

FINITE ÉTALE EXTENSIONS OF TATE RINGS AND DECOMPLETION OF PERFECTOID ALGEBRAS

KEI NAKAZATO AND KAZUMA SHIMOMOTO

ABSTRACT. In this paper, we examine the behavior of ideal-adic separatedness and completeness under certain ring extensions using trace map. Then we prove that adic completeness of a base ring is hereditary to its ring extension under reasonable conditions. We aim to give many results on ascent and descent of certain ring theoretic properties under completion. As an application, we give conceptual details to the proof of the almost purity theorem for Witt-perfect rings by Davis and Kedlaya. Witt-perfect rings have the advantage that one does not need to assume that the rings are complete and separated.

1. INTRODUCTION

In the basic part of perfectoid geometry, one of the most fundamental tools that is frequently used is the *Almost purity theorem*, which was first proved by Faltings for certain big algebras constructed from smooth algebras over a discrete valuation ring, and then by Scholze for perfectoid algebras

Key words and phrases. Almost purity, completion, étale extension, non-archimedean Banach ring, perfectoid algebra, Witt-perfect algebra.

2020 *Mathematics Subject Classification*: 11S15, 13A18, 13B22, 13B40, 13F35, 13J10, 14G45.

over a perfectoid field. One drawback of perfectoid rings is that one needs to work with p -adically complete rings, which prevents us from taking infinite integral extensions of p -adically complete rings directly. Roughly speaking, a *Witt-perfect* condition on a p -torsion free ring is defined in the same way as for perfectoid algebras, except that it need not be p -adically complete. This class of rings had been introduced by Davis and Kedlaya in [8] and [9]. However, a difficulty lurks in dealing with Witt-perfect rings, due to the lack of tilting correspondence for those rings.

The present note stems from authors' endeavor to reaching deeper understanding of the papers [8] and [9]. Our aim is to prove some basic results and explain their consequences which are of great importance in the situation where one wants to avoid taking p -adic completion. We also make extensive studies on the comparisons between (almost) Witt-perfect algebra and (almost) perfectoid algebras. It is clear from André's work [1] that almost perfectoid algebras naturally show up in certain applications.

Notation: All rings are assumed to be commutative with a unity. For a finite projective ring extension $A \hookrightarrow B$, denote by $\mathrm{Tr}_{B/A} : B \rightarrow A$ the trace map; see the book [13] for the construction. For a ring A and an A -algebra B , we denote by A_B^+ (resp. A_B^*) the A -subalgebra of B consisting of all elements that are integral (resp. almost integral) over A , which are found in Definition 2.1. For the definition of a Tate ring A with the subset of powerbounded elements A° , see Definition 2.10.

Let us state the main results; see Proposition 4.1, Proposition 4.2, Theorem 4.9 and Theorem 5.7 below.

Main Theorem 1. *Let A be a ring and let B be a finite étale A -algebra. Let $A_0 \subset A$ be a subring with an ideal $I_0 \subset A_0$. Let B_0 be an A_0 -subalgebra of B such that $B = \bigcup_{n \geq 1} (B_0 :_B I_0^n)$ (see (2.3) for this notation below). Assume that there exists an integer $c > 0$ such that $\mathrm{Tr}_{B/A}(tm) \in A_0$ for every $t \in I_0^c$ and every $m \in B_0$.*

- (1) *If A_0 is I_0 -adically separated, then so is B_0 .*
- (2) *If A_0 is I_0 -adically complete, then so is B_0 .*

Main Theorem 2. *Let (R, I) be a basic setup and let $f_0 : A_0 \rightarrow B_0$ be an R -algebra homomorphism with an element $t \in A_0$. Denote by $\widehat{A_0}$ and $\widehat{B_0}$ the t -adic completions of A_0 and B_0 , respectively. Let $\widehat{f_0} : \widehat{A_0} \rightarrow \widehat{B_0}$ be the R -algebra homomorphism induced by f_0 . Assume that the morphism of pairs $f_0 : (A_0, (t)) \rightarrow (B_0, (t))$ satisfies condition $(*)$ (cf. Definition 4.3). Then the following assertions hold.*

- (1) *The natural $\widehat{A_0}[\frac{1}{t}]$ -algebra homomorphism $B_0[\frac{1}{t}] \otimes_{A_0[\frac{1}{t}]} \widehat{A_0}[\frac{1}{t}] \rightarrow \widehat{B_0}[\frac{1}{t}]$ is an isomorphism.*
- (2) *$\widehat{f_0} : (\widehat{A_0}, (t)) \rightarrow (\widehat{B_0}, (t))$ also satisfies the condition $(*)$ (cf. Definition 4.3).*
- (3) *The following conditions are equivalent.*
 - (a) *B_0 is I -almost finitely generated and I -almost projective over A_0 .*
 - (b) *$\widehat{B_0}$ is I -almost finitely generated and I -almost projective over $\widehat{A_0}$.*
- (4) *The following conditions are equivalent.*
 - (a) *$f_0 : A_0 \rightarrow B_0$ is I -almost finite étale.*
 - (b) *$\widehat{f_0} : \widehat{A_0} \rightarrow \widehat{B_0}$ is I -almost finite étale.*

An important consequence that follows from the above results is the almost purity theorem for Witt-perfect rings; see Theorem 5.9. This statement was originally established by Davis and Kedlaya which ultimately relies on the almost purity theorem by Kedlaya-Liu; see papers [8] and [9] and [20].

Corollary 1.1 (Almost purity). *Let A_0 be a p -torsion free Witt-perfect ring and let $f_0 : A_0 \rightarrow B_0$ be a ring map. Put $I := \sqrt{pA_0}$. Assume that the morphism $f_0 : (A_0, (p)) \rightarrow (B_0, (p))$ satisfies*

condition $(*)$ (cf. Definition 4.3), A_0 is integrally closed in $A_0[\frac{1}{p}]$, $(A_0)_{B_0[\frac{1}{p}]}^+ \subset B_0$, and (A_0, I) is a basic setup. Then the following assertions hold.

- (1) B_0 is also Witt-perfect.
- (2) $f_0 : A_0 \rightarrow B_0$ is I -almost finite étale.

The structure of this paper goes as follows.

In §2, we give a review on Tate rings, a reasonable class of topological rings that are introduced by Huber [19, p. 456] as a generalization of classical Tate algebras. This class is useful for describing the structure as a topological ring of a Banach ring, and developing an algebraic theory approximate to non-archimedean analysis. As a preliminary to the study of uniform Banach rings, we introduce the notion of *preuniformity* for both Tate rings and pairs of rings (A, I) , where A is a ring and I is an ideal of A ; see Definition 2.14 and Definition 2.16. This notion is important when one needs to distinguish uniform Banach rings and uniform non-Banach rings and moreover, our definition is of algebraic nature that is appealing to algebraists. Thus, their properties are studied with connections to Banach rings.

In §3, we will use Fontaine's version of perfectoid rings that was introduced in [12] as a generalization of Scholze's perfectoid algebras; see Definition 3.9. We study its relation to Witt-perfect rings, which are decompletions of perfectoid algebras.

In §4, we study finite étale extensions over a Tate ring. In particular, the reader will find that a *trace map* becomes an essential tool for testing certain topological structure such as complete or separated, on module-finite algebras over Tate rings. The main results in this section are Proposition 4.1, Proposition 4.2 and Theorem 4.9. We also prove some basic results on (complete) integral closure and their behavior under completion. We believe that some of these results are known to experts. However, as they do not seem to be documented in existing literatures, we try to give detailed proofs with maximal generality.

In §5, by specializing the results obtained in §3, we complete the proof of the almost purity theorem for Witt-perfect rings by reducing to the case of perfectoid rings by Kedlaya-Liu [20]; see Theorem 5.7 and Theorem 5.9. A review on some basic definitions of almost ring theory is also given, borrowing from Gabber-Ramero's monograph [16].

In §6, we give some historical remarks on the almost purity theorems. The reason for the inclusion of this appendix is to help commutative algebraists to understand core ideas. No new results are proved here.

Let us point out that the almost purity theorem without completion has also been established by Gabber-Ramero in [17], under the name of *formal perfectoid rings*. Although their treatment is quite general, we think that our approach is short and concise. We plan to apply the results of this paper to the construction of almost Cohen-Macaulay algebras after establishing a variant of André's perfectoid Abhyankar's lemma in the forthcoming paper [23].

2. NOTATION AND PRELIMINARIES

For the definition of perfectoid algebras, we follow the original version by Scholze [25] and its essential extension by Fontaine [12]. There is, however, a more general version as introduced in the paper [4]. A *pair* is meant to be a pair (A, I) consisting of a ring A and an ideal $I \subset A$. A *morphism of pairs* $f : (A, I) \rightarrow (B, J)$ is a ring map $f : A \rightarrow B$ such that $I^n \subset f^{-1}(J)$ for some $n > 0$. Let (A, I) be a pair, M be an A -module, and N be an A -submodule of M . Then the *I -saturation of N in M* is defined to be the A -submodule

$$N^{I\text{-sat}} = \{m \in M \mid \text{for any } x \in I, \text{ there exists some } n > 0 \text{ such that } x^n m \in N\}.$$

In particular, for the ideal $(0) \subset A$, the I -saturation $(0)^{I\text{-sat}}$ denotes the ideal of A consisting of all I -torsion elements.

2.1. Integrality and almost integrality. Here we discuss the notion of integrality and almost integrality.¹ A general reference is [7].

Definition 2.1. Let $A \subset B$ be a ring extension.

- (1) An element $b \in B$ is *integral* over A , if $\sum_{n=0}^{\infty} A \cdot b^n$ is a finitely generated A -submodule of B . The set of all elements, denoted as C , of B that are integral over A forms an A -subalgebra of B . If $A = C$, then A is called *integrally closed* in B .
- (2) An element $b \in B$ is *almost integral* over A , if $\sum_{n=0}^{\infty} A \cdot b^n$ is contained in a finitely generated A -submodule of B . The set of all elements, denoted as C , of B that are almost integral over A forms an A -subalgebra of B , which is called the *complete integral closure* of A in B . If $A = C$, then A is called *completely integrally closed* in B .

This definition can be extended to any ring homomorphism $A \rightarrow B$ in a natural way: Let A be a ring, let B be an A -algebra and let $b \in B$ be an element. Then we say that b is *integral* (resp. *almost integral*) over A , if b is integral (resp. almost integral) over the image of A in B . Unlike integral closure, the complete integral closure of an integral domain in its field of fractions is not necessarily completely integrally closed in the same field of fractions; see [18] for such examples.

In the case when A is Noetherian, we have $A_B^+ = A_B^*$. However, these two rings may be quite different in general.

Example 2.2. Let G be the abelian group $\mathbb{Z} \oplus \mathbb{Z}$ equipped with the lexicographic order (i.e. $(a_1, a_2) \leq (b_1, b_2) \iff a_1 < b_1$, or $a_1 = b_1$ and $a_2 \leq b_2$). Let V be a valuation ring with value group G , $K = \text{Frac}(V)$, and let $v : K^\times \rightarrow G$ be a valuation corresponding to V . Let $t \in V$ be an element such that $v(t) = (1, 0)$. Then $K = V[\frac{1}{t}]$. Hence $a \in K$ is almost integral over V if and only if there exists some $l > 0$ such that $t^l a^n \in V$ for every $n > 0$. For $a \in K \setminus \{0\}$, the latter condition means that the first entry a_1 of $v(a)$ satisfies $a_1 \geq 0$. Hence V_K^* is a valuation ring of rank 1. On the other hand, since $V_K^+ = V$, V_K^+ is a valuation ring of rank 2. Thus the Krull dimension of V_K^+ and that of V_K^* are different.

We often use the following results.

Lemma 2.3. Let A_0 be a ring with a nonzero divisor t . Let B_0 be a t -torsion free A_0 -algebra such that the induced $A_0[\frac{1}{t}]$ -algebra $B_0[\frac{1}{t}]$ is module-finite. Then one has $t(A_0)_B^* \subset (A_0)_B^+$.

Proof. Put $A := A_0[\frac{1}{t}]$, $B := B_0[\frac{1}{t}]$ and $B'_0 := (A_0)_B^+$. Pick $b \in (A_0)_B^*$. Then there exists a finitely generated A_0 -submodule $N_0 \subset B$ such that b^n belongs to N_0 for every $n > 0$. On the other hand, since B is module-finite over A , we have $B = B'_0[\frac{1}{t}]$. Thus, $t^l N_0$ is contained in B'_0 for some $l > 0$. In particular, $(tb)^l (= t^l b^l)$ lies in B'_0 and therefore, so does tb by the definition of B'_0 . Hence tb is integral over A_0 , as desired. \square

Proposition 2.4. Let A_0 be a ring with a nonzero divisor t . Denote by $\widehat{A_0}$ the t -adic completion of A_0 . Put $A := A_0[\frac{1}{t}]$, $A' := \widehat{A_0}[\frac{1}{t}]$, $A^+ := (A_0)_A^+$, and $A^\circ := (A_0)_A^*$.

- (1) Suppose that there exists some $c \geq 0$ for which $t^c A^+ \subset A_0$ (resp. $t^c A^\circ \subset A_0$). Then the following assertions hold.

¹The notion of almost integrality is much older than I -almost integrality, which is relevant to the conclusion of Lemma 5.3. This nomenclature is somehow a mathematical incident in a positive sense. Indeed, one of our purposes is to relate almost integrality to various notions used in almost ring theory.

- (a) One has $t^c(\widehat{A_0})_{A'}^+ \subset \widehat{A_0}$ (resp. $t^c(\widehat{A_0})_{A'}^* \subset \widehat{A_0}$).
- (b) Denote by $\widehat{A^+}$ and $\widehat{A^\circ}$ the t -adic completions. Then the inclusion map $A_0 \hookrightarrow A^+$ (resp. $A_0 \hookrightarrow A^\circ$) induces an isomorphism $A' \xrightarrow{\cong} \widehat{A^+}[\frac{1}{t}]$ (resp. $A' \xrightarrow{\cong} \widehat{A^\circ}[\frac{1}{t}]$) whose restriction to $(\widehat{A_0})_{A'}^+$ (resp. $(\widehat{A_0})_{A'}^*$) yields an isomorphism $(\widehat{A_0})_{A'}^+ \xrightarrow{\cong} \widehat{A^+}$ (resp. $(\widehat{A_0})_{A'}^* \xrightarrow{\cong} \widehat{A^\circ}$).
- (2) Conversely, if there exists some $c \geq 0$ for which $t^c(\widehat{A_0})_{A'}^+ \subset \widehat{A_0}$ (resp. $t^c(\widehat{A_0})_{A'}^* \subset \widehat{A_0}$), then one has $t^c A^+ \subset A_0$ (resp. $t^c A^\circ \subset A_0$).

To prove this, let us verify a fundamental lemma.

Lemma 2.5. *Let A_0 be a ring and let $I_0 \subset A_0$ be a finitely generated ideal. Let $f_0 : N_0 \hookrightarrow M_0$ be an injective homomorphism between A_0 -modules. Denote by $\widehat{M_0}$ and $\widehat{N_0}$ the I_0 -adic completions of M_0 and N_0 , respectively. Let $\widehat{f_0} : \widehat{N_0} \rightarrow \widehat{M_0}$ be the $\widehat{A_0}$ -linear map induced by f_0 . Assume that the cokernel of f_0 is annihilated by I_0^m for some $m \geq 0$. Then, $\widehat{f_0}$ is also injective and the cokernel of $\widehat{f_0}$ is annihilated by $I_0^m \widehat{A_0}$.*

Proof of Lemma 2.5. Consider the exact sequence: $0 \rightarrow N_0 \xrightarrow{f_0} M_0 \rightarrow L_0 \rightarrow 0$ with L_0 being the cokernel of f_0 . By assumption, the A_0 -module L_0 is killed by I_0^m . For an arbitrary $n > 0$, we have the induced exact sequence:

$$(2.1) \quad 0 \rightarrow N_0/(I_0^n M_0 \cap N_0) \rightarrow M_0/I_0^n M_0 \rightarrow L_0/I_0^n L_0 \rightarrow 0.$$

Since $\varprojlim_n N_0/(I_0^n M_0 \cap N_0) \cong 0$ and $I_0^{m+n} M_0 \cap N_0 \subset I_0^n N_0$, the following sequence induced by (2.1) is exact:

$$0 \rightarrow \widehat{N_0} \rightarrow \widehat{M_0} \rightarrow \widehat{L_0} \cong L_0 \rightarrow 0,$$

where $\widehat{L_0}$ denotes the I_0 -adic completion of L_0 . In particular, the cokernel of $\widehat{f_0}$ is killed by $I_0^m \widehat{A_0}$. This yields the assertion. \square

Moreover, we need the following result from [2]; see also [28, Tag 0BNR].

Lemma 2.6 (Beauville-Laszlo). *Let A_0 be a ring with a nonzero divisor $t \in A_0$ and let $\widehat{A_0}$ be the t -adic completion. Then t is a nonzero divisor of $\widehat{A_0}$ and one has the commutative diagram:*

$$(2.2) \quad \begin{array}{ccc} A_0 & \xrightarrow{\psi} & \widehat{A_0} \\ \downarrow \iota & & \downarrow \iota' \\ A_0[\frac{1}{t}] & \xrightarrow{\psi_t} & \widehat{A_0}[\frac{1}{t}] \end{array}$$

that is cartesian. In other words, we have $A_0 \cong A_0[\frac{1}{t}] \times_{\widehat{A_0}[\frac{1}{t}]} \widehat{A_0}$.

Corollary 2.7. *Keep the notation as in Lemma 2.6. Suppose that A_0 is completely integrally closed in $A_0[\frac{1}{t}]$. Then $\widehat{A_0}$ is completely integrally closed in $\widehat{A_0}[\frac{1}{t}]$.*

Proof. Put $A' := \widehat{A_0}[\frac{1}{t}]$. Pick an arbitrary element $x \in (\widehat{A_0})_{A'}^*$. Then $t^d x \in \widehat{A_0}$ for some $d > 0$. Hence there exists some $a \in A_0$ such that $t^d x - \psi(a) \in t^d \widehat{A_0}$ or equivalently, $x - \psi_t(\frac{a}{t^d}) \in \widehat{A_0}$. Then, since x and any element in $\widehat{A_0}$ are contained in $(\widehat{A_0})_{A'}^*$, we find that $\psi_t(\frac{a}{t^d}) \in (\widehat{A_0})_{A'}^*$. Hence, there exists some $c > 0$ such that $\psi_t(t^c(\frac{a}{t^d})^n) \in \widehat{A_0}$ for every $n > 0$. Thus by Lemma 2.6, we have $\psi_t(t^c(\frac{a}{t^d})^n) \in \psi_t(A_0)$ for every $n > 0$. Now notice that $\text{Ker}(\psi_t) \subset A_0$. This is because $\text{Ker}(\psi) = \cap_{n=0}^\infty t^n A_0$ and $\text{Ker}(\psi)$ is t -divisible. Consequently, we find that $\frac{a}{t^d} \in A_0[\frac{1}{t}]$ is

almost integral over A_0 and therefore, it is contained in A_0 by assumption. Hence x lies in $\widehat{A_0}$, as desired. \square

Now let us start to prove Proposition 2.4.

Proof of Proposition 2.4. Notice that $\widehat{A_0}$, $\widehat{A^+}$ and $\widehat{A^\circ}$ are t -torsion free (cf. Lemma 2.6).

