mathfrak{h}^*_0 \subset \mathfrak{h}^*$ for the real span of the roots, $G$ for a connected Lie group with Lie algebra $\mathfrak{g}_0$ and finite center, $K \subset G$ for the connected Lie subgroup with Lie algebra $\mathfrak{t}_0$, and $A \subset G$ for the connected Lie subgroup with Lie algebra $\mathfrak{a}_0$.

3.1. The radial component map. The radial component map describes the factorisation of elements $x \in U(\mathfrak{g})$ along algebraic counterparts of the Cartan decomposition $G = KAK$. We first introduce some preliminary notations.

For $\lambda \in \mathfrak{h}^*$ the map

$$\xi_\lambda : A \to \mathbb{C}^*, \quad a \mapsto a^\lambda := e^{\lambda(\log(a))}$$

defines a complex-valued multiplicative character of $A$, which is real-valued for $\lambda \in \mathfrak{h}^*_0$. It satisfies $\xi_\lambda \xi_\mu = \xi_{\lambda + \mu}$ ($\lambda, \mu \in \mathfrak{h}^*$) and $\xi_0 \equiv 1$. 
The adjoint representation $\text{Ad} : G \to \text{Aut}(\mathfrak{g}_0)$ extends naturally to an action of $G$ on the universal enveloping algebra $U(\mathfrak{g})$ of $\mathfrak{g}$ by complex linear algebra automorphisms. We write $\text{Ad}_g(x)$ for the adjoint action of $g \in G$ on $x \in U(\mathfrak{g})$. Note that for $a \in A$,
\[ \text{Ad}_a(e_a) = a^\alpha e_a \quad \forall \alpha \in R \]
and $\text{Ad}_a$ fixes $\mathfrak{h}$ pointwise.

Each $g \in G$ admits a decomposition $g = kak'$ with $k, k' \in K$ and $a \in A$. The double cosets $KaK$ and $Ka'K$ ($a, a' \in A$) coincide if $a' \in Wa$ with $W := N_K(\mathfrak{h}_0)/M$ the analytic Weyl group of $G$, acting on $A$ by conjugation. Note that $W$ is isomorphic to the Weyl group of $R$ since $G$ is split. Set
\[ A_{\text{reg}} := \{ a \in A \mid a^\alpha \neq 1 \quad \forall \alpha \in R \}. \]
Then $\exp : \mathfrak{h}_{0,\text{reg}} \to A_{\text{reg}}$, with $\mathfrak{h}_{0,\text{reg}} := \{ h \in \mathfrak{h}_0 \mid \alpha(h) \neq 0 \quad \forall \alpha \in R \}$ the set of regular elements in $\mathfrak{h}_0$. The Weyl group $W$ acts freely on $A_{\text{reg}}$. (3.1)

Infinitesimal analogues of the Cartan decomposition of $G$ are realized through the vector space decompositions
\[ \mathfrak{g}_0 = \mathfrak{h}_0 \oplus \text{Ad}_{a^{-1}} \mathfrak{t}_0 \oplus \mathfrak{t}_0 \]
of $\mathfrak{g}_0$ for $a \in A_{\text{reg}}$. The decomposition (3.1) follows from the identity
\[ e_a = \frac{a^{-\alpha}(\text{Ad}_{a^{-1}}y_a) - y_a}{a^{-2\alpha} - 1}, \]
which shows that $\{ \text{Ad}_{a^{-1}}y_a, y_a \}$ is a linear basis of $\mathfrak{g}_{0,a} \oplus \mathfrak{g}_{0,-a}$ for $a \in A_{\text{reg}}$. Set
\[ \mathcal{V} := U(\mathfrak{h}) \otimes U(\mathfrak{t}) \otimes U(\mathfrak{t}). \]
By the Poincaré-Birkhoff-Witt-Theorem, for each $a \in A_{\text{reg}}$ the linear map
\[ \Gamma_a : \mathcal{V} \to U(\mathfrak{g}), \quad \Gamma_a(h \otimes x \otimes y) := \text{Ad}_{a^{-1}}(x)hy \]
is a linear isomorphism.

Extending the scalars of the complex vector space $\mathcal{V}$ to the ring $C^\infty(A_{\text{reg}})$ of complex valued smooth functions on $A_{\text{reg}}$ allows one to give the factorisation $\Gamma_a^{-1}(x)$ for $x \in U(\mathfrak{g})$ uniformly in $a \in A_{\text{reg}}$. It suffices to extend the scalars to the unital subring $\mathcal{R}$ of $C^\infty(A_{\text{reg}})$ generated by $\xi_{-\alpha}$ and $(1 - \xi^{-2\alpha})^{-1}$ for all $\alpha \in R^+$. For $a \in A_{\text{reg}}$ the extension of $\Gamma_a$ is then the complex linear map $\tilde{\Gamma}_a : \mathcal{R} \otimes \mathcal{V} \to U(\mathfrak{g})$ defined by
\[ \tilde{\Gamma}_a(f \otimes Z) := f(a)\Gamma_a(Z), \quad f \in \mathcal{R}, \quad Z \in \mathcal{V}. \]

**Theorem 3.1.** For $x \in U(\mathfrak{g})$ there exists a unique $\Pi(x) \in \mathcal{R} \otimes \mathcal{V}$ such that
\[ \tilde{\Gamma}_a(\Pi(x)) = x \quad \forall a \in A_{\text{reg}}. \]

For example, by (3.2),
\[ \Pi(e_a) = (\xi_{-\alpha} - \xi_{\alpha})^{-1} \otimes 1 \otimes y_a \otimes 1 - (\xi^{-2\alpha} - 1)^{-1} \otimes 1 \otimes 1 \otimes y_a. \]
The resulting linear map $\Pi : U(\mathfrak{g}) \to \mathcal{R} \otimes \mathcal{V}$ is called the radial component map.

### 3.2. $\sigma$-Spherical functions

The radial component map plays an important role in the study of spherical functions. Fix a finite dimensional representation $\sigma : K \times K \to \text{GL}(\mathcal{V}_\sigma)$. Denote by $C^\infty(G; \mathcal{V}_\sigma)$ the space of smooth $\mathcal{V}_\sigma$-valued functions on $G$.

**Definition 3.2.** We say that $f \in C^\infty(G; \mathcal{V}_\sigma)$ is a $\sigma$-spherical function on $G$ if
\[ f(k_1 g k_2^{-1}) = \sigma(k_1, k_2) f(g) \quad \forall g \in G, \quad \forall k_1, k_2 \in K. \]
We denote by $C^\infty_\sigma(G)$ the subspace of $C^\infty(G; \mathcal{V}_\sigma)$ consisting of $\sigma$-spherical functions on $G$. 
Let $V^M_\sigma$ be the subspace of $M$-invariant elements in $V_\sigma$, with $M$ acting diagonally on $V_\sigma$. Examples of $\sigma$-spherical functions on $G$ are

$$E^\sigma_\lambda(\cdot)v \in C^\infty_{\sigma}(G), \quad v \in V_\sigma$$

with $E^\sigma_\lambda : G \to \text{End}(V_\sigma)$ ($\lambda \in \mathfrak{h}^*$) the Eisenstein integral

$$(3.3) \quad E^\sigma_\lambda(g) := \int_K dx \xi_{-\rho}(a(g^{-1}x))\sigma(x,k(g^{-1}x)).$$

Here $\rho := \frac{1}{2} \sum_{\alpha \in R^+} \alpha \in \mathfrak{h}^*$ and $dx$ is the normalised Haar measure on $K$. The representation theoretic construction of $\sigma$-spherical functions (see, e.g., [5, §8]) will be discussed in Section [4].

The function space $C^\infty(A;V^M_\sigma)$ is a $W$-module with $w = kM$ ($k \in N_K(h_0)$) acting by

$$(w \cdot f)(a) := \sigma(k,k)f(k^{-1}ak)$$

for $a \in A$ and $f \in C^\infty(A;V^M_\sigma)$. We write $C^\infty(A;V^M_\sigma)^W$ for the subspace of $W$-invariant $V^M_\sigma$-valued smooth functions on $A$. By the Cartan decomposition of $G$, we have the following well known result.

**Corollary 3.3.** The restriction map $|_A : C^\infty(G;V_\sigma) \to C^\infty(A;V_\sigma)$, $f \mapsto f|_A$ restricts to an injective linear map from $C^\infty_{\sigma}(G)$ into $C^\infty(A;V^M_\sigma)^W$. Similarly, restriction to $A_{\text{reg}}$ gives an injective linear map $|_{A_{\text{reg}}} : C^\infty_{\sigma}(G) \hookrightarrow C^\infty(A_{\text{reg}};V^M_\sigma)^W$.

The action of left $G$-invariant differential operators on $C^\infty_{\sigma}(G)$, pushed through the restriction map $|_{A_{\text{reg}}}$, gives rise to differential operators on $A_{\text{reg}}$ that can be described explicitly in terms of the radial component map II. We describe them in the following subsection.

3.3. **Invariant differential operators.** Denote by $\ell$ and $r$ the left-regular and right-regular representations of $G$ on $C^\infty(G)$ respectively,

$$(\ell(g)f)(g') := f(g^{-1}g'), \quad (r(g)f)(g') := f(g'g),$$

with $g, g' \in G$ and $f \in C^\infty(G)$. Let $\mathbb{D}(G)$ be the ring of differential operators on $G$, and $\mathbb{D}(G)^G \subseteq \mathbb{D}(G)$ its subalgebra of left $G$-invariant differential operators. Differentiating $r$ gives an an isomorphism

$$r_* : U(\mathfrak{g}) \xrightarrow{\sim} \mathbb{D}(G)^G$$

of algebras.

Let $U(\mathfrak{g})^M \subseteq U(\mathfrak{g})$ be the subalgebra of $\text{Ad}(M)$-invariant elements in $U(\mathfrak{g})$. Embed $\mathbb{D}(G)$ into $\mathbb{D}(G) \otimes \text{End}(V_\sigma)$ by $D \mapsto D \otimes \text{id}_{V_\sigma}$ ($D \in \mathbb{D}(G)$). With respect to the resulting action $r_*$ of $U(\mathfrak{g})$ on $C^\infty(G;V_\sigma)$, the subspace $C^\infty_{\sigma}(G)$ of $\sigma$-spherical functions is a $U(\mathfrak{g})^M$-invariant subspace of $C^\infty(G;V_\sigma)$.

Let $\mathbb{D}(A)$ be the ring of differential operators on $A$ and $\mathbb{D}(A)^A$ the subalgebra of $A$-invariant differential operators. Let $r^A$ be the right-regular action of $A$ on $C^\infty(A)$. Its differential gives rise to an algebra isomorphism

$$(3.4) \quad r_*^A : U(\mathfrak{h}) \xrightarrow{\sim} \mathbb{D}(A)^A.$$

We will write $\partial_h := r_*^A(h) \in \mathbb{D}(A)^A$ for $h \in \mathfrak{h}_0$, which are the derivations

$$\left(\partial_h f\right)(a) = \frac{d}{dt} \bigg|_{t=0} f(a \exp_A(th))$$

for $f \in C^\infty(A)$ and $a \in A$. We also consider $\mathbb{D}(A)^A$ as the subring of $\mathbb{D}(A_{\text{reg}})$ consisting of constant coefficient differential operators and write

$$\mathbb{D}_{\text{R}} \subset \mathbb{D}(A_{\text{reg}})$$
for the algebra of differential operators
\[ D = \sum_{m_1, \ldots, m_r} c_{m_1, \ldots, m_r} \partial_{x_1}^{m_1} \cdots \partial_{x_r}^{m_r} \in \mathbb{D}(A_{\text{reg}}) \]
with coefficients \( c_{m_1, \ldots, m_r} \in \mathcal{R} \), where \( \{x_1, \ldots, x_r\} \) is an orthonormal basis of \( \mathfrak{h}_0 \) with respect to \((\cdot, \cdot)\). The algebra isomorphism (3.4) now extends to a complex linear isomorphism
\[ \tilde{r}^A : \mathcal{R} \otimes U(\mathfrak{h}) \xrightarrow{\sim} \mathbb{D}_R, \quad f \otimes h \mapsto \tilde{r}^A_f(h) \]
for \( f \in \mathcal{R} \) and \( h \in U(\mathfrak{h}) \). Finally, \( \mathbb{D}_R \otimes U(\mathfrak{t})^\otimes \) will denote the algebra of differential operators
\[ D = \sum_{m_1, \ldots, m_r} c_{m_1, \ldots, m_r} \partial_{x_1}^{m_1} \cdots \partial_{x_r}^{m_r} \in A_{\text{reg}} \]
with coefficients \( c_{m_1, \ldots, m_r} \in \mathcal{R} \otimes U(\mathfrak{t})^\otimes \). It acts naturally on \( C^\infty(A_{\text{reg}}; V_\sigma) \).

By the proof of [5, Thm. 3.1] we have for \( f \in C^\infty(G) \), \( h \in U(\mathfrak{h}) \) and \( x, y \in U(\mathfrak{t}) \),
\[ (r_\ast(\text{Ad}_{e^{-1}}(x)hy)f)(a) = \sigma(x \otimes S(y))(r_\ast(h)f)(a) \quad \forall a \in A_{\text{reg}}, \]
with \( S \) the antipode of \( U(\mathfrak{t}) \), defined as the anti-algebra homomorphism of \( U(\mathfrak{t}) \) such that \( S(x) = -x \) for all \( x \in \mathfrak{t} \). Combined with Theorem [5,1] this leads to the following result.

**Theorem 3.4.** With the above conventions, define the linear map
\[ \tilde{\Pi} : U(\mathfrak{g}) \to \mathbb{D}_R \otimes U(\mathfrak{t})^\otimes \]
by \( \tilde{\Pi} := (\tilde{r}^\ast \otimes \text{id}_{U(\mathfrak{t})} \otimes S)\Pi \), and set
\[ \tilde{\Pi}^\sigma := (\text{id}_{\mathbb{D}_R} \otimes \sigma)\tilde{\Pi} : U(\mathfrak{g}) \to \mathbb{D}_R \otimes \text{End}(V_\sigma). \]

a. For \( z \in U(\mathfrak{g}) \),
\[ (r_\ast(z)f)|_{A_{\text{reg}}} = \tilde{\Pi}^\sigma(z)(f|_{A_{\text{reg}}}) \quad \forall f \in C^\infty(G). \]

b. The restrictions of \( \tilde{\Pi} \) and \( \tilde{\Pi}^\sigma \) to \( Z(\mathfrak{g}) \) are algebra homomorphisms.

**Proof.** a. This is a well-known result of Harish-Chandra, see, e.g., [5, Thm. 3.1].

b. It is well-known that the differential operators \( \tilde{\Pi}(z) \) \( (z \in Z(\mathfrak{g})) \) pairwise commute when acting on \( C^\infty(A_{\text{reg}}; V_\sigma^M) \), see [5, Thm. 3.3]. The theory of formal spherical functions which we develop in Section 5 implies that they also commute as \( U(\mathfrak{t})^\otimes \)-valued differential operators.

The key point is that all formal spherical functions are formal power series eigenfunctions of \( \tilde{\Pi}(z) \) \( (z \in Z(\mathfrak{g})) \) to commute as \( U(\mathfrak{t})^\otimes \)-valued differential operators by the results in Section 6.3 for the special case \( N = 0 \).

**Remark 3.5.** By [5, Prop. 2.5] we have \( \tilde{\Pi}(z) \in \mathbb{D}_R \otimes U(\mathfrak{t} \oplus \mathfrak{t})^M \) for \( z \in U(\mathfrak{g})^M \), where \( U(\mathfrak{t} \oplus \mathfrak{t})^M \) is the space of \( M \)-invariance in \( U(\mathfrak{t} \oplus \mathfrak{t}) \) with respect to the diagonal adjoint action of \( M \) on \( U(\mathfrak{t} \oplus \mathfrak{t}) \). In particular, \( \tilde{\Pi}^\sigma(z) \in \mathbb{D}_R \otimes \text{End}_M(V_\sigma) \) for \( z \in U(\mathfrak{g})^M \), with \( M \) acting diagonally on \( V_\sigma \).

3.4. The radial component of the Casimir element. In this subsection we recall the computation of the radial component of the Casimir element. As before, let \( e_\alpha \in \mathfrak{g}_{0,\alpha} \) \( (\alpha \in R) \) such that \( [e_\alpha, e_{-\alpha}] = t_\alpha \) and \( h_0(e_\alpha) = -e_{-\alpha} \) \( (\alpha \in R) \), and \( \{x_1, \ldots, x_r\} \) an orthonormal basis of \( \mathfrak{h}_0 \) with respect to \((\cdot, \cdot)\). The Casimir element \( \Omega \in Z(\mathfrak{g}) \) is given by
\[ \Omega = \sum_{j=1}^r x_j^2 + \sum_{\alpha \in R} c_\alpha e_{-\alpha} \]
(3.5)
\[ = \sum_{j=1}^r x_j^2 + 2t_\rho + 2 \sum_{\alpha \in R^+} e_{-\alpha} e_\alpha. \]
By (3.6), the second line of (3.5), and by
\[ [y_a, \text{Ad}_{a^{-1}}y_a] = (a^{-\alpha} - a^\alpha)t_\alpha \quad \forall \ a \in A, \]
we obtain the following Cartan factorisation of \( \Omega \),
\[
(3.6) \quad \Omega = \sum_{j=1}^{r} x_j^2 + \frac{1}{2} \sum_{a \in R} \left( \frac{a^\alpha + a^{-\alpha}}{a^\alpha - a^{-\alpha}} \right) t_\alpha + \sum_{a \in R} \left( \frac{\text{Ad}_{a^{-1}}(y_a^2) - (a^\alpha + a^{-\alpha})\text{Ad}_{a^{-1}}(y_a)y_a + y_a^2}{(a^\alpha - a^{-\alpha})^2} \right)
\]
for arbitrary \( a \in A_{\text{reg}} \). It follows that
\[
(3.7) \quad \Pi(\Omega) = \sum_{j=1}^{r} 1 \otimes x_j^2 \otimes 1 \otimes 1 + \frac{1}{2} \sum_{a \in R} \left( \frac{\xi_\alpha + \xi^{-\alpha}}{\xi_\alpha - \xi^{-\alpha}} \right) t_\alpha \otimes 1 \otimes 1
\]
\[
+ \sum_{a \in R} \left\{ \frac{1}{(\xi_\alpha - \xi^{-\alpha})^2} \otimes 1 \otimes (y_a^2 \otimes 1 + 1 \otimes y_a^2) - \frac{(\xi_\alpha + \xi^{-\alpha})}{(\xi_\alpha - \xi^{-\alpha})^2} \otimes 1 \otimes y_a \otimes y_a \right\}.
\]
This gives the following result, cf., e.g., [61, Prop. 9.1.2.11].

**Corollary 3.6.** The differential operator \( \hat{\Pi}(\Omega) \in \mathbb{D}_R \otimes U(\mathfrak{t})^{\otimes 2} \) is given by
\[
(3.8) \quad \hat{\Pi}(\Omega) = \Delta + \frac{1}{2} \sum_{a \in R} \left( \frac{\xi_\alpha + \xi^{-\alpha}}{\xi_\alpha - \xi^{-\alpha}} \right) \partial t_\alpha + \sum_{a \in R} \left( \frac{1}{\xi_\alpha - \xi^{-\alpha}} \right) \prod_{\epsilon \in \{\pm 1\}} (y_a \otimes 1 + \epsilon \alpha(1 \otimes y_a))
\]
with \( \Delta := \sum_{j=1}^{r} \partial^2_{x_j} \) the Laplace-Beltrami operator on \( A \).

**Remark 3.7.** Note that the infinitesimal Cartan factorisations (3.6) of \( \Omega \) are parametrised by elements \( a \in A_{\text{reg}} \). In the context of boundary Knizhnik-Zamolodchikov equations (see Section 3), these will provide the dynamical parameters.

There are various ways to factorise \( \Omega \), of which (3.5) and the infinitesimal Cartan decomposition (3.6) are two natural ones. Another factorisation is
\[
(3.9) \quad \Omega = \sum_{j=1}^{r} x_j^2 + \frac{1}{2} \sum_{a \in R} \left( \frac{1 + a^{-2\alpha}}{1 - a^{-2\alpha}} \right) t_\alpha + 2 \sum_{a \in R} \frac{e^{-a}e_\alpha}{1 - a^{-2\alpha}}
\]
for \( a \in A_{\text{reg}} \), which is a dynamical version of (3.5). This formula can be easily proved by moving in (3.6) positive root vectors \( e_\alpha (\alpha \in R^+) \) to the left and using \( [e_\alpha, e_{-\alpha}] = t_\alpha \), which causes the "dynamical" dependence to drop out and reduces (3.6) to the second formula of (3.5). The decomposition (3.6) is the natural factorisation of \( \Omega \) in the context of Etingof’s and Schiffmann’s [15] generalised weighted trace functions and associated asymptotic KZB equations, as we shall explain in Section 4.

3.5. \( \chi \)-invariant vectors. Let \( V \) be a \( \mathfrak{g}_0 \)-module and fix \( \chi \in \text{ch}(\mathfrak{t}_0) \). We say that a vector \( v \in V \) is \( \chi \)-invariant if \( xv = \chi(x)v \) for all \( x \in \mathfrak{t}_0 \). We write \( V^\chi \) for the subspace of \( \chi \)-invariant vectors in \( V \),
\[
V^\chi = \{ v \in V \mid e_\alpha v - e_{-\alpha}v = \chi(y_\alpha)v \quad \forall \ \alpha \in R^+ \}.
\]
In case of the trivial one-dimensional representation \( \chi_0 \equiv 0 \), we write \( V^{\chi_0} = V^{10} \), which is the space of \( \mathfrak{t}_0 \)-fixed vectors in \( V \). From the computation of the radial component of the Casimir \( \Omega \) in the previous subsection, we obtain the following corollary.

**Corollary 3.8.** Let \( V \) be a \( \mathfrak{g}_0 \)-module such that \( \Omega|_V = c \text{Id}_V \) for some \( c \in \mathbb{R} \). Fix \( \chi \in \text{ch}(\mathfrak{t}_0) \) and \( v \in V^\chi \). Then
\[
\left( \sum_{j=1}^{r} x_j^2 + \frac{1}{2} \sum_{a \in R} \left( \frac{1 + a^{-2\alpha}}{1 - a^{-2\alpha}} \right) t_\alpha + \sum_{a \in R} \frac{1}{(a^\alpha - a^{-\alpha})^2} \prod_{\epsilon \in \{\pm 1\}} (\text{Ad}_{a^{-1}}(y_a) - a^{-\alpha}(\chi(y_a))) \right) v = c v
\]
for all $a \in A_{\text{reg}}$.

If $V$ is $h_{0}$-diagonalisable then Corollary 3.8 reduces to explicit recursion relations for the weight components of $v \in V^{\chi}$.

**Remark 3.9.** In the setup of the corollary, a vector $u \in V$ is a Whittaker vector of weight $a \in A_{\text{reg}}$ if $e_{\alpha}u = a^{\alpha}u$ for all $\alpha \in R^{+}$. Recursion relations for the weight components of Whittaker vectors are used in [9] §3.2 to derive a path model for Whittaker vectors ([9] Thm. 3.7), as well as for the associated Whittaker functions ([9] Thm. 3.9). It would be interesting to see what this approach entails for $\sigma$-spherical functions with $\sigma$ a one-dimensional representation of $K \times K$, when the role of the Whittaker vectors is taken over by $\chi$-invariant vectors.

### 3.6. $\sigma$-Spin quantum hyperbolic Calogero-Moser systems

We gauge the commuting differential operators $\hat{H}(z)$ ($z \in Z(\mathfrak{g})$) and write them as quantum Hamiltonians for the $\sigma$-spin generalisation of the quantum hyperbolic Calogero-Moser system. This extends results from [23 54 30] and [32 Part I, Chpt. 5], which deal with the “spinless” cases.

Write

$$A_{+} := \{a \in A \mid a^{\alpha} > 1 \quad \forall \alpha \in R^{+}\}$$

for the positive chamber of $A_{\text{reg}}$. Note that $\mathcal{R}$ is contained in the ring $C^\infty(A_{+})$ of analytic functions on $A_{+}$.

Let $\delta$ be the analytic function on $A_{+}$ given by

$$\delta(a) := a^{\rho} \prod_{\alpha \in R^{+}} (1 - a^{-2\alpha})^{\frac{1}{2}}. \tag{3.10}$$

Conjugation by $\delta$ defines an outer automorphism of $\mathbb{D}_{\mathcal{R}}$. For $z \in U(\mathfrak{g})$ we denote by

$$H_{z} := \delta \circ \hat{H}(z) \circ \delta^{-1} \in \mathbb{D}_{\mathcal{R}} \otimes U(\mathfrak{t})^{\otimes 2} \tag{3.11}$$

the corresponding gauged differential operator. We furthermore write

$$H := -\frac{1}{2} \delta \circ (\hat{H}(\Omega) + \|\rho\|^{2}) \circ \delta^{-1}. \tag{3.12}$$

**Proposition 3.10.** The assignment $z \mapsto H_{z}$ defines an algebra map $Z(\mathfrak{g}) \to \mathbb{D}_{\mathcal{R}} \otimes U(\mathfrak{t} \oplus \mathfrak{t})^{M}$. Furthermore,

$$H := \frac{1}{2} \Delta - \frac{1}{2} \sum_{\alpha \in \mathfrak{R}} \left( \frac{1}{\xi_{\alpha} - \xi_{-\alpha}} \right) \left( \|\rho\|^{2} + \prod_{\epsilon \in \{\pm 1\}} (y_{\alpha} \otimes 1 + \xi_{\alpha}(1 \otimes y_{\alpha})) \right). \tag{3.13}$$

**Proof.** The first statement is immediate from Theorem 3.9. The proof of (3.13) follows from the well known fact that

$$\delta \circ \left( \Delta + \sum_{\alpha \in \mathfrak{R}} \left( \frac{1}{\xi_{\alpha} - \xi_{-\alpha}} \right) \partial_{\alpha} \right) \circ \delta^{-1} = \Delta - \|\rho\|^{2} + \sum_{\alpha \in \mathfrak{R}} \frac{1}{2} \left( \xi_{\alpha} - \xi_{-\alpha} \right)^{2},$$

see, e.g., the proof of [32 Part I, Thm. 2.1.1].

