Construction of an Engel manifold with trivial automorphism group

Koji Yamazaki

February 10, 2020

Abstract
An Engel manifold is a 4-manifold with a completely non-integrable 2-distribution called Engel structure. I research the functorial relation between Engel manifolds and Contact 3-orbifolds. And I construct an Engel manifold that the automorphism group is trivial.

0 Introduction

A 2-distribution $\mathcal{D}$ on a 4-manifold $E$ is an Engel structure if $\mathcal{D}^2 \overset{\text{def}}{=} \mathcal{D} + [\mathcal{D}, \mathcal{D}]$ has rank 3, and $\mathcal{D}^3 \overset{\text{def}}{=} \mathcal{D}^2 + [\mathcal{D}^2, \mathcal{D}^2]$ has rank 4. The pair $(E, \mathcal{D})$ is called an Engel manifold. A Engel manifold has an unique 1-distribution $\mathcal{L} \subset \mathcal{D}$, called the characteristic foliation, such that $[\mathcal{L}, \mathcal{D}^2] \subset \mathcal{D}^2$.

Question (AIM Problem lists\(^1\)). Is there an Engel structure with trivial automorphism group?

We construct such an Engel manifold. However, the following question is open.

Question (Mitsumatsu). Is there a closed Engel manifold with trivial automorphism group?

Acknowledgements

The results is obtained thanks to discussions with members of Saturday Seminar (Dosemi). I grateful and would like to thank them.

1 Engel Manifolds

**Definition 1.1.** Let $E$ be a 4-manifold. An Engel structure on $E$ is a smooth rank 2 distribution $\mathcal{D} \subset T E$ with following condition:

$$\mathcal{D}^2 \overset{\text{def}}{=} \mathcal{D} + [\mathcal{D}, \mathcal{D}] \text{ has rank 3, and } \mathcal{D}^3 \overset{\text{def}}{=} \mathcal{D}^2 + [\mathcal{D}^2, \mathcal{D}^2] \text{ has rank 4.}$$

The pair $(E, \mathcal{D})$ is called an Engel manifold.

Let $(E_1, \mathcal{D}_1), (E_2, \mathcal{D}_2)$ be Engel manifolds. A Engel morphism $f : (E_1, \mathcal{D}_1) \rightarrow (E_2, \mathcal{D}_2)$ is a local diffeomorphism $f : E_1 \rightarrow E_2$ with $df(\mathcal{D}_1) \subset \mathcal{D}_2$.

**Example 1.2.** Let $(M, \xi)$ be a contact 3-manifold, let $E = \mathbb{P}(\xi) \overset{\text{def}}{=} \coprod_{x \in M} \mathbb{P}(\xi_x)$, and let $\pi : E \rightarrow M$ is the projective map. Now, we define a rank 2 distribution $\mathcal{D}$ on $E$ in the following way: For each $l \in E$ with $\pi(l) = x$, $l \subset \mathbb{P}(\xi_x)$ is a line that cross the origin. By the way, we define $\mathcal{D}_l \overset{\text{def}}{=} d\pi_{l^{-1}}(l) \subset T_l E$. Then, $\mathcal{D}$ is an Engel structure on $E$. This Engel manifold $(E, \mathcal{D})$ is called the Cartan prolongation, and we denote this $\mathbb{P}(M, \xi)$.

The functor $(M, \xi) \mapsto \mathbb{P}(M, \xi)$ is fully faithful. In particular, $\text{Aut}(\mathbb{P}(M, \xi)) \cong \text{Aut}(M, \xi)$ is a “very big” (infinite dimensional) group.

**Proposition 1.3 ([2], [1], [3]).** Let $(E, \mathcal{D})$ be an Engel manifold. There exists a unique rank 1 distribution $\mathcal{L} \subset \mathcal{D}$ such that $[\mathcal{L}, \mathcal{D}^2] \subset \mathcal{D}^2$.

The above $\mathcal{L}$ is called the characteristic foliation of $(E, \mathcal{D})$.

Any 3-dimensional submanifold $M \subset E$ intersecting transversally $\mathcal{L}$ has a contact structure $\mathcal{D}^2 \cap TM$. And any vector field tangent to $\mathcal{L}$ preserves the “even contact structure” $\mathcal{D}^2$. In particular, any holonomy of $\mathcal{L}$ is a germ of contact morphism. Immediately, $E/\mathcal{L}$ has a contact structure $\mathcal{D}^2/\mathcal{L}$.