We first prove the assertion (1). By assumption, $t^c A^+ \subset A_0$ (resp. $t^c A^\circ \subset A_0$) for some $c \geq 0$. Hence by applying Lemma 2.5 to the inclusion map $A_0 \hookrightarrow A^+$ (resp. $A_0 \hookrightarrow A^\circ$), we find that the induced map $\widehat{A_0} \rightarrow \widehat{A^+}$ (resp. $\widehat{A_0} \rightarrow \widehat{A^\circ}$) is injective and its cokernel is killed by t^c . Therefore, we have a canonical $\widehat{A_0}$ -isomorphism $A' \xrightarrow{\cong} \widehat{A^+}[\frac{1}{t}]$ (resp. $A' \xrightarrow{\cong} \widehat{A^\circ}[\frac{1}{t}]$). Moreover, $\widehat{A^+}$ (resp. $\widehat{A^\circ}$) is integrally closed (resp. completely integrally closed) in $\widehat{A^+}[\frac{1}{t}]$ (resp. $\widehat{A^\circ}[\frac{1}{t}]$) by [3, Lemma 5.1.2] (resp. Corollary 2.7).² Hence we have inclusions $\widehat{A_0} \subset (\widehat{A_0})_{A'}^+ \subset \widehat{A^+}$ (resp. $\widehat{A_0} \subset (\widehat{A_0})_{A'}^* \subset \widehat{A^\circ}$). Thus, we also have inclusions $t^c(\widehat{A_0})_{A'}^+ \subset t^c \widehat{A^+} \subset \widehat{A_0}$ (resp. $t^c(\widehat{A_0})_{A'}^* \subset t^c \widehat{A^\circ} \subset \widehat{A_0}$), which yields the assertion (a). In particular, $\{t^n \widehat{A_0}\}_{n \geq 1}$ gives a fundamental system of open neighborhoods of $0 \in (\widehat{A_0})_{A'}^+$ (resp. $0 \in (\widehat{A_0})_{A'}^*$). Hence $(\widehat{A_0})_{A'}^+$ (resp. $(\widehat{A_0})_{A'}^*$) is t -adically complete and separated. Thus, by the universal property of completion (cf. [15, Proposition 7.1.9 in Chapter 0]), we obtain the A^+ -linear map (resp. A° -linear map) $\widehat{A^+} \rightarrow (\widehat{A_0})_{A'}^+$ (resp. $\widehat{A^\circ} \rightarrow (\widehat{A_0})_{A'}^*$) and the composite $\widehat{A^+} \rightarrow (\widehat{A_0})_{A'}^+ \hookrightarrow \widehat{A^+}$ (resp. $\widehat{A^\circ} \rightarrow (\widehat{A_0})_{A'}^* \hookrightarrow \widehat{A^\circ}$) is the identity. Therefore $(\widehat{A_0})_{A'}^+ \hookrightarrow \widehat{A^+}$ (resp. $(\widehat{A_0})_{A'}^* \hookrightarrow \widehat{A^\circ}$) is an isomorphism, which yields the assertion (b).

Next we show the assertion (2). We consider the commutative diagram (2.2). Keeping the notation as above, assume that $t^c(\widehat{A_0})_{A'}^+ \subset \widehat{A_0}$ (resp. $t^c(\widehat{A_0})_{A'}^* \subset \widehat{A_0}$) for some $c \geq 0$. Pick an element $x \in A^+$ (resp. $y \in A^\circ$). Then one can check that $\psi_t(x) \in \widehat{A_0}[\frac{1}{t}]$ (resp. $\psi_t(y) \in \widehat{A_0}[\frac{1}{t}]$) is integral (resp. almost integral) over $\widehat{A_0}$, because the diagram (2.2) commutes. Hence by assumption, $\psi_t(t^c x)$ (resp. $\psi_t(t^c y)$) comes from $\widehat{A_0}$. Thus, letting B_0 (resp. C_0) be the A_0 -subalgebra of $A_0[\frac{1}{t}]$ generated by all elements of $t^c A^+$ (resp. $t^c A^\circ$), we find that the composite map $B_0 \hookrightarrow A_0[\frac{1}{t}] \xrightarrow{\psi_t} \widehat{A_0}[\frac{1}{t}]$ (resp. $C_0 \hookrightarrow A_0[\frac{1}{t}] \xrightarrow{\psi_t} \widehat{A_0}[\frac{1}{t}]$) factors through $\widehat{A_0}$. Therefore, Lemma 2.6 implies that $B_0 \subset A_0$ (resp. $C_0 \subset A_0$). Consequently, we have $t^c A^+ \subset A_0$ (resp. $t^c A^\circ \subset A_0$), as wanted. \square

Corollary 2.8. *Keep the notation as in Proposition 2.4. Then $(A_0)_A^+ = A_0$ (resp. $(A_0)_A^* = A_0$) if and only if $(\widehat{A_0})_{A'}^+ = \widehat{A_0}$ (resp. $(\widehat{A_0})_{A'}^* = \widehat{A_0}$).*

2.2. Tate rings. We first recall basic terms on Tate rings.

Definition 2.9 (Boundedness). Let A be a topological ring. We say that a subset $S \subset A$ is *bounded*, if for every open neighborhood U of $0 \in A$ there exists some open neighborhood V of $0 \in A$ such that $V \cdot S \subset U$, and we consider the empty set as being bounded.

Definition 2.10 (Tate ring). A topological ring A is called *Tate*, if there is an open subring $A_0 \subset A$ together with an element $t \in A_0$ such that the topology on A_0 induced from A is t -adic and t becomes a unit in A . A_0 is called a *ring of definition* and t is called a *pseudouniformizer* and the pair $(A_0, (t))$ is called a *pair of definition*. Denote by A° the set of powerbounded elements of A and by $A^{\circ\circ}$ the set of all topologically nilpotent elements of A . Then $A^{\circ\circ}$ is an ideal of A° and A° is a subring of A .

Any Tate ring comes from a pair of a ring and a nonzero divisor in it as follows.

²The complete integral closedness of A° in A is a not trivial issue. However, this is easily checked from the hypothesis $t^c(A_0)_A^* \subset A_0$. We will discuss this condition as *preuniformity* in the following section.

Lemma 2.11. *The following assertions hold:*

- (1) *Let A_0 be a ring with a nonzero divisor t , and put $A := A_0[\frac{1}{t}]$. Equip A with the linear topology defined by $\{t^n A_0\}_{n \geq 1}$. Then A is equipped with the structure as a Tate ring with a ring of definition A_0 and a pseudouniformizer $t \in A_0$.*
- (2) *Conversely, let A be a Tate ring with a ring of definition A_0 and a pseudouniformizer $t \in A_0$. Then one has $A = A_0[\frac{1}{t}]$.*

Proof. (1) is easy to check. Let us prove (2). Pick an element $a \in A$. It suffices to find some integer $c > 0$ such that $t^c a \in A_0$. Now by definition, the multiplication map

$$m : A \times A \rightarrow A, (a_1, a_2) \mapsto a_1 a_2$$

is continuous. In particular, for every open neighborhood V of $0 \in A$, there exists some open neighborhood U of $(a, 0) \in A \times A$ such that $m(U) \subset V$. Thus, since $\{t^n A_0\}_{n \geq 1}$ forms a fundamental system of open neighborhoods of $0 \in A$ by assumption, we have $m(\{a\} \times t^c A_0) \subset A_0$ for some $c > 0$. Hence the assertion follows. \square

Definition 2.12. Let (A_0, I_0) be a pair. If I_0 is generated by a nonzero divisor $t \in A_0$, then we call the Tate ring $A_0[\frac{1}{t}]$ in Lemma 2.11(1) the *Tate ring associated to (A_0, I_0)* .

The notion of integrality is useful for describing important subrings of a Tate ring. The following lemma should be well-known, but we insert its proof.

Lemma 2.13. *Let A be a Tate ring with a ring of definition A_0 and a pseudouniformizer $t \in A_0$.*

- (1) *The complete integral closure of A_0 in A coincides with A° . In particular, if A° is bounded, then A° is completely integrally closed in A .*
- (2) *One has $tA^\circ \subset (A_0)_A^+ \subset A^\circ$.*

Proof. Let us prove (1). For an element $a \in A$, a is almost integral over A_0 if and only if there exists some $c > 0$ such that $t^c a^m \in A_0$ for every $m > 0$. Here the latter condition is equivalent to the condition that a belongs to A° . Hence A° is the complete integral closure of A_0 in A . The second statement is clear, because any open and bounded subring of A forms a ring of definition. Next we prove (2). Pick $a \in A^\circ$. Then one has $(ta)^c = t^c a^c \in A_0$ for some $c > 0$. Hence $ta \in (A_0)_A^+$, as desired. \square

2.3. Preuniform rings and pairs. We will discuss *(pre)uniformity* of Tate rings in many contexts later. Here we give the definition.

Definition 2.14 (Preuniform rings). Let A be a Tate ring. We say that A is *preuniform* if A° is bounded. We say that A is *uniform* if it is preuniform and complete and separated.

Let us recall the following fact.

Lemma 2.15. *A separated preuniform Tate ring is reduced. In particular, a uniform Tate ring is reduced.*

Proof. Let A be a separated preuniform Tate ring. Then, since A° is bounded, we can take A° as a ring of definition of A . Pick a pseudouniformizer $t \in A^\circ$ of A . Then A° is t -adically separated because A is separated. Let $f \in A$ be such that $f^k = 0$ for some $k > 0$. Then for an integer $n > 0$, $t^{-n} f$ is nilpotent, and therefore we get $t^{-n} f \in A^\circ$. Hence $f \in t^n A^\circ$. Since A° is t -adically separated and n is arbitrary, it follows that $f = 0$. \square

We define preuniformity also for pairs that induce Tate rings.

Definition 2.16 (Preuniform pairs). Let (A_0, I_0) be a pair of a ring A_0 and an ideal $I_0 \subset A_0$.

- (1) We say that (A_0, I_0) is *preuniform*, if A_0 has a nonzero divisor t with the following property:
 - $I_0 = tA_0$, and there exists some $c > 0$ for which $t^c(A_0)_{A_0[\frac{1}{t}]}^+ \subset A_0$.
- (2) We say that (A_0, I_0) is *uniform*, if it is preuniform and A_0 is I_0 -adically complete and separated.

Recall that a morphism of pairs $f_0 : (A_0, I_0) \rightarrow (B_0, J_0)$ is required to be *continuous*. In other words, there exists $n > 0$ such that $I_0^n \subset f_0^{-1}(J_0)$. The above definition is derived from the following fact.

Lemma 2.17. *Let A_0 be a ring with a nonzero divisor $t \in A_0$ and let A be the Tate ring associated to $(A_0, (t))$. Then A is preuniform (resp. uniform) if and only if the pair $(A_0, (t))$ is preuniform (resp. uniform).*

Proof. It follows immediately from Lemma 2.13(2). \square

Let us give some guiding examples to understand the notion of preuniformity.

- Example 2.18.* (1) Let V be a valuation ring, and $t \in V$ a nonzero element. Then, since V is integrally closed in the field of fractions $K := \text{Frac}(V)$, we have $V_{V[\frac{1}{t}]}^+ = V$. Hence the pair $(V, (t))$ and the associated Tate ring $V[\frac{1}{t}]$ are preuniform. If V is t -adically separated, then the associated Tate ring $V[\frac{1}{t}]$ coincides with K as a ring (when $V \neq K$, the converse also holds; cf. [15, Proposition 6.7.2 in Chapter 0]). Notice that any valuation ring of finite rank that is not a field has such a nonzero element t . Indeed, if V is so, then it contains a prime ideal \mathfrak{p} of height 1. Since the localization $V_{\mathfrak{p}}$ is a valuation ring of rank 1 with maximal ideal $\mathfrak{p}V_{\mathfrak{p}}$, any nonzero element $t \in \mathfrak{p}$ satisfies $V_{\mathfrak{p}}[\frac{1}{t}] = K$, which implies $V[\frac{1}{t}] = K$ because $tV_{\mathfrak{p}} \subset \mathfrak{p}V_{\mathfrak{p}} \subset V$.
- (2) Let A_0 be the ring of dual numbers $\mathbb{Z}_p[T]/(T^2)$ over \mathbb{Z}_p . Then $p \in A_0$ is a nonzero divisor. Moreover, for every $n > 0$, $\frac{T}{p^n} \in A_0[\frac{1}{p}]$ is integral over A_0 because $(\frac{T}{p^n})^2 = 0$. However, $p^{n-1}(\frac{T}{p^n}) \notin A_0$. Hence the pair $(A_0, (p))$ is *not* preuniform. Let A be the Tate ring associated to $(A_0, (p))$. Then A is not preuniform but separated, and it would give a counter-example to Lemma 2.15 if the assumption of preuniformity is dropped.

2.3.1. Finitely generated modules over a Tate ring. One can define a canonical topology on a finitely generated module over a Tate ring. We introduce a notation. Let A be a ring with an ideal $I \subset A$ and let $f : N \rightarrow M$ be a homomorphism of A -modules. Set

$$(2.3) \quad (N :_M J) := \{m \in M \mid Jm \subset f(N)\},$$

which is a A -submodule of M .

Lemma 2.19. *Let A be a Tate ring and let M be a finitely generated A -module. Take a ring of definition $A_0 \subset A$, a pseudouniformizer $t \in A_0$ and a finite generating set S of M over A . Let $M_0 \subset M$ be the A_0 -submodule generated by S . Equip M with the linear topology defined by $\{t^n M_0\}_{n>0}$.*

- (1) *The topology on M is independent of the choices of A_0 , t and S .*
- (2) *For every finitely generated A_0 -submodule N_0 of M such that $M = N_0[\frac{1}{t}]$, the induced topology on N_0 coincides with the t -adic topology.*
- (3) *Let $f : M \rightarrow N$ be a homomorphism of A -modules, where N is finitely generated. Equip N with the topology defined above. Then f is continuous.*

Proof. Since $M = \bigcup_{n \geq 0} (M_0 :_M (t^n))$, there exists some $c > 0$ such that $t^c N_0 \subset M_0$ for every finitely generated A_0 -submodule N_0 of M . Hence (2) and (3) are easy to see. To show (1), let us consider another data: (A'_0, t', S', M'_0) . Pick an integer $m > 0$. Then it suffices to check that there exists some $m' > 0$ for which $t'^{m'} M'_0 \subset t^m M_0$ holds. Let $N'_0 \subset M$ be the A'_0 -submodule generated by S' . Then $t'^{c_1} M'_0 \subset N'_0$ for some $c_1 > 0$, as M'_0 is finitely generated. Meanwhile, since $t^m A_0 \subset A$ is open, there exists some $c_2 > 0$ such that $t'^{c_2} A'_0 \subset t^m A_0$ and so $t'^{c_2} N'_0 \subset t^m M_0$. Hence by putting $m' := c_1 + c_2$, we obtain $t'^{m'} M'_0 \subset t^m M_0$, as wanted. \square

Notice that one can set $M = A$ in Proposition 2.19, and the resulting topology on A coincides with the original one. Now we can give a canonical Tate ring structure to any module-finite algebra extension of a Tate ring.

Lemma 2.20. *Let A be a Tate ring and let B be a module-finite A -algebra. Equip B with the topology as in Lemma 2.19. Then B is equipped with the structure as a Tate ring with the following property:*

- *for every ring of definition A_0 and every pseudouniformizer $t \in A_0$ of A , there exists a ring of definition B_0 of B that is an integral A_0 -subalgebra of B with finitely many generators and $t \in B_0$ is a pseudouniformizer of B .*

Proof. Take a system of generators x_1, \dots, x_r of the A -module B . Multiplying each x_i by a power of t if necessary, we may assume that they are integral over A_0 . Let $B_0 \subset B$ be an A_0 -subalgebra generated by x_1, \dots, x_r . As $B = B_0[\frac{1}{t}]$, we can introduce a Tate ring structure into B with a ring of definition B_0 and a pseudouniformizer $t \in B_0$ as in Lemma 2.11(1). Meanwhile, since each x_i is integral over A_0 , B_0 is a module-finite A_0 -algebra. Hence the topology on B coincides with the one defined by setting $M = B$ in Lemma 2.19. \square

If a finitely generated module M over a Tate ring admits a structure of a finitely generated module over another Tate ring, then one can consider two canonical topologies on M . In the following situation, these topologies coincide.

Lemma 2.21. *Let A be a Tate ring and let B be a module-finite A -algebra. Equip B with the canonical structure as a Tate ring as in Lemma 2.20. Let M be a finitely generated B -module. Then the following two topologies:*

- *the canonical topology on M as a finitely generated A -module;*
- *the canonical topology on M as a finitely generated B -module;*

coincide.

Proof. Let A_0 be a ring of definition of A and let $t \in A_0$ be a pseudouniformizer of A . Then we can take a ring of definition B_0 of B that is finitely generated over A_0 and satisfies $B = B_0[\frac{1}{t}]$. Let M_0 be a finitely generated B_0 -submodule of M such that $M = M_0[\frac{1}{t}]$. Then, also as an A_0 -module, M_0 is finitely generated and satisfies $M = M_0[\frac{1}{t}]$. Hence the assertion follows. \square

Remark 2.22. Let A_0 be a ring with a nonzero divisor $t \in A_0$, and put $A := A_0[\frac{1}{t}]$. Let M be an A -module and let $M_0 \subset M$ be an A_0 -submodule such that $M = M_0[\frac{1}{t}]$. Equip M with the linear topology defined by $\{t^n M_0\}_{n \geq 1}$ (this situation already occurred in the above two lemmas). Now let us consider the completion M' of M (i.e. $M' = \varprojlim_n M/t^n M_0$). One applies the same operations to both A_0 and A . That is, $\widehat{A_0} := \varprojlim_n A_0/t^n A_0$ and $\widehat{A} := \varprojlim_n A/t^n A_0$. By [6, Chaptires III, Paragraph 6.5, Proposition 6, and Chapitres II, Paragraph 3.9, Corollaire 1], one checks that $\widehat{A_0}$ and \widehat{A} are rings. Now since M_0 is t -torsion free, so is the t -adic completion $\widehat{M_0}$ (cf. [26, Lemma

4.2]). We equip $(\widehat{M_0})[\frac{1}{t}]$ with the linear topology defined by $\{t^n \widehat{M_0}\}_{n \geq 1}$. Then $(\widehat{M_0})[\frac{1}{t}]$ is complete and separated. Since M_0 and $\widehat{M_0}$ are t -torsion free, one can check that the map

$$(2.4) \quad (\widehat{M_0})[\frac{1}{t}] \rightarrow M', \quad \frac{(m_n \bmod t^n M_0)_{n \geq 1}}{t^h} \mapsto \left(\frac{m_{n+h}}{t^h} \bmod t^n M_0\right)_{n \geq 1}$$

is well-defined. Indeed, consider the exact sequence $0 \rightarrow M_0 \rightarrow M \rightarrow M/M_0 \rightarrow 0$. Then it induces another exact sequence $0 \rightarrow M_0/t^n M_0 \rightarrow M/t^n M_0 \rightarrow M/M_0 \rightarrow 0$. Taking inverse limits, with respect to $n \in \mathbb{N}$, we obtain an exact sequence

$$(2.5) \quad 0 \rightarrow \widehat{M_0} \rightarrow M' \rightarrow M/M_0 \rightarrow 0.$$

Since we are assuming the condition $M = \bigcup_{n \geq 1} (M_0 :_M (t^n))$, tensoring $A_0[\frac{1}{t}]$ with the sequence (2.5), it follows that (2.4) is an isomorphism of A -modules. Next we observe that (2.4) gives an isomorphism of topological A_0 -modules. The map (2.4) is a continuous A_0 -homomorphism, and the map $M_0 \rightarrow \widehat{M_0}$ induces the continuous A_0 -homomorphism $M \rightarrow (\widehat{M_0})[\frac{1}{t}]$. Moreover, the resulting diagram

$$\begin{array}{ccc} (\widehat{M_0})[\frac{1}{t}] & \xrightarrow{\quad} & M' \\ & \nwarrow \quad \nearrow & \\ & M & \end{array}$$

commutes. Hence it follows from the universality of completion (cf. [15, Proposition 7.1.9 in Chapter 0]) that the map (2.4) is an A_0 -isomorphism that is also a homeomorphism.