For $\sigma : U(\mathfrak{t})^{\otimes 2} \to \text{End}(V_{\sigma})$ a finite dimensional representation we write

$$H_{z}^{\sigma} := (\text{id}_{\mathcal{D}_{\mathcal{R}}} \otimes \sigma)H_{z} \in \mathbb{D}_{\mathcal{R}} \otimes \text{End}(V_{\sigma}) \quad (z \in U(\mathfrak{g})).$$

Then $H_{z}^{\sigma}$ ($z \in Z(\mathfrak{g})$) are commuting $\text{End}(V_{\sigma})$-valued differential operators on $A$ which, by Proposition 3.10, serve as quantum Hamiltonians for the $\sigma$-spin generalisation of the quantum hyperbolic Calogero-Moser system with Schrödinger operator

$$H^{\sigma} := (\text{id}_{\mathcal{D}_{\mathcal{R}}} \otimes \sigma)(H).$$
We now list a couple of interesting special cases of the $\sigma$-spin quantum hyperbolic Calogero-Moser systems.

**The spinless case:** Take $\chi^f, \chi^r \in \text{ch}(t_0)$. Their extension to complex linear algebra morphisms $U(\mathfrak{t}) \to \mathbb{C}$ are again denoted by $\chi^f$ and $\chi^r$. Define $\chi^{\ell,r}_\alpha \in C^\infty(A)$ $(\alpha \in R)$ by

\[
\chi^{\ell,r}_\alpha(a) := \chi^f(y_\alpha) + a^\alpha \chi^r(y_\alpha), \quad a \in A_+.
\]

Note that $\chi^{\ell,r}_\alpha(a) = -(\chi^f(y_\alpha) + a^{-\alpha} \chi^r(y_\alpha))$ for $\alpha \in R$. The Schrödinger operator $H^{x^f \otimes x^r}$ then becomes

\[
H^{x^f \otimes x^r} = -\frac{1}{2}\Delta - \frac{1}{2} \sum_{\alpha \in R^+} \left( \frac{1}{\langle \xi_\alpha - \xi_\alpha \rangle^2} \sum_{2} \left( \frac{1}{\xi_\alpha - \xi_\alpha} \right)^2 + \left( \frac{1}{\xi_\alpha - \xi_\alpha} \right)^2 \right).
\]

The special case

\[
H^{x_0 \otimes x_0} = -\frac{1}{2}\Delta - \frac{1}{2} \sum_{\alpha \in R^+} \frac{1}{\langle \xi_\alpha - \xi_\alpha \rangle^2} \left( \sum_{\beta \in R^+} \left( \frac{1}{\xi_\beta - \xi_\beta} \right)^2 + \left( \frac{1}{\xi_\beta - \xi_\beta} \right)^2 \right)
\]

with $x_0 \in \text{ch}(t_0)$ the trivial representation is the quantum Hamiltonian of the quantum hyperbolic Calogero-Moser system associated to the Riemannian symmetric space $G/K$. If $\mathfrak{g}$ is simple and of type $C_r$ $(r \geq 1)$ then $\chi^f = c_\ell \chi_{sp}$ and $\chi^r = c_r \chi_{sp}$ for some $c_\ell, c_r \in \mathbb{C}$, see Subsection 2.3. Using the explicit description of $\chi_{sp}$ from Subsection 2.3, we then obtain

\[
H^{x^f \otimes x^r} = -\frac{1}{2}\Delta - \frac{1}{2} \sum_{\alpha \in R^+} \left( \frac{1}{\langle \xi_\alpha - \xi_\alpha \rangle^2} + \frac{1}{4} \sum_{\beta \in R^+} \left( \frac{1}{\xi_\beta - \xi_\beta} \right)^2 + \left( \frac{1}{\xi_\beta - \xi_\beta} \right)^2 \right)
\]

hence we recover a two-parameter subfamily of the BC$_r$ quantum hyperbolic Calogero-Moser system. This extends [12] Part I, Thm. 5.1.7, which deals with the special case that $\chi^f = -\chi^r$ with $\chi^f \in \text{ch}(t_0)$ integrating to a multiplicative character of $K$.

**The one-sided spin case:** Let $\chi \in \text{ch}(t_0)$ and $\sigma_\ell : U(\mathfrak{t}) \to \text{End}(V_\ell)$ a finite dimensional representation. Then

\[
H^{\sigma_\ell \otimes x} = -\frac{1}{2}\Delta - \frac{1}{2} \sum_{\alpha \in R^+} \left( \frac{1}{\langle \xi_\alpha - \xi_\alpha \rangle^2} + \prod_{c \in \{\pm 1\}} \left( \frac{1}{\xi_\alpha - \xi_\alpha} \right)^2 \right).
\]

In the special case that $\chi = x_0 \in \text{ch}(t_0)$ is the trivial representation the Schrödinger operator reduces to

\[
H^{x_0 \otimes x_0} = -\frac{1}{2}\Delta - \frac{1}{2} \sum_{\alpha \in R^+} \left( \frac{1}{\langle \xi_\alpha - \xi_\alpha \rangle^2} + \prod_{c \in \{\pm 1\}} \left( \frac{1}{\xi_\alpha - \xi_\alpha} \right)^2 \right).
\]

Finally, if $\mathfrak{g}$ is simple and of type $C_r$ $(r \geq 1)$ and $\chi = c_\chi_{sp}$ with $c \in \mathbb{C}$, then

\[
H^{\sigma_\ell \otimes x} = -\frac{1}{2}\Delta - \frac{1}{2} \sum_{\alpha \in R^+} \left( \frac{1}{\langle \xi_\alpha - \xi_\alpha \rangle^2} + \prod_{c \in \{\pm 1\}} \left( \frac{1}{\xi_\alpha - \xi_\alpha} \right)^2 \right)
\]

\[
+ \frac{1}{4} \sum_{\beta \in R^+} \left( \frac{1}{\xi_\beta - \xi_\beta} \right)^2 + \left( \frac{1}{\xi_\beta - \xi_\beta} \right)^2 + \left( \frac{1}{\xi_\beta - \xi_\beta} \right)^2.
\]

**Remark 3.11.** Fehér and Pusztai [13, 19] obtained the classical analog of the one-sided spin quantum Calogero-Moser system by Hamiltonian reduction. This is extended to double-sided spin Calogero-Moser systems in [57].
The matrix case: The following special case is relevant for the theory of matrix-valued spherical functions \([25, 31, 37]\). Let \(\tau : \mathfrak{gl}(V_\tau) \to \mathfrak{gl}(V_\tau)\) be a finite dimensional representation. Consider \(\text{End}(V_\tau)\) as left \(U(\mathfrak{g}) \otimes \mathbb{C}\)-module by
\[
\sigma_\tau(x \otimes y)T := \tau(x)T\tau(S(y))
\]
for \(x, y \in U(\mathfrak{g})\) and \(T \in \text{End}(V_\tau)\). Note that \(\text{End}(V_\tau) \simeq V_\tau \otimes V_\tau^*\) as \(U(\mathfrak{g}) \otimes \mathbb{C}\)-modules. The associated \(\text{Schrodinger}\) operator \(H_\tau\) acts on \(T \in C^\infty(\text{End}(V_\tau))\) by
\[
(H_\tau T)(a) = \frac{1}{2}(\Delta T)(a) - \frac{1}{2} \sum_{\alpha \in R} \frac{\|a\|^2}{2} T(a) + \tau(y_a^2)T(a) - (a^\alpha + a^{-\alpha})\tau(y_a)T(a)\tau(y_a) + T(a)\tau(y_a^2)
\]
for \(a \in A\).

3.7. \(\sigma\)-Harish-Chandra series. In this subsection we recall the construction of the Harish-Chandra series following \([61, \text{Chpt. 9}]\). They were defined by Harish-Chandra to analyse \(A\)-representations and of the associated spherical functions (see, e.g., \([2, 5, 32]\) and references therein).

Consider the ring \(\mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\) of formal power series at infinity in \(A_+\). We express elements \(f \in \mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\) as \(f = \sum_{\gamma \in Q_-} c_\gamma \xi_\gamma\) with \(c_\gamma \in \mathbb{C}\) and
\[
Q_- := \bigoplus_{j=1}^r \mathbb{Z}_{\leq 0} \alpha_j \subseteq Q := \mathbb{Z}R.
\]

We consider \(R\) as subring of \(\mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\) using power series expansion at infinity in \(A_+\) (e.g., \((1 - \xi_{-2\alpha})^{-1} = \sum_{m=0}^{\infty} \xi_{-2m\alpha}\) for \(\alpha \in R^+\)). Similarly, we view \(\xi_{-\rho}\) as element in \(\mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\) through its power series expansion at infinity, where \(\delta\) is given by \((3.10)\).

For \(A\) a complex associative algebra we write \(A[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}][[\xi_\lambda] for the \(\mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\)-module of formal series \(g = \sum_{\gamma \in Q_-} d_\gamma \xi_{\gamma + \gamma}\) with coefficients \(d_\gamma \in A\). If \(A = U(\mathfrak{g}) \otimes \mathbb{C}\) or \(A = \text{End}(V_0)\) for some \(\mathfrak{g} \oplus \mathfrak{g}\)-module \(V_0\) then \(A[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\) becomes a \(D_R \otimes U(\mathfrak{g}) \otimes \mathbb{C}\)-module.

Set
\[
b_\text{HC}^\ast := \{ \lambda \in \mathfrak{h}^\ast \mid (2(\lambda + \rho) + \gamma, \gamma) \neq 0 \ \forall \gamma \in Q_- \ \setminus \{0\} \}.
\]

The Harish-Chandra series associated to the triple \((g_0, h_0, \theta_0)\) is the following formal \(U(\mathfrak{g}) \otimes \mathbb{C}\)-valued eigenfunction of the \(U(\mathfrak{g}) \otimes \mathbb{C}\)-valued differential operator \(\hat{\Pi}(\Omega)\).

**Proposition 3.12.** Let \(\lambda \in b_\text{HC}^\ast\). There exists a unique \(U(\mathfrak{g}) \otimes \mathbb{C}\)-valued formal series
\[
\Phi_\lambda := \sum_{\gamma \in Q_-} \Gamma_\gamma(\lambda) \xi_{\lambda + \gamma} \in U(\mathfrak{g}) \otimes \mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]
\]
with coefficients \(\Gamma_\gamma(\lambda) \in U(\mathfrak{g}) \otimes \mathbb{C}\) and \(\Gamma_0(\lambda) = 1\), satisfying
\[
\hat{\Pi}(\Omega) \Phi_\lambda = (\lambda, \lambda + 2\rho) \Phi_\lambda.
\]

In fact, if \(\lambda \in b_\text{HC}^\ast\) then the eigenvalue equation \((3.18)\) for a formal series of the form \((3.17)\) gives recursion relations for its coefficients \(\Gamma_\lambda(\gamma)\) \((\gamma \in Q_-)\) which, together with the condition \(\Gamma_0(\lambda) = 1\), determine the coefficients \(\Gamma_\gamma(\lambda)\) uniquely. We call the \(\Gamma_\gamma(\lambda) \in U(\mathfrak{g}) \otimes \mathbb{C}\) \((\gamma \in Q_-)\) the Harish-Chandra coefficients.

The sum \(U(h) + \theta(n)U(g)\) in \(U(g)\) is an internal direct sum containing \(Z(g)\). Denote by \(\text{pr} : Z(g) \to U(h)\) the restriction to \(Z(g)\) of the projection \(U(h) \oplus \theta(n)U(g) \to U(h)\) on the first
direct summand. Then \(pr\) is an algebra homomorphism (see, e.g., [5, §1]). The central character at \(\lambda \in \mathfrak{h}^*\) is the algebra homomorphism
\[
\zeta_\lambda : Z(\mathfrak{g}) \rightarrow \mathbb{C}, \quad z \mapsto \lambda(pr(z))
\]
with \(\lambda(pr(z))\) the evaluation of \(pr(z) \in U(\mathfrak{h}) \simeq S(\mathfrak{h})\) at \(\lambda\). By the second expression of the Casimir element \(\Omega\) in (3.5) we have \(\zeta_\lambda(\Omega) = (\lambda, \lambda + 2\rho)\). Furthermore, by [10, Prop. 7.4.7], \(\zeta_{\lambda - \rho} = \zeta_{\mu - \rho}\) for \(\lambda, \mu \in \mathfrak{h}^*\) if and only if \(\lambda \in W\mu\).

**Proposition 3.13.** Let \(\lambda \in \mathfrak{h}_{\text{HC}}^*\). Then
\[
\hat{\Pi}(z)\Phi_{\lambda} = \zeta_\lambda(z)\Phi_{\lambda} \quad \forall \, z \in Z(\mathfrak{g})
\]
in \(U(\mathfrak{t}) \otimes [\kappa_{-1}, \ldots, \kappa_{-1}]\).  

**Proof.** Write \(x^n := x_1^n \cdots x_r^n \in S(\mathfrak{h})\) and \(\partial^n := \partial_{x_1}^n \cdots \partial_{x_r}^n \in D_\mathbb{R}\) for \(n \in \mathbb{Z}_{\geq 0}\). The leading symbol of \(D = \sum_{\eta \in \mathbb{Z}_{\geq 0}} (\sum_{\gamma \in Q_-} c_{\eta, \gamma}\xi_\gamma) \partial^n \in D_\mathbb{R} \otimes U(\mathfrak{t}) \otimes \mathfrak{g}\) is defined to be
\[
s_\infty(D) := \sum_{\eta \in \mathbb{Z}_{\geq 0}} c_{\eta, 0} x^n \in S(\mathfrak{h}) \otimes U(\mathfrak{t}) \otimes \mathfrak{g}.
\]
Fix \(z \in Z(\mathfrak{g})\). Let \(z_\lambda^\infty \in U(\mathfrak{t}) \otimes \mathfrak{g}\) be the evaluation of the leading symbol \(s_\infty(\hat{\Pi}(z))\) at \(\lambda\). Note that the \(\zeta_\lambda\)-component of the formal power series \(\hat{\Pi}(z)\Phi_{\lambda}\) is \(z_\lambda^\infty\). Furthermore, \(\hat{\Pi}(z)\Phi_{\lambda}\) is an eigenfunction of \(\hat{\Pi}(\Omega)\) with eigenvalue \((\lambda, \lambda + 2\rho)\) by Theorem 3.12. It thus follows that
\[
\hat{\Pi}(z)\Phi_{\lambda} = \zeta_\lambda(z)\Phi_{\lambda}^\infty.
\]
By [5, Prop. 2.6(ii)] we have
\[
s_\infty(\hat{\Pi}(z)) = s_\infty(\hat{\Pi}(pr(z))),
\]
hence \(z_\lambda^\infty = \lambda(pr(z))1_{U(\mathfrak{t}) \otimes \mathfrak{g}} = \zeta_\lambda(z)1_{U(\mathfrak{t}) \otimes \mathfrak{g}}\). This concludes the proof of the proposition. \(\square\)

**Remark 3.14.** By Remark 3.3 and by an argument similar to the proof of Proposition 3.13 it follows that \(\Gamma_\gamma(\lambda) \in U(\mathfrak{t} \otimes \mathfrak{t})^M\) for \(\lambda \in \mathfrak{h}_{\text{HC}}^*\) and \(\gamma \in Q_-\).

Fix a finite dimensional representation \(\sigma : U(\mathfrak{t}) \otimes \mathfrak{g} \rightarrow \text{End}(V_\sigma)\). For \(\lambda \in \mathfrak{h}_{\text{HC}}^*\) set
\[
(3.19) \quad \Phi_\sigma^\lambda := \sum_{\gamma \in Q_-} \sigma(\Gamma_\gamma(\lambda))\zeta_{\lambda + \gamma} \in \text{End}(V_\sigma)[\kappa_{-1}, \ldots, \kappa_{-1}]\zeta_{\lambda},
\]
We call \(\Phi_\sigma^\lambda\) the \(\sigma\)-Harish-Chandra series, and
\[
\Gamma_\gamma^\lambda(\lambda) := \sigma(\Gamma_\gamma(\lambda)) \in \text{End}(V_\sigma), \quad \gamma \in Q_-\]
the associated Harish-Chandra coefficients.

**Remark 3.15.** Suppose that \(V_\sigma\) integrates to a \(K \times K\)-representation. Let \(\text{End}_M(V_\sigma)\) be the space of \(M\)-intertwiners \(V_\sigma \rightarrow V_\sigma\) with respect to the diagonal action of \(M\) on \(V_\sigma\). Then \(\Gamma_\gamma^\lambda(\lambda) \in \text{End}_M(V_\sigma)\) for all \(\gamma \in Q_-\) by Remark 3.14.
Note that $\Phi_\lambda^\gamma$ is the unique formal power series $\sum_{\gamma \in Q_-} \Gamma_\gamma^\sigma(\lambda)\xi_{\lambda+\gamma}$ with $\Gamma_\gamma^\sigma(\lambda) \in \text{End}(V_\sigma)$ and $\Gamma_\gamma^\sigma(\lambda) = \text{id}_{V_\sigma}$ satisfying $\hat{\Pi}(\Omega)\Phi_\lambda^\gamma = (\lambda, \lambda + 2\rho)\Phi_\lambda^\sigma$. The $\sigma$-Harish-Chandra series in addition satisfies the eigenvalue equations $\hat{\Pi}(z)\Phi_\lambda^\sigma = \zeta_\lambda(z)\Phi_\lambda^\sigma$ for all $z \in Z(\mathfrak{g})$.

Endow $\text{End}(V_\sigma)$ with the norm topology. The recursion relations arising from the eigenvalue equation $\hat{\Pi}(\Omega)\Phi_\lambda^\sigma = \zeta_\lambda(\Omega)\Phi_\lambda^\sigma$ imply growth estimates for the Harish-Chandra coefficients $\Gamma_\gamma^\sigma(\lambda)$.

It leads to the following result (cf. [61] and references therein).

**Proposition 3.16.** Let $\lambda \in \mathfrak{h}_{\text{HC}}^\ast$. Then
\[ \Phi_\lambda^\gamma(a) := \sum_{\gamma \in Q_-} \Gamma_\gamma^\sigma(\lambda)a^{\lambda+\gamma}, \quad a \in A_+ \]
defines an $\text{End}(V_\sigma)$-valued analytic function on $A_+$.

**Remark 3.17.** Set $G_{\text{reg}} := KA_k K \subset G$, which is an open dense subset of $G$. We have $k_1ak_2^{-1} = k_1a'k_2^{-1}$ for $k_i, k_i', k_r, k_r' \in K$ and $a, a' \in A_+$ if $a' = a$ and $k_1^{-1}k_1' = k_2^{-1}k_2' \in M$. If $\sigma : K \times K \to \text{GL}(V_\sigma)$ is a finite dimensional $K \times K$-representation, then a smooth function $f : G_{\text{reg}} \to V_\sigma$ is called a $\sigma$-spherical function on $G_{\text{reg}}$ if
\[ f(k_1gk_2^{-1}) = \sigma(k_1, k_2)f(g) \quad \forall g \in G_{\text{reg}}, \forall k_1, k_2 \in K. \]

Then for $\lambda \in \mathfrak{h}_{\text{HC}}^\ast$ and $v \in V_\sigma^M$,
\[ H_\lambda^\sigma(k_1ak_2^{-1}) := \sigma(k_1, k_2)\Phi_\lambda^\sigma(a)v \quad (a \in A_+, k_1, k_2 \in K) \]
defines a $\sigma$-spherical function on $G_{\text{reg}}$. It in general does not extend to a $\sigma$-spherical function on $G$.

The Harish-Chandra series immediately provide ”asymptotically free” common eigenfunctions for the quantum Hamiltonians $H_\sigma^z$ ($z \in Z(\mathfrak{g})$) of the $\sigma$-spin quantum hyperbolic Calogero-Moser system.

**Theorem 3.18.** Fix $\lambda \in \mathfrak{h}_{\text{HC}}^\ast + \rho$. The $\text{End}(V_\sigma)$-valued analytic function
\[ (3.20) \quad \Phi_\lambda^\sigma(a) := \delta(a)\Phi_{\lambda - \rho}(a), \quad a \in A_+ \]
has a series expansion of the form
\[ \Phi_\lambda^\sigma = \sum_{\gamma \in Q_-} \Gamma_\gamma^\sigma(\lambda)\xi_{\lambda+\gamma} \in \text{End}(V_\sigma)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\xi_{\lambda} \]
with $\Gamma_\gamma^\sigma(\lambda) \in \text{End}(V_\sigma)$ and $\Gamma_0^\sigma(\lambda) = \text{id}_{V_\sigma}$. It satisfies the Schrödinger equation
\[ H_\sigma^\sigma(\Phi_\lambda^\sigma) = -\frac{(\lambda, \lambda)}{2} \Phi_\lambda^\sigma \]
as well as the eigenvalue equations
\[ H_\sigma^z\Phi_\lambda^\sigma = \zeta_{\lambda - \rho}(z)\Phi_\lambda^\sigma \quad \forall z \in Z(\mathfrak{g}) \]
as $\text{End}(V_\sigma)$-analytic functions on $A_+$.

**Proof.** This is an immediate consequence of Proposition 3.13 and the definitions of the differential operators $H_\sigma^\sigma$ and $H_\sigma^z$ ($z \in Z(\mathfrak{g})$). \qed
4. Principal series representations

We keep the conventions of the previous section. In particular, \((g_0, h_0, \theta_0)\) is a triple with \(g_0\) a split real semisimple Lie algebra, \(h_0\) a split Cartan subalgebra and \(\theta_0\) a Cartan involution such that \(\theta_0|_{h_0} = -\text{id}_{h_0}\), and \((G, K)\) is the associated non-compact split symmetric pair. We fix throughout this section two finite dimensional \(K\)-representations \(\sigma_k : K \to \text{GL}(V_k)\) and \(\tau_r : K \to \text{GL}(V_r)\). We write \((\cdot, \cdot)_{V_k}\) and \((\cdot, \cdot)_{V_r}\) for scalar products on \(V_k\) and \(V_r\) turning \(\sigma_k\) and \(\tau_r\) into unitary representations of \(K\). We view \(\text{Hom}(V_r, V_k)\) as finite dimensional \(K \times K\)-representation with representation map \(\sigma : K \times K \to \text{GL}(\text{Hom}(V_r, V_k))\) given by

\[
\sigma(k_\ell, k_r)T := \sigma_\ell(k_\ell)T\sigma_r(k_r^{-1})
\]

for \(k_\ell, k_r \in K\) and \(T \in \text{Hom}(V_r, V_k)\). It is canonically isomorphic to the tensor product representation \(V_k \otimes V_r^*\).

For further details on the first two subsections, see \([11]\) Chpt. 8.

4.1. Admissible representations and associated spherical functions. Let \(K^\wedge\) be the equivalence classes of the irreducible unitary representations of \(K\). A representation \(\pi : G \to \text{GL}(H)\) of \(G\) on a Hilbert space \(H\) is called admissible if the restriction \(\pi|_K\) of \(\pi\) to \(K\) is unitary and if the \(\tau\)-isotypical component \(H(\tau)\) of \(\pi|_K\) is finite dimensional for all \(\tau \in K^\wedge\).

Let \(\pi : G \to \text{GL}(H)\) be an admissible representation. The subspace

\[H^\infty := \{v \in H \mid G \to H, g \mapsto \pi(g)v \text{ is } C^\infty\}\]

of smooth vectors in \(H\) is a \(G\)-stable dense subspace of \(H\). Differentiating the \(G\)-action on \(H^\infty\) turns \(H^\infty\) into a left \(U(g)\)-module. We write \(x \mapsto x_{H^\infty}\) for the corresponding action of \(x \in U(g)\).

The algebraic direct sum

\[H^{K-\text{fin}} := \bigoplus_{\tau \in K^\wedge} H(\tau)\]

is the dense subspace of \(K\)-finite vectors in \(H\). It is contained in \(H^\infty\) since \(\pi\) is admissible. Furthermore, it inherits a \((g, K)\)-module structure from \(H^\infty\). The \((g, K)\)-module \(H^{K-\text{fin}}\) is called the Harish-Chandra module of \(H\).

For \(\phi_\ell \in \text{Hom}_K(H, V_k)\) and \(\phi_r \in \text{Hom}_K(V_r, H)\) we now obtain \(\sigma\)-spherical functions

\[f_{H, \ell}^{\phi_\ell, \phi_r} \in C^\infty_\sigma(G)\]

by

\[f_{H, \ell}^{\phi_\ell, \phi_r}(g) := \phi_\ell \circ \pi(g) \circ \phi_r, \quad g \in G.\]

The \(\sigma\)-spherical functions \(f_{H, \ell}^{\phi_\ell, \phi_r}\) are actually \(\text{Hom}(V_r, V_k)\)-valued real analytic functions on \(G\), see, e.g., \([11]\) Thm. 8.7]. Furthermore, \(f_{H, \ell}^{\phi_\ell, \phi_r}|_A\) takes values in \(\text{Hom}_M(V_r, V_k)\).