For simplicity, suppose that $E/\mathcal{L}$ is a manifold, Let $\pi : E \rightarrow E/\mathcal{L}$ be the quotient map. We define an Engel morphism $\phi : E \rightarrow \mathbb{P}(E/\mathcal{L}, \mathcal{D}^2/\mathcal{L})$ as $\phi(e) \overset{\text{def}}{=} d\pi(D_e)$. This $\phi$ is called the development map. And, the functor $(E, \mathcal{D}) \mapsto (E/\mathcal{L}, \mathcal{D}^2/\mathcal{L}) \mapsto \mathbb{P}(E/\mathcal{L}, \mathcal{D}^2/\mathcal{L})$ induces a group morphism $\Phi : \text{Aut}(E, \mathcal{D}) \rightarrow \text{Aut}(E/\mathcal{L}, \mathcal{D}^2/\mathcal{L}) \cong \text{Aut}(\mathbb{P}(E/\mathcal{L}, \mathcal{D}^2/\mathcal{L}))$.

**Theorem 1.4 (Y.[4]).** Let $(E, \mathcal{D})$ be a connected Engel manifold. Suppose that $E/\mathcal{L}$ is a manifold. If the development map $\phi$ is not covering, then the above $\Phi$ is injective.

**Example 1.5.** $E \overset{\text{def}}{=} \mathbb{R}^4 \ni (x, y, z, \theta)$. $\mathcal{D} \overset{\text{def}}{=} \langle \partial_\theta, \cos(\frac{\theta}{2})X + \sin(\frac{\theta}{2})Y \rangle$ ($X \overset{\text{def}}{=} \partial_x - y\partial_z, Y \overset{\text{def}}{=} \partial_y$). Then, $(E, \mathcal{D})$ is an Engel manifold. $\mathcal{L} = \langle \partial_\theta \rangle$ is the
characteristic foliation. And, $\mathcal{E} \overset{\text{def}}{=} D^2 = \langle \partial_\theta, X, Y \rangle$.
The leaf space is $M \overset{\text{def}}{=} E/\mathcal{L} \cong \mathbb{R}^3 \ni (x, y, z)$. And the contact structure is $\xi \overset{\text{def}}{=} \mathcal{E}/\mathcal{L} \cong \langle X, Y \rangle$. So, the Cartan prolongation is $M \times S^1 \cong \mathbb{P}(M, \xi); (x, [\theta]) \mapsto (\cos(\frac{\theta}{2})X_x + \sin(\frac{\theta}{2})Y_x)$.

Then, the development map $\phi : E \rightarrow M \times S^1; (x, [\theta]) \mapsto (x, [\theta])$ is covering.

**Example 1.6.** Fix a point $x_0 \in \mathbb{R}^3$ and a number $n \in \mathbb{Z} \geq 0$.
$E \overset{\text{def}}{=} \mathbb{R}^4 - \{x_0\} \times ((-\infty, -n\pi] \cup [n\pi + \epsilon, \infty)) \ (\epsilon \in (0, 2\pi]).$ $\mathcal{D}$ is as above. Then, $(E, \mathcal{D})$ is an Engel manifold.

Then, the development map $\phi : E \rightarrow M \times S^1; (x, [\theta]) \mapsto (x, [\theta])$ is not covering.

### 1.1 the twisting number function

Let $(E, \mathcal{D})$ be a connected Engel manifold. Suppose that $E/\mathcal{L}$ is a manifold.
Define $\sigma : E/\mathcal{L} \rightarrow \mathbb{Z}_{\geq 0} \cup \{\infty\}$ by $\sigma(L) \overset{\text{def}}{=} \min\{\#\phi^{-1}(y) | y \in \mathbb{P}(D^2/\mathcal{L})_L\}$.

**Definition 1.7.** The above $\sigma$ is the twisting number function of $(E, \mathcal{D})$.

**Proposition 1.8.** For any $f \in \text{Aut}(E, \mathcal{D})$, the induced automorphism $E/\mathcal{L} \rightarrow E/\mathcal{L}$ preserves the twisting number function $\sigma$.

*Proof.* Obvious. \hfill \Box

### 2 Construction

Take a countable dense subset $Q = \{x_n\}_{n=1}^\infty \subset \mathbb{R}^3$. $E \overset{\text{def}}{=} \mathbb{R}^4 - \bigcup_n \{x_n\} \times ((-\infty, -n\pi] \cup [n\pi + \epsilon, \infty)) \ (\epsilon \in (0, 2\pi]).$ $\mathcal{D}$ is as with Example 1.5.

**Theorem 2.1.** $\text{Aut}(E, \mathcal{D})$ is trivial.

*Proof.* The twisting number function $\sigma$ is the following:

$$\sigma(x) = \begin{cases} 
  n & (x = x_n) \\
  \infty & \text{(otherwise)}
\end{cases}$$

For any $f \in \text{Aut}(E, \mathcal{D})$, the induced automorphism $f : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ is the identity on $Q$. Because $Q \subset \mathbb{R}^3$ is dense, $f$ is the identity on $\mathbb{R}^3$. So $f$ is the identity. \hfill \Box