Next let us consider a base extension of a module-finite algebra over a Tate ring. Then one may define two types of canonical topologies on it, but they are the same.

Lemma 2.23. *Let A be a Tate ring, let $(A_0, (t))$ be a pair of definition of A and let $A \rightarrow A'$ be a continuous ring map between Tate rings. Let B be a module-finite A -algebra, and set $B' := B \otimes_A A'$. Equip B (resp. B') with the canonical topology by regarding it as a module-finite A -algebra (resp. A' -algebra). Let B_0 be a ring of definition of B that is an A_0 -subalgebra of B , and let A'_0 be a ring of definition of A' that is an A_0 -subalgebra of A' . Let B'_0 be the image of the natural map $B_0 \otimes_{A_0} A'_0 \rightarrow B'$. Then $(B'_0, (t))$ is a pair of definition of B' .*

Proof. Since $A = A_0[\frac{1}{t}]$, $A' = A'_0[\frac{1}{t}]$, and $B = B_0[\frac{1}{t}]$, we have $B' = B'_0[\frac{1}{t}]$. Thus by Lemma 2.11(1), it suffices to check that $\{t^n B'_0\}_{n \geq 1}$ forms a fundamental system of neighborhoods of $0 \in B'$. Now we may assume that B_0 is generated by finitely many elements $x_1, \dots, x_s \in B_0$ as an A_0 -submodule of B (such a ring of definition exists by the proof of Lemma 2.20). Put $x'_i := x_i \otimes_A 1_{A'}$ for $i = 1, \dots, s$. Then B'_0 is generated by x'_1, \dots, x'_s as an A'_0 -submodule of B' . Thus, since $B' = B'_0[\frac{1}{t}]$, the assertion follows. \square

2.4. Non-archimedean seminorms. Here we give a brief review and some new notation on non-archimedean seminorms. Our basic references are [5, Chapter 1], [15, Chapter 2, Appendix C] and [20, Chapter 2].

Definition 2.24. Let A be a commutative ring.

- (1) A function $\|\cdot\| : A \rightarrow \mathbb{R}_{\geq 0}$ is called a (*non-archimedean*) *seminorm* on A , if it satisfies the following conditions.
 - (a) $\|0\| = 0$.
 - (b) $\|f - g\| \leq \max\{\|f\|, \|g\|\}$ for every $f, g \in A$.
 - (c) $\|1\| \leq 1$.

- (d) $\|fg\| \leq \|f\|\|g\|$ for every $f, g \in A$.
 A seminorm $\|\cdot\|$ on A is called a *norm*, if it satisfies the following condition.
 (a') For $f \in A$, one has $\|f\| = 0$ if and only if $f = 0$.
 (2) Let $\|\cdot\|$ and $\|\cdot\|'$ be seminorms on A . We say that $\|\cdot\|$ and $\|\cdot\|'$ are *equivalent* (or $\|\cdot\|$ is *equivalent* to $\|\cdot\|'$), if there exist real numbers $C, C' > 0$ such that one has
- $$\|f\|' \leq C\|f\| \leq C'\|f\|'$$
- for every $f \in A$. We mean by $\|\cdot\| \sim \|\cdot\|'$ that $\|\cdot\|$ is equivalent to $\|\cdot\|'$.
 (3) Let $\|\cdot\|$ be a seminorm on A . We say that $f \in A$ is *powermultiplicative* with respect to $\|\cdot\|$, if $\|f^n\| = \|f\|^n$ holds for every $n > 0$. We say that $f \in A$ is *multiplicative* with respect to $\|\cdot\|$, if $\|fg\| = \|f\|\|g\|$ holds for every $g \in A$. We say that $\|\cdot\|$ is *powermultiplicative* (resp. *multiplicative*), if any $f \in A$ is powermultiplicative (resp. multiplicative) with respect to $\|\cdot\|$.

Here we list some basic facts on seminorms.

Lemma 2.25. *Let A be a ring and let $\|\cdot\|$, $\|\cdot\|'$, and $\|\cdot\|''$ be seminorms on A .*

- (1) *If $\|\cdot\| \sim \|\cdot\|'$ and $\|\cdot\|' \sim \|\cdot\|''$, then $\|\cdot\| \sim \|\cdot\|''$.*
 (2) *If $\|\cdot\|$ and $\|\cdot\|'$ are powermultiplicative and $\|\cdot\| \sim \|\cdot\|'$, then $\|\cdot\| = \|\cdot\|'$.*
 (3) *Let u be a unit in A . Suppose that $\|\cdot\|$ is not identically zero. Then $\|u\| \neq 0$. Moreover, u is multiplicative with respect to $\|\cdot\|$ if and only if $\|u^{-1}\| = \|u\|^{-1}$.*

Proof. The assertions (1) and (2) are easy to check. (3) follows from [5, §1.2.2, Proposition 4]. \square

Let A be a ring, and let $\|\cdot\|$ be a seminorm on A . We put $F_r := \{f \in A \mid \|f\| \leq r\}$ for every positive real number r . Then F_1 forms a subring of A , and each F_r forms an F_1 -submodule of A . Hence one can define the linear topology on A such that the filtration $\{F_r\}_{r>0}$ forms a fundamental system of open neighborhoods of $0 \in A$. Moreover, the ring A equipped with this topology is a topological ring. For this topological ring A , a subset $S \subset A$ is bounded (Definition 2.9) if and only if $S \subset F_r$ for some $r > 0$. If two seminorms $\|\cdot\|$ and $\|\cdot\|'$ on A are equivalent, then they define the same topology on A (but the converse does not necessarily hold). The following class of seminorms is useful for characterization of Tate rings.

Definition 2.26. Let A_0 be a ring with a nonzero divisor $t \in A_0$. We say that a seminorm $\|\cdot\|$ on $A_0[\frac{1}{t}]$ is *associated to* $(A_0, (t))$, if there exists a real number $c > 1$ such that $\|\cdot\|$ is equivalent to the seminorm $\|\cdot\|_{A_0, (t), c}$ defined by

$$\|f\|_{A_0, (t), c} := \begin{cases} c^{\min\{m \in \mathbb{Z} \mid t^m f \in A_0\}} & (f \notin \bigcap_{n=0}^{\infty} t^n A_0) \\ 0 & (f \in \bigcap_{n=0}^{\infty} t^n A_0). \end{cases}$$

Lemma 2.27. *Let A be a topological ring, let $t \in A$ be an element and let A_0 be a subring of A . Then the following conditions are equivalent.*

- (a) *A is a Tate ring with a ring of definition A_0 and a pseudouniformizer $t \in A_0$.*
 (b) *$t \in A$ is a unit, and there exists some seminorm $\|\cdot\|$ on A with the following properties:*
- *the topology on A is induced by $\|\cdot\|$;*
 - *$\|t\| < 1$, and t is multiplicative with respect to $\|\cdot\|$;*
 - *$A_0 = \{f \in A \mid \|f\| \leq 1\}$.*

Proof. To see (a) \Rightarrow (b), it is enough to consider the seminorm $\|\cdot\|_{A_0, (t), 2}$. Conversely, if (b) is satisfied, then $t^n A_0 = \{f \in A \mid \|f\| \leq \|t\|^n\}$ for every $n > 0$ by Lemma 2.25(3). Hence one can easily deduce (a) from (b). \square

For a ring A and a seminorm $\|\cdot\|$ on A , we define a function $\|\cdot\|_{\text{sp}} : A \rightarrow \mathbb{R}_{\geq 0}$ by

$$\|f\|_{\text{sp}} := \inf_{n \geq 1} \|f^n\|^{\frac{1}{n}} \quad (f \in A).$$

$\|\cdot\|_{\text{sp}}$ has the following properties.

Lemma 2.28 ([5, §1.3.2]). *Let A be a ring and let $\|\cdot\|$ be a seminorm on A .*

- (1) *One has $\|f\|_{\text{sp}} = \lim_{n \rightarrow \infty} \|f^n\|^{\frac{1}{n}}$ and $\|f\|_{\text{sp}} \leq \|f\|$ for every $f \in A$ and $\|\cdot\|_{\text{sp}}$ is a powermultiplicative seminorm on A .*
- (2) *If $f \in A$ is multiplicative with respect to $\|\cdot\|$, then f is also multiplicative with respect to $\|\cdot\|_{\text{sp}}$.*

We call $\|\cdot\|_{\text{sp}}$ the *spectral seminorm* associated to $\|\cdot\|$. Using spectral seminorms, we obtain the following characterization of preuniformity.

Lemma 2.29. *Let A_0 be a ring with a nonzero divisor $t \in A_0$.*

- (1) *$t \in A_0$ is multiplicative with respect to the seminorm $\|\cdot\|_{A_0, (t), c}$ for every $c > 1$.*
- (2) *The following conditions are equivalent.*
 - (a) *$(A_0, (t))$ is preuniform.*
 - (b) *For any seminorm $\|\cdot\|$ associated to $(A_0, (t))$, one has $\|\cdot\| \sim \|\cdot\|_{\text{sp}}$ (or equivalently, $\|\cdot\|$ is equivalent to a powermultiplicative seminorm).*

Proof. The assertion (1) is clear. Let us prove (2). To see (b) \Rightarrow (a), it is enough to consider the topology induced by a powermultiplicative seminorm. Here we show (a) \Rightarrow (b). Since A° is bounded with respect to (the topology induced by) $\|\cdot\|$, we may assume that $\|\cdot\| = \|\cdot\|_{A^\circ, (t), 2}$. Then t is multiplicative with respect to $\|\cdot\|$ and $\|\cdot\|_{\text{sp}}$. Thus, it suffices to show the existence of some constants $C, C' > 0$ such that $C\|a\| \leq \|a\|_{\text{sp}} \leq C'\|a\|$ for an arbitrary $a \in A^\circ \setminus tA^\circ$. Now $a^n \notin t^n A^\circ$ holds for an arbitrary $n > 0$; otherwise, $(t^{-1}a)^l$ would belong to A° for some $l > 0$, which implies that $a \in tA^\circ$ as A° is integrally closed in $A_0[\frac{1}{t}]$. Hence $\|t\| < \|a^n\|^{\frac{1}{n}}$ and therefore, $\|t\| \leq \|a\|_{\text{sp}} \leq 1$. Thus we have $2^{-1}\|a\| \leq \|a\|_{\text{sp}} \leq \|a\|$, as wanted. \square

Moreover, if A_0 is a valuation ring V and $V[\frac{1}{t}]$ is a field, then $\|\cdot\|_{\text{sp}}$ is a multiplicative norm.

Lemma 2.30. *Let V be a valuation ring and assume that there is a nonzero element $t \in V$ for which V is t -adically separated. Let $\|\cdot\| : V[\frac{1}{t}] \rightarrow \mathbb{R}_{\geq 0}$ be a seminorm associated to $(V, (t))$. Then the spectral seminorm $\|\cdot\|_{\text{sp}}$ is multiplicative.*

Proof. Since V is t -adically separated, it follows that $K := V[\frac{1}{t}]$ is the field of fractions of V by [15, Proposition 6.7.2 in Chapter 0]. In view of Lemma 2.25(1), Lemma 2.25(2) and Lemma 2.29(2), we may assume that $\|\cdot\| = \|\cdot\|_{V, (t), c}$ for a real number $c > 1$. It suffices to prove that any $f \in K$ is multiplicative with respect to $\|\cdot\|_{\text{sp}}$. As clearly $0 \in K$ is multiplicative, we assume that $f \neq 0$. By Lemma 2.25(3), we are reduced to showing that $\|f^{-1}\|_{\text{sp}} = \|f\|_{\text{sp}}^{-1}$. Pick an arbitrary $g \in K^\times$ and put $\lambda(g) := \min\{m \in \mathbb{Z} \mid t^m g \in V\}$. Since V is a valuation ring, we have $t^{-(\lambda(g)-1)}V \subset gV \subset t^{-\lambda(g)}V$. It implies that $t^{\lambda(g)}V \subset g^{-1}V \subset t^{\lambda(g)-1}V$. Therefore, we find that

$$\|g\|^{-1} = c^{-\lambda(g)} \leq \|g^{-1}\| \leq c^{-(\lambda(g)-1)} = c\|g\|^{-1}.$$

Thus we have $(\|f^n\|^{\frac{1}{n}})^{-1} \leq \|f^{-n}\|^{\frac{1}{n}} \leq c^{\frac{1}{n}}(\|f^n\|^{\frac{1}{n}})^{-1}$ for every $n > 0$. Taking the limits, we obtain $\|f\|_{\text{sp}}^{-1} = \|f^{-1}\|_{\text{sp}}$, as wanted. \square

Now let us recall *Banach rings*.

Definition 2.31 (Banach rings).

- (1) A *Banach ring* is a ring R equipped with a norm $\|\cdot\|$ such that R is complete with respect to the topology defined by $\|\cdot\|$.
- (2) Let R be a Banach ring equipped with a norm $\|\cdot\|$. We say that R is *uniform*, if R contains a unit t with $\|t\| < 1$, and $\|\cdot\|$ is equivalent to a powermultiplicative norm.
- (3) Let R and S be Banach rings and denote by $\|\cdot\|_R$ and $\|\cdot\|_S$ the norms on R and S , respectively. We say that a ring homomorphism $\varphi : R \rightarrow S$ is *bounded*, if one has $\|\varphi(f)\|_S \leq \|f\|_R$ for every $f \in R$ (notice that this property is stable under composition).
- (4) Let R be a Banach ring. A *Banach R -algebra* is a Banach ring S equipped with a bounded homomorphism $\varphi : R \rightarrow S$.
- (5) Let A_0 be a ring with a nonzero divisor $t \in A_0$ that is t -adically complete and separated. We say that a Banach ring R is *associated to* $(A_0, (t))$, if the underlying ring R is equal to $A_0[\frac{1}{t}]$ and the norm on R is associated to $(A_0, (t))$.

From now on, we view a Banach ring also as a (complete and separated) topological ring by considering the topology defined by the norm. Then we can compare Banach rings with Tate rings as follows.

Lemma 2.32. *Let R be a Banach ring equipped with a norm $\|\cdot\|$. Then the following assertions hold.*

- (1) *If R contains a unit t with $\|t\| < 1$, then R is a complete and separated Tate ring that has a ring of definition*

$$R_0 = \{f \in R \mid \|f\| \leq 1\}$$

and a pseudouniformizer t .

- (2) *If R is a Banach ring associated to $(A_0, (t))$ as in Definition 2.31(5), then R is the Tate ring associated to $(A_0, (t))$.*
- (3) *If R is uniform (in the sense of Definition 2.31(2)), then R is a uniform Tate ring (in the sense of Definition 2.14).*

Proof. (1): By definition, t lies in R_0 . Hence it suffices to show that $\{t^n R_0\}_{n \geq 1}$ forms a fundamental system of open neighborhoods of $0 \in R$. Recall that R admits a fundamental system of open neighborhoods $\{F_r\}_{r > 0}$ (where $F_r = \{f \in R \mid \|f\| \leq r\}$) at $0 \in R$. Since $t^n R_0 \subset F_{\|t\|^n}$ for every $n \geq 1$, we are reduced to showing that there exists some $C_n > 0$ with $F_{C_n} \subset t^n R_0$.

First we consider the case when $\|t^{-1}\| = 0$. Then for every $f \in R$, we have $\|f\| = 0$ by Lemma 2.25(3), and hence $f = 0$. Therefore, R is the zero ring.³ Thus $F_1 = t^n R_0$ for every $n \geq 1$, which yields the assertion.

Next we assume that $\|t^{-1}\| \neq 0$. Set $C := \|t^{-1}\|$. Let us show that $F_{C^{-n}} \subset t^n R_0$ for every $n \geq 1$. Pick $f \in R$ with $\|f\| \leq C^{-n}$. Then we have

$$\|t^{-n} f\| \leq \|t^{-1}\|^n \|f\| = C^n \|f\| \leq 1.$$

Hence $t^{-n} f \in R_0$, which means that $f \in t^n R_0$. Thus the assertion follows.

(2): It follows immediately from Lemma 2.27.

(3): Let $\|\cdot\|'$ be a powermultiplicative norm on R that is equivalent to $\|\cdot\|$. Then $\|t^l\|' < 1$ for some $l \geq 1$, and hence $\|t\|' < 1$ because $\|\cdot\|'$ is powermultiplicative. Thus, since $\|\cdot\|$ and $\|\cdot\|'$ define the same topology on R , R is a Tate ring that has a ring of definition

$$R'_0 := \{f \in R \mid \|f\|' \leq 1\}$$

³The zero ring $\{0\}$ equipped with the unique topology is a Tate ring whose pair of definition is $(\{0\}, (0))$. Notice that any ring is 0-adically complete and separated.

and a pseudouniformizer t by the assertion (1). Moreover, since $\|\cdot\|'$ is powermultiplicative, R'_0 is completely integrally closed in $R = R'_0[\frac{1}{t}]$. Hence the assertion follows from Lemma 2.13. \square

An *almost perfectoid algebra* (cf. Definition 3.18) is an important example of a Banach algebra. We use the following lemma to describe the relationship between almost perfectoid algebras and almost Witt-perfect algebras (cf. Proposition 3.20).

Lemma 2.33. *Let A_0 be a ring with a nonzero divisor $t \in A_0$ and let B_0 be a t -torsion free A_0 -algebra. Assume that A_0 and B_0 are t -adically complete and separated. Then there exist Banach rings R and S with the following properties:*

- R is associated to $(A_0, (t))$ and S is associated to $(B_0, (t))$;
- the ring homomorphism $R \rightarrow S$ induced by the homomorphism $A_0 \rightarrow B_0$ is bounded.

If further $(A_0, (t))$ and $(B_0, (t))$ are uniform, then one can take R so that the norm on R is powermultiplicative.

Proof. To see the first assertion, it suffices to take a real number $c > 1$ and equip $A_0[\frac{1}{t}]$ and $B_0[\frac{1}{t}]$ with the norms $\|\cdot\|_{A_0, (t), c}$ and $\|\cdot\|_{B_0, (t), c}$, respectively. To check the last assertion, it is enough to replace $\|\cdot\|_{A_0, (t), c}$ and $\|\cdot\|_{B_0, (t), c}$ with their respective spectral norms. \square

Hereafter, we use the following notation: for a Banach ring R with a norm $\|\cdot\|$, we equip the ring $R[T^{\frac{1}{p^\infty}}]$ with the norm $\|\cdot\|_{\text{Gauss}}$ defined by $\|\sum_{h \in \mathbb{Z}[\frac{1}{p}]} r_h T^h\|_{\text{Gauss}} := \sup_{h \in \mathbb{Z}[\frac{1}{p}]} \{\|r_h\|\}$ (where $r_h \in R$), and denote by $R\langle T^{\frac{1}{p^\infty}} \rangle$ the resulting Banach ring obtained by completion.

3. ALMOST RING THEORY AND ALMOST SURJECTIVITY OF THE FROBENIUS MAP

3.1. Basic setup and semiperfect rings. We start with basic part of the theory of almost rings and modules. We say that a pair (R, I) is a *basic setup*, if I is an ideal of a ring R , $I = I^2$ and I is a flat R -module.⁴ An R -module map $f : M \rightarrow N$ is said to be *I -almost injective* (resp. *I -almost surjective*), if the kernel (resp. cokernel) of f is annihilated by I . Moreover, f is said to be an *I -almost isomorphism*, if it is both I -almost injective and I -almost surjective. A general reference is the book [16]. We will be mainly concerned with the following cases:

- $(R, I) = (\mathbb{Z}[T^{\frac{1}{p^\infty}}], (T)^{\frac{1}{p^\infty}})$.
- $(R, I) = (K^\circ \langle T^{\frac{1}{p^\infty}} \rangle, (T)^{\frac{1}{p^\infty}} K^{\circ\circ} K^\circ \langle T^{\frac{1}{p^\infty}} \rangle)$, where K is a perfectoid field and $K^{\circ\circ}$ is the set of topologically nilpotent elements of K (see Definition 2.10).
- $(R, I) = (A_0, I)$, where A_0 is a ring of definition of a Tate ring A (see Example 3.1 below).