Since \(V_k\) and \(V_r\) are finite dimensional, we have canonical isomorphisms

\[
\text{Hom}_K(H, V_k) \simeq \text{Hom}_K(H^\infty, V_k) \simeq \text{Hom}_K(H^{K-\text{fin}}, V_k),
\]

\[
\text{Hom}_K(V_r, H) \simeq \text{Hom}_K(V_r, H^\infty) \simeq \text{Hom}_K(V_r, H^{K-\text{fin}}).
\]

The \(\sigma\)-spherical function \(f_{H, \ell}^{\phi_\ell, \phi_r}\) can be expressed in terms of matrix coefficients of \(\pi\) as follows. Let \(\{v_i\}_i\) and \(\{w_j\}_j\) be linear bases of \(V_k\) and \(V_r\), respectively. Expand \(\phi_\ell \in \text{Hom}_K(H, V_k)\) and

\[\phi_r \in \text{Hom}_K(V_r, H)\]

as

\[\phi_\ell = \sum_i \langle \cdot, f_i \rangle_H v_i, \quad \phi_r = \sum_j \langle \cdot, w_j \rangle_H h_j\]

with \(f_i, h_j \in H^{K-\text{fin}},\) where \(\langle \cdot, \cdot \rangle_H\) is the scalar product of \(H\). The fact that \(\phi_\ell\) and \(\phi_r\) are \(K\)-intertwiners implies that \(\sum_i f_i \otimes v_i\) and \(\sum_j w_j \otimes h_j\) are \(K\)-fixed in \(H \otimes V_k\) and \(V_r \otimes H\), respectively.
The $\sigma$-spherical function $f_{H,\phi}^{\lambda,\phi_r} \in C_{0}^{\infty}(G)$ is then given by
\begin{equation}
  f_{H,\phi}^{\lambda,\phi_r}(g) = \sum_{i,j} \langle \pi(g)h_{ij}, f_{ij} \rangle_{H}(\cdot, w_{ij})v_{i}v_{j}.
\end{equation}

Clearly, for an admissible representation $(\pi, H)$, the subspace of $\sigma$-spherical functions spanned by $f_{H,\phi}^{\lambda,\phi_r}$ ($\phi_{\ell} \in \text{Hom}_{K}(H, V_{\ell})$, $\phi_{r} \in \text{Hom}_{K}(V_{r}, H)$), is finite dimensional.

4.2. Principal series representations and $K$-intertwiners. Recall that $M := Z_K(h_0) \subseteq K$ is a finite group, since $g_0$ is split. Furthermore, if $G$ has a complexification then $G$ is abelian (see [32, Thm. 7.53]). We fix a finite dimensional irreducible representation $\xi : M \rightarrow GL(L_{\xi})$.

Write $\langle \cdot, \cdot \rangle_{\xi}$ for the scalar product on $L_{\xi}$ turning it into a unitary representation. Fix a linear functional $\lambda \in \mathfrak{h}^*$ and extend it to a representation $\eta^{\xi}_{\lambda} : P \rightarrow GL(L_{\xi})$ of the minimal parabolic subgroup $P = MAN$ of $G$ by
\[
  \eta^{\xi}_{\lambda}(m) := a^{\lambda}(m) \quad (m \in M, a \in A, n \in N).
\]

Consider the pre-Hilbert space $U^{\xi}_{\lambda}$ consisting of continuous, compactly supported functions $f : G \rightarrow L_{\xi}$ satisfying
\[
  f(gp) = \eta_{\lambda+\rho}(p^{-1})f(g) \quad (g \in G, p \in P)
\]
with scalar product
\[
  \langle f_1, f_2 \rangle^{\xi}_{\lambda} := \int_{K} \langle f_1(x), f_2(x) \rangle_{\xi} dx \quad (f_1, f_2 \in U^{\xi}_{\lambda}).
\]

Consider the action of $G$ on $U^{\xi}_{\lambda}$ by $(\pi^{\xi}_{\lambda}(g)f)(g') := f(g^{-1}g')$ for $g, g' \in G$ and $f \in U^{\xi}_{\lambda}$. Its extension to an admissible representation $\pi^{\xi}_{\lambda} : G \rightarrow GL(H^{\xi}_{\lambda})$, with $H^{\xi}_{\lambda}$ the Hilbert space completion of $U^{\xi}_{\lambda}$, is called the principal series representation of $G$. The representation $\pi^{\xi}_{\lambda}$ is unitary if $\eta^{\xi}_{\lambda}$ is unitary, i.e., if $\lambda(h_0) \subset i\mathbb{R}$.

Analogously, let $\eta_{\lambda} : AN \rightarrow \mathbb{C}^*$ be the one-dimensional representation defined by $\eta_{\lambda}(an) := a^{\lambda}$ for $a \in A$ and $n \in N$, and consider the pre-Hilbert space $U_{\lambda}$ consisting of continuous, compactly supported functions $f : G \rightarrow \mathbb{C}$ satisfying
\[
  f(gb) = \eta_{\lambda+\rho}(b^{-1})f(g) \quad (g \in G, b \in AN)
\]
with scalar product
\[
  \langle f_1, f_2 \rangle_{\lambda} := \int_{K} f_1(x)\overline{f_2(x)} dx \quad (f_1, f_2 \in U_{\lambda}).
\]

Turning $U_{\lambda}$ into a $G$-representation by $(\pi_{\lambda}(g)f)(g') := f(g^{-1}g')$ for $g, g' \in G$ and completing, gives an admissible representation $\pi_{\lambda} : G \rightarrow GL(H_{\lambda})$. Note that $\pi_{\lambda}|_{K} : K \rightarrow GL(H_{\lambda})$ is isomorphic to the left regular representation of $K$ on $L^{2}(K)$. In particular, $\dim(H_{\lambda}(\tau)) = \deg(\tau)^{2}$ for all $\tau \in K^{\wedge}$, where $\deg(\tau)$ is the degree of $\tau$. Furthermore, $H_{\Lambda} \simeq \bigoplus_{\xi \in M^*} (H^{\xi}_{\lambda})^{|\text{deg}(\xi)|}$. Define for $\phi_{\ell} \in \text{Hom}_{K}(H_{\lambda}, V_{\ell})$ the adjoint map $\phi_{\ell}^{\ast} : V_{\ell} \rightarrow H_{\lambda}$ by
\[
  (\phi_{\ell}(f), v)_{V_{\ell}} = \langle f, \phi_{\ell}^{\ast}(v) \rangle_{\lambda} \quad \forall f \in H_{\lambda}, \forall v \in V_{\ell}.
\]
Since $H_{\Lambda}$ is unitary as $K$-representation for all $\lambda \in \mathfrak{h}^*$, the assignment $\phi_{\ell} \mapsto \phi_{\ell}^{\ast}$ defines a conjugate linear isomorphism from $\text{Hom}_{K}(H_{\lambda}, V_{\ell})$ onto $\text{Hom}_{K}(V_{\ell}, H_{\lambda})$.

The $\sigma$-spherical functions $f_{H,\phi}^{\lambda,\phi_r}$ obtained from the $G$-representation $H_{\lambda}$ using the $K$-intertwiners $\phi_{\ell} \in \text{Hom}_{K}(H_{\lambda}, V_{\ell})$ and $\phi_{r} \in \text{Hom}_{K}(V_{r}, H_{\lambda})$ now admit the following explicit description in terms of the Eisenstein integral.

**Proposition 4.1.** Fix $\lambda \in \mathfrak{h}^*$. 

a. The map \( j_{\lambda,V_i} : \text{Hom}_K(V_r, \mathcal{H}_\lambda) \to V_r^* \),
\[ j_{\lambda,V_i} (\phi)(v) := \phi(v)(1) \quad (v \in V_r), \]
is a linear isomorphism.

b. For \( \phi \in \text{Hom}_K(\mathcal{H}_\lambda, V_\ell) \) let \( \iota_{\lambda,V_i}(\phi) \in V_i \) be the unique vector such that
\[ (v, \iota_{\lambda,V_i}(\phi))_{V_i} = \phi(v)(1) \quad \forall v \in V_\ell. \]
The resulting map \( \iota_{\lambda,V_i} : \text{Hom}_K(\mathcal{H}_\lambda, V_\ell) \to V_\ell \) is a linear isomorphism.

c. The assignment \( \phi \otimes \phi \mapsto T_{\lambda}^{\phi_1,\phi_2} := \iota_{\lambda,V_i}(\phi) \otimes j_{\lambda,V_i}(\phi) \) defines a linear isomorphism
\[ \text{Hom}_K(\mathcal{H}_\lambda, V_\ell) \otimes \text{Hom}_K(V_r, \mathcal{H}_\lambda) \iso V_\ell \otimes V_r^* \iso \text{Hom}(V_r, V_\ell). \]

Furthermore,
\[ f_{\mathcal{H}_\lambda}^{\phi_1,\phi_2}(g) = E_\lambda^\phi(g) T_{\lambda}^{\phi_1,\phi_2} \quad (g \in G) \]
for \( \phi \in \text{Hom}_K(\mathcal{H}_\lambda, V_\ell) \) and \( \phi \otimes \phi \in \text{Hom}_K(V_r, \mathcal{H}_\lambda) \), with \( E_\lambda^\phi(g) \) the Eisenstein integral.

Proof. Our choice of parametrisation of the \( \sigma \)-spherical functions associated to \( \pi_\lambda \), which deviates from the standard choice (see, e.g., [11, §8.2]), plays an important role in Section 6 when discussing the applications to asymptotic boundary KZB equations. We provide here a proof directly in terms of our present conventions.

We will assume without loss of generality that \( \sigma, \sigma_\ell \in K^\times. \)

a. Since \( \dim(\text{Hom}_K(V_r, \mathcal{H}_\lambda)) = \deg(\sigma_\ell) \) it suffices to show that \( j_{\lambda,V_i} \) is injective. Fix an orthonormal basis \( \{v_i\} \) of \( V_r \). Let \( \phi \in \text{Hom}_K(V_r, \mathcal{H}_\lambda) \) and consider its expansion \( \phi = \sum_j \langle \cdot, v_j \rangle_{V_r} h_j \) with \( h_j \in \mathcal{H}_\lambda^{K-\text{fin}} \).

(4.5)
\[ j_{\lambda,V_i}(\phi) = \sum_j h_j(1)(\cdot, v_j)_{V_r}. \]

Furthermore, for each index \( j \) we have
\[ h_j(x) = \sum_i h_i(1)(v_j, \sigma_\ell(x)v_i)_{V_r} \quad \forall x \in K \]
since \( \phi \) is a \( K \)-intertwiner.

Suppose now that \( j_{\lambda,V_i}(\phi) = 0 \). Then \( h_j(1) = 0 \) for all \( j \) by (4.5). By (4.6) we conclude that \( h_j(kan) = a^{-\lambda-\rho} h_j(k) = 0 \) for \( k \in K, a \in A \) and \( n \in N \), so \( \phi = 0 \).

b. This immediately follows from part a and the fact that
\[ (v, \iota_{\lambda,V_i}(\phi))(v_i) = j_{\lambda,V_i}(\phi)(v) \]
for \( v \in V_r \) and \( \phi \in \text{Hom}_K(\mathcal{H}_\lambda, V_\ell) \).

c. The first statement immediately follows from a and b. Let \( \{v_i\} \) be an orthonormal basis of \( V_r \) and \( \{w_j\} \) an orthonormal basis of \( V_\ell \). For \( \phi = \sum_i \langle \cdot, f_i \rangle \lambda v_i \in \text{Hom}_K(\mathcal{H}_\lambda, V_r) \) and \( \phi_\ell = \sum_j \langle \cdot, w_j \rangle \forall h_j \in \mathcal{H}_\lambda^{K-\text{fin}} \) a direct computation gives
\[ f_{\mathcal{H}_\lambda}^{\phi,\phi_\ell}(g) = E_\lambda^\phi(g) \tilde{T}_{\lambda}^{\phi,\phi_\ell} \]
with \( \tilde{T}_{\lambda}^{\phi,\phi_\ell} \in \text{Hom}(V_r, V_\ell) \) given by
\[ \tilde{T}_{\lambda}^{\phi,\phi_\ell}(w) = \sum_{i,j} h_j(1)(f_i(1)(w, w_j)_{V_r} v_i) \quad (w \in V_r). \]

By (4.6) this can be rewritten as
\[ \tilde{T}_{\lambda}^{\phi,\phi_\ell}(w) = j_{\lambda,V_i}(\phi)(w) \sum_i f_i(1)v_i \quad w \in V_r, \]
hence it suffices to show that
\[
(4.7) \quad \iota_{\lambda,V_\ell}(\phi_\ell) = \sum_i f_i(1) v_i.
\]
Define \(\tilde{\chi}_{\lambda,V_\ell} \in \mathcal{H}_K^{K-\text{fin}}\) by
\[
\tilde{\chi}_{\lambda,V_\ell}(\text{kan}) := \deg(\sigma_\ell) a^{-\lambda - \rho, \chi_{V_\ell}}(k) \quad (k \in K, a \in A, n \in N),
\]
with \(\chi_{V_\ell}\) the character of \(V_\ell\). Fix \(v \in V_\ell\). Since \(\phi_\ell^*(v) \in \mathcal{H}_\lambda(\sigma_\ell)\), its restriction \(\phi_\ell^*(v)|_K\) to \(K\) lies in the \(\sigma_\ell\)-isotypical component of \(L^2(K)\) with respect to the left-regular \(K\)-action. By the Schur orthogonality relations we then have
\[
\phi_\ell^*(v)(1) = \deg(\sigma_\ell) \int_K dx \phi_\ell^*(v)(x) \chi_{V_\ell}(x) = \langle \phi_\ell^*(v), \tilde{\chi}_{\lambda,V_\ell} \rangle = \langle v, \phi_\ell(\tilde{\chi}_{\lambda,V_\ell}) \rangle_{V_\ell}.
\]
This show that
\[
\iota_{\lambda,V_\ell}(\phi_\ell) = \phi_\ell(\tilde{\chi}_{\lambda,V_\ell}).
\]
Now substitute \(\phi_\ell = \sum_i \langle \cdot, f_i \rangle_{\lambda} v_i\) and use that \(f_i \in \mathcal{H}_\lambda(\sigma_\ell^r)\) with \(\sigma_\ell^r\) the irreducible \(K\)-representation dual to \(\sigma_\ell\), we get \((4.7)\) by another application of the Schur’s orthogonality relations,
\[
\iota_{\mu,V_\ell}(\phi_\ell) = \phi_\ell(\tilde{\chi}_{\lambda,V_\ell}) = \sum_i \deg(\sigma_\ell) \left( \int_K dx \chi_{V_\ell}(x) f_i(x) \right) v_i = \sum_i f_i(1) v_i.
\]
\[\square\]

Remark 4.2. a. For \(a \in A\) and \(m \in M\) one has
\[
\sigma(m,m) E_\lambda^a(a) = E_\lambda^a(a).
\]

In particular, \(E_\lambda^a(a)\) maps \(\text{Hom}(V_\ell, V_\ell)\) into \(\text{Hom}_M(V_\ell, V_\ell)\).

b. For \(\xi \in M^\wedge\) and intertwiners \(\phi_\ell \in \text{Hom}_K(\mathcal{H}_\lambda^{(\xi)}(V_\ell))\) and \(\phi_\ell \in \text{Hom}_K(V_\ell, \mathcal{H}_\lambda^{(\xi)}(V_\ell))\), write
\[
\phi_\ell = \sum_i \langle \cdot, f_i \rangle_{\lambda} v_i, \quad \phi_\ell = \sum_j \langle \cdot, w_j \rangle_{V_\ell} h_j
\]
with \(f_i, h_j \in \mathcal{H}_\lambda^{(\xi), K-\text{fin}}\). Then
\[
(4.8) \quad f_{\mathcal{H}_\lambda^{(\xi)}, \phi_\ell, \phi_\ell}(g) = E_\lambda^a(g) T_{\lambda}^{(\xi), \phi_\ell, \phi_\ell}(g \in G)
\]
with \(T_{\lambda}^{(\xi), \phi_\ell, \phi_\ell} \in \text{Hom}_M(V_\ell, V_\ell)\) the \(M\)-intertwiner
\[
T_{\lambda}^{(\xi), \phi_\ell, \phi_\ell}(w) := \sum_{i,j} \langle h_j(1), f_i(1) \rangle_{\lambda}^{(\xi)} (w, w_j)_{V_\ell} v_i \quad (w \in V_\ell).
\]

4.3. Algebraic principal series representations. We first introduce some general facts and notations regarding \(g\)-modules, following [10].

Let \(V\) be a \(g\)-module with representation map \(\tau : g \to g(V)\). The representation map of \(V\), viewed as \(U(g)\)-module, will also be denoted by \(\tau\). The dual of \(V\) is defined by
\[
(\tau^*(x)f)(v) = -f(\tau(X)v), \quad x \in g, \ f \in V^*, \ v \in V.
\]

Fix a reductive Lie subalgebra \(I \subseteq g\) (in this paper \(I\) will either be the fix-point Lie subalgebra \(\mathfrak{k}\) of the Chevalley involution \(\theta\), or the Cartan subalgebra \(\mathfrak{h}\)). Let \(I^\vee\) be the isomorphism classes of the finite dimensional irreducible \(I\)-modules. For \(\tau \in I^\vee\) we write \(\deg(\tau)\) for the degree of \(\tau\) and \(V(\tau)\) for the \(\tau\)-isotypical component of \(V\). A \(g\)-module \(V\) is called a Harish-Chandra module with respect to \(I\) if \(V = \sum_{\tau \in I^\vee} V(\tau)\) (it is automatically a direct sum). The isotypical component \(V(\tau)\) then decomposes in a direct sum of copies of \(\tau\). The number of copies, denoted by \(\text{mtp}(\tau, V)\), is called the multiplicity of \(\tau\) in \(V\). The Harish-Chandra module \(V\) is called admissible if \(\text{mtp}(\tau, V) < \infty\) for all \(\tau \in I^\vee\).
For a $g$-module $V$ let $V^{t-\text{fin}}$ be the subspace of $t$-finite vectors,

$$V^{t-\text{fin}} := \{ v \in V \mid \dim(U(l)v) < \infty \}.$$ 

Then $V^{t-\text{fin}} \subset V$ is a $g$-submodule. In fact, $V^{t-\text{fin}}$ is a Harish-Chandra module with respect to $I$ satisfying $V^{t-\text{fin}}(\tau) = V(\tau)$ for all $\tau \in \mathfrak{t}^\vee$ (see [10, 1.7.9]).

For $I$-modules $U, V$ with $U$ or $V$ finite dimensional we identify

$$U \otimes V^* \simeq \text{Hom}(V, U)$$

as vector spaces by $u \otimes f \mapsto f(-)u$. With the $U(l) \otimes U(l')$-module structure on $\text{Hom}(V, U)$ defined by

$$(x \otimes z)f)(u) := xf(S(z)u)$$

for $x, z \in U(l), u \in U$ and $f \in \text{Hom}(V, U)$, it is an isomorphism of $U(l) \otimes U(l')$-modules.

Differentiating the multiplicative character $\eta_\lambda : AN \to \mathbb{C}^*$ of the previous subsection gives a one-dimensional $b$-module, whose representation map we also denote by $\eta_\lambda$. Then $\eta_\lambda : b \to \mathbb{C}$ is concretely given by

$$\eta_\lambda(h + u) := \lambda(h), \quad h \in \mathfrak{h}, \ u \in \mathfrak{n}.$$ 

We write $\mathbb{C}_\lambda$ for the associated one-dimensional $U(b)$-module.

**Definition 4.3.** Let $\lambda \in \mathfrak{h}^*$. Write

$$Y_\lambda := \text{Hom}_{U(b)}(U(g), \mathbb{C}_{\lambda + \rho})$$

for the space of linear functionals $f : U(g) \to \mathbb{C}$ satisfying $f(xz) = \eta_{\lambda + \rho}(x)f(z)$ for $x \in U(b)$ and $z \in U(g)$. We view $Y_\lambda$ as $g$-module by

$$(yf)(z) := f(zy), \quad y \in g, \ z \in U(g).$$

By [10, Chpt. 9], the Harish-Chandra module $Y_\lambda^{t-\text{fin}}$ is admissible with $\text{mtp}(\tau, Y_\lambda^{t-\text{fin}}) = \deg(\tau)$ for all $\tau \in \mathfrak{t}^\vee$. Consider $K^\vee$ as subset of $\mathfrak{t}^\vee$. Note that the inclusion $K^\vee \hookrightarrow \mathfrak{t}^\vee$ is strict unless $K$ is simply connected and semisimple.

**Proposition 4.4.** For $\lambda \in \mathfrak{h}^*$ we have an injective morphism of $g$-modules

$$Y_\lambda^{t-\text{fin}} \hookrightarrow H_\lambda^{K-\text{fin}}, \quad f \mapsto \tilde{f}$$

with

$$\tilde{f}(z) := (r_*(S(z))f)(1)$$

for $f \in H_\lambda^{K-\text{fin}}$ and $z \in U(g)$. For $\tau \in K^\vee$ the embedding restricts to an isomorphism

$$H_\lambda(\tau) \xrightarrow{\sim} Y_\lambda(\tau)$$

of $\mathfrak{t}$-modules.

**Proof.** Let $f \in H_\lambda^{K-\text{fin}}$. Then $f : G \to \mathbb{C}$ is analytic and satisfies $r_*(S(x))f = \eta_{\lambda + \rho}(x)f$ for all $x \in U(b)$. Hence (4.10) is a well defined injective linear map. A direct computation shows that (4.10) intertwines the $\mathfrak{g}_0$-action. This proves the first part of the proposition.

For $\tau \in K^\vee$ we have $\dim(H_\lambda(\tau)) = \deg(\tau)^2 = \dim(Y_\lambda(\tau))$, hence (4.11) follows from the first part of the proposition. \qed

**Remark 4.5.** The embedding (4.10) is an isomorphism if $K$ is simply connected and semisimple. In general, the algebraic description of the $(\mathfrak{g}_0, K)$-modules $H_\lambda^{K-\text{fin}}$ and $H_\lambda^{(G), K-\text{fin}}$ within $Y_\lambda^{t-\text{fin}}$ amounts to taking the direct sum of isotypical components $Y_\lambda(\tau)$ for $\tau$ running over suitable subsets of $K^\vee$ (see [10, §9.3]).
Let $\phi \in \text{Hom}_K(\mathcal{H}_\lambda, V)$, $\phi \in \text{Hom}_K(V_r, \mathcal{H}_\lambda)$. The associated $\sigma$-spherical function $f_{\mathcal{H}_\lambda}^{\phi_\lambda, \phi_e} \in C^\infty(G)$ is an elementary $\sigma$-spherical function, meaning that it is a common eigenfunction of the biinvariant differential operators on $G$. Indeed, by Proposition 4.3 it suffices to note that $Y_\lambda$ admits a central character. This follows from [10, Thm. 9.3.3],

\[(4.12)\quad zf = \zeta_{-\rho}(z)f \quad (z \in Z(g), \ f \in Y_\lambda).
\]

This also follows from the observation that $Y_\lambda$ is isomorphic to $M_{-\lambda-\rho}$ (see Lemma [52]) and the fact that $\zeta_{-\rho} = \zeta_{w_0-\rho}$ for $w \in W$.

As a consequence, the restriction $f_{\mathcal{H}_\lambda}^{\phi_\lambda, \phi_e}|_{A_\text{reg}}$ of $f_{\mathcal{H}_\lambda}^{\phi_\lambda, \phi_e} \in C^\infty(G)$ to $A_\text{reg}$ are common eigenfunctions of $\hat{\Pi}(z) (z \in Z(g))$,

\[(4.13)\quad \hat{\Pi}(z)(f_{\mathcal{H}_\lambda}^{\phi_\lambda, \phi_e}|_{A_\text{reg}}) = \zeta_{-\rho}(z)f_{\mathcal{H}_\lambda}^{\phi_\lambda, \phi_e}|_{A_\text{reg}} \quad \forall z \in Z(g)
\]

(it is sometimes more natural to write the eigenvalue as $\zeta_{w_0(\lambda+\rho)}(z)$ with $w_0 \in W$ the longest Weyl group element). By Proposition 4.1 it follows that the restriction $E_\lambda^\sigma|_{A_\text{reg}}$ of the Eisenstein integral to $A_\text{reg}$ is an $\text{End}(\text{Hom}(V_r, V))$-valued smooth function on $A_\text{reg}$ satisfying the differential equations

\[(4.14)\quad \hat{\Pi}(z)(E_\lambda^\sigma|_{A_\text{reg}}) = \zeta_{-\rho}(z)E_\lambda^\sigma|_{A_\text{reg}} \quad \forall z \in Z(g).
\]

**Corollary 4.6.** The normalised smooth End($\text{Hom}(V_r, V)$)-valued function on $A_+$ defined by

\[E_\lambda^\sigma(a') := \delta(a')E_\lambda^\sigma(a') = \delta(a') \int_K dx \zeta_{-\lambda-\rho}(a(a'^{-1}x))\sigma(x, k(a'^{-1}x))
\]

for $a' \in A_+$ is a common $\text{End}(\text{Hom}(V_r, V))$-valued eigenfunction for the quantum Hamiltonians of the $\sigma$-spin quantum hyperbolic Calogero-Moser system,

\[H^\sigma(E_\lambda^\sigma) = -\frac{(\lambda, \lambda)}{2} E_\lambda^\sigma
\]

and

\[H_a^\sigma(E_\lambda^\sigma) = \zeta_{-\rho}(z)E_\lambda^\sigma \quad (z \in Z(g)).
\]

**Remark 4.7.** For sufficiently generic $\lambda \in \mathfrak{h}^*$, the $\sigma$-Harish-Chandra series $\Phi^\sigma_{w\lambda-\rho}$ ($w \in W$) exist and satisfy the same differential equations (4.14) on $A_+$ as $E_\lambda^\sigma|_{A_+}$. Harish-Chandra’s [27] proved for generic $\lambda \in \mathfrak{h}^*$,

\[(4.15)\quad E_\lambda^\sigma(a)T = \sum_{w \in W} e^\sigma(w; \lambda)\Phi^\sigma_{w\lambda-\rho}(a)T
\]

for $a \in A_+$ and $T \in \text{Hom}_M(V_r, V)$, with leading coefficients $e^\sigma(w; \lambda) \in \text{End}(\text{Hom}_M(V_r, V))$ called $c$-functions (see [27, Thm. 5]). The $c$-function expansion (4.15) plays an important role in the harmonic analysis on $G$.

For the left hand side of (4.15), Remark 4.2 provides a representation theoretic interpretation in terms of the principal series representation of $G$. In the next section we obtain a similar representation theoretic interpretation for the $\sigma$-Harish-Chandra series $\Phi^\sigma_{w\lambda-\rho}$ in terms of Verma modules.

5. **Formal elementary $\sigma$-spherical functions**

We fix in this section two finite dimensional representations $\sigma_\ell : \mathfrak{t} \to \mathfrak{gl}(V)$ and $\sigma_\tau : \mathfrak{t} \to \mathfrak{gl}(V_r)$. We write $\sigma$ for the $\mathfrak{t} \oplus \mathfrak{t}$-representation map $\sigma_\ell \otimes \sigma_\tau^*$ of the $\mathfrak{t} \oplus \mathfrak{t}$-module $V_\ell \otimes V_r^*$. 
5.1. Verma modules. In this subsection we relate the algebraic principal series representations to Verma modules. Let \( V \) be a \( g \)-module \( V \). Write

\[
V[\mu] := \{ v \in V \mid hv = \mu(h)v \quad \forall h \in h \}
\]

for the weight space of \( V \) of weight \( \mu \in h^* \). Then

\[
\overline{V} := \bigoplus_{\mu \in h^*} V[\mu]
\]

inherits from \( V \) the structure of a \( g \)-module as follows. Let \( v = (v[\mu])_{\mu \in h^*} \in \overline{V} \) and \( z_\alpha \in g_\alpha \) \((\alpha \in R \cup \{0\})\), where \( g_0 = h \). Then \( z_\alpha v = ((z_\alpha v)[\mu])_{\mu \in h^*} \) with

\[
(z_\alpha v)[\mu] := z_\alpha v[\mu - \alpha].
\]

Clearly \( V \subseteq \overline{V} \) as \( h \)-submodule. Note that \( \overline{V}^{h^{\text{fin}}} = V \) for \( h \)-semisimple \( g \)-modules \( V \).

For \( \mu \in h^* \) write

\[
(5.1) \quad \text{proj}_{\mu}^V : \overline{V} \to V[\mu], \quad v \mapsto v[\mu]
\]

for the canonical projection, and \( \text{incl}_{\mu}^V : V[\mu] \hookrightarrow \overline{V} \) for the inclusion map. We omit the sublabel \( V \) from the notations \( \text{proj}_{\mu}^V \) and \( \text{incl}_{\mu}^V \) if the representation \( V \) is clear from the context.

**Definition 5.1.** The Verma module \( M_\lambda \) with highest weight \( \lambda \in h^* \) is the induced \( g \)-module

\[
M_\lambda := U(g) \otimes_{U(h)} \mathbb{C}_\lambda.
\]

The Verma module \( M_\lambda \) and its irreducible quotient \( L_\lambda \) are highest weight modules of highest weight \( \lambda \). In particular, they are \( h \)-diagonalizable with finite dimensional weight spaces. The weight decompositions are \( M_\lambda = \bigoplus_{\mu \leq \lambda} M_\lambda[\mu] \) and \( L_\lambda = \bigoplus_{\mu \leq \lambda} L_\lambda[\mu] \) with \( \leq \) the dominance order on \( h^* \) with respect to \( R^+ \) and with one-dimensional highest weight spaces \( M_\lambda[\lambda] \) and \( L_\lambda[\lambda] \). We fix once and for all a highest weight vector \( 0 \neq m_\lambda \in M_\lambda[\lambda] \), and write \( 0 \neq \ell_\lambda \in L_\lambda[\lambda] \) for its projection onto \( L_\lambda \). Note that \( M_\lambda \) and \( L_\lambda \) admit the central character \( \zeta_\lambda \).

The set \( h_{\text{irr}}^\bullet \) of highest weights \( \lambda \) for which \( M_\lambda \) is irreducible is given by

\[
h_{\text{irr}}^\bullet = \{ \lambda \in h^* \mid (\lambda + \rho, \alpha^\vee) \not\in \mathbb{Z}_{>0} \quad \forall \alpha \in R^+ \},
\]

with \( \alpha^\vee := 2\alpha/||\alpha||^2 \) the co-root of \( \alpha \). Note that \( h_{\text{irr}}^{\text{HC}} \subseteq h_{\text{irr}}^\bullet \).

For a \( g \)-module \( V \) write \( \theta V \) for \( V \) endowed with the \( \theta \)-twisted \( g \)-module structure

\[
x \star v := \theta(x)v, \quad x \in g, \ v \in V.
\]

**Lemma 5.2.** Let \( \lambda \in h^* \).

a. We have

\[
M_\lambda \xrightarrow{\sim} Y_{-\lambda - \rho}
\]

as \( g \)-modules, with the isomorphism \( f \mapsto \hat{f} \) given by \( \hat{f}(x) := f(S(x)m_\lambda) \) for \( f \in M_\lambda^{\text{fin}} \) and \( x \in U(g) \).

b. If \( \lambda \in h_{\text{irr}}^\bullet \), then

\[
M_\lambda \cong \theta Y_{-\lambda - \rho}
\]

as \( g \)-modules. In particular, \( M_\lambda \cong \theta Y^{h^{\text{fin}}}_{-\lambda - \rho} \) as \( g \)-modules.

**Proof.**

a. This is immediate (it is a special case of [10, Prop. 5.5.4]).

b. The Shapovalov form is the nondegenerate symmetric bilinear form on \( L_\lambda \) satisfying

\[
B_\lambda(xu, v) = -B_\lambda(u, \theta(x)v)
\]

for \( x \in g \) and \( u, v \in L_\lambda \) and normalised by \( B_\lambda(\ell_\lambda, \ell_\lambda) = 1 \). It induces an isomorphism of \( g \)-modules

\[
(5.2) \quad \theta T_\lambda \xrightarrow{\sim} L_\lambda^{\text{fin}}
\]
mapping \((e[i])_{i \in B} \in \mathcal{L}_\lambda\) to the linear functional \(u \mapsto \sum_{i \in B} B_\lambda(e[i], u)\) on \(L_\lambda\). If \(\lambda \in \mathfrak{h}_\text{tr}^*\) then \((M_\lambda = L_\lambda)\) and the result follows part a of the lemma. □

**Remark 5.3.** a. The dual \(M^\vee\) of a module \(M\) in category \(\mathcal{O}\) is defined by \(M^\vee := {}^0 M^* \circ \mathfrak{h} - \mathfrak{fn}\). The final conclusion of part b of the lemma corresponds to the well known fact that \(L^\vee_\lambda \cong L_\lambda\).

b. Combining Proposition \ref{prop} and Lemma \ref{lem}a, we have \(\lambda \in \mathfrak{h}_\text{tr}^*\) an embedding of \(g\)-modules

\[
\mathcal{H}_\lambda^{K-\mathfrak{fn}} \hookrightarrow M_{\lambda-\rho}^*, \quad f \mapsto \tilde{f},
\]

with \(\tilde{f}(xm_{\lambda-\rho}) := (r_\alpha(x)f)(1)\) for all \(x \in U(\mathfrak{g})\). It restricts to an isomorphism \(\mathcal{H}_\lambda(\tau) \cong M_{\lambda-\rho}(\tau)\) for each \(\tau \in K^\wedge\).

**5.2. Spaces of \(\mathfrak{t}\)-intertwiners.** In Subsection 4.2 we have constructed linear isomorphisms \(\iota_{\lambda, V_\ell} : \text{Hom}_K(\mathcal{H}_\lambda, V_\ell) \cong V_\ell\) and \(\iota_{\lambda, V_\ell} : \text{Hom}_K(V_\ell, \mathcal{H}_\lambda) \cong V_\ell^*,\) with \(\mathcal{H}_\lambda\) the principal series representation. For Verma modules we have the following analogous result. Write \(m_\lambda^*\) for the \(\mathfrak{t}\)-linear functional on \(\overline{M}_\lambda\) that vanishes on \(\prod_{\mu < \lambda} M_\lambda[\mu]\) and maps \(m_\lambda\) to 1.

**Proposition 5.4.** Fix \(\lambda \in \mathfrak{h}_\text{tr}^*\).

a. The map \(\text{ev}_{\lambda, V_\ell} : \text{Hom}_\mathfrak{t}(M_\lambda, V_\ell) \rightarrow V_\ell\)

\[
\text{ev}_{\lambda, V_\ell}(\phi_\ell) := \phi_\ell(m_\lambda),
\]

is a linear isomorphism.

b. The linear map \(\text{hw}_{\lambda, V_\ell} : \text{Hom}_\mathfrak{t}(V_\ell, \overline{M}_\lambda) \rightarrow V_\ell^*,\) defined by

\[
\text{hw}_{\lambda, V_\ell}(\phi_\ell)(v) := m_\lambda^*(\phi_\ell(v)) \quad (v \in V_\ell),
\]

is a linear isomorphism when \(\lambda \in \mathfrak{h}_\text{tr}^*\).

**Proof.** We assume without loss of generality that \(\sigma_\ell, \sigma_\ell \in \mathfrak{t}^\wedge\).

a. By Lemma \ref{lem}a we have

\[
\text{Hom}_\mathfrak{t}(M_\lambda, V_\ell) \cong \text{Hom}_\mathfrak{t}(V_\ell^*, Y_{\lambda-\rho})
\]
as vector spaces. The latter space is of dimension \(\text{deg}(\sigma_\ell)\). Hence it suffices to show that \(\text{ev}_{\lambda, V_\ell}\) is injective. This follows from \(M_\lambda = U(\mathfrak{t})m_\lambda,\) which is an immediate consequence of the Iwasawa decomposition \(\mathfrak{g}_0 = \mathfrak{t}_0 \oplus \mathfrak{h}_0 \oplus \mathfrak{n}_0\) of \(\mathfrak{g}_0\).

b. Since \(\lambda \in \mathfrak{h}_\text{tr}^*\) we have \(\text{Hom}_\mathfrak{t}(V_\ell, \overline{M}_\lambda) \cong \text{Hom}(V_\ell, Y_{\lambda-\rho})\) as vector spaces by Lemma \ref{lem}a and the latter space is of dimension \(\text{deg}(\sigma_\ell)\). It thus suffices to show that \(\text{hw}_{\lambda, V_\ell}\) is injective. Let \(\phi_\ell \in \text{Hom}_\mathfrak{t}(V_\ell, \overline{M}_\lambda)\) be a nonzero intertwiner and consider the nonempty set

\[
\mathcal{P} := \{\mu \in \mathfrak{h}_\text{tr}^* \mid \text{proj}_{M_\mu}(\phi_\ell(v)) \neq 0 \text{ for some } v \in V_\ell\}.
\]

Take a maximal element \(\nu \in \mathcal{P}\) with respect to the dominance order \(\leq\) on \(\mathfrak{h}_\text{tr}^*\). Fix \(v \in V_\ell\) with \(\text{proj}_{M_\nu}(\phi_\ell(v)) \neq 0\). Suppose that \(e_\alpha(\phi_\ell(v)[\nu]) \neq 0\) in \(M_\lambda\) for some \(\alpha \in \mathfrak{R}^+.\) Then \(\text{proj}_{M_\nu}(\phi_\ell(v)) \neq 0\), but this contradicts the fact that \(\nu + \alpha \notin \mathcal{P}\). It follows that \(\text{proj}_{M_\nu}(\phi_\ell(v))\) is a highest weight vector in \(M_\lambda\) of highest weight \(\nu\). This forces \(\nu = \lambda\) since \(M_\lambda\) is irreducible, hence \(\text{hw}_{\lambda, V_\ell}(\phi_\ell)(v) \neq 0\). It follows that \(\text{hw}_{\lambda, V_\ell}\) is injective, which completes the proof. □

**Definition 5.5.** Let \(\lambda \in \mathfrak{h}_\text{tr}^*\).

a. We call \(\text{ev}_{\lambda, V_\ell}(\phi_\ell)\) the expectation value of the intertwiner \(\phi_\ell \in \text{Hom}_\mathfrak{t}(M_\lambda, V_\ell)\). We write \(\phi_{\ell, \lambda}^\ell \in \text{Hom}_\mathfrak{t}(M_\lambda, V_\ell)\) for the \(\mathfrak{t}\)-intertwiner with expectation value \(v \in V_\ell\).

b. We call \(\text{hw}_{\lambda, V_\ell}(\phi_\ell)\) the highest weight component of the intertwiner \(\phi_\ell \in \text{Hom}_\mathfrak{t}(V_\ell, \overline{M}_\lambda)\). If \(\lambda \in \mathfrak{h}_\text{tr}^*\) then we write \(\phi_{\ell, \lambda}^\ell \in \text{Hom}_\mathfrak{t}(V_\ell, \overline{M}_\lambda)\) for the intertwiner with highest weight component \(f \in V_\ell^*\).
The exact relation with the intertwiners from Proposition 4.1 is as follows. Consider for \( \sigma \) : \( K \rightarrow GL(V_t) \) a finite dimensional \( K \)-representation the chain of linear isomorphisms

\[
\text{Hom}_K(V_t^*, \mathcal{H}_{-\lambda - \rho}) \cong \text{Hom}_R(M_\lambda, V_t) \cong \text{Hom}_R(M_\lambda, V_t) \cong V_t.
\]

The first isomorphism is the pushforward of the map defined in Remark 5.3 the second map is transposition and the third map is \( \theta_{\lambda, V_t} \). Their composition is the linear isomorphism \( j_{-\lambda - \rho, V_t} : \text{Hom}_K(V_t^*, \mathcal{H}_{-\lambda - \rho}) \cong V_t \) defined in Proposition 4.1. Similarly, for \( \lambda \in \mathfrak{h}^*_\text{irr} \) and \( \sigma_r : K \rightarrow GL(V_r) \) a finite dimensional \( K \)-representation we have the chain of linear isomorphisms

\[
\text{Hom}_K(V_r, \mathcal{H}_{-\lambda - \rho}) \cong \text{Hom}_R(M_\lambda, V_r) \cong \text{Hom}_R(M_\lambda, V_r) \cong V_r.
\]

In this case the first isomorphism is the pushforward of the map defined in Remark 5.3 the second isomorphism is the pushforward of the \( g \)-intertwiner \( M_\lambda \cong \mathcal{M}_\lambda \) realized by the Shapovalov form (see Lemma 5.2b and its proof), and the third map is \( hw_{\lambda, V_r} \). Their composition is the linear isomorphism \( j_{-\lambda - \rho, V_r} : \text{Hom}_K(V_r, \mathcal{H}_{-\lambda - \rho}) \cong V_r^* \) defined in Proposition 4.1.

The following corollary is the analogue of Proposition 4.1c for Verma modules.

**Corollary 5.6.** Let \( V_t \) and \( V_r \) be finite dimensional \( \mathfrak{t} \)-modules. The linear map

\[
\text{Hom}_R(M_\lambda, V_t) \otimes \text{Hom}_R(V_r, \mathcal{M}_\lambda) \rightarrow V_t \otimes V_r^* \cong \text{Hom}(V_r, V_t)
\]

defined by \( \phi_t \otimes \phi_r \mapsto S_{t\ell,\phi_r} : ev_{\lambda, V_t}(\phi_t) \otimes hw_{\lambda, V_t}(\phi_r), \) is a linear isomorphism when \( \lambda \in \mathfrak{h}^*_\text{irr} \).

In Subsection 5.3 we will give a representation interpretation of the analytic \( \text{Hom}(V_r, V_t) \)-valued function \( a \mapsto \Phi^\lambda_t(a)S_{t\ell,\phi_r} \) for \( \phi_t \in \text{Hom}_R(M_\lambda, V_t) \), \( \phi_r \in \text{Hom}_R(V_r, \mathcal{M}_\lambda) \) and \( a \in A_+ \), with \( \sigma \) the representation map of the \( \mathfrak{t} \oplus \mathfrak{t} \)-module \( V_t \otimes V_r^* \cong \text{Hom}(V_r, V_t) \).

### 5.3. The construction of the formal elementary spherical functions

We first introduce \((\mathfrak{h}, \mathfrak{t})\)-finite and \((\mathfrak{t}, \mathfrak{h})\)-finite matrix coefficients of Verma modules. Let \( \lambda, \mu \in \mathfrak{h}^* \) with \( \mu \leq \lambda \).

Recall the projection and inclusion maps \( \text{incl}^\mu_\lambda \) and \( \text{proj}^\mu_\lambda \). They are \( \mathfrak{h} \)-intertwiners

\[
\text{incl}^\mu_\lambda \in \text{Hom}_\mathfrak{h}(M_\lambda[\mu], M_\lambda), \quad \text{proj}^\mu_\lambda \in \text{Hom}_\mathfrak{h}(\mathcal{M}_\lambda, M_\lambda[\mu]).
\]

Let \( \lambda, \mu \in \mathfrak{h}^* \) with \( \mu \leq \lambda \), and fix \( \mathfrak{t} \)-intertwiners \( \phi_t \in \text{Hom}_\mathfrak{t}(M_\lambda, V_t) \) and \( \phi_r \in \text{Hom}_\mathfrak{t}(V_r, \mathcal{M}_\lambda) \).

We write

\[
\phi^\mu_\lambda := \phi_t \circ \text{incl}^\mu_\lambda \in \text{Hom}(M_\lambda[\mu], V_t), \quad \phi^\mu_t := \text{proj}^\mu_\lambda \circ \phi_r \in \text{Hom}(V_r, M_\lambda[\mu])
\]

for the weight-\( \mu \) components of \( \phi_t \) and \( \phi_r \), respectively. The map \( \phi^\mu_t \) encodes \((\mathfrak{t}, \mathfrak{h})\)-finite matrix coefficients of \( M_\lambda \) of type \((\sigma_\mu, \lambda)\), and \( \phi^\mu_r \) the \((\mathfrak{h}, \mathfrak{t})\)-finite matrix coefficients of \( M_\lambda \) of type \((\mu, \sigma_r)\).

Formal elementary spherical functions are now defined to be the generating series of the compositions \( \phi^\mu_t \circ \phi^\mu_r \) of the weight compositions of the \( \mathfrak{t} \)-intertwiners \( \phi_t \) and \( \phi_r \):

**Definition 5.7.** Let \( \lambda \in \mathfrak{h}^* \). For \( \phi_t \in \text{Hom}_\mathfrak{t}(M_\lambda, V_t) \) and \( \phi_r \in \text{Hom}_\mathfrak{t}(V_r, \mathcal{M}_\lambda) \) let

\[
F_{M_\lambda}^{\phi_t, \phi_r} \in (V_t \otimes V_r^*)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]_{\lambda}
\]

be the formal \( V_t \otimes \mathfrak{U} \otimes V_r^* \)-valued power series

\[
F_{M_\lambda}^{\phi_t, \phi_r} := \sum_{\mu \leq \lambda} (\phi^\mu_t \circ \phi^\mu_r) \xi^\mu = \sum_{\mu \leq \lambda} (\phi^\mu_t \circ \phi^\mu_r) \xi^\mu.
\]

We call \( F_{M_\lambda}^{\phi_t, \phi_r} \) the formal elementary \( \sigma \)-spherical function associated to \( M_\lambda \), \( \phi_t \) and \( \phi_r \).

Note that under the natural identification \( \text{Hom}(V_r, V_t) \cong V_t \otimes V_r^* \) we have

\[
\phi^\mu_t \circ \phi^\mu_r = ev_{\lambda, V_t}(\phi_t) \otimes hw_{\lambda, V_t}(\phi_r) = S_{t\ell,\phi_r}.
\]
hence \( F^{\phi_t, \phi_r}_{M_\lambda} \) has leading coefficient \( S^{\phi_t, \phi_r}_{M_\lambda} \). By Corollary 5.6 if \( \lambda \in \mathfrak{h}^*_r \) and \( v \in V_\ell, f \in V_\ell^* \), the formal elementary \( \sigma \)-spherical function \( F^{\phi_t, \phi_r}_{M_\lambda} \) is the unique formal elementary \( \sigma \)-spherical function associated to \( M_\lambda \) with leading coefficient \( v \otimes f \). We will denote it by \( F^{v, f}_{M_\lambda} \).

5.4. Relation to \( \sigma \)-Harish-Chandra series. Recall the Harish-Chandra coefficients \( \Gamma^\sigma_{M_\lambda}(\mu) \in \mathbb{V} \otimes V_\ell^* \) in the power series expansion of the \( \sigma \)-Harish-Chandra series \( \Phi^\sigma_{M_\lambda} \), see Proposition 3.12. We have the following main result of Section 5.

**Theorem 5.8.** Let \( \lambda \in \mathfrak{h}^* \), \( \phi_t \in \text{Hom}_t(M_\lambda, V_\ell) \) and \( \phi_r \in \text{Hom}_t(V_\ell, M_\lambda) \).

a. For \( z \in Z(\mathfrak{g}) \),
\[
\widehat{\Pi}^\sigma(z) F^{\phi_t, \phi_r}_{M_\lambda} = \zeta_\lambda(z) F^{\phi_t, \phi_r}_{M_\lambda}
\]
as identity in \( (V_\ell \otimes V_\ell^*)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]] \lambda \).

b. For \( \lambda \in \mathfrak{h}_{\text{HC}}^* \) and \( \mu \preceq \lambda \) we have
\[
\phi_t \circ \phi_r^\ell = \phi_r^\ell \circ \phi_t = \Gamma^\sigma_{\mu}(\lambda) S^{\phi_r, \phi_t}_{M_\lambda}.
\]
c. For \( \lambda \in \mathfrak{h}_{\text{HC}}^* \), \( v \in V_\ell \) and \( f \in V_\ell^* \) we have
\[
F^{v, f}_{M_\lambda} = \Phi^\sigma_{M_\lambda}(\lambda)(v \otimes f).
\]
In particular, \( F^{v, f}_{M_\lambda} \) is a \( V_\ell \otimes V_\ell^* \)-valued analytic function on \( A_+ \).

**Proof.** Since \( \mathfrak{h}_{\text{HC}}^* \subset \mathfrak{h}_r^* \), part b and c of the theorem directly follow from part a, Proposition 3.12, Proposition 3.10 and the fact that the leading coefficient of \( F^{v, f}_{M_\lambda} \) is \( v \otimes f \). It thus suffices to prove (5.3).

Consider the \( Q \)-grading \( U(\mathfrak{g}) = \bigoplus_{\gamma \in Q} U[\gamma] \) with \( U[\gamma] \subset U(\mathfrak{g}) \) the subspace consisting of elements \( x \in U(\mathfrak{g}) \) satisfying \( Ad_a(x) = a^\gamma x \) for all \( a \in A \). Set
\[
\Lambda := \{ \mu \in \mathfrak{h}^* \mid \mu \preceq \lambda \}, \quad \Lambda_m := \{ \mu \in \Lambda \mid (\lambda - \mu, \rho^\vee) \leq m \}
\]
for \( m \in \mathbb{Z}_{\geq 0} \), where \( \rho^\vee = \frac{1}{2} \sum_{\alpha \in R^+} \alpha^\vee \). Then \( (\lambda - \mu, \rho^\vee) \) is the height of \( \lambda - \mu \in \sum_{i=1}^r \mathbb{Z}_{\geq 0} \alpha_i \) with respect to the basis \( \{ \alpha_1, \ldots, \alpha_r \} \) of \( R \). We will prove that
\[
\widehat{\Pi}^\sigma(z) F^{\phi_t, \phi_r}_{M_\lambda} = \sum_{\mu \in \Lambda} \phi_t(x \phi_r^\ell) \xi_\mu \quad (x \in U[0])
\]
in \( \text{Hom}(V_\ell, V_\ell)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}] \lambda \). This implies (5.3), since \( Z(\mathfrak{g}) \subset U[0] \) and \( M_\lambda \) admits the central character \( \xi_\lambda \).

Fix \( x \in U[0] \) and write \( \Pi(x) = \sum_{j \in J} f_j \otimes h_j \otimes y_j \otimes z_j \) with \( f_j \in \mathbb{R}, h_j \in U(\mathfrak{h}) \) and \( y_j, z_j \in U(\mathfrak{t}) \). By Theorem 3.11 we get the infinitesimal Cartan decomposition
\[
x = \text{Ad}_a(x) = \sum_{j \in J} f_j(a) y_j h_j \text{Ad}_a(z_j) \quad (a \in A_+)
\]
of \( x \in U[0] \). We will now substitute this decomposition in the truncated version \( \sum_{\lambda \in \Lambda_m} \phi_t(x \phi_r^\ell) \xi_\mu \) of the right hand side of (5.6).

Note that \( \sum_{\lambda \in \Lambda_m} \phi_t(x \phi_r^\ell) \xi_\mu \in \text{Hom}(V_\ell, V_\ell)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}] \lambda \) is a trigonometric quasi-polynomial, hence it can be evaluated at \( a \in A_+ \). Substituting (5.7) and using that \( \phi_t \) is a \( \mathfrak{t} \)-intertwining we obtain the formula
\[
\sum_{\lambda \in \Lambda_m} \phi_t(x \phi_r^\ell) a^\mu = \sum_{j \in J} \sum_{\mu \in \Lambda_m} f_j(a) \sigma_\ell(y_j) \phi_t(h_j \text{Ad}_a(z_j)) \phi_r^\ell(a) a^\mu
\]
in $\text{Hom}(V_r, V_t)$. Now expand $z_j = \sum_{\gamma \in I_j} z_j[\gamma]$ along the $Q$-grading of $U(g)$ with $z_j[\gamma] \in U[\gamma]$ (but no longer in $U(\mathfrak{t})$). Here $I_j \subset Q$ denotes the finite set of weights for which $z_j[\gamma] \neq 0$. Then (5.8) implies
\[
\sum_{\mu \in \Lambda} \phi_{\ell}(x \phi_{\mu}^r) a^\mu = \sum_{j \in J} \sum_{\gamma \in I_j} \sum_{\mu \in \Lambda} \omega_j(z_j[\gamma]) \phi_{\ell}(z_j[\gamma]) \phi_{\mu}^r f_j(a) a^{\mu + \gamma}
\]
for all $a \in A_+$. Let $\eta \geq \lambda$ such that $\lambda + \gamma \leq \eta$ for all $\gamma \in I := \cup_{j \in J} I_j$. Then we conclude that
\[
\sum_{\mu \in \Lambda} \phi_{\ell}(x \phi_{\mu}^r) \xi_{\mu} = \sum_{j \in J} \sum_{\gamma \in I_j} \sum_{\mu \in \Lambda} \omega_j(z_j[\gamma]) \phi_{\ell}(z_j[\gamma]) \phi_{\mu}^r f_j \xi_{\mu + \gamma}
\]
in $\text{Hom}(V_r, V_t)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_{\ell}}]] \xi_0$ (here the $f_j \in \mathcal{R}$ are represented by their convergent power series $f_j = \sum_{\beta \in Q_-} c_{j, \beta} \xi_{\beta}$ on $A_+$ ($c_{j, \beta} \in \mathbb{C}$)). We now claim that (5.9) is valid with the truncated sum over $\Lambda_m$ replaced by the sum over $\Lambda$,
\[
\sum_{\mu \in \Lambda} \phi_{\ell}(x \phi_{\mu}^r) \xi_{\mu} = \sum_{j \in J} \sum_{\gamma \in I_j} \sum_{\mu \in \Lambda} \omega_j(z_j[\gamma]) \phi_{\ell}(z_j[\gamma]) \phi_{\mu}^r f_j \xi_{\mu + \gamma}
\]
in $\text{Hom}(V_r, V_t)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_{\ell}}]] \xi_0$.