Example 3.1. Fix a prime number $p > 0$. Let A_0 be a ring with a sequence of nonzero divisors $\{t_n\}_{n \geq 0}$ such that A_0 is integrally closed in $A := A_0[\frac{1}{t_0}]$ and assume that for every $n \geq 0$ we have $t_{n+1}^p = t_n u_n$ for some unit $u_n \in A_0^\times$. Denote by I the ideal $\sqrt{(t_0)} \subset A_0$. Then the pair (A_0, I) is a basic setup. Let us observe it. Pick $x \in I$. Then we have $x^{p^m} = t_0 a$ for some $m > 0$ and $a \in A_0$. Thus, since $t_m^{p^m} = t_0 u$ for some unit $u \in A_0$, an equality $(\frac{x}{t_m})^{p^m} = au^{-1}$ holds in A . Hence x lies in $t_m A_0$, because A_0 is integrally closed in A . Consequently, we have $I = \varinjlim_n t_n A_0$. Therefore, we find that $I = I^p$ and I is flat over A_0 .

We give definitions of (almost) semiperfect rings that include both classes of Witt-perfect and perfectoid algebras.

Definition 3.2 (Almost semiperfect ring). Let A_0 be a ring and fix a prime number $p > 0$.

⁴The flatness of I is important for developing a solid theory of almost rings and modules.

- (1) We say that A_0 is *perfect* (resp. *semiperfect*), if the Frobenius endomorphism on $A_0/(p)$ is bijective (resp. surjective).
- (2) Assume that A_0 is a $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebra with a basic setup $(\mathbb{Z}[T^{\frac{1}{p^\infty}}], (T)^{\frac{1}{p^\infty}})$. We say that A_0 is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect, if the Frobenius endomorphism $F : A_0/(p) \rightarrow A_0/(p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost surjective, where the target ring of F is regarded as an A_0 -module via the Frobenius map.

First we give several lemmas on (almost) semiperfect rings for later use. For an element t in a ring A_0 , we say that A_0 is *t-adically Zariskian*, if t is contained in the Jacobson radical of A_0 ; see [15] and [29] for details on Zariskian geometry. Notice that for any ring, one can define a trivial $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebra structure by assigning the unity to each $T^{\frac{1}{p^n}}$. Over such a $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebra, $(T)^{\frac{1}{p^\infty}}$ -almost semiperfectness is equivalent to semiperfectness.

Lemma 3.3. *Let A_0 be a ring with a nonzero divisor ϖ such that $p \in \varpi^p A_0$. Assume that A_0 is ϖ -adically Zariskian and $A_0/(\varpi^p)$ is semiperfect. Then there exists a sequence $\{\varpi_n\}_{n \geq 0}$ in A_0 such that $\varpi_0 = \varpi$ and for every $n \geq 0$, we have $\varpi_{n+1}^p = \varpi_n u_n$ for some unit $u_n \in A_0^\times$.*

Proof. We carry out the proof by induction. Put $\varpi_0 := \varpi$. Then, since $A_0/(\varpi_0^p)$ is semiperfect, we find $a_0, b_0 \in A_0$ for which $a_0^p = \varpi_0 + \varpi_0^p b_0 = \varpi_0(1 + \varpi_0^{p-1} b_0)$. Here $1 + \varpi_0^{p-1} b_0$ is a unit in A_0 , because A_0 is ϖ -adically Zariskian. Hence we can take $\varpi_1 = a_0$. Next pick an integer $m > 0$ and assume that the assertion holds true for every $n \leq m-1$. Take $a_m, b_m \in A_0$ for which $\varpi_m = a_m^p + \varpi^p b_m$. Now $(\varpi_m^{p^m}) = (\varpi)$ as ideals by assumption and therefore, we have $c_m \in A$ for which $\varpi = \varpi_m c_m$. Then it holds that $\varpi_m^p = \varpi_m(1 + \varpi_m^{p-1} c_m^p b_m)$ and $1 + \varpi_m^{p-1} c_m^p b_m \in A_0^\times$. Hence we can take $\varpi_{m+1} = a_m$, which completes the proof. \square

Lemma 3.4. *Let A_0 be a $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebra with a basic setup $(\mathbb{Z}[T^{\frac{1}{p^\infty}}], (T)^{\frac{1}{p^\infty}})$. Then the following conditions are equivalent.*

- (1) A_0 is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect.
- (2) There is a semiperfect $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebra B_0 with the following property: $A_0/(p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost isomorphic to $B_0/(p)$ as $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebras.

Proof. First we assume (1). We denote by $g^{\frac{1}{p^n}}$ the image of $T^{\frac{1}{p^n}}$ in $A_0/(p)$ for every $n \geq 0$. Consider the inverse perfection $A_0^b := \varprojlim_{x \mapsto x^p} A_0/(p)$, together with a ring map $\mathbb{Z}[T^{\frac{1}{p^\infty}}] \rightarrow A_0^b$ that assigns $(g, g^{\frac{1}{p}}, g^{\frac{1}{p^2}}, \dots) \in A_0^b$ to T . Let $\Phi_{A_0} : A_0^b \rightarrow A_0/(p)$ be the projection map defined by the rule $(a_0, a_1, a_2, \dots) \mapsto a_0$. Then the induced map $A_0^b/\text{Ker}(\Phi_{A_0}) \hookrightarrow A_0/(p)$ is a $(T)^{\frac{1}{p^\infty}}$ -almost isomorphism and $A_0^b/\text{Ker}(\Phi_{A_0})$ is semiperfect. Hence the implication (1) \Rightarrow (2) follows. The converse is easy to check. \square

For a surjective ring map $A_0 \twoheadrightarrow B_0$ with B_0 semiperfect, clearly the semiperfectness does not lift to A_0 in general. On the other hand, in the situations we deal with later, the following assertion holds.

Lemma 3.5. *Let A_0 be a $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebra with a nonzero divisor ϖ such that $p \in \varpi^p A_0$. Assume that ϖ admits a p -th root $\varpi^{\frac{1}{p}} \in A_0$. Then the following assertions hold.*

- (1) $A_0/(\varpi)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect if and only if $A_0/(\varpi^p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect.

(2) Equip A_0 with the ϖ -adic topology and assume further that $(p) \subset A_0$ is closed and A_0 is complete and separated. Then $A_0/(\varpi^p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect if and only if $A_0/(p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect.

Proof. If $A_0/(\varpi^p)$ (resp. $A_0/(p)$) is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect, then clearly so is $A_0/(\varpi)$ (resp. $A_0/(\varpi^p)$). So it suffices to prove the inverse implications. Fix an arbitrary integer $n > 0$, and put $g^{\frac{1}{p^k}} := T^{\frac{1}{p^k}} \cdot 1 \in A_0$ for every $k \geq 0$. Assume that $A_0/(\varpi)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect. Pick an element $a \in A_0$ and put $a' := g^{\frac{1}{p^n}} a$. Then by assumption, there exist some $a_0, b_0 \in A_0$ such that $g^{\frac{p-1}{p^{n+1}}} a = a_0^p + \varpi b_0$. Multiplying both sides by $g^{\frac{1}{p^{n+1}}}$, we obtain $a' = g^{\frac{1}{p^{n+1}}} a_0^p + \varpi(g^{\frac{1}{p^{n+1}}} b_0)$. Similarly, we can find some $a_1, b_1 \in A_0$ such that $g^{\frac{1}{p^{n+1}}} b_0 = g^{\frac{1}{p^{n+2}}} a_1^p + \varpi(g^{\frac{1}{p^{n+2}}} b_1)$. This procedure yields the following assertion: if a system of elements $a_0, \dots, a_m \in A_0$ satisfies $a' \equiv \sum_{i=0}^m g^{\frac{1}{p^{n+i+1}}} a_i^p \varpi^i \pmod{(g^{\frac{1}{p^{n+m+1}}} \varpi^{m+1})}$, then there exists some $a_{m+1} \in A_0$ for which $a' \equiv \sum_{i=0}^{m+1} g^{\frac{1}{p^{n+i+1}}} a_i^p \varpi^i \pmod{(g^{\frac{1}{p^{n+m+2}}} \varpi^{m+2})}$. Hence by axiom of choice, we obtain a sequence $\{a_m\}_{m \geq 0}$ in A_0 such that $a' \equiv \sum_{i=0}^m g^{\frac{1}{p^{n+i+1}}} a_i^p \varpi^i \pmod{(g^{\frac{1}{p^{n+m+1}}} \varpi^{m+1})}$ for every $m \geq 0$. In particular, we have

$$a' \equiv \sum_{i=0}^{p-1} g^{\frac{1}{p^{n+i+1}}} a_i^p \varpi^i \equiv \left(\sum_{i=0}^{p-1} g^{\frac{1}{p^{n+i+2}}} a_i \varpi^{\frac{i}{p}} \right)^p \pmod{(\varpi^p)},$$

which yields (1). To prove (2), we equip A_0 with the ϖ -adic topology, and assume further that $(p) \subset A_0$ is closed and A_0 is complete and separated. Set $b_m := \sum_{i=0}^m g^{\frac{1}{p^{n+i+2}}} a_i \varpi^{\frac{i}{p}}$ ($m \geq 0$) and $b := \lim_{m \rightarrow \infty} b_m \in A_0$. Then $\sum_{i=0}^m g^{\frac{1}{p^{n+i+1}}} a_i^p \varpi^i - b_m^p \in (p)$ for every m . Hence it follows that

$$a' - b^p = \lim_{m \rightarrow \infty} \sum_{i=0}^m g^{\frac{1}{p^{n+i+1}}} a_i^p \varpi^i - \lim_{m \rightarrow \infty} b_m^p = \lim_{m \rightarrow \infty} \left(\sum_{i=0}^m g^{\frac{1}{p^{n+i+1}}} a_i^p \varpi^i - b_m^p \right) \in (p),$$

because $(p) \subset A_0$ is a closed ideal and so (2) follows. \square

Corollary 3.6. *Let A_0 be a ring with a nonzero divisor ϖ such that $p \in \varpi^p A_0$ and A_0 is integrally closed in $A_0[\frac{1}{\varpi}]$ and let $g \in A_0$ be an element. Assume that A_0 admits compatible systems of p -power roots $\varpi^{\frac{1}{p^n}}, g^{\frac{1}{p^n}} \in A_0$. Then the following conditions are equivalent.*

- (a) *The Frobenius endomorphism on $A_0/(\varpi^p)$ is $(g)^{\frac{1}{p^\infty}}$ -almost surjective.*
- (b) *The Frobenius endomorphism on $A_0/(\varpi^p)$ is $(\varpi g)^{\frac{1}{p^\infty}}$ -almost surjective.*

Proof. (a) \Rightarrow (b) is clear. To show the converse, we assume (b). Fix an arbitrary integer $n > 0$, and put $\varpi^{-\frac{1}{p^k}} := (\varpi^{\frac{1}{p^k}})^{-1}$ for every $k \geq 1$. Pick $a \in A_0$. Then there exist elements $b, c \in A_0$ such that $\varpi^{\frac{1}{p^n}} g^{\frac{1}{p^n}} a = b^p + \varpi^p c$ and therefore, $g^{\frac{1}{p^n}} a = (\varpi^{-\frac{1}{p^{n+1}}} b)^p + \varpi(\varpi^{-\frac{1}{p^n}} \varpi^{p-1} c)$ and $\varpi^{-\frac{1}{p^n}} \varpi^{p-1} c$ belongs to A_0 . Moreover, $\varpi^{-\frac{1}{p^{n+1}}} b$ belongs to A_0 , because $(\varpi^{-\frac{1}{p^{n+1}}} b)^p \in A_0$ and A_0 is integrally closed in $A_0[\frac{1}{\varpi}]$. Thus we see that the Frobenius endomorphism on $A_0/(\varpi)$ is $(g)^{\frac{1}{p^\infty}}$ -almost surjective and Lemma 3.5 implies (a), as wanted. \square

If a Tate ring A is given, one can consider a subring $A^+ \subset A^\circ$ that is open and integrally closed in A . Clearly, A° is the biggest ring having such properties. As one can observe in Example 2.2,

A^+ and A° are essentially different in general.⁵ On the other hand, they have a common feature on semiperfectness in certain situations arising from the theory of perfectoid algebras.

Lemma 3.7. *Let A be a Tate ring. Let A^+ be a $\mathbb{Z}[T^{\frac{1}{p^\infty}}]$ -algebra that is an open and integrally closed subring of A contained in A° . Assume that A has a pseudouniformizer ϖ that satisfies $p \in \varpi^p A^+$ and admits a p -th root $\varpi^{\frac{1}{p}} \in A^+$. Then the following conditions are equivalent.*

- (a) $A^\circ/(\varpi^p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect.
- (b) $A^+/(\varpi^p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect.

Proof. Fix an arbitrary integer $n > 0$ and put $g^{\frac{1}{p^n}} := T^{\frac{1}{p^n}} \cdot 1 \in A^+$. Assume that $A^\circ/(\varpi^p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect. Pick $a \in A^+$. Then $g^{\frac{1}{p^n}} a = b^p + \varpi^p c$ for some $b, c \in A^\circ$. Since $\varpi^{p-1} c \in A^+$ by Lemma 2.13(2), we find that $b^p \in A^+$ which gives $b \in A^+$. Hence $A^+/(\varpi)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect, which implies that $A^+/(\varpi^p)$ is also $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect in view of Lemma 3.5. Hence (a) \Rightarrow (b) holds. To show the converse, assume that $A^+/(\varpi^p)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect. Pick $d \in A^\circ$. Then $\varpi d \in A^+$ and thus $g^{\frac{1}{p^n}} \varpi d = e^p + \varpi^p f$ for some $e, f \in A^+$. Then $g^{\frac{1}{p^n}} d = (\frac{e}{\varpi^{1/p}})^p + \varpi^{p-1} f$. Since A° is integrally closed in A , we obtain $\frac{e}{\varpi^{1/p}} \in A^\circ$. Hence $A^\circ/(\varpi)$ is $(T)^{\frac{1}{p^\infty}}$ -almost semiperfect. Therefore, $A^\circ/(\varpi^p)$ is semiperfect in view of Lemma 3.5, as required. \square

Proposition 3.8. *Let A_0 be a p -torsion free semiperfect ring and assume that a finite group G acts on A_0 as ring automorphisms with $|G|$ invertible on A_0 . Then the ring of invariants A_0^G is also semiperfect.*

Proof. Pick an element $x \in A_0^G$. Since A_0 is semiperfect, one can find elements $a, b \in A_0$ such that $a^p = x + pb$. As $|G|$ is invertible on A_0 , the Reynolds operator: $\sigma(a) := \frac{1}{|G|} \sum_{g \in G} g(a)$ gives a well-defined element of A_0^G . We compute

$$\sigma(a)^p = \left(\frac{1}{|G|} \sum_{g \in G} g(a) \right)^p = \left(\frac{1}{|G|^p} \right) \left(\sum_{g \in G} g(a^p) + pf \right) \text{ for some } f \in A_0.$$

After plugging the equality $a^p = x + pb$ into the above formula, we deduce that

$$\begin{aligned} & \left(\frac{1}{|G|^p} \right) \left(\sum_{g \in G} g(a^p) + pf \right) = \left(\frac{1}{|G|^p} \right) \left(\sum_{g \in G} (g(x) + pg(b)) + pf \right) \\ & = \left(\frac{1}{|G|^p} \right) \left(\sum_{g \in G} x \right) + p \left(\frac{1}{|G|^p} \right) \left(\sum_{g \in G} (g(b)) + f \right) = \frac{x}{|G|^{p-1}} + pg \text{ for some } g \in A_0. \end{aligned}$$

We write this as

$$(3.1) \quad |G|^{p-1} \sigma(a)^p = x + pg |G|^{p-1}.$$

For simplicity, let $m := |G|^{p-1}$. Then considering the image of m in the finite field $\mathbb{Z}/(p) \hookrightarrow A_0/(p)$, one can find integers $k, h \in \mathbb{Z}$ such that $k^p = m + ph$. After plugging this into (3.1), we get

$$(k\sigma(a))^p = x + pt \text{ for some } t \in A_0.$$

The Reynolds operator implies that $A_0^G \rightarrow A_0$ splits as a sequence of A_0^G -modules, we have $pA_0^G = A_0^G \cap pA_0$. The fact $pt = (k\sigma(a))^p - x \in A_0^G$ implies that $t \in A_0^G$. So we conclude that the image of $k\sigma(a)$ in $A_0^G/(p)$ maps to $\bar{x} \in A_0^G$ under the Frobenius map, as desired. \square

⁵In [25], the distinction between A^+ and A° does not cause any serious issue. Lemma 3.7 is one of the reasons.

3.2. Witt-perfect and perfectoid algebras. We now recall Fontaine's perfectoid rings; see [12] for reference.

Definition 3.9 (Fontaine). We say that a Banach ring R is *perfectoid*, if R is uniform and R has a pseudouniformizer ϖ such that $p \in \varpi^p R^\circ$ and $R^\circ/(\varpi^p)$ is semiperfect. We call such $\varpi \in R$ a *perfectoid pseudouniformizer* of R .

Notice that for a Banach ring R , it only depends on the topological ring structure whether R is perfectoid or not.

Definition 3.10. Let R be a perfectoid Banach ring.

- (1) A *perfectoid field* is a perfectoid Banach ring K that is a field and whose topology can be defined by a multiplicative norm on K .
- (2) A *perfectoid R -algebra* is a Banach R -algebra that is perfectoid.

Notice that our definition of a perfectoid field and a perfectoid K -algebra (where K is a perfectoid field) coincides with Scholze's original one. To see this, it suffices to check the following.

Lemma 3.11. *Let K be a field equipped with a norm $\|\cdot\|$.*

- (1) *The following conditions are equivalent.*
 - (a) *K is a perfectoid field.*
 - (b) *K is complete, K° is a non-Noetherian valuation ring of rank 1, $\|\cdot\|$ is equivalent to an absolute value associated to K° , $\|p\| < 1$ and $K^\circ/(p)$ is semiperfect.*
- (2) *Suppose that K is a perfectoid field, and let R be a Banach K -algebra. Then the following conditions are equivalent.*
 - (a) *R is a perfectoid K -algebra.*
 - (b) *R is uniform and for every $\varpi \in K$ such that $\|p\| \leq \|\varpi\| < 1$, $R^\circ/(\varpi)$ is semiperfect.*

Proof. (1): Let us assume (b) first. Then by [25, Lemma 3.2], we have some $\varpi \in K^\circ$ for which $p \in \varpi^p K^\circ$. Hence it is easily seen that (a) holds. Next we assume (a) conversely. Then K is complete and K° is a valuation ring of rank 1 by assumption. Now $\|\cdot\| \sim \|\cdot\|_{\text{sp}}$ by Lemma 2.29(2), and $\|\cdot\|_{\text{sp}}$ coincides with an absolute value associated to K° by Lemma 2.30. Moreover, $\|\cdot\|_{\text{sp}}$ is not discretely valued in view of [22, Lemma 1.1(iii)]. The remaining part follows from Lemma 3.5, because $(p) \subset K^\circ$ is closed with respect to the topology defined by $\|\cdot\|_{\text{sp}}$.