Fix $\nu \in \mathfrak{h}^*$ with $\nu \leq \eta$. It suffices to show that the $\xi_\nu$-component of the left (resp. right) hand side of (5.10) is the same as the $\xi_\nu$-component of the left (resp. right) hand side of (5.9) when $m \in \mathbb{Z}_{\geq 0}$ satisfies $(\eta - \nu, \rho^\vee) \leq m$.

Choose $m \in \mathbb{Z}_{\geq 0}$ with $(\eta - \nu, \rho^\vee) \leq m$. The $\xi_\nu$-component of the left hand side of (5.11) is zero if $\nu \notin \Lambda$ and $\phi_{\ell}(x \phi_{\mu}^r) \xi_{\mu}$ otherwise. Since $(\lambda - \nu, \rho^\vee) \leq (\eta - \nu, \rho^\vee) \leq m$, this coincides with the $\xi_\nu$-component of the left hand side of (5.9). The $\xi_\nu$-component of the right hand side of (5.11) is
\[
\sum_{j, \beta, \gamma, \mu} \omega_j(z_j[\gamma]) \phi_{\ell}(z_j[\gamma]) \phi_{\mu}^r f_j \xi_{\mu + \gamma}
\]
with the sum over the finite set of weights for four tuples $(j, \beta, \gamma, \mu) \in J \times Q_- \times I \times \Lambda$ satisfying $\gamma \in I_j$ and $\mu + \gamma + \beta = \nu$. For such a four tuple we have
\[
(\lambda - \mu, \rho^\vee) = (\lambda + \gamma - \nu + \beta, \rho^\vee) \leq (\eta - \nu, \rho^\vee) \leq m,
\]
from which it follows that (5.11) is also the $\xi_\nu$-component of the right hand side of (5.9). This concludes the proof of (5.10).

Since $\phi_{\ell}$ is a $\mathfrak{t}$-intertwiner, we have for fixed $\nu \in \mathfrak{h}^*$,
\[
\sum_{(\gamma, \mu) \in \Lambda \times I_j} z_j[\gamma] \phi_{\mu}^r = \phi_{\nu}^r \sigma_\ell(z_j)
\]
in $\text{Hom}(V_r, M_{\lambda}[\nu])$ (in particular, it is zero when $\nu \notin \Lambda$). Hence (5.10) simplifies to
\[
\sum_{\mu \in \Lambda} \phi_{\ell}(x \phi_{\mu}^r) \xi_{\mu} = \sum_{j \in J} \sum_{\nu \in \Lambda} \omega_j(z_j[\gamma]) \phi_{\ell}(z_j[\gamma]) \phi_{\mu}^r f_j \nu(x) \xi_{\mu}
\]
(5.12) in $\text{Hom}(V_r, V_t)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_{\ell}}]] \xi_\nu$, as desired. \hfill \Box

Recall the normalisation factor $\delta$, defined by (3.10). We will also view $\delta$ as formal series in $\mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_{\ell}}]]$. We shall expand $\phi_{\mu}^r$ in its power series expansion at infinity within $A_+$.

**Definition 5.9.** Let $\lambda \in \mathfrak{h}^*$ and fix $\mathfrak{t}$-intertwiners $\phi_{\ell} \in \text{Hom}_\mathfrak{t}(M_{\lambda - \rho}, V_t)$ and $\phi_{\nu} \in \text{Hom}_\mathfrak{t}(V_r, M_{\lambda - \rho})$. We call
\[
F^{\phi_{\ell}, \phi_{\nu}}_{\lambda} := \delta F^{\phi_{\ell}, \phi_{\nu}}_{\lambda} \in (V_r \otimes V_t^*)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_{\ell}}]] \xi_\lambda
\]
the normalised formal elementary $\sigma$-spherical function of weight $\lambda$. We furthermore write for $\lambda \in h^*_{\text{reg}} + \rho$ and $v \in V_\ell$, $f \in V_\ell^*$,

$$F^{\nu,f}_\lambda := \delta F_{M_\lambda - \nu}^{\nu} f,$$

which is the normalised formal elementary $\sigma$-spherical function of weight $\lambda$ with leading coefficient $\nu \otimes f$.

By Theorem 5.8c we have for $\lambda \in h^{*}_{\text{reg}} + \rho$, $v \in V_\ell$ and $f \in V_\ell^*$,

$$F^{\nu,f}_\lambda = \Phi^{\nu}_\sigma (v \otimes f).$$

In particular, $F^{\nu,f}_\lambda$ is an $V_\ell \otimes V_\ell^*$-valued analytic function on $A_+$ when $\lambda \in h^*_{\text{reg}} + \rho$.

Theorem 5.8 now immediately gives the interpretation of $\hat{\Phi}^{\rho,\phi_r}$ as formal eigenstates for the $\sigma$-spin quantum hyperbolic Calogero-Moser system for all weights $\lambda \in h^*$.

**Theorem 5.10.** Let $\lambda \in h^*$, $\phi_t \in \text{Hom}_t(M_\lambda, V_\ell)$ and $\phi_r \in \text{Hom}_r(V_\ell, M_\lambda)$. The normalised formal elementary $\sigma$-spherical function $F^{\phi_t,\phi_r}_\lambda$ of weight $\lambda$ satisfies the Schrödinger equation

$$H^T(\Phi^{\rho,\phi_r}_\lambda) = -\frac{\lambda(\lambda)}{2} \Phi^{\rho,\phi_r}_\lambda,$$

as well as the eigenvalue equations

$$H^T(\Phi^{\phi_t,\phi_r}_\lambda) = \zeta_{\lambda - \rho}(z) \Phi^{\phi_t,\phi_r}_\lambda, \quad z \in Z(g),$$

in $(V_\ell \otimes V_\ell^*)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]] \lambda$.

**Proof.** This follows from the differential equations (5.3) for the formal eigenstates of the Harish-Chandra series $\Phi^{\rho,\phi_r}_\lambda$, and the results in Subsection 5.6. \hfill $\square$

**Remark 5.11.**

\textbf{a.} Let $\lambda \in h^{*}_{\text{reg}}$ and fix $V_\ell, V_r$ finite dimensional $K$-representations. Let $\sigma$ be the resulting tensor product representation of $K \times K$ on $V_{\sigma} := V_\ell \otimes V_r^* \simeq \text{Hom}(V_\ell, V_r)$. For $T \in \text{Hom}_M(V_\ell, V_r)$ write $H^T_\lambda$ for the $V_\sigma$-valued smooth function on $G_{\text{reg}}$ constructed from the Harish-Chandra series $\Phi^{\rho,\phi_r}_\lambda$ by

$$H^T_\lambda(k_1, k_2) := \sigma(k_1, k_2) \Phi^{\rho,\phi_r}_\lambda(a) T \quad (a \in A_+, k_1, k_2 \in K),$$

See Remark 3.17. Then 5.5 gives an interpretation of $H^T_\lambda$ as formal elementary $\sigma$-spherical function associated with $M_\lambda$. This should be compared with 1.18, which gives an interpretation of the Eisenstein integral as spherical function associated to the principal series representation of $G$.

\textbf{b.} In [13, Thm. 4.4] Kolb proved an affine rank one analogue of Theorem 5.5 for the pair $(\mathfrak{sl}_2, \tilde{\theta})$, where $\tilde{\theta}$ the Chevalley involution on the affine Lie algebra $\mathfrak{sl}_2$ associated to $\mathfrak{sl}_2$. The generalisation of Theorem 5.5 to arbitrary split affine symmetric pairs will be discussed in a followup paper.

### 5.5. The rank one example

In this subsection we consider $g_0 = \mathfrak{sl}(2; \mathbb{R})$ with linear basis

$$H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad F = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix},$$

and we take $h_0 = RH$ as split Cartan subalgebra. Then $\theta_0(x) = -x^t$ with $x^t$ the transpose of $x \in g_0$. Note that the $\frac{H}{2\sqrt{2}} \in h_0$ has norm one with respect to the Killing form. Let $\alpha$ be the unique positive root, satisfying $\alpha(H) = 2$. Then $e_\alpha = \frac{F}{2}$ and we can take $e_{-\alpha} = \frac{E}{2}$ and $e_{-\alpha} = \frac{E}{2}$.

With this choice we have $f_0 = 0_y$ with $y := y_0 = \frac{E}{2} - \frac{F}{2}$.

We identify $h^* \sim \mathbb{C}$ by the map $\lambda \mapsto \lambda(H)$. The positive root $\alpha \in h^*$ then corresponds to $2$. The bilinear form on $h^*$ becomes $(\lambda, \mu) = \frac{1}{2} \lambda \mu$ for $\lambda, \mu \in \mathbb{C}$. Furthermore, $h^*_{\sigma} = h^*_{\text{reg}}$ becomes $\mathbb{C} \setminus \mathbb{Z}_{\geq 0}$. We also identify $A \sim \mathbb{R}_{>0}$ by $\exp_A(sH) \mapsto e^s$ ($s \in \mathbb{R}$). With these identifications, the multiplicative character $\chi_\lambda$ on $A$ ($\lambda \in h^*$) becomes $\chi_\lambda(a) = a^\lambda$ for $a \in \mathbb{R}_{>0}$ and $\lambda \in \mathbb{C}$.
For \( \nu \in \mathbb{C} \) let \( \chi_\nu \in \mathfrak{t}^\wedge \) be the one-dimensional representation mapping \( y \to \nu \). We write \( \mathbb{C}_\nu \) for \( \mathbb{C} \) regarded as \( \mathfrak{t} \)-module by \( \chi_\nu \). For \( \lambda \in \mathbb{C} \setminus \mathbb{Z}_{\geq 0} \) and \( \nu_\ell, \nu_r \in \mathbb{C} \), the scalar-valued Harish-Chandra series \( \Phi^{|X_\nu|,X_\nu}_\lambda \) is the unique analytic function on \( \mathbb{A}_+ \) admitting a power series of the form

\[
\Phi^{|X_\nu|,X_\nu}_\lambda(a) = \sum_{n \geq 0} \Gamma^{|X_\nu|,X_\nu}_0(\lambda) a^{-2n} \quad (a \in \mathbb{A}_+)
\]

with \( \Gamma^{|X_\nu|,X_\nu}_0(\lambda) = 1 \) that satisfies the differential equation

\[
\mathfrak{P}(\Omega) \Phi^{|X_\nu|,X_\nu}_\lambda = \frac{\lambda(\lambda + 2)}{8} \Phi^{|X_\nu|,X_\nu}_\lambda
\]

(see Proposition 3.12). By Corollary 3.6, \( \Phi^{|X_\nu|,X_\nu}_\lambda \) is the associated asymptotically free solution.

An explicit expression for \( \Phi^{|X_\nu|,X_\nu}_\lambda \) can be now derived as follows. Rewrite (5.15) as a second order differential equation for \( h \Phi^{|X_\nu|,X_\nu}_\lambda \) with

\[
h(a) := (a + a^{-1})^{\nu_r - \nu_r}(a - a^{-1})^{-i(\nu_r + \nu_r)}.
\]

One then recognizes the resulting differential equation as the second-order differential equation (HS (2.10]) satisfied by the Jacobi function (which is the Gauss’ hypergeometric differential equation after an appropriate change of coordinates). Its solutions can be expressed in terms of the Gauss’ hypergeometric series

\[
2F_1(a, b; c | s) := \sum_{k=0}^{\infty} \frac{(a)_k (b)_k}{(c)_k k!} s^k,
\]

where \( (a)_k := (a+1) \cdots (a+k-1) \) is the Pochhammer symbol (the series (5.16) converges for \( |s| < 1 \). Then \( \Phi^{|X_\nu|,X_\nu}_\lambda \) corresponds to the solution (HS (2.15]) of the second-order differential equation (HS (2.10]). Performing the straightforward computations gives the following result.

**Proposition 5.12.** For \( \lambda \in \mathbb{C} \setminus \mathbb{Z}_{\geq 0} \) we have

\[
\Phi^{|X_\nu|,X_\nu}_\lambda(a) = (a + a^{-1})^{|\lambda|} \frac{(a - a^{-1})^{i(\nu_r + \nu_r)}}{(a + a^{-1})^{-\nu_r}} 2F_1\left(-\frac{\lambda}{2} + i\nu_r, -\frac{\lambda}{2} + i\nu_r; -\lambda + \frac{4}{(a + a^{-1})^2}\right)
\]

for \( a > 1 \).

If \( \chi_{-\nu_r}, \chi_{-\nu_r} \in K^\wedge \) (i.e., if \( \nu_r, \nu_r \in i\mathbb{Z} \)), the restriction of the elementary spherical function \( f_{\lambda}^{|X_\nu|,X_\nu} \) to \( \mathbb{A}_+ \) is an associated Jacobi function. It can also be expressed in terms of a single \( 2F_1 \) (see HS §4.2) and references therein for details).

We compute now an alternative expression for \( \Phi^{|X_\nu|,X_\nu}_\lambda \) using its realisation as generating function for compositions of weight components of \( \mathfrak{t} \)-intertwiners (see Theorem 5.8).

The Verma module \( M_\lambda \) with highest weight \( \lambda \in \mathbb{C} \) is explicitly realised as

\[
M_\lambda = \bigoplus_{n=0}^{\infty} \mathbb{C} u_n
\]
with \( u_n := \frac{1}{n!} F^n m_\lambda \) and \( g \)-action \( H u_n = (\lambda - 2n) u_n, \) \( E u_n = (\lambda - n + 1) u_{n-1} \) and \( F u_n = (n + 1) u_{n+1} \), where we have set \( u_{-1} := 0 \). We will identify \( \text{Hom}_\mathfrak{g}(C_\nu, M_\lambda) \rightarrow M_\lambda^{\chi_\nu}, \quad \psi \mapsto \psi(1), \) with \( M_\lambda^{\chi_\nu} \) the space of \( \chi_\nu \)-invariant vectors in \( M_\lambda \) (cf. Subsection 5.5). Note furthermore that
\[
\text{Hom}_\mathfrak{g}(M_\lambda, C_\nu) \simeq M_\lambda^{\ast X^{-\nu}}.
\]

To apply Theorem 5.8 to \( \Phi^{\lambda \nu} \otimes \chi_\nu \), we thus need to describe the weight components of the nonzero vectors in the one-dimensional subspaces \( M_\lambda^{\ast X^{-\nu}} \) and \( M_\lambda^{\chi_\nu} \) for \( \lambda \in \mathbb{C} \setminus \mathbb{Z}_{\geq 0} \) (here we use that \( C_\nu \simeq C_{-\nu} \) as \( \mathfrak{g} \)-modules). For this we need some facts about Meixner-Pollaczek polynomials, which we recall from [40] [89, 7].

Meixner-Pollaczek polynomials are orthogonal polynomials depending on two parameters \((\lambda, \phi)\), of which we only need the special case \( \phi = \frac{\pi}{2} \). The monic Meixner-Pollaczek polynomials \( \{p_n^{(\lambda)}(s) \mid n \in \mathbb{Z}_{\geq 0}\} \) with \( \phi = \frac{\pi}{2} \) are given by
\[
p_n^{(\lambda)}(s) = (2\lambda)_n \left( \frac{i}{2} \right)_n \binom{2n}{n} (-n, \lambda + is; 2\lambda | 2).
\]

They satisfy the three-term recursion relation
\[
(p_{n+1}^{(\lambda)}(s) - sp_n^{(\lambda)}(s) + \frac{n(n + 2\lambda - 1)}{4} p_{n-1}^{(\lambda)}(s) = 0,
\]
where \( p_{-1}^{(\lambda)}(s) := 0 \).

The following result should be compared with [4] [49], where mixed matrix coefficients of discrete series representations of \( \text{SL}(2; \mathbb{R}) \) with respect to hyperbolic and elliptic one-parameter subgroups of \( \text{SL}(2, \mathbb{R}) \) are expressed in terms of Meixner-Pollaczek polynomials.

**Lemma 5.13.** Fix \( \lambda \in \mathbb{C} \setminus \mathbb{Z}_{\geq 0} \) and \( \nu \in \mathbb{C} \).

1. **a.** We have
   \[
   M_\lambda^{\chi_\nu} = \mathbb{C} v_{\lambda, \nu}
   \]
   with the \((\lambda - 2n)\)-weight coefficient of \( v_{\lambda, \nu} \) given by
   \[
v_{\lambda, \nu}[\lambda - 2n] = \frac{(-2)^n p_n^{(-\lambda/2)}(-\nu)}{(-\lambda)_n} u_n, \quad n \in \mathbb{Z}_{\geq 0}.
   \]
2. **b.** We have
   \[
   M_\lambda^{\ast X^{-\nu}} = \mathbb{C} \psi_{\lambda, \nu}
   \]
   with \( \psi_{\lambda, \nu} \) satisfying
   \[
   \psi_{\lambda, \nu}(u_n) = \frac{2^n p_n^{(-\lambda/2)}(-\nu)}{n!}, \quad n \in \mathbb{Z}_{\geq 0}.
   \]

**Proof.** **a.** The requirement \( yv = -\nu\) for an element \( v \in M_\lambda \) with weight components of the form
\[
v[\lambda - 2n] = \frac{(-2)^n c_n}{(-\lambda)_n} u_n
\]
is equivalent to the condition that the coefficients \( c_n \in \mathbb{C} \) \((n \geq 0)\) satisfy the three-term recursion relation
\[
c_{n+1} + \nu c_n + \frac{n(n - \lambda - 1)}{4} c_{n-1} = 0, \quad n \in \mathbb{Z}_{\geq 0},
\]
where \( c_{-1} := 0 \). By (5.17), the solution of this three-term recursion relation satisfying \( c_0 = 1 \) is given by
\[
c_n = p_n^{(-\lambda/2)}(-\nu) \quad (n \in \mathbb{Z}_{\geq 0}).
\]
**b.** The proof is similar to the proof of part **a.**

\[\Box\]
Let \( \nu_r, \nu_r \in \mathbb{C} \) and \( \lambda \in \mathbb{C} \setminus \mathbb{Z}_{\geq 0} \). We obtain from Lemma 6.13 and Theorem 5.8 the following expression for the Harish-Chandra series \( \Phi_{\lambda}^{\nu_r \otimes \nu_r} \).

**Corollary 5.14.** Fix \( \lambda \in \mathbb{C} \setminus \mathbb{Z}_{\geq 0} \) and \( \nu_r, \nu_r \in \mathbb{C} \). We have for \( a \in \mathbb{R}_{>1} \),

\[
\Phi_{\lambda}^{\nu_r \otimes \nu_r}(a) = a^{\lambda} \sum_{n=0}^{\infty} \frac{4^n n^{\nu_r}(\frac{-\lambda}{2}) (\frac{-\nu_r}{2}) (-a^{-2})^n}{(-\lambda)_n n!}.
\]

**Proof.** Note that \( v_{\nu_r} [\lambda] = m_\lambda \) and \( ev_{\nu_r, C_{\nu_r}}(\psi_{\nu_r}) = \psi_{\nu_r}(m_\lambda) = 1 \), hence

\[
S_{\nu_r, C_{\nu_r}} = 1
\]

(we identify \( \text{Hom}(C_{\nu_r}, C_{\nu_r}) \xrightarrow{\sim} \mathbb{C} \) by \( T \mapsto T(1) \)). By Theorem 5.8 we then get

\[
\Phi_{\lambda}^{\nu_r \otimes \nu_r}(a) = \sum_{n=0}^{\infty} \psi_{\nu_r, C_{\nu_r}}(\nu_r, C_{\nu_r} [\lambda - 2n]) a^{\lambda - 2n}
\]

for \( a \in \mathbb{R}_{>1} \). The result now follows from Lemma 5.13. \( \square \)

Combined with Proposition 5.12 we reobtain the following special case of the Poisson kernel identity [11 §2.5.2 (12)] for Meixner-Pollaczek polynomials.

**Corollary 5.15.** We have for \( a \in \mathbb{R}_{>1} \),

\[
a^{\lambda} \sum_{n=0}^{\infty} \frac{4^n n^{\nu_r}(\frac{-\lambda}{2}) (\frac{-\nu_r}{2}) (-a^{-2})^n}{(-\lambda)_n n!} =
\]

\[
= (a + a^{-1})^\lambda \left( \frac{a - a^{-1}}{a + a^{-1}} \right)^{i(\nu_r + \nu_r)} 2F_1 \left( \frac{\lambda}{2} + i\nu_r - \frac{\lambda}{2} + i\nu_r; \frac{-4}{(a + a^{-1})^2} \right).
\]

**Remark 5.16.** For a different representation theoretic interpretation of the Poisson kernel identity for Meixner-Pollaczek polynomials, see [17, Prop. 2.1].

### 6. N-point spherical functions

#### 6.1. Factorisations of the Casimir element.** Let \( M, M', U \) be \( g \)-modules. We will call \( g \)-intertwiners \( M \to M' \otimes U \) vertex operators. This terminology is stretching the standard representation theoretic notion of vertex operators as commonly used in the context of Wess-Zumino-Witten conformal field theory. In that case (see, e.g., [10]), it refers to intertwiners \( M' \to M' \otimes U(z) \) for affine Lie algebra representations \( M, M' \) and \( U(z) \) with \( M \) and \( M' \) highest weight representations (playing the role of auxiliary spaces), and \( U(z) \) an evaluation representation (playing the role of state space).

The space \( \text{Hom}(M, M' \otimes U) \) of all linear maps \( M \to M' \otimes U \) admits the following left and right \( U(g) \otimes 2 \)-action,

\[
((x \otimes y)\Psi)(m) := (x \otimes y)\Psi(m),
\]

\[
(\Psi * (x \otimes y))(m) := (1 \otimes S(x))\Psi(y m)
\]

for \( x, y \in U(g) \), \( \Psi \in \text{Hom}(M, M' \otimes U) \) and \( m \in M \), with \( S \) the antipode of \( U(g) \). Here we suppress the representation maps if no confusion can arise. We sometimes also write \( x_M \) for the action of \( x \in U(g) \) on the \( g \)-module \( M \).

**Definition 6.1.** We say that a triple \( (\tau^l, \tau^r, d) \) with \( \tau^l, \tau^r \in \mathfrak{g} \otimes \mathfrak{g} \) and \( d \in U(g) \) is a factorisation of the Casimir element \( \Omega \in \mathcal{Z}(g) \) if for all \( \mathfrak{g} \)-modules \( M, M', U \) and for all vertex operators \( \Psi \in \text{Hom}_g(M, M' \otimes U) \) we have

\[
\frac{1}{2}((\Omega \otimes 1)\Psi - \Psi \Omega) = \tau^l \Psi - \Psi \tau^r + (1 \otimes d)\Psi
\]

in $\text{Hom}(M, M' \otimes U)$.

Suppose that $(\tau^f, \tau^r, d)$ is a factorisation of $\Omega$. If $\Omega_M = \zeta_M \text{id}$ and $\Omega_M' = \zeta_M' \text{id}$ for some constants $\zeta_M, \zeta_M' \in \mathbb{C}$ then we arrive at the asymptotic operator Knizhnik-Zamolodchikov-Bernard (KZB) equation for vertex operators $\Psi \in \text{Hom}_g(M, M' \otimes U)$,

$$\frac{1}{2}(\zeta_M' - \zeta_M)\Psi = \tau^f \Psi - \Psi \ast \tau^r + (1 \otimes d)\Psi$$

(compare with the operator KZ equation from [22, Thm. 2.1]).

Consider now vertex operators $\Psi_i \in \text{Hom}_g(M_i, M_{i-1} \otimes U_i)$ for $i = 1, \ldots, N$. Denote $U := U_1 \otimes U_2 \otimes \cdots \otimes U_N$ and write $\Psi \in \text{Hom}_g(M_N, M_0 \otimes U)$ for the composition

$$\Psi := (\Psi_1 \otimes \text{id}_{U_2 \otimes \cdots \otimes U_N}) \cdots (\Psi_{N-1} \otimes \text{id}_{U_N})\Psi_N$$

of the vertex operators $\Psi_i$. Assume that $\Omega_M = \zeta_M \text{id}_M$ for some constants $\zeta_M \in \mathbb{C}$ ($0 \leq i \leq N$). The asymptotic operator KZB equation (6.2) now extends to the following system of equations for $\Psi$.

**Corollary 6.2.** Let $(\tau^f, \tau^r, d)$ be a factorisation of $\Omega$ with expansions $\tau^f = \sum_k \alpha_k^f \otimes \beta_k^f$ and $\tau^r = \sum_m \alpha_m^r \otimes \beta_m^r$ in $g \otimes g$. Under the above assumptions and conventions we have

$$\frac{1}{2}(\zeta_{M_i-1} - \zeta_{M_i})\Psi = \left(\sum_{j=1}^{i-1} \tau_{U_i, U_i}^f - \sum_{j=i+1}^{N} \tau_{U_i, U_j}^r + d_{U_i}\right)\Psi$$

$$+ \sum_k (\alpha_k^f)_M (\beta_k^f)_M \Psi + \sum_m (\alpha_m^r)_U (\beta_m^r)_M \Psi^M$$

for $i = 1, \ldots, N$.

**Proof.** Write $\Psi_{M_i} := \Psi_i \otimes \text{id}_{U_{i+1} \otimes \cdots \otimes U_N}$. Then

$$\frac{1}{2}(\zeta_{M_i-1} - \zeta_{M_i})\Psi = \frac{1}{2} \Psi_{M_1} \cdots \Psi_{M_{i-1}} (\Omega_{M_i-1} \Psi_{M_i} - \Psi_{M_i} \Omega_{M_i}) \Psi_{M_{i+1}} \cdots \Psi_{M_N}.$$ 

Now (6.1) gives

$$\frac{1}{2}(\Omega_{M_i-1} \Psi_{M_i} - \Psi_{M_i} \Omega_{M_i}) = \sum_k (\alpha_k^f)_{M_i-1} (\beta_k^f)_U \Psi_{M_i} + \sum_m (\alpha_m^r)_U (\beta_m^r)_M \Psi_{M_i}.$$ 

Substitute this equation in (6.5) and push the action of $\alpha_k^f$ on $M_{i-1}$ (resp. the action of $\beta_m^r$ on $M_i$) through the product $\Psi_{M_1} \cdots \Psi_{M_{i-1}}$ (resp. $\Psi_{M_{i+1}} \cdots \Psi_{M_N}$) of vertex operators using the fact that

$$(x \otimes 1)\Psi - \Psi x = -(1 \otimes x)\Psi$$

for $x \in g$ and $\Psi \in \text{Hom}_g(M, M' \otimes U)$. This immediately results in (6.3). \hfill $\Box$

The asymptotic operator KZB equations (6.2) for an appropriate factorisation of $\Omega$ give rise to boundary KZB type equations that are solved by asymptotical $N$-point correlation functions for boundary WZW conformal field theory on a cylinder. Here asymptotical means that the "positions" of the local observables in the correlation functions escape to infinity. We will define the asymptotical $N$-point correlation functions directly in Subsections 7.3 & 7.4 and call them (formal) $N$-point spherical functions. The discussion how they arise as limits of correlation functions is postponed to a followup paper.

We give now first two families of examples of factorisations of $\Omega$. The first family is related to the expression (5.3) of $\Omega$. It leads to asymptotic KZB equations for generalised weighted trace functions (see [15]). As we shall see later, this family also gives rise to the asymptotic boundary KZB equations for the (formal) $N$-point spherical functions using a reflection argument. The second family is related to the Cartan decomposition (3.3) of $\Omega$, and leads directly to
asymptotic boundary KZB equations. This second derivation of the asymptotic boundary KZB equations is expected to be crucial for the generalisation to quantum groups.

Felder’s [20], [13] trigonometric dynamical r-matrix $r \in \mathcal{R} \otimes \mathfrak{g}^\otimes 2$ is given by

$$r := -\frac{1}{2} \sum_{j=1}^{r} x_j \otimes x_j - \sum_{\alpha \in \mathcal{R}} \frac{e_{-\alpha} \otimes e_{\alpha}}{1 - \xi^{-2\alpha}}.$$  

(6.6)

Set

$$r^{\theta_i} := (\theta \otimes \text{id}_g)r \equiv \frac{1}{2} \sum_{j=1}^{r} x_j \otimes x_j + \sum_{\alpha \in \mathcal{R}} \frac{e_{\alpha} \otimes e_{-\alpha}}{1 - \xi^{-2\alpha}}.$$  

(6.7)

For $s = \sum_i s_i \otimes t_i \in \mathfrak{g} \otimes \mathfrak{g}$ we write $s_{21} := \sum_i t_i \otimes s_i$ and $s_{21}^{\theta} := (1 \otimes \theta)s_{21}$. Note that $r^{\theta_i}$ is a symmetric tensor,

$$r_{21}^{\theta} = r^{\theta_i}.$$  

We will write below $r_{21}^{\theta}$ for the occurrences of the $\theta$-twisted r-matrices in the asymptotic boundary KZB equations, since this is natural when viewing the asymptotic boundary KZB equations as formal limit of integrable boundary qKZB equations (this will be discussed in future work).

Define folded r-matrices by

$$r^\pm := \pm r + r_{21}^{\theta}.$$  

Note that $r^+ \in \mathcal{R} \otimes \mathfrak{t} \otimes \mathfrak{g}$ and $r^- \in \mathcal{R} \otimes \mathfrak{p} \otimes \mathfrak{g}$. The folded r-matrices $r^\pm$ are explicitly given by

$$r^+ = \sum_{\alpha \in \mathcal{R}} \frac{g_\alpha \otimes e_{\alpha}}{1 - \xi^{-2\alpha}},$$  

(6.8)

$$r^- = \sum_{j=1}^{r} x_j \otimes x_j + \sum_{\alpha \in \mathcal{R}} \frac{(e_{\alpha} + e_{-\alpha}) \otimes e_{-\alpha}}{1 - \xi^{-2\alpha}}.$$  

Proposition 6.3. Fix $a \in A_{\text{reg}}$. The following triples $(\tau^\ell, \tau^r, d)$ give factorisations of the Casimir $\Omega \in Z(\mathfrak{g})$.

a. $\tau^\ell = \tau^r = r(a)$, $d = -\frac{1}{2} \sum_{\alpha \in \mathcal{R}^+} \left(\frac{1 + \xi^{-2\alpha}}{1 - \xi^{-2\alpha}}\right) t_\alpha$.

b. $\tau^\ell = r^+(a)$, $\tau^r = -r^-(a)$, $d = b(a)$ with

$$b := \frac{1}{2} \sum_{j=1}^{r} x_j^2 - \frac{1}{2} \sum_{\alpha \in \mathcal{R}^+} \left(\frac{1 + \xi^{-2\alpha}}{1 - \xi^{-2\alpha}}\right) t_\alpha + \sum_{\alpha \in \mathcal{R}^+} \frac{\xi^{-\alpha}}{1 - \xi^{-2\alpha}} \in \mathcal{R} \otimes U(\mathfrak{g}).$$  

(6.8)

Proof. The factorisations are obtained from the explicit expressions [5.9] and [5.6] of $\Omega$ by moving Lie algebra elements in the resulting expression of $\frac{1}{2}((\Omega \otimes 1)\psi - \psi \Omega)$ through the vertex operator $\Psi$ following a particular (case-dependent) strategy. The elementary formulas we need are

$$\begin{align*}
(x \otimes 1)\psi - \psi x &= -(1 \otimes x)\psi, \\
(xy \otimes 1)\psi - \psi xy &= -(1 \otimes x)\psi y - (x \otimes y)\psi
\end{align*}$$

\hspace{1cm} (6.9)

for $x, y \in \mathfrak{g}$ and $\psi \in \text{Hom}_g(M, M' \otimes U)$. Note that the second formula gives an expression of $(xy \otimes 1)\psi - \psi xy$ with $x$ no longer acting on $M$ and $y$ no longer acting on $M'$. For case b we also need formulas such that both $x$ and $y$ are not acting on $M'$ (resp. on $M$),

$$\begin{align*}
(xy \otimes 1)\psi - \psi xy &= -(1 \otimes x)\psi y - (1 \otimes y)\psi x + (1 \otimes xy)\psi, \\
(xy \otimes 1)\psi - \psi xy &= -(x \otimes y)\psi - (y \otimes x)\psi - (1 \otimes xy)\psi
\end{align*}$$

\hspace{1cm} (6.10)

for $x, y \in \mathfrak{g}$ and $\psi \in \text{Hom}_g(M, M' \otimes U)$. These equations are easily obtained by combining the two formulas of (6.9).

a. Substitute (6.9) into $\frac{1}{2}((\Omega \otimes 1)\psi - \psi \Omega)$ and apply (6.10) to the terms. The resulting identity
can be written as $\tau^f\Psi - \Psi*\tau^r + (1 \otimes d)\Psi$ with $(\tau^f, \tau^r, d)$ as stated.

b. Use that

$$\frac{1}{2}((\Omega \otimes 1)\Psi - \Psi\Omega) = \frac{1}{2}(\text{Ad}_a(\Omega) \otimes 1)\Psi - \Psi\text{Ad}_a(\Omega)$$

and substitute (3.6) in the right hand side of this equation. For the quadratic terms $xy(x, y \in g)$ in the resulting formula we use the second formula of (6.9) when $x \in \mathfrak{t}$ and $y \in \text{Ad}_a(\mathfrak{t})$, the first formula of (6.10) when both $x, y \in \text{Ad}_a(\mathfrak{t})$ or both $x, y \in \mathfrak{h}$, and the second formula of (6.10) when both $x, y \in \mathfrak{t}$. It results in the formula (6.11) with $(\tau^f, \tau^r, d)$ given by

$$\tau^f = \frac{1}{2} \sum_{a \in R}\frac{(a^\alpha + a^{-\alpha})\text{Ad}_a(y_\alpha) - 2y_\alpha)}{(a^\alpha - a^{-\alpha})^2},$$

$$\tau^r = -\sum_{j=1}^r x_j \otimes x_j + \frac{1}{2} \sum_{a \in R}(a^\alpha + a^{-\alpha})y_\alpha - 2\text{Ad}_a(y_\alpha) \otimes \text{Ad}_a(y_\alpha),$$

$$d = \frac{1}{2} \sum_{j=1}^r x_j^2 - \frac{1}{2} \sum_{a \in R^+}(1 + a^{-2\alpha})t_\alpha + \frac{1}{2} \sum_{a \in R}(a^\alpha - a^{-\alpha})^2.$$ 

By the elementary identities

$$2\text{Ad}_a(y_\alpha) - (a^\alpha + a^{-\alpha})y_\alpha = (a^\alpha - a^{-\alpha})(e_\alpha + e_{-\alpha}),$$

$$\text{Ad}_a(y_\alpha^2) - y_\alpha^2 = (2a^{2\alpha} - 1)e_\alpha^2 + (a^{-2\alpha} - 1)e_{-\alpha}^2$$

the above expressions for $\tau^f, \tau^r$ and $d$ simplify to the expressions (6.7) and (6.8) for $r^+(a), -r^-(a)$ and $b(a)$.

**Remark 6.4.** The limit $\inf r := \lim_{a \to \infty} r(a)$ (meaning $a^\alpha \to \infty$ for all $\alpha \in R^+$) gives the classical $r$-matrix

$$\inf r = -\frac{1}{2} \sum_{j=1}^r x_j \otimes x_j - \sum_{a \in R^+} e_{-\alpha} \otimes e_\alpha \in \theta(\mathfrak{b}) \otimes \mathfrak{b}.$$ 

The corresponding limit for the folded $r$-matrices $r^{\pm}(a)$ gives

$$\inf r^{\pm} := +\inf r + \inf \theta(\mathfrak{h}).$$

As a consequence of Proposition 6.3 we then obtain the following two (nondynamical) factorisations of the Casimir $\Omega$,

a. $(\sigma, r, d) = (\inf r, -2t_\rho),$ 

b. $(\sigma, r, d) = (\inf r^+, -\inf r^-, \inf b)$ with

$$\inf b := \frac{1}{2} \sum_{j=1}^r x_j^2 - t_\rho + \sum_{a \in R^+} e_\alpha^2 \in U(\mathfrak{g}).$$

6.2. **Differential vertex operators.** In Subsection 6.3 we apply the results of the previous subsection to $M_i = H^\infty_\lambda$ with $\lambda_i \in \mathfrak{h}^*$ ($i = 0, \ldots, N$) and to finite dimensional $G$-representations $U_j (j = 1, \ldots, N)$. Before doing so, we first describe the appropriate class of vertex operators in this context, which consists of $G$-equivariant differential operators. We use the notion of vector-valued $G$-equivariant differential operators between spaces of global sections of complex vector bundles, see [33, Chpt. II] as well as [50, §1].

Identify the $G$-space $H^\infty_\lambda$ with the space of global smooth sections of the complex line bundle $L_\lambda := (G \times C)/\sim_\lambda$ over $G/AN \simeq K$, with equivalence relation $\sim_\lambda$ given by

$$\lambda b, \eta_\lambda ce^{-1}c) \sim_\lambda (g, c), \quad (g \in G, b \in AN, c \in C).$$

(6.12)
For $\lambda, \mu \in \mathfrak{h}^*$ and $U$ a finite dimensional $G$-representation let $\mathcal{D}(\mathcal{H}_\infty^\infty, \mathcal{H}_\mu^\infty \otimes U)$ be the space of differential $G$-intertwiners $\mathcal{H}_\lambda^\infty \rightarrow \mathcal{H}_\mu^\infty \otimes U$ (note that $\mathcal{H}_\mu^\infty \otimes U$ is the space of smooth section of the vector bundle $(G \times U)/\sim$, with $\sim$ given by the same formula (6.12) with $c \in U$). We call $D \in \mathcal{D}(\mathcal{H}_\infty^\infty, \mathcal{H}_\mu^\infty \otimes U)$ a differential vertex operator.

Let $\mathcal{D}_0'(\mathcal{L}_\lambda)$ be the $\mathfrak{g}$-module consisting of distributions on $\mathcal{L}_\lambda$ supported at $1 \in K$. Note that $\mathcal{D}_0'(\mathcal{L}_\lambda)$ is contained in the continuous linear dual of $\mathcal{H}_\lambda^\infty$. A straightforward adjustment of the proof of [7, Lem. 2.4] yields a linear isomorphism

$$\mathcal{D}(\mathcal{H}_\infty^\infty, \mathcal{H}_\mu^\infty \otimes U) \simeq \text{Hom}_g(\mathcal{D}_0'(\mathcal{L}_\mu), \mathcal{D}_0'(\mathcal{L}_\lambda) \otimes U)$$

via dualisation. Furthermore,

$$M_{\lambda-\rho} \simeq \mathcal{D}_0'(\mathcal{L}_\lambda)$$

as $\mathfrak{g}$-modules by Schwartz' theorem, with the distribution $\omega$ associated to $xm_{\lambda-\rho}$ ($x \in U(\mathfrak{g})$) defined by

$$\omega(\phi) := (r_*(x)\phi)(1) \quad (\phi \in \mathcal{H}_\infty^\infty)$$

(see again the proof of [7, Lem. 2.4]). We thus reach the following conclusion.

**Proposition 6.5.** For $\lambda, \nu \in \mathfrak{h}^*$ and $U$ a finite dimensional $G$-representation we have

$$\mathcal{D}(\mathcal{H}_\infty^\infty, \mathcal{H}_\nu^\infty \otimes U) \simeq \text{Hom}_g(M_{\mu-\nu}, M_{\lambda-\rho} \otimes U).$$

**Remark 6.6.** The inverse of the isomorphism (6.13) can be described explicitly as follows. Fix a vertex operator $\Psi \in \text{Hom}_g(M_{\mu-\nu}, M_{\lambda-\rho} \otimes U)$. Let $\{u_i\}_i$ be a linear basis of $U$ and write $\{u_i^*\}_i$ for its dual basis. Let $Y_i \in U(\mathfrak{g})$ be the unique elements such that

$$\Psi(m_{\mu-\nu}) = \sum_i Y_i m_{\lambda-\rho} \otimes u_i,$$

cf. the proof of Proposition 5.4a. Under the isomorphism (6.13), the intertwiner $\Psi$ is mapped to the differential vertex operator $D_\Psi = \sum_i L_i \otimes u_i \in \mathcal{D}(\mathcal{H}_\infty^\infty, \mathcal{H}_\mu^\infty \otimes U)$ with the scalar differential operators $L_i : \mathcal{H}_\infty^\infty \rightarrow \mathcal{H}_\infty^\infty$ explicitly given by

$$(L_i \phi)(g) = \sum_j u_i^*(gu_j)(r_*(Y_j)\phi)(g) \quad (\phi \in \mathcal{H}_\infty^\infty, g \in G).$$

For $\Psi_V \in \text{Hom}_g(M_{\mu-\nu}, M_{\lambda-\rho} \otimes V)$ and $\Psi_U \in \text{Hom}_g(M_{\mu-\nu}, M_{\lambda-\rho} \otimes U)$ set

$$\Psi_{V,U} := (\Psi_V \otimes \text{id}_U)\Psi_U \in \text{Hom}_g(M_{\mu-\nu}, M_{\lambda-\rho} \otimes V \otimes U),$$

$$(6.14) \quad D_{U,V} := (D_{\Psi_V} \otimes \text{id}_V)D_{\Psi_U} \in \mathcal{D}(\mathcal{H}_\infty^\infty, \mathcal{H}_\nu^\infty \otimes U \otimes V).$$

These two composition rules are compatible with the isomorphism from Proposition 6.5.

**Proposition 6.7.** Let $P_{UV} : U \otimes V \rightarrow V \otimes U$ be the $G$-linear isomorphism flipping the two tensor components. Then

$$D_{\Psi_{V,U}} = (\text{id}_{\mathcal{H}_\infty^\infty} \otimes P_{UV})D_{U,V} \in \mathcal{D}(\mathcal{H}_\lambda^\infty, \mathcal{H}_\mu^\infty \otimes V \otimes U).$$

**Proof.** This follows by a straightforward but lengthy computation using Remark 6.6. \hfill \Box

Next we consider the parametrisation of the spaces of vertex operators. Write $m^*_\mu \in M^*_{\mu}$ for the linear functional satisfying $m^*_\mu(m_\mu) = 1$ and $m^*_\mu(v) = 0$ for $v \in \bigoplus_{\nu < \mu} M^*_{\mu}[v]$.

**Definition 6.8.** Let $U$ be a finite dimensional $\mathfrak{g}$-module, $\lambda, \mu \in \mathfrak{h}^*$, and $\Psi \in \text{Hom}_g(M_{\lambda}, M_{\mu} \otimes U)$. Then

$$\langle \Psi \rangle := (m^*_\mu \otimes \text{id}_U)\Psi(m_{\lambda}) \in U[\lambda - \mu]$$

is called the expectation value of the vertex operator $\Psi$. 

The expectation value of the associated differential vertex operators read as follows.

**Lemma 6.9.** For $\Psi \in \text{Hom}_g(M_{-\mu - \rho}, M_{-\lambda - \rho} \otimes U)$ we have

$$(D_{\Psi} \mathbb{I}_\lambda)(1) = \langle \Psi \rangle$$

in $U[\lambda - \mu]$, where $\mathbb{I}_\lambda \in \mathcal{H}^\infty_\lambda$ is the function

$$\mathbb{I}_\lambda(kan) := a^{-\lambda - \rho} \quad (k \in K, a \in A, n \in N).$$

**Proof.** Using the notations from Remark 6.6, we have

$$\langle \Psi \rangle = \sum_i \epsilon(Y_i) u_i$$

with $\epsilon$ the counit of $U(\mathfrak{h})$. On the other hand,

$$(D_{\Psi} \mathbb{I}_\lambda)(1) = \sum_i (L_i \mathbb{I}_\lambda)(1) u_i = \sum_i (r_*(Y_i) \mathbb{I}_\lambda)(1) u_i = \sum_i \epsilon(Y_i) u_i,$$

hence the result. $\Box$

By [12, Lem. 3.3] we have the following result.

**Lemma 6.10.** Let $U$ be a finite dimensional $\mathfrak{g}$-module, $\lambda \in \mathfrak{h}^*$ and $\mu \in \mathfrak{h}_{\text{irr}}^*$. The expectation value map $\langle \cdot \rangle$ defines a linear isomorphism

$$\langle \cdot \rangle : \text{Hom}_g(M_\lambda, M_\mu \otimes U) \xrightarrow{\sim} U[\lambda - \mu].$$

The weights of a finite dimensional $\mathfrak{g}$-module $U$ lie in the integral weight lattice

$$P := \{ \mu \in \mathfrak{h}^* \mid (\mu, \alpha^\vee) \in \mathbb{Z} \quad \forall \alpha \in R \}.$$

Hence for $\mu \in \mathfrak{h}_{\text{irr}}^*$, the space $\text{Hom}_g(M_\lambda, M_\mu \otimes U)$ of vertex operators is trivial unless $\lambda \in \mu + P$.

At a later stage (see Section 6.5), we want to restrict to highest weights $\lambda_0 \in \mathfrak{h}_{\text{irr}}^*$ such that for any vertex operator $\Psi \in \text{Hom}_g(M_{\lambda_0}, M_{\lambda_0} \otimes U)$, given as a product of vertex operators $\Psi_i \in \text{Hom}_g(M_{\lambda_i}, M_{\lambda_i-1} \otimes U_i)$ ($i = 1, \ldots, N$), has the property that $\lambda_{i-1} \in \mathfrak{h}_{\text{irr}}^*$ for $i = 1, \ldots, N$ (i.e., all vertex operators are determined by their expectation values). In that case we will restrict to highest weights from the dense open subset

$$\mathfrak{h}_{\text{reg}}^* := \{ \nu \in \mathfrak{h}^* \mid (\nu, \alpha^\vee) \notin \mathbb{Z} \quad \forall \alpha \in R \}$$

of $\mathfrak{h}$. The (differential) vertex operators are then denoted as follows.

**Definition 6.11.** Let $\lambda \in \mathfrak{h}_{\text{reg}}^*$.

a. If $U$ is a finite dimensional $\mathfrak{g}$-module and $u \in U[\lambda - \mu]$ is a weight vector of weight $\lambda - \mu$, then we write $\Psi^u_\lambda \in \text{Hom}_g(M_\lambda, M_\mu \otimes U)$ for the unique vertex operator with expectation value $\langle \Psi^u_\lambda \rangle = u$.

b. If $U$ is a finite dimensional $G$-representation and $u \in U[\lambda - \mu]$ is a weight vector of weight $\lambda - \mu$, then we write $D^u_\lambda \in \mathbb{D}(\mathcal{H}^\infty_\lambda, \mathcal{H}^\infty_\mu \otimes U)$ for the unique differential vertex operator with $(D^u_\lambda \mathbb{I}_\lambda)(1) = u$.

The expectation value of products of vertex operators gives rise to the fusion operator. We recall its definition in Subsection 6.5, where we also discuss boundary versions of fusion operators.
6.3. N-point spherical functions and asymptotic boundary KZB equations. Fix finite dimensional $G$-representations $U_1, \ldots, U_N$ with representation maps $\tau_{U_1}, \ldots, \tau_{U_N}$, and differential vertex operators $D_i \in \mathcal{D}(H^\infty_\Lambda, H^\infty_{\Lambda_i} \otimes U_i)$ for $i = 1, \ldots, N$. Write $\underline{\Lambda} = (\lambda_0, \lambda_1, \ldots, \lambda_N)$ and $U := U_1 \otimes \cdots \otimes U_N$. Write $D \in \mathcal{D}(H^\infty_\Lambda, H^\infty_{\Lambda_0} \otimes U)$ for the product of the $N$ differential vertex operators $D_i$ ($1 \leq i \leq N$),

$$D = (D_1 \otimes \text{id}_{U_2} \otimes \cdots \otimes U_N) \cdots (D_{N-1} \otimes \text{id}_{U_N}) D_N,$$

which we call a differential vertex operator of weight $\underline{\Lambda}$.

For $i = 1, \ldots, N$, let $\sigma_i$ be the representation map of the tensor product $K$-representation $V_i \otimes U$. We consider $(V_i \otimes U) \otimes V^* \simeq \text{Hom}(V_i, V_i \otimes U)$ as $K \times K$-representation, with representation map $\sigma := \sigma_i \otimes \sigma_r$. Note that if $\phi_\ell \in \text{Hom}_K(H_{\lambda_\ell}, V_\ell)$ then

$$\phi_\ell \otimes \text{id}_U D \in \text{Hom}_K(H_{\lambda_N}, V_\ell \otimes U)$$

by [12].

**Definition 6.12.** Let $\phi_\ell \in \text{Hom}_K(H_{\lambda_\ell}, V_\ell)$, $\phi_r \in \text{Hom}_K(V_r, H_{\lambda_r})$ and $D$ a differential vertex operator of weight $\underline{\Lambda}$. We call the the smooth $\sigma^{(N)}$-spherical function

$$f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}}(g) := (\phi_\ell \otimes \text{id}_U) D (\pi_{\lambda_N}(g) \phi_r) \quad (g \in G)$$

an $N$-point $\sigma^{(N)}$-spherical function associated with the $N + 1$-tuple of principal series representations $\underline{\Lambda} := (\lambda_0, \ldots, \lambda_N)$.

To keep the notations manageable we write from now on the action of $U(\mathfrak{g})$ on $H^\infty_\Lambda$ without specifying the representation map if no confusion can arise. For instance, for $x \in U(\mathfrak{g})$, $g \in G$ and $v \in H^\infty_\Lambda$, we write $g x v \in H^\infty_\Lambda$ for the smooth vector $\pi_{\lambda_N}(g)((x)_{H^\infty_\Lambda} v)$, and the $N$-point spherical function will be written as

$$f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}}(g) := (\phi_\ell \otimes \text{id}_U) D (g \phi_r) \quad (g \in G).$$

In Subsection 6.4 we define formal $N$-point spherical functions, which are asymptotic $N$-point correlation functions for boundary Wess-Zumino-Witten conformal field theory on the cylinder when the positions escape to infinity. The $N$-point spherical functions in Definition 6.12 are their analogues in the context of principal series.