(2): (b) \Rightarrow (a) is clear. Now we deduce (b) from (a). Since K is a perfectoid field, $p \in K$ is a topologically nilpotent unit or equal to zero. The same assertion also holds for $p \in R$, as $K \rightarrow R$ is continuous. Hence $(p) \subset R^\circ$ is closed with respect to the induced topology from R . Thus, (a) implies that $R^\circ/(p)$ is semiperfect in view of Lemma 3.5. Therefore (a) \Rightarrow (b) holds. \square

Any perfectoid pseudouniformizer can be replaced so that the following statement holds.

Lemma 3.12. *Let A be a perfectoid Banach ring and let A^+ be an open and integrally closed subring of A contained in A° . Then the following assertions hold.*

- (1) *There exists some $\varpi' \in A^+$ such that $p \in \varpi'^p A^+$ and $A^+ / (\varpi'^p)$ is semiperfect.*
- (2) *Assume further that $p \in A$ is a topologically nilpotent unit. Then $A^+ / (p)$ is semiperfect, and there exists some $t \in A^+$ such that $p = t^p u$ for some unit $u \in A^+$. Moreover, there exists some $s \in A^+$ such that $s^p \equiv p \pmod{p^2 A^+}$.*

Proof. (1): Let $\varpi \in A^\circ$ be a perfectoid pseudouniformizer of A . Then by Lemma 3.3, we find some $\varpi_1 \in A^\circ$ such that $\varpi = \varpi_1^p u_1$ for some unit $u_1 \in A^\circ$ (notice that ϖ_1 is a topologically nilpotent unit in A). Hence $p \in \varpi_1^p \varpi^{p-1} A^\circ$ and since $\varpi^{p-1} A^\circ \subset A^+$, we have $p \in \varpi_1^p A^+$. Moreover, since

$A^\circ/(\varpi_1^p)$ is semiperfect, $A^+/(\varpi_1^p)$ is also semiperfect by Lemma 3.7. So letting $\varpi' := \varpi_1$ completes (1).

(2): Next assume further that $p \in A$ is a topologically nilpotent unit. Then, since $(p) \subset A^+$ is closed with respect to the ϖ_1 -adic topology, $A^+/(p)$ is semiperfect in view of Lemma 3.5(2). To prove the existence of $t \in A^+$ and a unit $u \in A^+$ such that $p = t^p u$, we take $a \in A^+$ for which $p = \varpi_1^p a$. Then we have $b, c \in A^+$ that satisfy $a = b^p + pc$ and so $p(1 - \varpi_1^p c) = (\varpi_1 b)^p$. Thus, since $u := 1 - \varpi_1^p c \in A^+$ is a unit, it suffices to take $t = \varpi_1 b$. Finally, let us prove the existence of $s \in A^+$ as in the assertion. Take $d, e \in A^+$ such that $u = d^p + pe$. Then $p = t^p(d^p + pe)$ and therefore, $p = (td)^p + pt^p e$. Here notice that $t^p = pu^{-1} \in pA^+$. Thus we have $(td)^p \equiv p \pmod{p^2 A^+}$, as wanted. \square

Example 3.13. We exhibit a specific example of perfectoid ring in the sense of Fontaine, but does not fit into the original definition of perfectoid algebras by Scholze. Fix a prime number $p > 0$. For an integer $n > 0$, let $R_n := \mathbb{Z}_p[[T]][p^{\frac{1}{p^n}}, T^{\frac{1}{p^n}}]$, denote by $R_n[(\frac{p}{T})^{\frac{1}{p^n}}]$ the R_n -subalgebra $R_n[(T^{\frac{1}{p^n}})^{-1}p^{\frac{1}{p^n}}]$ of $R_n[(T^{\frac{1}{p^n}})^{-1}] = R_n[\frac{1}{T}]$ and let $R_\infty[(\frac{p}{T})^{\frac{1}{p^\infty}}]$ be the ring $\bigcup_{n>0} R_n[(\frac{p}{T})^{\frac{1}{p^n}}]$. Since R_n is a regular local ring with a regular system of parameters $p^{\frac{1}{p^n}}, T^{\frac{1}{p^n}}$, one can easily show that $R_n[(\frac{p}{T})^{\frac{1}{p^n}}]$ is completely integrally closed in $R_n[\frac{1}{T}]$. Hence $R_\infty[(\frac{p}{T})^{\frac{1}{p^\infty}}]$ is completely integrally closed in $R_\infty[(\frac{p}{T})^{\frac{1}{p^\infty}}][\frac{1}{T}]$. Denote by $\widehat{R_\infty}((\frac{p}{T})^{\frac{1}{p^\infty}})$ the T -adic completion of $R_\infty[(\frac{p}{T})^{\frac{1}{p^\infty}}]$, and let A be a Banach ring associated to $(\widehat{R_\infty}((\frac{p}{T})^{\frac{1}{p^\infty}}), (T))$. Then A is uniform and $A^\circ = \widehat{R_\infty}((\frac{p}{T})^{\frac{1}{p^\infty}})$ by Lemma 2.8. Hence A is a perfectoid ring in the sense of Fontaine by putting $\varpi = T^{\frac{1}{p}}$. Indeed, we have $p \in \varpi^p A^\circ$. In this example, let us point out that if $x \in A^\circ$ satisfies $\varpi^p x = p$, then x is not a unit.

Fix a prime number $p > 0$ and let us recall the definition of *Witt-perfect rings* due to Davis and Kedlaya as in [8] and [9].

Definition 3.14 (Witt-perfect ring). Let $p > 0$ be a prime number. Then we say that a ring A_0 is *Witt-perfect*, if the Witt-Frobenius map $\mathbf{F} : \mathbf{W}_{p^n}(A_0) \rightarrow \mathbf{W}_{p^{n-1}}(A_0)$ is surjective for all $n \geq 2$.

For the rest of the paper, we often assume that A_0 is p -torsion free. We describe the relationship between Witt-perfect and perfectoid algebras in Proposition 3.16 and Proposition 3.20. These results say that Witt-perfect rings are viewed as “decompletions” of perfectoid algebras under a kind of preuniformity assumptions (cf. Definition 2.16). Our proof is based on the following criterion for being Witt-perfect.

Lemma 3.15 ([8, Theorem 3.2]). *For a prime number $p > 0$, assume that A_0 is a p -torsion free ring. Then the following statements are equivalent.*

- (1) A_0 is a Witt-perfect ring.
- (2) The Frobenius endomorphism on $A_0/(p)$ is surjective and for every $a \in A_0$, one can find $b \in A_0$ such that $b^p \equiv pa \pmod{p^2 A_0}$.

Proposition 3.16. *Let A_0 be a p -torsion free ring. Denote by $\widehat{A_0}$ the p -adic completion of A_0 .*

- (1) *The following conditions are equivalent.*
 - (a) A_0 is Witt-perfect and integrally closed (resp. completely integrally closed) in $A_0[\frac{1}{p}]$.
 - (b) For any Banach ring R associated to $(\widehat{A_0}, (p))$ (cf. Definition 2.31(5)), R is perfectoid in the sense of Fontaine and $\widehat{A_0}$ is open and integrally closed in R (resp. $R^\circ = \widehat{A_0}$).
- (2) *Assume further that A_0 is a p -adically separated valuation ring. Then the following conditions are equivalent.*

- (a) A_0 is Witt-perfect and of rank 1.
- (b) For any Banach ring K associated to $(\widehat{A_0}, (p))$, K is a perfectoid field and $K^\circ = \widehat{A_0}$.

Proof. (1): Let R be a Banach ring associated to $(\widehat{A_0}, (p))$. First we assume that A_0 is Witt-perfect and integrally closed in $A_0[\frac{1}{p}]$. Then $\widehat{A_0}$ is integrally closed in R by Corollary 2.8, $\widehat{A_0}/(p)$ is semiperfect, and there is some $\varpi \in \widehat{A_0}$ such that $\varpi^p \equiv p \pmod{p^2\widehat{A_0}}$. In particular, $p = \varpi^p u$ holds for some unit $u \in \widehat{A_0}$, because $\widehat{A_0}$ is p -adically Zariskian. Thus we also have some $t \in \widehat{A_0}$ for which $t^p \equiv \varpi \pmod{p\widehat{A_0}}$ (and so $\varpi = t^p u'$ for some unit $u' \in \widehat{A_0}$). Hence by Lemma 3.7, $R^\circ/(p)$ is semiperfect. Therefore, R is perfectoid. If further A_0 is completely integrally closed in $A_0[\frac{1}{p}]$, then $\widehat{A_0}$ is completely integrally closed in R by Corollary 2.8, and so $R^\circ = \widehat{A_0}$. Consequently we obtain the implication (a) \Rightarrow (b). Conversely, we then assume the condition (b) (i.e. R is perfectoid and $\widehat{A_0}$ is open and integrally closed in R). Then A_0 is integrally closed in A by Corollary 2.8. Moreover, $\widehat{A_0}/(p) \cong A_0/(p)$ is semiperfect and there is some $t \in \widehat{A_0}$ for which $t^p \equiv p \pmod{p^2\widehat{A_0}}$ by Lemma 3.12(2). Hence A_0 is Witt-perfect. If further $R^\circ = \widehat{A_0}$, then A_0 is completely integrally closed in $A_0[\frac{1}{p}]$ by Corollary 2.8. Consequently we find that (b) implies (a), as required.

(2): First we assume (a). Then $\widehat{A_0}$ is a valuation ring of rank 1 with the fraction field $\widehat{A_0}[\frac{1}{p}]$. Thus, for a norm $\|\cdot\|$ on $\widehat{A_0}[\frac{1}{p}]$ associated with $(\widehat{A_0}, (p))$, the spectral norm $\|\cdot\|_{\text{sp}}$ is multiplicative by Lemma 2.30. We equip $\widehat{A_0}[\frac{1}{p}]$ with the norm $\|\cdot\|_{\text{sp}}$. Then by the assertion (1), we find that $\widehat{A_0}[\frac{1}{p}]$ is perfectoid (and so it is a perfectoid field) and $(\widehat{A_0}[\frac{1}{p}])^\circ = \widehat{A_0}$. Hence (b) follows. Next we assume (b), conversely. Then in view of (1), A_0 is Witt-perfect and completely integrally closed in $A_0[p^{-1}]$. Therefore, the value group is of rank 1. Hence (a) follows. \square

Corollary 3.17. *Let A_0 be a p -torsion free Witt-perfect ring that is integrally closed in $A_0[\frac{1}{p}]$. Denote by $\widehat{A_0}$ the p -adic completion of A_0 . Denote by I and I' the ideals $\sqrt{(p)} \subset A_0$ and $\sqrt{(p)} \subset \widehat{A_0}$, respectively. Then one has $I' = I\widehat{A_0}$ and $I = I'^2$.*

Proof. By Lemma 3.15, there is a sequence $\{\varpi_n\}_{n \geq 0}$ in A_0 such that $\varpi_0 = p$, $\varpi_1^p \equiv \varpi_0 \pmod{(p^2)}$, and $\varpi_{n+1}^p \equiv \varpi_n \pmod{(p)}$ for every $n \geq 0$. By induction on n , we have $\varpi_{n+1}^p = \varpi_n u_n$ for some unit $u_n \in \widehat{A_0}$, because I' is contained in the Jacobson radical of $\widehat{A_0}$. Let R be a Banach ring associated to $(\widehat{A_0}, (p))$. Then $R^{\circ\circ} = I'$. Moreover, by Lemma 2.29(2) and Lemma 3.16(1), we may assume that the norm on R is powermultiplicative. Hence I' is generated by $\{\varpi_n\}_{n \geq 0}$. Therefore, one has $I' = I\widehat{A_0}$ and $I' = I'^2$. In particular, $I\widehat{A_0} = I'^2\widehat{A_0}$. Next pick an element $x \in I$. Then by the equality stated just now, we have $x = \sum_{i=1}^r y_i \alpha_i$ for some $y_i \in I^2$ and $\alpha_i \in \widehat{A_0}$ ($i = 1, \dots, r$). Take $a_i \in A_0$ for which $a_i \equiv \alpha_i \pmod{p^2\widehat{A_0}}$ ($i = 1, \dots, r$). Then we have $x - \sum_{i=1}^r y_i a_i \in p^2\widehat{A_0} \cap A_0 = p^2 A_0$. Therefore, $x \in I^2$, as wanted. \square

3.3. Almost Witt-perfect and almost perfectoid algebras. Let us recall André's almost perfectoid algebras (cf. Definition 3.5.2 and Proposition 3.5.4 in [1]).

Definition 3.18 (Almost perfectoid $K\langle T^{\frac{1}{p^\infty}} \rangle$ -algebra). Let K be a perfectoid field and let R be a uniform Banach $K\langle T^{\frac{1}{p^\infty}} \rangle$ -algebra. Let $\mathfrak{m} := (T)^{\frac{1}{p^\infty}} K^{\circ\circ} K^\circ \langle T^{\frac{1}{p^\infty}} \rangle$ be an ideal of $K^\circ \langle T^{\frac{1}{p^\infty}} \rangle$. We say that R is an *almost perfectoid $K\langle T^{\frac{1}{p^\infty}} \rangle$ -algebra*, if the Frobenius endomorphism on $R^\circ/(p)$ is \mathfrak{m} -almost surjective.

We then introduce the following class of rings to establish a variant of Lemma 3.16 fitting for almost mathematics.

Definition 3.19 (Almost Witt-perfect ring). Let A_0 be a p -torsion free ring with an element $g \in A_0$ admitting a compatible system of p -power roots $g^{\frac{1}{p^n}} \in A_0$. Then we say that A_0 is $(g)^{\frac{1}{p^\infty}}$ -almost Witt-perfect, if the following conditions are satisfied.

- (1) The Frobenius endomorphism on $A_0/(p)$ is $(g)^{\frac{1}{p^\infty}}$ -almost surjective.
- (2) For every $a \in A_0$ and every $n > 0$, there is an element $b \in A_0$ such that $b^p \equiv pg^{\frac{1}{p^n}}a \pmod{p^2 A_0}$.

Proposition 3.20. *Let V be a p -adically separated p -torsion free valuation domain and let A_0 be a p -torsion free $V[T^{\frac{1}{p^\infty}}]$ -algebra. Put $g^{\frac{1}{p^n}} := T^{\frac{1}{p^n}} \cdot 1 \in A_0$ for every $n \geq 0$ and denote by \widehat{V} and $\widehat{A_0}$ the p -adic completions of V and A_0 , respectively. Then the following conditions are equivalent.*

- (a) *V is a Witt-perfect valuation domain of rank 1 and A_0 is $(g)^{\frac{1}{p^\infty}}$ -almost Witt-perfect and integrally closed (resp. completely integrally closed) in $A_0[\frac{1}{p}]$.*
- (b) *There exist a perfectoid field K and an almost perfectoid $K\langle T^{\frac{1}{p^\infty}} \rangle$ -algebra R with the following properties:*
 - *K is a Banach ring associated to $(\widehat{V}, (p))$, the norm on K is multiplicative and $K^\circ = \widehat{V}$;*
 - *R is a Banach ring associated to $(\widehat{A_0}, (p))$, and $\widehat{A_0}$ is open and integrally closed in R (resp. $R^\circ = \widehat{A_0}$);*
 - *the bounded homomorphism $K\langle T^{\frac{1}{p^\infty}} \rangle \rightarrow R$ is induced by the ring map $V[T^{\frac{1}{p^\infty}}] \rightarrow A_0$.*

Proof. We first prove $(a) \Rightarrow (b)$. We denote by $\|\cdot\|_1$ (resp. $\|\cdot\|_2$) the norm $\|\cdot\|_{\widehat{V},(p),p}$ on $\widehat{V}[\frac{1}{p}]$ (resp. the norm $\|\cdot\|_{\widehat{A_0},(p),p}$ on $\widehat{A_0}[\frac{1}{p}]$), and let $\|\cdot\|_{1,\text{sp}}$ (resp. $\|\cdot\|_{2,\text{sp}}$) be the associated spectral seminorm. Notice that $\|\cdot\|_{1,\text{sp}}$ (resp. $\|\cdot\|_{2,\text{sp}}$) is equivalent to $\|\cdot\|_{\widehat{V},(p),p}$ (resp. $\|\cdot\|_{\widehat{A_0},(p),p}$) by Corollary 2.8 and Lemma 2.29(2). We then equip $\widehat{V}[\frac{1}{p}]$ with $\|\cdot\|_{1,\text{sp}}$ (resp. $\widehat{A_0}[\frac{1}{p}]$ with $\|\cdot\|_{2,\text{sp}}$), and denote by K (resp. R) the resulting Banach ring. Then the ring map $V[T^{\frac{1}{p^\infty}}] \rightarrow A_0$ induces a bounded map $K\langle T^{\frac{1}{p^\infty}} \rangle \rightarrow R$. Moreover, K is a perfectoid field with $K^\circ = \widehat{V}$ by Proposition 3.16(2), and $\widehat{A_0}$ forms an open and integrally closed subring of R by Corollary 2.8. Let $\varpi \in K^\circ$ be a perfectoid pseudouniformizer that satisfies $p = \varpi^p u$ for some unit $u \in K^\circ$ and admits a compatible system of p -power roots (such an element ϖ exists by Lemma 3.12 and [4, Lemma 3.9]). Then, since the Frobenius endomorphism on $\widehat{A_0}/(p)$ is $(g)^{\frac{1}{p^\infty}}$ -almost surjective, the Frobenius endomorphism on $R^\circ/(p)$ is $(\varpi g)^{\frac{1}{p^\infty}}$ -almost surjective by Corollary 2.8, Corollary 3.6 and Lemma 3.7. So we conclude that R is an almost perfectoid $K\langle T^{\frac{1}{p^\infty}} \rangle$ -algebra. The remaining part follows from Corollary 2.8 and Lemma 2.13.

Next we prove $(b) \Rightarrow (a)$. Assume (b) . In view of Corollary 2.8 and Proposition 3.16(2), it suffices to show that A_0 is $(g)^{\frac{1}{p^\infty}}$ -almost Witt-perfect. Let $\varpi \in K^\circ$ be a perfectoid pseudouniformizer with the property mentioned above. Since $K^\circ = \widehat{V}$ and the map $K \rightarrow R$ carries \widehat{V} into $\widehat{A_0}$, there is some unit $u \in \widehat{A_0}$ such that $p = \varpi^p u$. Moreover, the Frobenius endomorphism on $R^\circ/(p)$ is $(\varpi g)^{\frac{1}{p^\infty}}$ -almost surjective by assumption. Hence by Corollary 3.6 and Lemma 3.7, the Frobenius endomorphism on $\widehat{A_0}/(p) \cong A_0/(p)$ is $(g)^{\frac{1}{p^\infty}}$ -almost surjective. Thus it is enough to check the condition (2) in Definition 3.19 for $a = 1$. Fix an integer $n > 0$. Then we have $g^{\frac{1}{p^n}}p = \varpi^p(g^{\frac{1}{p^n}}u)$, and there exist some $b, c \in \widehat{A_0}$ such that $g^{\frac{1}{p^n}}u = b^p + pc$. Thus we have $g^{\frac{1}{p^n}}p = (\varpi b)^p + \varpi^p pc =$

$(\varpi b)^p + p^2 u^{-1} c$, which yields $(\varpi b)^p \equiv p g^{\frac{1}{p^n}} \pmod{p^2 \widehat{A_0}}$. Since $\widehat{A_0}/(p^2) \cong A_0/(p^2)$, the assertion follows. \square

4. FINITE ÉTALE EXTENSIONS

4.1. Finite étale extensions and completeness. Let A_0 be a ring, let $I_0 \subset A_0$ be an ideal, and let M_0 be an A_0 -module. Assume that A_0 is I_0 -adically complete and separated. Then one may ask the question: Is M_0 also I_0 -adically complete and separated? As is well known, if A_0 is Noetherian and M_0 is a finitely generated A_0 -module, then the question is affirmative; see [21, Theorem 8.7]. However, in the absence of Noetherian property, this question is subtle and often require a careful argument (or even counterexamples exist). Now we consider the following case: there exists a ring extension $A_0 \subset A$ such that M_0 is an A_0 -submodule of some finite projective A -algebra B . Then in some situations, the completeness is ensured by a condition on the trace map (even if M_0 or I_0 is not finitely generated). A detailed account of the trace map for finite projective ring extensions is found in [13].