By Proposition 4.1, the $N$-point spherical function $f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}}$ admits the (Eisenstein) integral representation

$$f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}}(g) = \int_K dx \xi_{-\lambda_N - \rho}(a(g^{-1} x)) \left( \sigma_\ell(x) \otimes \tau_{U_1}(x) \otimes \cdots \right. \left. \cdots \otimes \tau_{U_N}(x) \otimes \sigma_r^*(k(g^{-1} x)) \right) T^{(\phi_\ell \otimes \text{id}_U) D, \phi_r}_{\lambda_N}$$

with the vector $T^{(\phi_\ell \otimes \text{id}_U) D, \phi_r}_{\lambda_N} \in V_\ell \otimes U \otimes V^*_r$ given by

$$T^{(\phi_\ell \otimes \text{id}_U) D, \phi_r}_{\lambda_N} = \iota_{\lambda_N, V_\ell \otimes U}((\phi_\ell \otimes \text{id}_U) D) \otimes J_{\lambda_N, V_r}(\phi_r).$$

Theorem 6.3 gives the family of differential equations

$$\Pi^{(N)}(z)(f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}} |_{A_{\text{reg}}}) = \zeta_{\lambda_N - \rho}(z) f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}} |_{A_{\text{reg}}}, \quad z \in Z(\mathfrak{g})$$

for the restriction of $f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}}$ to $A_{\text{reg}}$. We will now show that $f^{\phi_\ell, D, \phi_r}_{\underline{\Lambda}} |_{A_{\text{reg}}}$ satisfies $N$ additional first order asymptotic boundary KZB type differential equations. Recall the factorisation $(r^+, -r^-(a), b(a))$ of $\Omega$ for $a \in A_{\text{reg}}$, with $r^\pm$ the folded $r$-matrices (6.1) and $b$ given by (6.3).
Proposition 6.13. The $N$-point $\sigma^{(N)}$-spherical function $f_{H, \lambda}^{\phi_\ell, D, \phi_r}$ satisfies

\[
\left(\frac{\lambda_i - 1}{2} - \frac{\lambda_i + 1}{2}\right) + \sum_{j=1}^{r} \left(x_j \partial_{x_j}\right) f_{H, \lambda}^{\phi_\ell, D, \phi_r} |_{A_{reg}} = 0
\]

(6.18)

\[
= \left(r_{V_i} U_i + b U_i + \sum_{j=1}^{N} r_{U_i} U_j + \tilde{r}_{i} V_i\right) f_{H, \lambda}^{\phi_\ell, D, \phi_r} |_{A_{reg}}
\]

for $i = 1, \ldots, N$, with right boundary term

(6.19)

\[
\tilde{r} := \sum_{a \in A} (\xi_a - \xi_{-a})^+ \in R \otimes g \otimes \mathfrak{t}
\]

satisfying $\tilde{r} := (A_{a-1} \otimes 1)r_{2a}^*(a)$ for $a \in A_{reg}$.

We derive the asymptotic boundary KZB type equations (6.18) in two different ways. The first proof uses Proposition 6.3 involving the folded versions of Felder’s dynamical $r$-matrix, the second proof uses Proposition 6.3a with a reflection argument. The second argument is of interest from the conformal field theoretic point of view, and provides some extra insights in the term $b$ (6.8) appearing in the asymptotic boundary KZB equations.

**Proof 1** (using the factorisation of $\Omega$ in terms of folded $r$-matrices).

Let $a \in A_{reg}$. By Corollary 6.2 applied to the factorisation $(r^+(a), -r^-(a), b(a))$ of $\Omega$, we have

\[
\frac{1}{2}(\zeta_{\lambda_i - \rho}(\Omega) - \zeta_{\lambda_i - \rho}(\Omega)) f_{H, \lambda}^{\phi_\ell, D, \phi_r}(a) = \left(\sum_{j=1}^{r} r_{V_i} U_i(a) + b U_i(a) + \sum_{j=1}^{N} r_{U_i} U_j(a)\right) f_{H, \lambda}^{\phi_\ell, D, \phi_r}(a)
\]

\[
+ \sum_{k} (\phi_\ell \otimes \text{id}) \left(\frac{\alpha_k^+}{H_{\alpha_k}^+} + (\beta_k^- U_k D(\alpha_\rho)\right)
\]

\[
- \sum_{k} (\phi_\ell \otimes \text{id}) \left(\frac{\alpha_k^-}{H_{\alpha_k}^-} + (\beta_k^- U_k D(\alpha_\rho)\right)
\]

where we have written $r^+(a) = \sum_k \alpha_k^+ \otimes \beta_k^+$. Now using $r^+(a) \in \mathfrak{t} \otimes g$ and

\[
(1 \otimes A_{a-1}) r^- (a) = \sum_{j=1}^{r} x_j \otimes x_j + \tilde{r}^+(a)
\]

with $\tilde{r}^+(a) \in \mathfrak{g} \otimes \mathfrak{t}$ given by (6.19), the asymptotic boundary KZB type equation (6.18) follows from the fact that $\phi_\ell$ and $\phi_r$ are $K$-intertwiners and $\zeta_{\lambda_i - \rho}(\Omega) - \zeta_{\lambda_i - \rho}(\Omega) = (\lambda_i - 1, \lambda_i - 1)$.

**Proof 2** (using a reflection argument).

Let $a \in A_{reg}$. Recall that the unfolded factorisation of $\Omega$ is $(r(a), r(a), d(a))$ with

\[
d(a) := -\frac{1}{2} \sum_{\alpha \in R} \left(1 + a^{-2\alpha}\right) f_{\alpha}.
\]

Then it follows from a direct computation that

(6.20)

\[
b(a) = d(a) + m(r^{d_1}(a)).
\]

Furthermore,

(6.21)

\[
- r^{d_1}(a) D - D * r^{d_1}(a) = (1 \otimes m(r^{d_1}(a))) D
\]

for a differential vertex operator $D$. This follows from the fact that $r^{d_1}(a)$ is a symmetric tensor in $g \otimes g$ and

\[
-(x \otimes x) D - D * (x \otimes x) = (1 \otimes x^2) D
\]
with $r(a) = \sum k \alpha_k \otimes \beta_k$. We now apply the identity

$$\left( \phi_x \otimes \text{id}_U \right)(r_{H_{\infty_0}}^{H}(a)) = r_{V_2}^{r_1}(a)\left( \phi_x \otimes \text{id}_U \right) - \left( \phi_x \otimes \text{id}_U \right) r_{H_{\infty_0}}^{H}(a)$$

in $\text{Hom}(H_{\infty_0} \otimes U, V_{\ell} \otimes U)$ to the left boundary term and the identity

$$\sum_{k}(\text{id}_{U})_{U_i}(\beta_k a \phi_r) = -\sum_{j=1}^{r}(x_j)_{U_i}(a x_j \phi_r)$$

$$+ \sum_{k}(\theta(\alpha_k))_{U_i}(\beta_k a \phi_r) + r_{U_i}^{r_1}(a)\text{D}(a \phi_r)$$

in $U \otimes V_{\ell}^{*}$ to the right boundary term. The latter equality follows from the easily verified identities

$$- (\text{id} \otimes \theta \text{Ad}_{a^{-1}})(r(a)) = - \sum_{j=1}^{r}(x_j \otimes x_j + (\text{id} \otimes \text{Ad}_{a^{-1}})(r_{d_1}^{d_1}(a)),$$

$$- (\text{Ad}_{a^{-1}} \otimes \text{id})(r_{d_2}^{d_2}(a)) = (\text{id} \otimes \text{Ad}_{a^{-1}})(r(a)) + (\text{id} \otimes \theta \text{Ad}_{a^{-1}})(r(a)).$$

We thus arrive at the formula

$$\left( \frac{\lambda_{i-1} \lambda_{i-1}}{2} - \frac{\lambda_i \lambda_i}{2} \right) + \sum_{j=1}^{r}(x_j)_{U_i}(a x_j \phi_r) =$$

$$= \left( r_{V_2}^{r_1}(a) + \sum_{j=1}^{d_1} r_{U_i}^{d_1}(a) + d_{U_i}(a) - \sum_{j=1}^{N} r_{U_i}^{d_1}(a) + r_{U_i}^{r_1}(a) \right) \phi_x r_{H_{\infty_0}}^{H}(a)$$

$$- \left( \phi_x \otimes \text{id}_U \right)(r_{H_{\infty_0}}^{H}(a)\text{D}(a \phi_r)) + \sum_{k}(\phi_x \otimes \text{id}_U)((\theta(\alpha_k))_{U_i}(\beta_k a \phi_r)).$$

Now pushing $r_{H_{\infty_0}}^{H}(a)$ through the differential vertex operators $D_j$ ($1 \leq j < i$) and pushing the action of $\beta_k$ through $D_j$ ($i < j \leq N$) using (6.9) and using the fact that $r_{d_1}^{d_1}(a)$ is a symmetric tensor in $\text{g} \otimes \text{g}$, the last line becomes

$$- \left( \phi_x \otimes \text{id}_U \right)(r_{H_{\infty_0}}^{H}(a)\text{D}(a \phi_r)) + \sum_{k}(\phi_x \otimes \text{id}_U)((\theta(\alpha_k))_{U_i}(\beta_k a \phi_r))$$

$$= \left( \sum_{j=1}^{d_1} r_{U_i}^{d_1}(a) + \sum_{j=1}^{N} r_{U_i}^{d_1}(a) \right) \phi_x r_{H_{\infty_0}}^{H}(a)$$

$$+ \left( \phi_x \otimes \text{id}_U \right)(D_{H_{\infty_0}}^{H_1} \cdots D_{H_{\infty_0}}^{H_N}(\tilde{D}_i \otimes \text{id}_{U_{i+1} \cdots \otimes U_N}) D_{H_{\infty_0}}^{H_{i+1} \cdots H_{\infty_0}}(a \phi_r))$$

with $D_{H_{\infty_0}}^{H_j} := D_j \otimes \text{id}_{U_{j+1} \cdots \otimes U_N}$ and

$$\tilde{D}_i := - r_{d_1}^{d_1}(a) D_i - D_i * r_{d_1}^{d_1}(a).$$
Remark 6.15. Note that \( r \) is placed.

The first-order differential operators

\[ D := \sum_{i=1}^{r} \partial_{x_i} \otimes x_i \]

in \( D_R \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \) are called the asymptotic boundary KZB operators. Here the subindices indicate which tensor factor of \( U_1 \) in \( U \) is placed. This implies that the first-order differential operators

\[ D := \sum_{i=1}^{r} \partial_{x_i} \otimes x_i \]

in \( D_R \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \) are called the asymptotic boundary KZB operators.

Furthermore, write

\[ E := \sum_{i=1}^{r} \partial_{x_i} \otimes x_i \in D R \otimes U(\mathfrak{g}). \]

The asymptotic boundary KZB operators are now defined as follows.

**Definition 6.14.** The first-order differential operators

\[ D_i := E_i - \sum_{j=1}^{i-1} \partial_{x_{i'}} \otimes x_{i'} - \sum_{j=i+1}^{N} r_{ij}^0 \]

in \( D_R \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \) are called the asymptotic boundary KZB operators.

Here the subindices indicate which tensor factor of \( U(\mathfrak{g}) \otimes U(\mathfrak{g}) \) the \( U(\mathfrak{g}) \)-components of \( E \) and \( r \) are placed.

**Remark 6.15.** Note that \( \kappa_{\text{core}} \) is the part of \( \kappa \) that survives when the \( U(\mathfrak{g}) \)-components act according to the trivial representation of \( \mathfrak{g} \). Note furthermore that

\[ D_i \in D_R \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \]

Consider the family \( H_z^{(N)} \in D_R \otimes U(\mathfrak{g}) \otimes U(\mathfrak{g}) \) of commuting differential operators

\[ H_z^{(N)} := (\Delta^{(N)} \otimes \text{id}_{U(\mathfrak{g})}) H_z \]

with \( \Delta^{(N)} : U(\mathfrak{g}) \to U(\mathfrak{g}) \otimes U(\mathfrak{g}) \) the \( N \)th iterate comultiplication map of \( U(\mathfrak{g}) \) and \( H_z \) given by (5.11). Then \( H^{(N)} := -\frac{1}{2}(H^{(N)} + \|\rho\|^2) \) is the double spin quantum Calogero-Moser Hamiltonian

\[ V^{(N)} := -\frac{1}{2} \sum_{\alpha \in R} \frac{1}{(\xi_{\alpha} - \xi_{-\alpha})^2} \left( \|\alpha\|^2 + \prod_{\alpha \in \{\pm 1\}} (\Delta^{(N)}(\alpha_{\alpha}) \otimes 1 + \xi_{\alpha}(1 \otimes \alpha_{\alpha} + \alpha_{\alpha} \otimes 1)) \right) \]

by Proposition 3.10.
**Theorem 6.16.** Let \( \lambda \in \mathfrak{h}^* \), \( \varphi \in \text{Hom}_K(H_{\lambda}, V) \), \( \varphi_r \in \text{Hom}_K(V_r, H_{\lambda_r}) \) and \( D \) a differential vertex operator of weight \( \lambda = (\lambda_0, \ldots, \lambda_N) \). Consider the smooth \( V_t \otimes U \otimes V^* \)-valued function

\[
\Gamma_{\lambda,D,\varphi} := \delta f_{H_{\lambda,D,\varphi}}|_{A_+}
\]

on \( A_+ \), called the normalised \( N \)-point \( \sigma^{(N)} \)-spherical function of weight \( \lambda \), which admits the explicit integral representation

\[
\Gamma_{\lambda,D,\varphi}(a') = \delta(a') \int_K dx \xi_{-\lambda_0-\rho}(a(a'-1)x)) \sigma(\xi) \otimes \tau_\xi(x) \otimes \cdots \otimes \tau_{U_N}(x) \otimes \sigma^r(k(a'-1)x)) T_{\lambda,N}^{(\varphi \otimes \text{id}_U)}D,\varphi_r.
\]

It satisfies the systems of differential equations

\[
\mathcal{D}_i(\Gamma_{\lambda,D,\varphi}) = \left( \frac{\lambda_i - \lambda_i}{2} - \frac{\lambda_i - \lambda_{i-1}}{2} \right) \Gamma_{\lambda,D,\varphi} \quad (i = 1, \ldots, N),
\]

\[
\mathcal{H}^{(N)}(\Gamma_{\lambda,D,\varphi}) = \frac{\lambda_N - \lambda_N}{2} \Gamma_{\lambda,D,\varphi}
\]

on \( A_+ \). Furthermore, \( \mathcal{H}^{(N)}(\Gamma_{\lambda,D,\varphi}) = \zeta_{N-\rho}(z) \Gamma_{\lambda,D,\varphi} \) on \( A_+ \) for \( z \in Z(\mathfrak{g}) \).

**Proof.** The integral representation follows from (6.16). The second line of (6.27) follows from 6.17. By Proposition 6.13 we have

\[
\tilde{\mathcal{D}}_i(\Gamma_{\lambda,D,\varphi}) = \left( \frac{\lambda_i - \lambda_i}{2} - \frac{\lambda_i - \lambda_{i-1}}{2} \right) \Gamma_{\lambda,D,\varphi} \quad (i = 1, \ldots, N)
\]

with \( \tilde{\mathcal{D}}_i = E_i - \sum_{j=1}^{i-1} r^+_j - \tilde{k}_i = \sum_{j=i+1}^{N} r^+ - \tilde{k}_i \) and

\[
\tilde{k} := r^+ \otimes 1 + 1 \otimes b \otimes 1 + 1 \otimes \bar{r}^+ = k - \frac{1}{2} \sum_{\alpha \in R^+} \frac{1 + \xi - 2\alpha}{1 - \xi - 2\alpha} t_\alpha.
\]

To prove the first set of equations of (6.27) it thus suffices to show that

\[
\delta E(\delta^{-1}) = -\frac{1}{2} \sum_{\alpha \in R^+} \frac{1 + \xi - 2\alpha}{1 - \xi - 2\alpha} t_\alpha
\]

in \( \mathcal{R} \otimes \mathfrak{h} \). This follows from the following computation,

\[
\delta E(\delta^{-1}) = -\sum_{j=1}^{\tilde{k}} \left( \rho(x_j) x_j - \frac{\xi - 2\alpha x_j x_j}{1 - \xi - 2\alpha} \right)
\]

\[
= -t_\rho - \sum_{\alpha \in R^+} \frac{\xi - 2\alpha t_\alpha}{1 - \xi - 2\alpha} = -\frac{1}{2} \sum_{\alpha \in R^+} \frac{1 + \xi - 2\alpha}{1 - \xi - 2\alpha} t_\alpha.
\]

\( \square \)

### 6.4. Formal \( N \)-point spherical functions

In this subsection we introduce the analogue of \( N \)-point spherical functions in the context of Verma modules. They give rise to asymptotically free solutions of the asymptotic boundary KZB operators.

Fix finite dimensional \( \mathfrak{g} \)-representations \( \tau_i : \mathfrak{g} \rightarrow \mathfrak{gl}(U_i) \) \((1 \leq i \leq N)\). Let \( \lambda = (\lambda_0, \ldots, \lambda_N) \) with \( \lambda_i \in \mathfrak{h}^* \) and choose vertex operators \( \Psi_i \in \text{Hom}_\mathfrak{g}(M_{\lambda_i}, M_{\lambda_{i-1}} \otimes U_i) \) for \( i = 1, \ldots, N \). Set

\[
\Psi := (\Psi_1 \otimes \text{id}_{U_2} \otimes \cdots \otimes U_N) \cdots (\Psi_{N-1} \otimes \text{id}_{U_N}) \Psi_N,
\]

which is a \( \mathfrak{g} \)-intertwiner \( M_{\lambda_N} \rightarrow M_{\lambda_0} \otimes \mathfrak{g} \). Let \((\sigma_t, V_t), (\sigma_r, V_r)\) be two finite dimensional \( \mathfrak{f} \)-modules. Write \( \sigma_t^{(N)} \) for the representation map of the \( \mathfrak{f} \)-module \( V_t \otimes U \), and \( \sigma_r^{(N)} = \sigma_r^{(N)} \otimes \sigma_r^* \) for the representation map of the associated \( \mathfrak{f} \oplus \mathfrak{f} \)-module \( (V_t \otimes U) \otimes V_r^* \).
Definition 6.17. For \( \phi \in \text{Hom}(M_{\lambda_0}, V_i) \), \( \phi_r \in \text{Hom}(V_r, M_{\lambda_N}) \) and vertex operator \( \Psi \) given by (6.30). Then \( (\phi \otimes \text{id}_U)\Psi \in \text{Hom}(M_{\lambda_0}, V_i \otimes U) \) and the associated formal elementary \( \sigma^{(N)} \)-spherical function

\[
F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} := F_{M_{\lambda_0}}^{(\phi \otimes \text{id}_U)\Psi, \phi_r}
\]

is called a formal \( N \)-point \( \sigma^{(N)} \)-spherical function associated with the \( N + 1 \)-tuple of Verma modules \( (M_{\lambda_0}, \ldots, M_{\lambda_N}) \).

By Theorem 5.8 the formal \( N \)-point \( \sigma^{(N)} \)-spherical function \( F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} \) is analytic on \( A_+ \) for \( \lambda_N \in \mathfrak{h}_{HC}^* \).

Recall the normalisation factor \( \delta \) defined by (3.10) (which we will view as formal power series in \( \mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]][\lambda] \)).

Definition 6.18. Let \( \Psi \in \text{Hom}_g(M_{\lambda_N - \rho}, M_{\lambda_{i-\rho}} \otimes U_i) \) \((1 \leq i \leq N)\) and write

\[
\Psi \in \text{Hom}_g(M_{\lambda_N - \rho}, M_{\lambda_0 - \rho} \otimes U)
\]

for the resulting vertex operator (6.30). We call

\[
F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} := \delta F_{M_{\lambda_0 - \rho}}^{\phi_r, \Psi, \phi_r} \in (V_r \otimes U \otimes V_i^*)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]][\lambda_N]
\]

a normalised \( N \)-point \( \sigma^{(N)} \)-spherical function of weight \( \lambda := (\lambda_0 - \rho, \lambda_1 - \rho, \ldots, \lambda_N - \rho) \).

For weight \( \lambda \) with \( \lambda_N \in \mathfrak{h}_{HC}^* + \rho \) the normalised formal \( N \)-point \( \sigma^{(N)} \)-spherical function \( F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} \) is an \( V_r \otimes U \otimes V_i^* \)-valued analytic function on \( A_+ \). In terms of the normalised formal elementary \( \sigma^{(N)} \)-spherical functions, we have

\[
F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} = F_{M_{\lambda_0}}^{(\phi \otimes \text{id}_U)\Psi, \phi_r}
\]

and hence

\[
H^{(N)}_{\lambda_0} (F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r}) = -\left(\frac{\lambda_N, \lambda_N}{2}\right) F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r},
\]

\[
H^{(N)}_{\lambda_0} (F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r}) = \zeta_{\lambda_N - \rho}(z) F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r}, \quad z \in \mathbb{Z}(\mathfrak{g})
\]

by Theorem 5.10. We now show by a suitable adjustment of the algebraic arguments from Subsection 6.1 that the normalised formal \( N \)-point \( \sigma^{(N)} \)-spherical functions are eigenfunctions of the asymptotic boundary KZB operators.

Theorem 6.19. Let \( \phi \in \text{Hom}(M_{\lambda_0}, V_i) \), \( \phi_r \in \text{Hom}(V_r, M_{\lambda_N}) \) and let \( \Psi \) be a product of \( N \) vertex operators as given in Definition 6.18. The normalised formal \( N \)-point \( \sigma^{(N)} \)-spherical function \( F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} \) satisfies the system of differential equations

\[
D_i (F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r}) = \left(\frac{\lambda_i, \lambda_i}{2} - \frac{\lambda_{i-1}, \lambda_{i-1}}{2}\right) F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} \quad (i = 1, \ldots, N)
\]

in \( (V_r \otimes U \otimes V_i^*)[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]][\lambda_N] \). For \( \lambda_N \in \mathfrak{h}_{HC}^* + \rho \) the differential equations (6.34) are valid as analytic \( V_r \otimes U \otimes V_i^* \)-valued analytic functions on \( A_+ \).

Proof. As in the proof of Theorem 6.10 the differential equations (6.34) are equivalent to

\[
\bar{D}_i (F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r}) = \frac{1}{2} (\zeta_{\lambda_i} - \zeta_{\lambda_{i-1}}) F_{M_{\lambda_0}}^{\phi_r, \Psi, \phi_r} \quad (i = 1, \ldots, N)
\]
with \( \tilde{D}_i = E_i - \sum_{j=1}^{i-1} r_{ji}^+ - \tilde{\kappa}_i - \sum_{j=i+1}^N r_{ij}^- \) and

\[
\tilde{\kappa} := \kappa - \frac{1}{2} \sum_{\alpha \in R} \left( \frac{1 + \xi_{-2\alpha}}{1 - \xi_{-2\alpha}} \right) t_{\alpha} = r^+ \otimes 1 + 1 \otimes b \otimes 1 + 1 \otimes r^+
\]

(here \( b \) is given by (6.8)).

Write \( \Lambda = \{ \mu \in \mathfrak{h}^* \mid \mu \leq \lambda_N \} \) and \( \Lambda_m := \{ \mu \in \Lambda \mid (\lambda_N - \mu, \rho') \leq m \} \) (\( m \in \mathbb{Z}_{\geq 0} \)). Consider the \( V_r \otimes U \otimes V_r^* \)-valued quasi-polynomial

\[
F_{\phi, \psi, m}^{\phi, \psi, m} := \sum_{\mu \in \Lambda_m} ((\phi \otimes id_U)\psi \phi)\xi_{\mu}
\]

for \( m \in \mathbb{Z}_{\geq 0} \). Fix \( a \in A_+ \). Then we have

\[
(\zeta_{\lambda_i - 1}(\Omega) - \zeta_{\lambda_i}(\Omega)) F_{\phi, \psi, m}^{\phi, \psi, m}(a) = \sum_{\mu \in \Lambda_m} ((\phi \otimes id_U)(\psi_{\lambda_i - 1} \tilde{\kappa}_i \psi_{\lambda_i + 1} \psi \psi_{\lambda_N} \phi)\mu) a^\mu.
\]

This being valid for all \( a \in A_+ \), hence we get

\[
(\zeta_{\lambda_i - 1}(\Omega) - \zeta_{\lambda_i}(\Omega)) + E_{U_i} - \sum_{j=1}^{i-1} r_{U_j U_i}^+ + r_{U_j U_i}^- + b_{U_i} - \sum_{j=i+1}^N r_{U_j U_i}^- \]

\[
= - \sum_{\mu \in \Lambda_m} \sum_{\alpha \in R} (e_\alpha + e_{-\alpha}) U_i (\phi \otimes id_U)(\psi(\alpha) \psi_{\lambda_N} \phi)\mu \frac{\xi_{\mu}}{(1 - \xi_{-2\alpha})},
\]

viewed as identity in \( (V_r \otimes U \otimes V_r^*)[[\xi_{-2\alpha}, \ldots, \xi_{-2\alpha}]] \langle \lambda_N \rangle \langle 1 - \xi_{-2\alpha} \rangle \). We claim that the identity (6.36) is also valid when the summation over \( \Lambda_m \) is replaced by summation over \( \Lambda \):

\[
(\zeta_{\lambda_i - 1}(\Omega) - \zeta_{\lambda_i}(\Omega)) + E_{U_i} - \sum_{j=1}^{i-1} r_{U_j U_i}^+ + r_{U_j U_i}^- + b_{U_i} - \sum_{j=i+1}^N r_{U_j U_i}^- \]

\[
= - \sum_{\mu \in \Lambda} \sum_{\alpha \in R} (e_\alpha + e_{-\alpha}) U_i (\phi \otimes id_U)(\psi(\alpha) \psi_{\lambda_N} \phi)\mu \frac{\xi_{\mu}}{(1 - \xi_{-2\alpha})},
\]

in \( (V_r \otimes U \otimes V_r^*)[[\xi_{-2\alpha}, \ldots, \xi_{-2\alpha}]] \langle \lambda_N \rangle \). Take \( \eta \in \Lambda \) and let \( m \in \mathbb{N} \) such that \( (\lambda_N - \eta, \rho') \leq m \). Then the \( \xi_{\eta} \)-coefficient of the left hand side of (6.37) is the same as the \( \xi_{\eta} \)-coefficient of the left hand side of (6.36) since the coefficients of \( r^\pm \) and \( \tilde{\kappa} \) are in \( \mathbb{C}[[\xi_{-2\alpha}, \ldots, \xi_{-2\alpha}]] \). Exactly the same argument applies to the \( \xi_{\mu} \)-coefficients of the right hand sides of (6.37) and (6.36), from which
Lemma 6.21. Let \( \phi \in \text{Hom}_g(6.38) \) be a universal fusion operator, in the sense that its action on all finite dimensional \( \text{V} \)-modules gives rise to the fusion operator:

\[
\text{Definition 6.11.} \quad \text{The fusion operator } J_U(\lambda) \text{ is the } h \text{-linear automorphism of } U \text{ defined by}
\]

\[
u \in U_1 \otimes \cdots \otimes U_N \mapsto (m_{\lambda_0} \otimes \text{id}_U)(\Psi^{\nu_1}_{\lambda_1} \otimes \text{id}_U^{\nu_2} \cdots \otimes U_N) \cdots (\Psi^{\nu_{N-1}}_{\lambda_{N-1}} \otimes \text{id}_U^{\nu_N})(m_\lambda)
\]

for \( u_i \in U_{\mu_i} \) (\( \mu_i \in P \)), where \( \lambda_i := \lambda - \mu_{i+1} \cdots - \mu_N \) for \( i = 0, \ldots, N - 1 \) and \( \lambda_N = \lambda \).

We suppress the dependence on \( U \) and denote \( J_U(\lambda) \) by \( J(\lambda) \) if no confusion is possible (in fact, a universal fusion operator exists, in the sense that its action on \( U \) reproduces \( J_U(\lambda) \) for all finite dimensional \( g \)-modules, see, e.g., [12] Prop. 3.19 and references therein).

Lemma 6.10 shows that for \( u := u_1 \otimes \cdots \otimes u_N \) with \( u_i \in U_{\mu_i} \) and \( \lambda \in h_{\text{reg}}^\ast \), we have

\[
\Psi_{\lambda}^{J(\mu)u} = (\Psi^{\nu_1}_{\lambda_1} \otimes \text{id}_U^{\nu_2} \cdots \otimes U_N) \cdots (\Psi^{\nu_{N-1}}_{\lambda_{N-1}} \otimes \text{id}_U^{\nu_N})(m_\lambda)
\]

in \( \text{Hom}_g(M_\lambda, M_\lambda \otimes U) \).

Fix from now on a finite dimensional \( \ell \)-module \( V_\ell \). Recall the parametrisation of \( \ell \)-intertwiners \( \phi_{\ell, \lambda} \in \text{Hom}_g(M_\lambda, V_\ell) \) by their expectation value \( v \in V_\ell \) as introduced in Definition 6.5.5a.

**Lemma 6.21.** Let \( \lambda \in h_{\text{reg}}^\ast \). The linear operator \( J_{\ell, U}(\lambda) \in \text{End}(V_\ell \otimes U) \), defined by

\[
J_{\ell, U}(\lambda)(v \otimes u) := (\phi_{\ell, \lambda-\mu} \otimes \text{id}_U)\Psi_{\lambda}^{J(\mu)u}(m_\lambda)
\]

for \( v \in V_\ell \) and \( u \in U_{\mu} \) (\( \mu \in P \)), is a linear automorphism.

**Proof.** For \( v \in V_\ell \) and \( u \in U_{\mu} \), we have

\[
\Psi_{\lambda}^{J(\mu)u}(m_\lambda) \in m_{\lambda-\mu} \otimes J(\lambda)u + \bigoplus_{\nu>\mu} M_{\lambda-\mu} \otimes U_{\nu}.
\]
and consequently we get
\[ J_{\ell, U}(\lambda)(v \otimes u) \in v \otimes J(\lambda)u + \bigoplus_{\nu > \mu} V_\ell \otimes U[\nu]. \]

Choose an ordered tensor product basis of \( V_\ell \otimes U \) in which the \( U \)-components consist of weight vectors. Order the tensor product basis in such a way that is compatible with the dominance order on the weights of the \( U \)-components of the basis elements. With respect to such a basis, \( J_{\ell, U}(\lambda)(id_{V_\ell} \otimes J(\lambda)^{-1}) \) is represented by a triangular operator with ones on the diagonal, hence it is invertible.\( \square \)

We call \( J_{\ell, U}(\lambda) \) the (left) boundary fusion operator on \( V_{\ell} \otimes U \) (we denote \( J_{\ell, U}(\lambda) \) by \( J_{\ell}(\lambda) \) if no confusion is possible). A right version \( J_{\ell}(\lambda) \) of the left boundary fusion operator \( J_{\ell}(\lambda) \) can be constructed in an analogous manner. We leave the straightforward details to the reader.

Let \( \lambda \in \mathfrak{h}_{\text{reg}}^\ast \). By Proposition 5.4 and Lemma 6.21, the map
\[ V_{\ell} \otimes U \to \text{Hom}_L(M_{\lambda}, V_{\ell} \otimes U), \quad v \otimes u \mapsto \phi_{\ell, \lambda}^{J(\lambda)(v \otimes u)} \]
is a linear isomorphism. The \( \mathfrak{f} \)-intertwiner \( \phi_{\ell, \lambda}^{J(\lambda)(v \otimes u)} \) admits the following alternative description.

**Corollary 6.22.** Let \( \lambda \in \mathfrak{h}_{\text{reg}}^\ast, \mu \in P \) and \( v \in V_{\ell} \). For \( u \in U[\mu] \) we have
\[ \phi_{\ell, \lambda}^{J(\lambda)(v \otimes u)} = (\phi_{\ell, \lambda-\mu}^{J(\lambda)} \otimes id_U) \Psi_{\lambda}^{J(\lambda)u}. \]

For \( u = u_1 \otimes \cdots \otimes u_N \) with \( u_i \in U_i[\mu_i] \) \((1 \leq i \leq N)\) we furthermore have
\[ \phi_{\ell, \lambda}^{J(\lambda)(v \otimes u)} = (\phi_{\ell, \lambda_0}^{J(\lambda_0)} \otimes id_U)(\Psi_{\lambda_1}^{u_1} \otimes id_{U_2} \otimes \cdots \otimes id_{U_N}) \cdots (\Psi_{\lambda_{N-1}}^{u_{N-1}} \otimes id_{U_N}) \Psi_{\lambda_N}^{u_N}, \]
with \( \lambda_i := \lambda - \mu + 1 \cdots - \mu N \) \((i = 0, \ldots, N - 1)\), and \( \lambda_N := \lambda \).

**Proof.** The result follows immediately from Proposition 5.4, Lemma 6.21 and (6.38). \( \square \)

**Definition 6.23.** Let \( V_{\ell}, V_f \) be finite dimensional \( \mathfrak{f} \)-modules. Let \( \lambda = (\lambda_0, \ldots, \lambda_N) \) with \( \lambda_N \in \mathfrak{h}_{\text{reg}}^\ast \) and with \( \mu_i := \lambda_i - \lambda_{i-1} \in P \) for \( i = 1, \ldots, N \). Let \( v \in V_{\ell}, f \in V_f^* \) and \( u = u_1 \otimes \cdots \otimes u_N \) with \( u_i \in U_i[\mu_i] \). We write
\[ F_{\lambda}^{u, v, f} := F_{\lambda, \mu}^{J(\lambda)(v \otimes u) \otimes f} \]
for the formal \( N \)-point spherical function with leading coefficient \( J_{\ell}(\lambda_N)(v \otimes u) \otimes f \), and
\[ F_{\lambda}^{\mu, u, f} := \delta F_{\lambda}^{u, v, f} = F_{\lambda}^{J(\lambda-\mu)(v \otimes u) \otimes f} \]
for its normalised version.

Note that
\[ F_{\lambda}^{u, v, f} = \phi_{\ell, \lambda_0}^{J(\lambda_0)u} \phi_{\ell, \lambda_N}^{J(\lambda_N)v} \]
by Lemma 6.22. Written out as formal power series we thus have the following three expressions for \( F_{\lambda}^{u, v, f} \),
\[ F_{\lambda}^{u, v, f} = \sum_{\mu \leq \lambda_N} \phi_{\ell, \lambda_N}^{J(\lambda_N)u}(\text{proj}_{M_{\lambda_N}}^{\mu} \phi_{\ell, \lambda_N}^{J(\lambda_N)v}) \xi_\mu \]
\[ = \sum_{\mu \leq \lambda_N} (\phi_{\ell, \lambda_0}^{J(\lambda_0)u} \otimes id_U) \Psi_{\lambda_N}^{J(\lambda_N)u}(\text{proj}_{M_{\lambda_N}}^{\mu} \phi_{\ell, \lambda_N}^{J(\lambda_N)v}) \xi_\mu \]
\[ = \sum_{\mu \leq \lambda_N} (\phi_{\ell, \lambda_0}^{J(\lambda_0)u} \otimes id_U)(\Psi_{\lambda_1}^{u_1} \otimes id_{U_2} \otimes \cdots \otimes id_{U_N}) \cdots (\Psi_{\lambda_{N-1}}^{u_{N-1}} \otimes id_{U_N}) \Psi_{\lambda_N}^{u_N}(\text{proj}_{M_{\lambda_N}}^{\mu} \phi_{\ell, \lambda_N}^{J(\lambda_N)v}) \xi_\mu. \]

The main results of the previous subsection for \( \lambda \in \mathfrak{h}_{\text{reg}}^\ast \) can now be reworded as follows.
Lemma 6.25. Let $\lambda \in \mathfrak{h}^*_\text{reg}$. Let $\lambda = (\lambda_0, \ldots, \lambda_N)$ with $\lambda_N \in \mathfrak{h}^*_\text{reg}$ and with $\mu_i := \lambda_i - \lambda_{i-1} \in P$ for $i = 1, \ldots, N$. Let $v \in V_{\ell_1}, f \in V_{\ell^*}$ and $u = u_1 \otimes \cdots \otimes u_N$ with $u_i \in U_i[\mu_i]$ $(i = 1, \ldots, N)$. Then we have for $i = 1, \ldots, N$,

$$D_i(\mathbf{F}^{v,u,f}_\lambda) = \left(\frac{\lambda_i}{2} - \frac{\lambda_{i-1}}{2}\right)\mathbf{F}^{v,u,f}_\lambda,$$

and 

$$H^{(N)}(\mathbf{F}^{v,u,f}_\lambda) = -\frac{\lambda_N}{2}\mathbf{F}^{v,u,f}_\lambda,$$

for certain vectors $v_1, \ldots, v_r$ and $f_1, \ldots, f_r$ respectively. Take the basis elements $b_j$ of the form $b_j = u_1^{(j)} \otimes \cdots \otimes u_N^{(j)}$ with $u_k^{(j)}$ a weight vector in $U_k$ of weight $\mu_k(b_j)$ $(1 \leq k \leq N)$. For $q \in \sum_{k=1}^N \mathbb{Z}_{\geq 0} \alpha_k$ we have

$$\Delta(\mathbf{b}_j) - q := (\lambda - q - \mu_1(b_j) - \cdots - \mu_N(b_j), \ldots, \lambda - q - \mu_N(b_j), \lambda - q).$$

We then have

$$\mathbf{F}^{v_1, b_j, f_s}_{\Delta(\mathbf{b}_j) - q} = (J_s(\lambda - q)(v_1 \otimes b_j) \otimes f_s)\xi_{\lambda - q} + \sum_{\mu < \lambda - q} e_{i,j,s,q}(\mu)\xi_{\mu}$$

for certain vectors $e_{i,j,s,q}(\mu) \in V_{\ell_1} \otimes \mathcal{U} \otimes V_{\ell^*}$. Lemma 6.24 then implies that

$$\{\mathbf{F}^{v_1, b_j, f_s}_{\Delta(\mathbf{b}_j) - q} \mid (i,j,s) \in I \times J \times S, q \in \sum_{k=1}^r \mathbb{Z}_{\geq 0} \alpha_k\}$$

is a topological linear basis of $(V_{\ell_1} \otimes \mathcal{U} \otimes V_{\ell^*})[[\xi_{-\mu_1}, \ldots, \xi_{-\mu_N}]]$. Finally Corollary 6.24 shows that the basis elements $\mathbf{F}^{v_1, b_j, f_s}_{\Delta(\mathbf{b}_j) - q}$ are simultaneous eigenfunctions of $D_k$ $(1 \leq k \leq N)$ and $H^{(N)}_z$ $(z \in \mathcal{Z}(\mathfrak{g}))$. \hfill $\square$
We can now show the universal integrability of the asymptotic boundary KZB operators, as well as their compatibility with the quantum Hamiltonians $H_z^{(N)} (z \in Z(g))$.

**Theorem 6.26.** In $\mathbb{D} \otimes U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$ we have

$$[D_i, D_j] = 0, \quad [D_i, H_z^{(N)}] = 0, \quad [H_z^{(N)}, H_z^{(N)}] = 0$$

for $i, j = 1, \ldots, N$ and $z, z' \in Z(g)$.

**Proof.** By the previous lemma, it suffices to show that if the differential operator

$$L \in \mathbb{D} \otimes U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$$

acts as zero on $V[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]][\xi]$ for all finite dimensional $U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$-modules $V$ and all $\lambda \in \mathfrak{h}_{\text{reg}}$, then $L = 0$.

We identify the algebra $\mathbb{D}(A)^A$ of constant coefficient differential operators on $A$ with the algebra $S(\mathfrak{h}^*)$ of complex polynomials on $\mathfrak{h}^*$, by associating $\partial_h (h \in \mathfrak{h}_0)$ with the linear polynomial $\lambda \mapsto \lambda(h)$. For $p \in S(\mathfrak{h}^*)$ we write $p(\partial)$ for the corresponding constant coefficient differential operator on $A$.

Now we can expand

$$L = \sum_{i,j} f_{ij} p_{ij}(\partial)$$

(finite sum), with $\{f_i\}_i$ a linear independent set in $\mathbb{R} \subset \mathbb{C}[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]$, $\{a_{ij}\}_{i,j}$ a linear independent set in $U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$ and $p_{ij} \in S(\mathfrak{h}^*)$. Then

$$0 = L(v\xi) = \sum_i \left( \sum_j p_{ij}(\lambda) a_{ij}(v) \right) f_i \xi$$

in $V[[\xi_{-\alpha_1}, \ldots, \xi_{-\alpha_r}]]\xi$ for $v \in V$ and $\lambda \in \mathfrak{h}_{\text{reg}}$, where $V$ is an arbitrary finite dimensional $U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$-module. Since the $\{f_i\}_i$ are linear independent, we get

$$\sum_j p_{ij}(\lambda) a_{ij}(v) = 0$$

in $V$ for all $i$, for all $\lambda \in \mathfrak{h}_{\text{reg}}$ and all $v \in V$, with $V$ any finite dimensional $U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$-module. Then [10 Thm. 2.5.7] implies that

$$\sum_j p_{ij}(\lambda) a_{ij} = 0$$

in $U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$ for all $i$ and all $\lambda \in \mathfrak{h}_{\text{reg}}$. By the linear independence of $\{a_{ij}\}_{i,j}$, we get $p_{ij}(\lambda) = 0$ for all $i, j$ and all $\lambda \in \mathfrak{h}_{\text{reg}}$, hence $p_{ij} = 0$ for all $i, j$. This completes the proof of the theorem. \[\square\]

### 6.7. Folded dynamical trigonometric $r$-and $k$-matrices.** We end this section by discussing the reformulation of the commutator relations

$$[D_i, D_j] = 0$$

in $\mathbb{D} \otimes U(\mathfrak{t}) \otimes U(\mathfrak{g})^{\otimes N} \otimes U(\mathfrak{t})$ for $1 \leq i, j \leq N$ in terms of explicit consistency conditions for the constituents $r^\kappa$ and $k$ of the asymptotic boundary KZB operators $D_i$ (see [16,20]).

Before doing so, we first discuss as a warm-up the situation for the usual asymptotic KZB equations (see [15] and references therein), which we will construct from an appropriate "universal" version of the operators that are no longer integrable. Recall that $\Delta^{N-1} : U(\mathfrak{g}) \rightarrow U(\mathfrak{g})^{\otimes N}$ is the $(N-1)$th iterated comultiplication of $U(\mathfrak{g})$. 

□
Proposition 6.27. Fix \( \hat{r} \in \mathcal{R} \otimes U(\mathfrak{g})^{\otimes 2} \) satisfying the invariance property
\[
\Delta(h, \hat{r}) = 0 \quad \forall h \in \mathfrak{h}.
\]
For \( N \geq 2 \) and \( 1 \leq i \leq N \) write,
\[
\hat{D}^{(N)}_i := E_i - \sum_{s=1}^{i-1} \hat{r}_{is} + \sum_{k=1}^{N} \hat{r}_{ik} \in \mathcal{D}_\mathcal{R} \otimes U(\mathfrak{g})^{\otimes N}
\]
with \( E = \sum_{k=1}^{r} \partial_{x_k} \otimes x_k \), see (6.25). The following two statements are equivalent.

- **a.** For \( N \geq 2 \) and \( 1 \leq i \neq j \leq N \),
  \[
  E^{(N)}_i, E^{(N)}_j = - \sum_{k=1}^{r} \partial_{x_k} (\hat{r}) \Delta^{(N-1)}(x_k)
  \]
  in \( \mathcal{D}_\mathcal{R} \otimes U(\mathfrak{g})^{\otimes N} \).
- **b.** \( \hat{r} \) is a solution of the classical dynamical Yang-Baxter equation,
  \[
  \sum_{k=1}^{r} ((x_k)_3 \partial_{x_k} (\hat{r})_2 - (x_k)_2 \partial_{x_k} (\hat{r})_1) + (x_k)_1 \partial_{x_k} (\hat{r})_3) + [\hat{r}_1, \hat{r}_2, \hat{r}_3] = 0
  \]
  in \( \mathcal{R} \otimes U(\mathfrak{g})^{\otimes 3} \).

Proof. By direct computations,
\[
[E^{(2)}_1, E^{(2)}_2] = - \sum_{k=1}^{r} \partial_{x_k} (\hat{r}) \Delta(x_k)
\]
in \( \mathcal{D}_\mathcal{R} \otimes U(\mathfrak{g})^{\otimes 2} \) and
\[
[E^{(3)}_1, E^{(3)}_2] = - \sum_{k=1}^{r} \partial_{x_k} (\hat{r}) \Delta^{(2)}(x_k) + [\hat{r}_1, \hat{r}_2, \hat{r}_3] + [\hat{r}_1, \hat{r}_2, \hat{r}_3] + [\hat{r}_1, \hat{r}_2, \hat{r}_3]
\]
in \( \mathcal{D}_\mathcal{R} \otimes U(\mathfrak{g})^{\otimes 3} \). Hence a implies b.

It is a straightforward but tedious computation to show that classical dynamical Yang-Baxter equation (6.41) implies (6.42) for all \( N \geq 2 \) and all \( 1 \leq i \neq j \leq N \). \( \square \)

Corollary 6.28 (KZB operators). Let \( N \geq 2 \). Let \( U_1, \ldots, U_N \) be finite dimensional \( \mathfrak{g} \)-modules and write \( U := U_1 \otimes \cdots \otimes U_N \) as before. Let \( \hat{r} \in \mathcal{R} \otimes U(\mathfrak{g})^{\otimes 2} \) be a solution of the classical dynamical Yang-Baxter equation (6.41) satisfying the invariance property (6.42). Define differential operators \( \hat{D}^{U}_i \in \mathcal{D}_\mathcal{R} \otimes \text{End}(U[0]) \) for \( i = 1, \ldots, N \) by
\[
\hat{D}^{U}_i := \hat{D}^{(N)}_i|_{U[0]}.
\]
Then \( \hat{D}^{U}_i, \hat{D}^{U}_j = 0 \) in \( \mathcal{D}_\mathcal{R} \otimes \text{End}(U[0]) \) for \( i, j = 1, \ldots, N \).

Remark 6.29. Let \( \lambda \in \mathfrak{h}_{\text{reg}}^* \). Let \( u = u_1 \otimes \cdots \otimes u_N \in U[0] \) with \( u_i \in U_i[\mu_i] \) and \( \sum_{j=1}^{N} \mu_j = 0 \), and write \( \lambda_i := \lambda - \mu_{i+1} - \cdots - \mu_N \) (\( i = 1, \ldots, N-1 \)) and \( \lambda_N := \lambda \). By [15, 12], the weighted trace of the product \( \Psi^{(\lambda)} \) of the \( N \) vertex operators \( \Psi^{(\lambda)} \) is \( \text{Hom}_q(M_{\lambda_i}, M_{\lambda_{i-1}}) \otimes U_i \) are common eigenfunctions of the asymptotic KZB operators \( \hat{D}^{U}_i \) (\( 1 \leq i \leq N \)) with \( \hat{r} \) given by Felder’s solution (6.3) of the classical dynamical Yang-Baxter equation.
Now we prove the analogous result for asymptotic boundary KZB type operators. This time the universal versions of the asymptotic boundary KZB operators themselves will already be integrable. This is because we are considering asymptotic boundary KZB operators associated to split Riemannian symmetric pairs $G/K$ (note that the representation theoretic context from Remark 6.29 relates the asymptotic KZB operators to the group $G$ viewed as the symmetric space $G \times G$/diag($G$), with diag($G$) the group $G$ diagonally embedding into $G \times G$).

**Proposition 6.30** (general asymptotic boundary KZB operators). Let $A_l$ and $A_r$ be two complex unital associative algebras. Let $\tilde{r}^\pm \in R \otimes U(\mathfrak{g})^{\otimes 2}$ and $\tilde{\kappa} \in R \otimes A_l \otimes U(\mathfrak{g}) \otimes A_r$ and suppose that

\[ (6.45) \quad [h \otimes 1, \tilde{r}^+] = [1 \otimes h, \tilde{r}^-] \quad \forall h \in \mathfrak{h}. \]

Write for $N \geq 2$ and $1 \leq i \leq N$,

\[ \tilde{D}^{(N)}_i := E_i - \sum_{s=1}^{N} \tilde{r}^s_{13} - \tilde{\kappa}_i - \sum_{s=i+1}^{N} \tilde{r}^s_{13} \in D_R \otimes A_l \otimes U(\mathfrak{g})^{\otimes N} \otimes A_r \]

with $E$ given by (6.26) and with the indices indicating in which tensor components of $U(\mathfrak{g})^{\otimes N}$ the $(g)$-components of $\tilde{r}^\pm$ and $\tilde{\kappa}$ are placed. The following statements are equivalent.

a. For all $N \geq 2$ and all $1 \leq i, j \leq N$,

\[ [\tilde{D}^{(N)}_i, \tilde{D}^{(N)}_j] = 0 \]

in $D_R \otimes A_l \otimes U(\mathfrak{g})^{\otimes N} \otimes A_r$.

b. $\tilde{r}^+$ and $\tilde{r}^-$ are solutions of the following three mixed classical dynamical Yang-Baxter equations,

\[ \sum_{k=1}^r (x_k)_{123}(\tilde{r}^-_{12}) - (x_k)_{23}(\tilde{r}^+_{13}) = [\tilde{r}^-_{12}, \tilde{r}^+_{13}] + [\tilde{r}^-_{13}, \tilde{r}^-_{12}] + [\tilde{r}^-_{13}, \tilde{r}^-_{12}], \]

\[ \sum_{k=1}^r (x_k)_{123}(\tilde{r}^-_{12}) - (x_k)_{13}(\tilde{r}^-_{12}) = [\tilde{r}^-_{13}, \tilde{r}^-_{12}] + [\tilde{r}^-_{13}, \tilde{r}^-_{12}] + [\tilde{r}^-_{12}, \tilde{r}^-_{13}], \]

\[ \sum_{k=1}^r (x_k)_{123}(\tilde{r}^-_{12}) - (x_k)_{12}(\tilde{r}^+_{13}) = [\tilde{r}^-_{12}, \tilde{r}^+_{13}] + [\tilde{r}^-_{12}, \tilde{r}^+_{13}] + [\tilde{r}^-_{13}, \tilde{r}^-_{12}], \]

in $R \otimes U(\mathfrak{g})^{\otimes 3}$, and $\tilde{\kappa}$ is a solution of the mixed classical dynamical reflection equation

\[ \sum_{k=1}^r (x_k)_{12}(\tilde{\kappa}^- + \tilde{r}^-) - \sum_{k=1}^r (x_k)_{13}(\tilde{\kappa}^- + \tilde{r}^-) = [\tilde{\kappa}^- + \tilde{r}^-, \tilde{\kappa}^- + \tilde{r}^-] \]

in $R \otimes A_l \otimes U(\mathfrak{g})^{\otimes 2} \otimes A_r$.

**Proof.** By direct computations, $[\tilde{D}^{(2)}_i, \tilde{D}^{(2)}_j] = 0$ is equivalent to the mixed dynamical reflection equation (6.41) and $[\tilde{D}^{(3)}_i, \tilde{D}^{(3)}_j] = 0$ for $(i, j) = (1, 2), (1, 3), (2, 3)$ is equivalent to the three mixed classical dynamical Yang-Baxter equations. Hence a implies b. Conversely, a direct but tedious computation shows that the three mixed classical dynamical Yang-Baxter equations and the mixed classical dynamical reflection equation imply $[\tilde{D}^{(N)}_i, \tilde{D}^{(N)}_j] = 0$ for $N \geq 2$ and $1 \leq i, j \leq N$. \qed

Applied to the asymptotic boundary KZB operators $D_i$ ($1 \leq i \leq N$) given by (6.26), we obtain from Theorem 6.29 with $A_l = U(\mathfrak{t}) = A_r$, the following main result of this subsection.
Theorem 6.31. The folded dynamical $r$-matrices $r^\pm \in \mathcal{R} \otimes \mathfrak{g} \otimes \mathfrak{g}$ (see (6.24)) and the dynamical $k$-matrix $\kappa \in \mathcal{R} \otimes \mathfrak{g} \otimes \mathfrak{g}$ (see (6.25)) satisfy the mixed classical dynamical Yang-Baxter equations (6.27) in $\mathcal{R} \otimes \mathfrak{g} \otimes \mathfrak{g}$ and the mixed classical dynamical reflection equation (6.27) in $\mathcal{R} \otimes \mathfrak{g} \otimes \mathfrak{g}$.