Proposition 4.1. *Let A be a ring and let B be a finite étale A -algebra. Let $A_0 \subset A$ be a subring with an ideal $I_0 \subset A_0$. Let B_0 be an A_0 -subalgebra of B such that $B = \bigcup_{n \geq 1} (B_0 :_B I_0^n)$. Assume that there exists an integer $c > 0$ such that $\text{Tr}_{B/A}(tm) \in A_0$ for every $t \in I_0^c$ and every $m \in B_0$.*

- (1) *If A_0 is I_0 -adically separated, then so is B_0 .*
- (2) *If A_0 is I_0 -adically complete, then so is B_0 .*

Proof. First note that since B is finite étale over A , the A -homomorphism

$$(4.1) \quad B \rightarrow \text{Hom}_A(B, A), \quad b \mapsto \text{Tr}_{B/A}(b \cdot)$$

is an isomorphism by [13, Corollary 4.6.8].

Let us prove (1). Pick $m \in \bigcap_{n=0}^{\infty} I_0^n B_0$. Since (4.1) is injective, it suffices to show that $\text{Tr}_{B/A}(mx) = 0$ for an arbitrary element $x \in B$. Take $l > 0$ for which $I_0^l x \subset B_0$. Then for every $n > 0$, we have $m \in I_0^{n+c+l} B_0$ and thus, there exist $t_{n,i} \in I_0^n$, $u_{n,i} \in I_0^{c+l}$, and $m_{n,i} \in B_0$ ($i = 1, \dots, r$) such that $m = \sum_{i=1}^r t_{n,i} u_{n,i} m_{n,i}$. Hence

$$\text{Tr}_{B/A}(mx) = \sum_{i=1}^r t_{n,i} \text{Tr}_{B/A}(u_{n,i} x m_{n,i}) \in I_0^n A_0$$

for every $n > 0$. Thus, since A_0 is I_0 -adically separated, we have $\text{Tr}_{B/A}(mx) = 0$, as desired.

Next we prove (2). Since B is a finite projective A -module, there exist A -homomorphisms $s : B \rightarrow A^{\oplus d}$ and $\pi : A^{\oplus d} \rightarrow B$ such that $\pi \circ s$ is the identity. Let us equip A (resp. $A^{\oplus d}$, resp. B) with the topology such that $\{I_0^n A_0\}_{n \geq 1}$ (resp. $\{I_0^n A_0^{\oplus d}\}_{n \geq 1}$, resp. $\{I_0^n B_0\}_{n \geq 1}$) forms a system of fundamental open neighborhoods of 0. We consider these topologies in what follows. Since (4.1) is surjective, there exist $b_1, \dots, b_d \in B$ such that $s(x) = (\text{Tr}_{B/A}(b_1 x), \dots, \text{Tr}_{B/A}(b_d x))$ for every $x \in B$. Let $\{m_n\}_{n \geq 1}$ be a Cauchy sequence in B_0 with respect to the I_0 -adic topology. Then for each $i = 1, \dots, d$, $\{\text{Tr}_{B/A}(b_i m_n)\}_{n \geq 1}$ forms a Cauchy sequence in A . Hence by assumption, each $\{\text{Tr}_{B/A}(b_i m_n)\}_{n \geq 1}$ converges to some $a_i \in A$. Then $\{s(m_n)\}_{n \geq 1}$ converges to $(a_1, \dots, a_d) \in A^{\oplus d}$. Thus, $\{m_n\}_{n \geq 1} = \{\pi(s(m_n))\}_{n \geq 1}$ converges to $\pi((a_1, \dots, a_d)) \in B$. Since $\pi((a_1, \dots, a_d)) - m_n \in B_0$ for $n \gg 0$, we have $\pi((a_1, \dots, a_d)) \in B_0$. Hence the assertion follows. \square

Proposition 4.2. *Let A_0 be a ring with a nonzero divisor t and put $A = A_0[\frac{1}{t}]$. Let B be a finite étale A -algebra. Let $B_0 \subset B$ be an A_0 -subalgebra for which $B = B_0[\frac{1}{t}]$. Assume that there exists some $l > 0$ such that $\text{Tr}_{B/A}(t^l b) \in A_0$ for every $b \in B_0$. Denote by $\widehat{A_0}$ and $\widehat{B_0}$ the t -adic completions*

of A_0 and B_0 , respectively. Then the natural A_0 -algebra homomorphism $B_0 \otimes_{A_0} \widehat{A_0} \rightarrow \widehat{B_0}$ induces an isomorphism:

$$(4.2) \quad (B_0 \otimes_{A_0} \widehat{A_0}) / (0)^{t\text{-sat}} \xrightarrow{\cong} \widehat{B_0}$$

(where $(0)^{t\text{-sat}}$ denotes the (t) -saturation of the ideal $(0) \subset B_0 \otimes_{A_0} \widehat{A_0}$). In particular, the natural A -algebra homomorphism

$$(B_0 \otimes_{A_0} \widehat{A_0})[\frac{1}{t}] \rightarrow (\widehat{B_0})[\frac{1}{t}]$$

is an isomorphism.

Proof. Since $\widehat{B_0}$ is t -torsion free, the map $\varphi : B_0 \otimes_{A_0} \widehat{A_0} \rightarrow \widehat{B_0}$ induces a commutative diagram:

$$\begin{array}{ccc} B_0 \otimes_{A_0} \widehat{A_0} & \xrightarrow{\pi} & (B_0 \otimes_{A_0} \widehat{A_0}) / (0)^{t\text{-sat}} \\ & \searrow \varphi & \downarrow \tilde{\varphi} \\ & & \widehat{B_0} \end{array}$$

where π is the canonical projection map. We prove that $\tilde{\varphi}$ is an isomorphism. First we show that $(B_0 \otimes_{A_0} \widehat{A_0}) / (0)^{t\text{-sat}}$ is t -adically complete and separated. Let us apply Proposition 4.1 by setting $I_0 = (t)$. Put $A' := (\widehat{A_0})[\frac{1}{t}]$. Notice that $(B_0 \otimes_{A_0} \widehat{A_0}) / (0)^{t\text{-sat}}$ is isomorphic to the $\widehat{A_0}$ -subalgebra $C_0 \subset (B_0 \otimes_{A_0} \widehat{A_0})[\frac{1}{t}]$ that is the image of $B_0 \otimes_{A_0} \widehat{A_0} \rightarrow (B_0 \otimes_{A_0} \widehat{A_0})[\frac{1}{t}]$, and $(B_0 \otimes_{A_0} \widehat{A_0})[\frac{1}{t}]$ is identified with the finite étale A' -algebra $B \otimes_A A'$. Since we have

$$\text{Tr}_{B \otimes_A A' / A'}(b \otimes_A 1_{A'}) = \text{Tr}_{B/A}(b) \otimes_A 1_{A'} \quad (\forall b \in B),$$

it follows that every element $c \in C_0$ satisfies $\text{Tr}_{B \otimes_A A' / A'}(t^l c) \in \widehat{A_0}$. Hence C_0 is t -adically complete and separated by Proposition 4.1, and therefore so is $(B_0 \otimes_{A_0} \widehat{A_0}) / (0)^{t\text{-sat}}$, as wanted. Now note that the t -adic completion $\widehat{B_0 \otimes_{A_0} \widehat{A_0}}$ of $B_0 \otimes_{A_0} \widehat{A_0}$ is naturally isomorphic to $\widehat{B_0}$. Then by the universality of completion [15, Proposition 7.1.9 in Chapter 0], the isomorphism $\widehat{B_0 \otimes_{A_0} \widehat{A_0}} \xrightarrow{\cong} \widehat{B_0}$ factors as

$$\widehat{B_0 \otimes_{A_0} \widehat{A_0}} \xrightarrow{\hat{\pi}} (B_0 \otimes_{A_0} \widehat{A_0}) / (0)^{t\text{-sat}} \xrightarrow{\tilde{\varphi}} \widehat{B_0},$$

where the map $\hat{\pi}$ is surjective, because π is so. Since $\tilde{\varphi} \circ \hat{\pi}$ is an isomorphism, it follows that $\hat{\pi}$ is an isomorphism. Thus, $\tilde{\varphi}$ is also an isomorphism. Finally, It readily follows that $(B_0 \otimes_{A_0} \widehat{A_0})[\frac{1}{t}] \rightarrow (\widehat{B_0})[\frac{1}{t}]$ is an isomorphism. \square

As the condition on the trace map in Proposition 4.2 is subtle, we will unravel some verifiable hypotheses on ring maps with a desired trace map in the next subsection.

4.2. Studies on preuniform pairs and the condition (*). Here we establish several basic properties of preuniform pairs (cf. Definition 2.16). We especially investigate the following condition.

Definition 4.3. Let $f_0 : (A_0, I_0) \rightarrow (B_0, J_0)$ be a morphism of pairs. Then we say that f_0 satisfies “the condition (*)”, if $I_0 = tA_0$ and $J_0 = tB_0$ for some $t \in A_0$ and f_0 satisfies the following axioms:

- (a) (A_0, I_0) is preuniform.
- (b) The ring map $A_0[\frac{1}{t}] \rightarrow B_0[\frac{1}{t}]$ induced by f_0 is finite étale.
- (c) B_0 is t -torsion free, and $B_0 \subset (A_0)_{B_0[\frac{1}{t}]}^*$.

Example 4.4. Let V be a valuation ring with a non-zero element $t \in V$ for which V is t -adically separated. Set $K := \text{Frac}(V)$. Then, as we observed in Example 2.18(1), the pair $(V, (t))$ is preuniform and $K = V[\frac{1}{t}]$. Let L be a finite separable extension of K , and W the integral closure of V in L . Then any $x \in L$ is integral over K , and hence satisfies $t^l x \in W$ for some $l > 0$ because $K = V[\frac{1}{t}]$. Therefore, $L = W[\frac{1}{t}]$. Hence the inclusion map $V \hookrightarrow W$ becomes finite étale after inverting t , and we have $W = V_{W[\frac{1}{t}]}^+ \subset V_{W[\frac{1}{t}]}^*$. Thus the morphism $(V, (t)) \rightarrow (W, (t))$ satisfies (*).

A morphism $(A_0, (t)) \rightarrow (B_0, (t))$ satisfying (*) has the following good properties. In particular, the condition imposed on the trace map of Proposition 4.2 may be realized by it.

Proposition 4.5. *Let $f_0 : (A_0, (t)) \rightarrow (B_0, (t))$ be a morphism of pairs that satisfies the condition (*). Put $A := A_0[\frac{1}{t}]$ and $B := B_0[\frac{1}{t}]$. Then the following assertions hold.*

- (1) *There exists an integer $c > 0$ such that $\text{Tr}_{B/A}(t^c B_0) \subset A_0$.*
- (2) *There exist an integer $l > 0$, a finite free A_0 -module F , and A_0 -homomorphisms $B_0 \rightarrow F \rightarrow B_0$ whose composition is multiplication by t^l . In particular, $t^l B_0$ is contained in a finitely generated A_0 -submodule of B_0 .*
- (3) *One has $(A_0)_B^* = (B_0)_B^*$.*
- (4) *The pair $(B_0, (t))$ is preuniform.*

To prove this, we need the following lemma.

Lemma 4.6. *Let A_0 be a ring with a nonzero divisor t , and put $A = A_0[\frac{1}{t}]$. Let B be a finite étale A -algebra. Assume that A_0 is integrally closed in A . Then for every integral element $b \in B$ over A , $\text{Tr}_{B/A}(b)$ belongs to A_0 .*

Proof of Lemma 4.6. A proof of the lemma in the special case that t is a prime number is given in [9, Lemma 2.6], but the same proof is valid for the general case. \square

Here notice the following fact.

Lemma 4.7. *Keep the notation as in Proposition 4.5. Put $A^+ := (A_0)_A^+$ and $B^+ := (A_0)_B^+$. Let $f : A \rightarrow B$ be the ring map induced by f_0 , and let $f^+ : A^+ \rightarrow B^+$ be the ring map such that $f|_{A^+}$ factors through f^+ . Then $B = B^+[\frac{1}{t}]$, and the morphism $f^+ : (A^+, (t)) \rightarrow (B^+, (t))$ satisfies the condition (*).*

Proof of Lemma 4.7. It is clear because B is integral over A and $A = A_0[\frac{1}{t}]$. \square

Now let us start to prove Proposition 4.5.

Proof of Proposition 4.5. We define the morphism $f^+ : (A^+, (t)) \rightarrow (B^+, (t))$ as in Lemma 4.7. Then by Lemma 4.6, we have $\text{Tr}_{B/A}(B^+) \subset A^+$. Thus, since $(A_0, (t))$ is preuniform, there exists some $c_1 > 0$ such that $\text{Tr}_{B/A}(t^{c_1} B^+) \subset A_0$. Meanwhile, we have $tB_0 \subset t(A_0)_B^* \subset B^+$ by Lemma 2.3. Thus it holds that $\text{Tr}_{B/A}(t^{c_1+1} B_0) \subset A_0$, which yields the assertion (1).

Let us prove (2). Since B is finite projective over A , we have A -homomorphisms $\pi : A^{\oplus d} \rightarrow B$ and $s : B \rightarrow A^{\oplus d}$ such that $\pi \circ s$ is the identity. Now since (4.1) is surjective, there exist $b_1, \dots, b_d \in B$ such that $s(x) = (\text{Tr}_{B/A}(b_1 x), \dots, \text{Tr}_{B/A}(b_d x))$ for every $x \in B$. Hence by (1), there exists $l_1 > 0$ such that $(t^{l_1} s)|_{B_0}$ factors through an A_0 -homomorphism $s_{l_1} : B_0 \rightarrow A_0^{\oplus d}$. Now there also exists an integer $l_2 > 0$ such that $(t^{l_2} \pi)|_{A_0^{\oplus d}}$ factors through an A_0 -homomorphism $\pi_{l_2} : A_0^{\oplus d} \rightarrow B_0$. Then $\pi_{l_2} \circ s_{l_1}$ is multiplication by $t^{l_1+l_2}$, which yields the claim.

Next we prove (3). The containment $(A_0)_B^* \subset (B_0)_B^*$ is easy to see. Let us show the reverse inclusion. Pick an element $b \in B$ and assume that b is almost integral over B_0 . Then, since

$B = B_0[\frac{1}{t}]$, there exists some $m > 0$ such that $t^m(\sum_{n=0}^{\infty} B_0 \cdot b^n) \subset B_0$. Hence by the assertion (2), $t^{l+m}(\sum_{n=0}^{\infty} B_0 \cdot b^n)$ is contained in a finitely generated A_0 -submodule of B_0 . Therefore, $\sum_{n=0}^{\infty} A_0 \cdot b^n$ is contained in a finitely generated A_0 -submodule of B . Hence $b \in B$ is almost integral over A_0 , as desired.

Finally we prove (4). By the assertion (3), we have $(B_0)_B^+ \subset (B_0)_B^* \subset (A_0)_B^*$. Hence in view Lemma 2.3, we have $t(B_0)_B^+ \subset t(A_0)_B^* \subset (A_0)_B^+$. On the other hand, by Lemma 4.7 and the assertion (2), there exists some $l' > 0$ such that $t^{l'}(A_0)_B^+$ is contained in a finitely generated $(A_0)_A^+$ -submodule N_0 of $(A_0)_B^+$. Moreover, since $(A_0, (t))$ is preuniform and $B = B_0[\frac{1}{t}]$, we have $t^{c'}N_0 \subset B_0$ for some $c' > 0$. Thus, $t^{c'+l'+1}(B_0)_B^+$ is contained in B_0 . This yields the assertion. \square

Corollary 4.8. *Let A be a preuniform Tate ring. Let $f : A \rightarrow B$ be a finite étale ring map. Equip B with the canonical structure as a Tate ring (cf. Lemma 2.20). Then the following assertions hold.*

- (1) *B is also preuniform. In particular, for any ring of definition A_0 of A , $(A_0)_B^+$ and $(A_0)_B^*$ are rings of definition of B .*
- (2) *For any topologically nilpotent unit $t \in A$, the morphism $(A^\circ, (t)) \rightarrow (B^\circ, (t))$ satisfies the condition (*).*
- (3) *$B^\circ = (A^\circ)_B^*$.*
- (4) *If f is injective, then $f^{-1}(B^\circ) = A^\circ$.*
- (5) *If A is uniform, then so is B .*

Proof. The assertions (1), (2) and (3) are immediate consequences of Lemma 2.3, Lemma 2.20 and Proposition 4.5. The assertion (5) follows from (1) and Proposition 4.1. Let us prove (4). Assume that f is injective. Since the containment $A^\circ \subset f^{-1}(B^\circ)$ is clear, it suffices to show the reverse inclusion. Pick $a \in A$ for which $f(a) \in B^\circ$. Then, since $B^\circ = (A^\circ)_B^*$ by the assertion (3), there is some $l > 0$ such that $t^l a^n \in A^\circ$ for every $n > 0$. Hence we have $a \in (A^\circ)_A^* = A^\circ$, as wanted. \square

In the next theorem, we show that the condition (*) is stable under completion. This property is quite important for our study (cf. Corollary 4.10 and Theorem 5.7). The theorem itself can be interpreted as a practical form of Proposition 4.2.

Theorem 4.9. *Keep the notation as in Proposition 4.5. Denote by $\widehat{A_0}$ and $\widehat{B_0}$ the t -adic completions of A_0 and B_0 , respectively. Let $\widehat{f_0} : (\widehat{A_0}, (t)) \rightarrow (\widehat{B_0}, (t))$ be the morphism of pairs induced by f_0 . Put $A' := \widehat{A_0}[\frac{1}{t}]$ and $B' := \widehat{B_0}[\frac{1}{t}]$. Then the following assertions hold.*

- (1) *The natural A' -algebra homomorphism $B \otimes_A A' \rightarrow B'$ is an isomorphism.*
- (2) *$\widehat{f_0} : (\widehat{A_0}, (t)) \rightarrow (\widehat{B_0}, (t))$ also satisfies the condition (*).*

Proof. (1) is a consequence of Proposition 4.2 and Proposition 4.5(1). Let us prove (2). By Proposition 2.4, the morphism $\widehat{f_0} : (\widehat{A_0}, (t)) \rightarrow (\widehat{B_0}, (t))$ satisfies (a) in Definition 4.3. Moreover, as a corollary of the assertion (1), one finds that $\widehat{f_0}$ also satisfies (b). Hence the remaining part is to show that $\widehat{B_0}$ is contained in $(\widehat{A_0})_{B'}^*$. To carry out this, we take a finitely generated A_0 -submodule $N_0 \subset B_0$ such that $t^l B_0 \subset N_0$ for some $l > 0$ by applying Proposition 4.5(2). Denote by $\widehat{N_0}$ the t -adic completion of N_0 . Then by Lemma 2.5, $\widehat{N_0}$ is viewed as an $\widehat{A_0}$ -submodule of $\widehat{B_0}$ such that

$$(4.3) \quad t^l \widehat{B_0} \subset \widehat{N_0}.$$

By applying the topological Nakayama's lemma [21, Theorem 8.4], one finds that

$$(4.4) \quad \widehat{N_0} \text{ is a finitely generated } \widehat{A_0}\text{-module,}$$

because $\widehat{N}_0/t\widehat{N}_0 \cong N_0/tN_0$ is finitely generated over $\widehat{A}_0/t\widehat{A}_0 \cong A_0/tA_0$. Combining (4.3) and (4.4) together, we conclude that \widehat{B}_0 is contained in a finitely generated \widehat{A}_0 -submodule of B' . In particular it holds that $\widehat{B}_0 \subset (\widehat{A}_0)_{B'}^*$, as wanted. \square

Corollary 4.10. *Let $(A_0, (t))$ be a preuniform pair with the associated Tate ring A . Let \widehat{A}_0 be the t -adic completion of A_0 and let \mathcal{A} be the Tate ring associated to $(\widehat{A}_0, (t))$. Suppose that B is a finite étale A -algebra and denote by \mathcal{B} the finite étale \mathcal{A} -algebra $B \otimes_A \mathcal{A}$. Equip B and \mathcal{B} with the canonical structure as a Tate ring (cf. Lemma 2.20) respectively. Then the following assertions hold.*

- (1) *Let \widehat{B}° be the t -adic completion of B° . Then the natural ring map $\varphi : \mathcal{B} \rightarrow \widehat{B}^\circ[\frac{1}{t}]$ is an isomorphism which induces an isomorphism $\mathcal{B}^\circ \xrightarrow{\cong} \widehat{B}^\circ$.*
- (2) *For the natural map $\psi : B \rightarrow \mathcal{B}$, it holds that $\psi^{-1}(\mathcal{B}^\circ) = B^\circ$.*

Proof. We first prove (1). Let \widehat{A}° be the t -adic completion of A° and put $A' := \widehat{A}^\circ[\frac{1}{t}]$ and $B' := \widehat{B}^\circ[\frac{1}{t}]$. Then the natural ring map $\mathcal{A} \rightarrow A'$ is an isomorphism by Lemma 2.5, and it induces $\widehat{A}^\circ \xrightarrow{\cong} \mathcal{A}^\circ$ by Corollary 2.8. Since the morphism $(A^\circ, (t)) \rightarrow (B^\circ, (t))$ satisfies the condition $(*)$ by Corollary 4.8(2), φ is an isomorphism by Theorem 4.9(1). Thus, φ induces an isomorphism of \widehat{A}° -algebras $(\mathcal{A}^\circ)_{\mathcal{B}}^* \xrightarrow{\cong} (\widehat{A}^\circ)_{B'}^*$. Therefore it suffices to show that

$$(4.5) \quad \mathcal{B}^\circ = (\mathcal{A}^\circ)_{\mathcal{B}}^* \text{ and } \widehat{B}^\circ = (\widehat{B}^\circ)_{B'}^* = (\widehat{A}^\circ)_{B'}^*.$$

By Theorem 4.9(2), the morphism $(\widehat{A}^\circ, (t)) \rightarrow (\widehat{B}^\circ, (t))$ also satisfies the condition $(*)$. Hence (4.5) follows from Proposition 4.5(3) and Corollary 4.8(3), as wanted.

Let us prove the assertion (2). Let B'_0 denote the subring $\psi^{-1}(\mathcal{B}^\circ)$ of B . By Corollary 4.8(3), we have $B^\circ = (A^\circ)_B^*$ and $\mathcal{B}^\circ = (\mathcal{A}^\circ)_{\mathcal{B}}^* = (\widehat{A}^\circ)_{\mathcal{B}}^*$. On the other hand, we have

$$\psi((A^\circ)_B^*) \subset (A^\circ)_{\mathcal{B}}^* \subset (\widehat{A}^\circ)_{\mathcal{B}}^*.$$

Thus it follows that $B^\circ \subset B'_0$. We then prove the reverse inclusion. By the assertion (1), we have the commutative diagram:

$$\begin{array}{ccc} \mathcal{B}^\circ & \xrightarrow{\cong} & \widehat{B}^\circ \\ \downarrow & & \downarrow \\ \mathcal{B} & \xrightarrow[\varphi]{\cong} & \widehat{B}^\circ[\frac{1}{t}] \end{array}$$

where the vertical arrows denote the inclusion maps. Hence the map $(\varphi \circ \psi)|_{B'_0}$ factors through \widehat{B}° . Thus by Lemma 2.6, we have $B'_0 \subset B^\circ$, as wanted. \square

Finally, we remark the following result. Compare it with Lemma 2.5.

Lemma 4.11. *Let $(A_0, (t))$ be a preuniform pair and let $A_0 \hookrightarrow B_0$ be an integral ring extension such that B_0 is t -torsion free. Denote by \widehat{A}_0 and \widehat{B}_0 the t -adic completions of A_0 and B_0 , respectively. Then $\widehat{A}_0 \rightarrow \widehat{B}_0$ is an injective ring map between t -torsion free rings.*

Proof. The t -torsion freeness of \widehat{A}_0 and \widehat{B}_0 follows from Lemma 2.6. Let us prove the injectivity of the homomorphism $\widehat{A}_0 \rightarrow \widehat{B}_0$. Put $A = A_0[\frac{1}{t}]$ and choose an integer $c > 0$ for which $t^c(A_0)_A^+ \subset A_0$. Then it suffices to prove that $A_0 \cap t^{n+c}B_0 \subset t^nA_0$ for every $n > 0$. Let $x \in A_0 \cap t^{n+c}B_0$. Then one can write $x = t^{n+c}b$ for $b \in B_0$ and hence

$$b = \frac{x}{t^{n+c}} \in B_0 \cap A.$$

As B_0 is integral over A_0 , we have $t^c b \in A_0$. Hence we have $x = t^n(t^c b) \in t^n A_0$, as required. \square

5. THE ALMOST PURITY THEOREM FOR WITT-PERFECT RINGS

5.1. Almost étale ring maps. First we review the definition of almost étale ring maps and the statement of the almost purity theorem, due to Davis and Kedlaya. For the results concerning classical étale ring maps, the recent book [13] is a good reference. The large part of almost ring theory is concerned around almost counterparts of certain finiteness conditions, so let us recall some definitions. The original definition of almost finitely generated (presented) modules is quite intricate; see [16, Definition 2.3.8]. However, the following characterization is more straightforward and found in [16, Proposition 2.3.10].

Definition 5.1. Let (R, I) be a basic setup, let A be an R -algebra and let M be an A -module.

- (1) M is said to be *I -almost finitely generated*, if for every finitely generated subideal $I_0 \subset I$, there exists a finitely generated A -submodule $N \subset M$ such that $I_0 M \subset N$.
- (2) M is said to be *I -almost finitely presented*, if for every finitely generated subideal $I_0 \subset I$, there is a complex of A -modules: $A^{\oplus m} \xrightarrow{\psi} A^{\oplus n} \xrightarrow{\phi} M$ such that $I_0 \text{Coker}(\phi) = 0$ and $I_0 \text{Ker}(\phi) \subset \text{Im}(\psi)$.

As our main concern is around étale ring maps and their almost variants, we refer the reader to [16, Definition 2.4.4] for the definitions of I -almost flatness and I -almost projectivity. We refer the reader to [16, Definition 3.1.1] for the following definitions.

Definition 5.2. Fix a basic setup (R, I) and let $A \rightarrow B$ be an R -algebra homomorphism.

- (1) $A \rightarrow B$ is called *I -almost weakly unramified*, if the diagonal map $B \otimes_A B \rightarrow B$ is I -almost flat.
- (2) $A \rightarrow B$ is called *I -almost unramified*, if the diagonal map $B \otimes_A B \rightarrow B$ is I -almost projective.
- (3) $A \rightarrow B$ is called *I -almost weakly étale*, if $A \rightarrow B$ is I -almost flat and I -almost weakly unramified.
- (4) $A \rightarrow B$ is called *I -almost étale*, if $A \rightarrow B$ is I -almost flat and I -almost unramified.
- (5) $A \rightarrow B$ is called *I -almost finite étale*, if it is I -almost étale and B is an I -almost finitely presented A -module.

So far, we have been using the symbol (A_0, I_0) to emphasize that A_0 is a ring of definition of some Tate ring and I_0 is its ideal of definition.⁶ One should keep in mind that (R, I) is a basic setup; R is a ring and I is its idempotent ideal. Before going further, we clarify the relationship between “almost integrality” and “ I -almost integrality” in a special case.

Lemma 5.3. *Let A_0 be a ring with a sequence of nonzero divisors $\{t_n\}_{n \geq 0}$ such that for every $n \geq 0$ we have $t_{n+1}^{k_n} = t_n u_n$ for some integer $k_n \geq 2$ and some unit $u_n \in A_0^\times$. Put $A := A_0[\frac{1}{t_0}]$. Then $a \in (A_0)_A^*$ implies that $t_n a \in (A_0)_A^+$ for every $n \geq 0$. Moreover, the converse holds true if $(A_0, (t_0))$ is preuniform.*

Proof. Let us choose an element $a \in A$ and let $n > 0$ be an integer. Put $c_n := \prod_{0 \leq i \leq n-1} k_i$. Then by assumption, $t_n^{c_n} = t_0 v_n$ for some unit $v_n \in A_0^\times$. Suppose that $a \in (A_0)_A^*$. Then there exists some $d > 0$ such that $t_0^d a^m \in A_0$ for every $m \geq 1$. Thus, we have $(t_n a)^{c_n d} \in A_0$ and therefore, $t_n a \in (A_0)_A^+$. This yields the first assertion. To show the converse, we suppose that $(A_0, (t_0))$ is preuniform and $t_m a \in (A_0)_A^+$ for every $m \geq 1$. Then we have $t_0 a^{c_n} = (t_n a)^{c_n} v_n^{-1} \in (A_0)_A^+$. Thus,

⁶The exceptional places are Lemma 2.5, Proposition 4.1, and the introductory remark to it. We should remark that no finiteness conditions are not imposed on I_0 in Proposition 4.1.

since $c_n \rightarrow \infty$ ($n \rightarrow \infty$), it is easy to check $t_0 a^m \in (A_0)_A^+$ for every $m \geq 1$. Here by assumption, there exists some $e > 0$ for which $t_0^e (A_0)_A^+ \subset A_0$. Hence we have $a \in (A_0)_A^*$, as wanted. \square

Corollary 5.4. *Let (R, I) be a basic setup and let A_0 be an R -algebra. Assume that I admits a sequence of elements $\{t_n\}_{n \geq 0}$ such that A_0 is t_0 -torsion free, IA_0 is generated by the set of all $t_n \in A_0$ ($n \geq 0$) and for every $n \geq 0$ we have $t_{n+1}^{k_n} = t_n u_n$ for some integer $k_n \geq 2$ and some unit $u_n \in A_0^\times$. Put $A := A_0[\frac{1}{t_0}]$. Then the following assertions hold.*

- (1) *Let $A'_0 \subset A$ be a subring containing $(A_0)_A^+$. If one has $A'_0 \subset (A_0)_A^*$, then the inclusion map $(A_0)_A^+ \hookrightarrow A'_0$ is an I -almost isomorphism (in particular, $(A_0)_A^+ \hookrightarrow (A_0)_A^*$ is an I -almost isomorphism). Moreover, the converse holds true if $(A_0, (t_0))$ is preuniform.*
- (2) *Equip A with a linear topology so that A is the Tate ring associated to $(A_0, (t_0))$. Let $A \rightarrow B$ be a module-finite extension of Tate rings as in Lemma 2.20. Then one has $(A_0)_B^+ \subset B^\circ$ and the inclusion map is an I -almost isomorphism.*

Proof. The assertion (1) follows from Lemma 5.3 immediately. To show (2), take a ring of definition $B_0 \subset B$ as in Lemma 2.20. Then $B^\circ = (B_0)_B^*$ and $(A_0)_B^+ = (B_0)_B^+$, because B_0 is integral over A_0 . Hence the assertion follows from (1). \square

In the situation of Corollary 5.4, one can obtain an “almost” variant of Corollary 2.8.

Lemma 5.5. *Keep the notation and the assumption as in Corollary 5.4. Denote by $\widehat{A_0}$ the t_0 -adic completion of A_0 and put $A' := \widehat{A_0}[\frac{1}{t_0}]$. Then the following conditions are equivalent.*

- (a) *The inclusion map $A_0 \hookrightarrow (A_0)_A^+$ (resp. $A_0 \hookrightarrow (A_0)_A^*$) is an I -almost isomorphism.*
- (b) *The inclusion map $\widehat{A_0} \hookrightarrow (\widehat{A_0})_{A'}^+$ (resp. $\widehat{A_0} \hookrightarrow (\widehat{A_0})_{A'}^*$) is an I -almost isomorphism.*

Proof. The proof of the lemma follows immediately from Proposition 2.4 and Corollary 5.4, because the sequence of ideals $\{t_n A_0\}_{n \geq 0}$ defines the same adic topology on A_0 . \square

Moreover, notice the following.

Lemma 5.6 ([25, Lemma 5.3(i)]). *Keep the notation and the assumption as in Corollary 5.4. Let M_0 be an I -almost flat A_0 -module. Then $(M_0^a)_*$ is t_0 -torsion free, where $(M_0^a)_* := \text{Hom}_R(I, M_0)$ (see [16, 2.2.10] for this notation).*

Proof. By the assumption on I and A_0 , any I -almost zero element in $\text{Hom}_R(I, M_0)$ must be zero. Thus the argument in the proof of [25, Lemma 5.3(i)] still works under our setting. \square

Next we prove a key result in this section. This is an important consequence of studies in §4.2.

Theorem 5.7. *Let (R, I) be a basic setup and let $f_0 : A_0 \rightarrow B_0$ be an R -algebra homomorphism with an element $t \in A_0$. Denote by $\widehat{A_0}$ and $\widehat{B_0}$ the t -adic completions of A_0 and B_0 , respectively. Let $\widehat{f_0} : \widehat{A_0} \rightarrow \widehat{B_0}$ be the R -algebra homomorphism induced by f_0 . Assume that the morphism of pairs $f_0 : (A_0, (t)) \rightarrow (B_0, (t))$ satisfies the condition (*). Then the following assertions hold.*

- (1) *The following conditions are equivalent.*
 - (a) *B_0 is I -almost finitely generated and I -almost projective over A_0 .*
 - (b) *$\widehat{B_0}$ is I -almost finitely generated and I -almost projective over $\widehat{A_0}$.*
- (2) *The following conditions are equivalent.*
 - (a) *$f_0 : A_0 \rightarrow B_0$ is I -almost finite étale.*
 - (b) *$\widehat{f_0} : \widehat{A_0} \rightarrow \widehat{B_0}$ is I -almost finite étale.*

To prove this theorem, we need the following lemma.

Lemma 5.8. *Keep the notation as in Theorem 5.7. Assume that $f_0 : (A_0, (t)) \rightarrow (B_0, (t))$ satisfies the condition (*). Assume further that for every $\varepsilon \in I$ and for every integer $n > 0$ there exist a finite free A_0 -module F and A_0 -homomorphisms $B_0 \rightarrow F \rightarrow B_0$ whose composition is congruent to multiplication by ε modulo (t^n) . Then B_0 is I -almost finitely generated and I -almost projective over A_0 .*

Proof of Lemma 5.8. Fix $\varepsilon \in I$ arbitrarily. By Proposition 4.5(2), there exist an integer $l > 0$, a finite free A_0 -module F_1 , and A_0 -linear maps $\pi_l : F_1 \rightarrow B_0$, $s_l : B_0 \rightarrow F_1$ such that $\pi_l \circ s_l$ is multiplication by t^l . On the other hand, by assumption we have A_0 -linear maps $\pi_{\varepsilon,l} : F_2 \rightarrow B_0$ and $s_{\varepsilon,l} : B_0 \rightarrow F_2$ for some finite free A_0 -module F_2 , such that $\pi_{\varepsilon,l} \circ s_{\varepsilon,l}$ is congruent to multiplication by ε modulo (t^l) . Thus one can define the A_0 -linear maps

$$f_\varepsilon : B_0 \rightarrow B_0, \quad x \mapsto \frac{1}{t^l}(\varepsilon x - (\pi_{\varepsilon,l} \circ s_{\varepsilon,l})(x))$$

and

$$s_\varepsilon : B_0 \rightarrow F_1 \oplus F_2, \quad x \mapsto ((s_l \circ f_\varepsilon)(x), s_{\varepsilon,l}(x)).$$

Consider the A_0 -linear map

$$\pi_\varepsilon : F_1 \oplus F_2 \rightarrow B_0, \quad (a_1, a_2) \mapsto \pi_l(a_1) + \pi_{\varepsilon,l}(a_2).$$

Then $\pi_\varepsilon \circ s_\varepsilon$ is multiplication by ε . Hence the assertion follows. \square

Now let us complete the proof of Theorem 5.7.

Proof of Theorem 5.7. Put $A := A_0[\frac{1}{t}]$, $A' := \widehat{A_0}[\frac{1}{t}]$, $B := B_0[\frac{1}{t}]$, and $B' := \widehat{B_0}[\frac{1}{t}]$. Notice that the morphism $\widehat{f_0} : (\widehat{A_0}, (t)) \rightarrow (\widehat{B_0}, (t))$ satisfies the condition (*) by Theorem 4.9. In particular, B' is finite étale over A' .

(1): We first show $(a) \Rightarrow (b)$. Assume that (a) is satisfied. Then for an arbitrary $\varepsilon \in I$, there exist A_0 -linear maps $\pi_\varepsilon : A_0^{\oplus d} \rightarrow B_0$ and $s_\varepsilon : B_0 \rightarrow A_0^{\oplus d}$ such that $\pi_\varepsilon \circ s_\varepsilon$ is multiplication by ε . Let $\widehat{\pi}_\varepsilon : (\widehat{A_0})^{\oplus d} \rightarrow \widehat{B_0}$ and $\widehat{s}_\varepsilon : \widehat{B_0} \rightarrow (\widehat{A_0})^{\oplus d}$ be the induced $\widehat{A_0}$ -linear maps. Then we have the natural commutative diagram of A_0 -linear maps:

$$\begin{array}{ccccc} B_0 & \xrightarrow{s_\varepsilon} & A_0^{\oplus d} & \xrightarrow{\pi_\varepsilon} & B_0 \\ \downarrow & & \downarrow & & \downarrow \\ \widehat{B_0} & \xrightarrow{\widehat{s}_\varepsilon} & (\widehat{A_0})^{\oplus d} & \xrightarrow{\widehat{\pi}_\varepsilon} & \widehat{B_0}, \end{array}$$

where the vertical maps become isomorphisms after base extension along $A_0 \rightarrow A_0/t^n A_0$ for an arbitrary $n > 0$. Hence $\widehat{\pi}_\varepsilon \circ \widehat{s}_\varepsilon$ is multiplication by ε modulo (t^n) . Thus, we can apply Lemma 5.8 to this situation. Therefore (b) is satisfied.

Next we show $(b) \Rightarrow (a)$. Assume that (b) is satisfied. Like the proof of the inverse implication, it suffices to construct A_0 -linear maps $B_0 \rightarrow A_0^{\oplus d}$ and $A_0^{\oplus d} \rightarrow B_0$ whose composition $B_0 \rightarrow B_0$ is multiplication by ε modulo (t^n) for an arbitrary $\varepsilon \in I$ and an arbitrary $n > 0$. By assumption, there exist $\widehat{A_0}$ -linear maps $\widehat{\pi}_\varepsilon : (\widehat{A_0})^{\oplus d} \rightarrow \widehat{B_0}$ and $\widehat{s}_\varepsilon : \widehat{B_0} \rightarrow (\widehat{A_0})^{\oplus d}$ such that $\widehat{\pi}_\varepsilon \circ \widehat{s}_\varepsilon$ is multiplication by ε . These maps induce A_0 -linear maps $\overline{\pi}_\varepsilon : A_0^{\oplus d}/(t^n) \rightarrow B_0/(t^n)$ and $\overline{s}_\varepsilon : B_0/(t^n) \rightarrow A_0^{\oplus d}/(t^n)$ such that $\overline{\pi}_\varepsilon \circ \overline{s}_\varepsilon$ is multiplication by ε . Since there exists an A_0 -linear map $\pi_\varepsilon : A_0^{\oplus d} \rightarrow B_0$ that is a lift of $\overline{\pi}_\varepsilon$, we are reduced to constructing an A_0 -linear map $B_0 \rightarrow A_0^{\oplus d}$ that is a lift of \overline{s}_ε . By inverting t , \widehat{s}_ε is extended to a A' -linear map $\widehat{s}'_\varepsilon : B' \rightarrow A'^{\oplus d}$. Since B' is finite étale over A' , there exist $\widehat{b}_1, \dots, \widehat{b}_d \in B'$ such that $\widehat{s}'_\varepsilon(x) = (\text{Tr}_{B'/A'}(\widehat{b}_1 x), \dots, \text{Tr}_{B'/A'}(\widehat{b}_d x))$ for every $x \in B'$ (and thus,

for each $i = 1, \dots, d$, $\mathrm{Tr}_{B'/A'}(\widehat{b_i}x) \in \widehat{A_0}$ if $x \in \widehat{B_0}$). For an integer $k > 0$, we take $b_1, \dots, b_d \in B$ such that $\widehat{b_i} \equiv b_i \pmod{t^{2k}\widehat{B_0}}$ for each i (cf. Remark 2.22). Pick $m \in B_0$. Then

$$\mathrm{Tr}_{B'/A'}(b_i m) = \mathrm{Tr}_{B'/A'}(\widehat{b_i} m) + t^k (\mathrm{Tr}_{B'/A'}(t^k x_i)) \quad (i = 1, \dots, d)$$

for some $x_i \in \widehat{B_0}$. Now by Proposition 4.5(1), we have $\mathrm{Tr}_{B'/A'}(t^l \widehat{B_0}) \subset \widehat{A_0}$ for some $l > 0$. Thus we may assume that $\mathrm{Tr}_{B'/A'}(t^k x_i) \in \widehat{A_0}$ ($i = 1, \dots, d$) by increasing k if necessary. Hence we have

$$(5.1) \quad \mathrm{Tr}_{B'/A'}(b_i m) \equiv \mathrm{Tr}_{B'/A'}(\widehat{b_i} m) \pmod{t^k \widehat{A_0}} \quad (i = 1, \dots, d).$$

In particular, $\mathrm{Tr}_{B'/A'}(b_i m) \in \widehat{A_0}$. Meanwhile, since $B \otimes_A A' \cong B'$ by Theorem 4.9, the diagram of B -linear maps

$$\begin{array}{ccc} B & \xrightarrow{\mathrm{Tr}_{B/A}} & A \\ \downarrow & & \downarrow \\ B' & \xrightarrow{\mathrm{Tr}_{B'/A'}} & A' \end{array}$$

commutes. Hence $\mathrm{Tr}_{B/A}(b_i m) \in A_0$ in view of Lemma 2.6. Therefore, one can define the A_0 -linear map

$$s_\varepsilon : B_0 \rightarrow A_0^{\oplus d}, \quad m \mapsto (\mathrm{Tr}_{B/A}(b_1 m), \dots, \mathrm{Tr}_{B/A}(b_d m)),$$

which is a lift of \overline{s}_ε in view of (5.1).

(2): First we assume that (a) is satisfied. Then $\widehat{B_0}$ is an I -almost finitely generated projective $\widehat{A_0}$ -module in view of the assertion (1). Hence by [16, Remark 2.4.12 and Proposition 2.4.18], it follows that $\widehat{B_0}$ is an I -almost flat and I -almost finitely presented $\widehat{A_0}$ -module. On the other hand, since $A' \rightarrow B'$ is unramified by Theorem 4.9 and $\widehat{A_0}/(t) \rightarrow \widehat{B_0}/(t)$ is I -almost unramified by [16, Lemma 3.1.2], it follows from [16, Theorem 5.2.12], together with the fact that $\widehat{B_0}$ is an I -almost finitely presented $\widehat{A_0}$ -module, that $\widehat{A_0} \rightarrow \widehat{B_0}$ is I -almost unramified. Thus we find that (b) is satisfied. The inverse implication (b) \Rightarrow (a) can be shown similarly. \square

5.2. Proof of the almost purity theorem. Now we are ready to prove the almost purity theorem by Davis and Kedlaya. In this subsection, we fix a prime number $p > 0$, and for any ring R , we denote by \widehat{R} the p -adic completion of R . Moreover for a ring map $f : R \rightarrow S$, we denote by \widehat{f} the ring map $\widehat{R} \rightarrow \widehat{S}$ induced by f .

Theorem 5.9 (Almost purity). *Let A_0 be a p -torsion free Witt-perfect ring and let $f_0 : A_0 \rightarrow B_0$ be a ring map. Put $I := \sqrt{pA_0}$. Assume that the morphism $f_0 : (A_0, (p)) \rightarrow (B_0, (p))$ satisfies the condition (*), A_0 is integrally closed in $A_0[\frac{1}{p}]$, $(A_0)_{B_0[\frac{1}{p}]}^+ \subset B_0$, and (A_0, I) is a basic setup⁷. Then the following assertions hold.*

- (1) B_0 is also Witt-perfect.
- (2) $f_0 : A_0 \rightarrow B_0$ is I -almost finite étale.

Proof. Let \mathcal{A} and \mathcal{B} be Banach rings associated to complete Tate rings $(\widehat{A_0}, (p))$ and $(\widehat{B_0}, (p))$ respectively such that the map $\mathcal{A} \rightarrow \mathcal{B}$ induced by $\widehat{f_0}$ is bounded. Then by Proposition 3.16 and Corollary 3.17, \mathcal{A} is perfectoid and $\mathcal{A}^{\circ\circ} = I\widehat{A_0}$. Moreover, since $(\widehat{A_0}, (p)) \rightarrow (\widehat{B_0}, (p))$ satisfies the

⁷For example, this assumption is realized if A_0 admits $\{p^{\frac{1}{p^n}}\}_{n \geq 0}$, A_0 is p -adically Zariskian, or A_0 is an algebra over a p -torsion free Witt-perfect valuation domain of rank 1 (cf. Example 3.1 and Lemma 3.3).

condition $(*)$ by Theorem 4.9, $\mathcal{A} \rightarrow \mathcal{B}$ is finite étale, $\widehat{B}_0 \subset (\widehat{A}_0)^*_\mathcal{B}$, and $(\widehat{A}_0)^*_\mathcal{B} = (\widehat{B}_0)^*_\mathcal{B}$ by Proposition 4.5(3). Meanwhile, we also have $p(B_0)^*_\mathcal{B} = p(A_0)^*_\mathcal{B} \subset (A_0)^+_B \subset B_0$ by Lemma 2.3 and Proposition 4.5(3), which implies that $p(\widehat{B}_0)^*_\mathcal{B} \subset \widehat{B}_0$ by Proposition 2.4. Thus we find that

$$p\widehat{B}_0 \subset p(\widehat{A}_0)^*_\mathcal{B} = p(\widehat{B}_0)^*_\mathcal{B} \subset \widehat{B}_0.$$

Hence, the topology on \mathcal{B} coincides with the canonical topology on $\widehat{B}_0[\frac{1}{p}]$ as a finitely generated \mathcal{A} -module by Corollary 4.8(1). Thus, in view of Corollary 5.4, the maps $\widehat{A}_0 \hookrightarrow \mathcal{A}^\circ$ and $\widehat{B}_0 \hookrightarrow \mathcal{B}^\circ$ are I -almost isomorphisms. Moreover, by almost purity theorem by Kedlaya-Liu [20, Theorem 3.6.21 and 5.5.9], it follows that $\mathcal{A}^\circ \rightarrow \mathcal{B}^\circ$ is I -almost finite étale (and therefore so is \widehat{f}_0) and \mathcal{B} is perfectoid. In particular, B_0 is Witt-perfect by Lemma 3.7. Now the assertion (2) follows from Theorem 5.7. \square

Remark 5.10. Resume the notation of Theorem 5.9. Here is a way to check almost flatness for the extension $A_0 \rightarrow B_0$. Suppose that $A_0[\frac{1}{p}] \rightarrow B_0[\frac{1}{p}]$ is flat and $A_0/(p) \rightarrow B_0/(p)$ is I -almost flat. Then since p is a nonzero divisor on both A_0 and B_0 , a simple discussion using the short exact sequence: $0 \rightarrow A_0 \xrightarrow{p} A_0 \rightarrow A_0/(p) \rightarrow 0$ shows that $\mathrm{Tor}_i^{A_0}(B_0, A_0/(p)) = 0$ for $i > 0$. By applying [16, Lemma 5.2.1] (see also [14, Lemma 1.2.5] for the absolute version), one sees that B_0 is an I -almost flat A_0 -module.

In [23], we apply Theorem 5.9 to construct big (almost) Cohen-Macaulay algebras with distinguished properties. Here we illustrate a key step to it in a simple situation.

Example 5.11. Let R be a Noetherian complete local domain of mixed characteristic $p > 0$ with perfect residue field k . Let p, x_2, \dots, x_d be a system of parameters in R . Then there exists a module-finite extension $\iota : W(k)[[x_2, \dots, x_d]] \hookrightarrow R$ by Cohen's structure theorem. Since the induced field extension $\mathrm{Frac}(W(k)[[x_2, \dots, x_d]]) \hookrightarrow \mathrm{Frac}(R)$ is finite separable, there exists an element $g \in W(k)[[x_2, \dots, x_d]] \setminus (p)$ such that ι becomes finite étale after inverting pg . Here, we assume that $g = 1$ for simplicity ([23] deals with the general cases). Set

$$A_0 := \bigcup_{n>0} W(k)[[x_2, \dots, x_d]][p^{\frac{1}{p^n}}, x_2^{\frac{1}{p^n}}, \dots, x_d^{\frac{1}{p^n}}].$$

Then A_0 is a Witt-perfect ring. Moreover, by base change, we obtain a finite étale ring map

$$f : A_0[\frac{1}{p}] \rightarrow (A_0 \otimes_{W(k)[[x_2, \dots, x_d]]} R)[\frac{1}{p}].$$

Let B_0 be the integral closure of A_0 in $(A_0 \otimes_{W(k)[[x_2, \dots, x_d]]} R)[\frac{1}{p}]$. Then by Theorem 5.9, the induced map $A_0 \rightarrow B_0$ is $(p)^{\frac{1}{p^\infty}}$ -almost finite étale, and B_0 is Witt-perfect. In particular, $A_0 \rightarrow B_0$ is $(p)^{\frac{1}{p^\infty}}$ -almost flat. Hence B_0 is an almost Cohen-Macaulay R -algebra with respect to (p, x_2, \dots, x_d) in the sense of [27, Definition 5.4]. Notice that the map $R \rightarrow B_0$ is integral.

Let (R, I) be a basic setup and let A be an R -algebra. Let us denote by $\mathbf{Alg}^a(A)$ the quotient category of the category of A -algebras $\mathbf{Alg}(A)$ by the Serre subcategory of objects in $\mathbf{Alg}(A)$ that are I -almost zero. Let $(\)_* : \mathbf{Alg}^a(A) \rightarrow \mathbf{Alg}(A)$ be the *functor of almost elements* (see [16, 2.2.10]). We define $\mathbf{F.Et}(A)$ to be the category of finite étale A -algebras. We also define $\mathbf{F.Et}^a(A)$ to be the full subcategory of $\mathbf{Alg}^a(A)$ that consist of I -almost finite étale A -algebras.

Corollary 5.12. *Let A_0 be a p -torsion free algebra over a p -torsion free Witt-perfect valuation domain V of rank 1. Assume that A_0 is Witt-perfect and integrally closed in $A_0[\frac{1}{p}]$. Put $I := \sqrt{p}A_0$.*

Consider the basic setup (A_0, I) and the diagram of functors:

$$(5.2) \quad \begin{array}{ccc} \mathbf{F.Et}^a(A_0) & \xrightarrow{\Phi_1} & \mathbf{F.Et}^a(\widehat{A_0}) \\ \Phi_2 \downarrow & & \downarrow \Phi_4 \\ \mathbf{F.Et}(A_0[\frac{1}{p}]) & \xrightarrow{\Phi_3} & \mathbf{F.Et}(\widehat{A_0}[\frac{1}{p}]) \end{array}$$

where Φ_1, Φ_2, Φ_3 and Φ_4 are given by the association $B_0 \mapsto B_0 \otimes_{A_0^a} (\widehat{A_0})^a$, $B_0 \mapsto (B_0)_*[\frac{1}{p}]$, $B \mapsto B \otimes_{A_0[\frac{1}{p}]} \widehat{A_0}[\frac{1}{p}]$, and $B'_0 \mapsto (B'_0)_*[\frac{1}{p}]$, respectively (cf. [16, Lemma 3.1.2(i)]). Then the following assertions hold.

- (1) Φ_2 and Φ_4 yield equivalences of categories. Moreover, for an I -almost finite étale A_0 -algebra C_0 , the natural A_0 -algebra homomorphism $C_0 \otimes_{A_0} \widehat{A_0} \rightarrow \widehat{C_0}$ is an I -almost isomorphism.
- (2) Assume that A_0 is henselian along the ideal (p) . Then Φ_1 and Φ_3 yield equivalences of categories.

Proof. We can equip $\widehat{V}[\frac{1}{p}]$ and $\widehat{A_0}[\frac{1}{p}]$ with norms so that $\widehat{V}[\frac{1}{p}]$ is a perfectoid field and $\widehat{A_0}[\frac{1}{p}]$ is a perfectoid $\widehat{V}[\frac{1}{p}]$ -algebra by Proposition 3.20. Thus by the almost purity theorem for perfectoid $\widehat{V}[\frac{1}{p}]$ -algebras [25, Theorem 4.17, Theorem 5.2, Proposition 5.22, and Theorem 7.9] and Proposition 4.5(3), Φ_4 admits a quasi-inverse $\Psi_4 : \mathbf{F.Et}(\widehat{A_0}[\frac{1}{p}]) \rightarrow \mathbf{F.Et}^a(\widehat{A_0})$ given by the association $B' \mapsto (\widehat{A_0})_{B'}^{*a}$. More precisely, in view of [25, Lemma 5.6], for any $B'_0 \in \text{ob}(\mathbf{F.Et}^a(\widehat{A_0}))$ we have

$$(5.3) \quad (\widehat{A_0})_{\Phi_4(B'_0)}^* = (B'_0)_*.$$

On the other hand, by Theorem 5.9, we can also define a functor $\Psi_2 : \mathbf{F.Et}(A_0[\frac{1}{p}]) \rightarrow \mathbf{F.Et}^a(A_0)$ given by the association $B \mapsto (A_0)_B^{*a}$. Let us show that Ψ_2 gives a quasi-inverse of Φ_2 . The nontrivial part is to prove the existence of a functorial isomorphism $B_0 \cong (\Psi_2 \circ \Phi_2)(B_0)$ for $B_0 \in \text{ob}(\mathbf{F.Et}^a(A_0))$. We let C_0 be the I -almost finite étale A_0 -algebra $(B_0)_*$. Then C_0 is p -torsion free by Lemma 5.6, and thus $\widehat{A_0} \rightarrow \widehat{C_0}$ is also I -almost finite étale by Theorem 5.7. Put $C := C_0[\frac{1}{p}]$ and $C' := \widehat{C_0}[\frac{1}{p}]$. Since $C' = \Phi_4((\widehat{C_0})^a)$, we have $(\widehat{C_0})_{C'}^* = (\widehat{A_0})_{C'}^* = ((\widehat{C_0})^a)_*$ by Proposition 4.5(3) and (5.3). Therefore the inclusion map $\widehat{C_0} \hookrightarrow (\widehat{C_0})_{C'}^*$ is an I -almost isomorphism. Hence by Lemma 5.5, $C_0 \hookrightarrow (C_0)_C^*$ is also an I -almost isomorphism. Applying the functor of almostification $(\cdot)^a$, we obtain an isomorphism $C_0^a \cong (\Psi_2 \circ \Phi_2)(B_0)$, which yields the desired isomorphism. Next we apply the functor $\Phi_4 \circ (\cdot)^a$ to the natural map $\varphi : C_0 \otimes_{A_0} \widehat{A_0} \rightarrow \widehat{C_0}$. Then we obtain the natural map $(C_0 \otimes_{A_0} \widehat{A_0})[\frac{1}{p}] \rightarrow \widehat{C_0}[\frac{1}{p}]$, which is an isomorphism by Theorem 4.9. Thus, since Φ_4 is fully faithful, we find that φ is an I -almost isomorphism. Hence the assertion (1) follows. If further A_0 is henselian along the ideal (p) , then Φ_3 yields an equivalence of categories due to [16, Proposition 5.4.53], and therefore (1) implies that Φ_1 yields an equivalence of categories (because (5.2) is essentially commutative). It completes the proof. \square

6. APPENDIX: A HISTORICAL REMARK ON THE (ALMOST) PURITY THEOREM

In this appendix, we will provide some background history around the almost purity theorem as well as its classical version, which is known as the *Purity over Noetherian local rings*. Let us begin with the definition of purity for schemes.

Definition 6.1 (Purity). Let X be a scheme together with an open subset $U \subset X$. Let $\mathbf{Et}(Y)$ denote the category of étale finite Y -schemes. If the restriction functor:

$$\mathbf{F.Et}(X) \rightarrow \mathbf{F.Et}(U); Y \mapsto Y' := Y \times_X U$$

is an equivalence of categories, then we say that (X, U) is a *pure pair*.

To make this definition work, one is required to put more conditions, such as normality. Let us recall the following classical result due to Grothendieck.

Theorem 6.2 (Grothendieck). *Assume that (R, \mathfrak{m}) is a Noetherian local ring and let $X := \mathrm{Spec}(R)$ and $U := \mathrm{Spec}(R) \setminus \{\mathfrak{m}\}$. Then the following assertions hold:*

- (1) *If R is a regular local ring with $\dim R \geq 2$, then (X, U) is pure.*
- (2) *If R is a complete intersection with $\dim R \geq 3$, then (X, U) is pure.*

Proof. The proof of the first statement is in [28, Tag 0BMA], while the second statement is in [28, Tag 0BPD]. \square

These results are of use to the proof of the so-called *Zariski-Nagata's purity theorem* whose proof is found in [28, Tag 0BMB].

Theorem 6.3 (Purity of branch locus). *Assume that $f : X \rightarrow S$ is a finite dominant morphism of Noetherian integral schemes such that S is regular and X is normal. Then the ramification locus of f is of pure codimension one.*

The almost analogue of pure pair has been suggested in Gabber-Ramero's treatise [17, Definition 14.4.1], in which case the almost purity theorem takes the form of $X = \mathrm{Spec}(R)$ and $U = \mathrm{Spec}(R[\frac{1}{p}])$ for a certain big ring R . To the best of authors' knowledge, the first appearance of the almost purity theorem is Tate's work on p -divisible groups over local fields [30] and its higher-dimensional analog was studied by Faltings [10], who also outlined ideas of almost ring theory. Faltings gave another proof in [11], where he made an effective use of the Frobenius action on certain local cohomology modules combined with his normalized length. We refer the reader to Olsson's notes [24]. An ultimate version of the almost purity was proved by Scholze in [25], using adic spaces. We remark that Faltings started with an essentially smooth algebra over a discrete valuation ring and then constructed a huge ring extension on which the Frobenius map has good behavior. His proof required complicated ramification theory. On the other hand, Scholze started with a ring that is already big enough so that he avoided ramification theory.

Acknowledgement . The authors are grateful to Professor K. Fujiwara for encouragement and comments on this paper. Our gratitude also goes to some anonymous referee for reading the paper thoroughly and providing many constructive comments that has led to improve the presentation of the present article.
