Damien Woods ${ }^{\S}$

#### Abstract

We prove a Pumping Lemma for the noncooperative abstract Tile Assembly Model, a model central to the theory of algorithmic self-assembly since the beginning of the field. This theory suggests, and our result proves, that small differences in the nature of adhesive bindings between abstract square molecules gives rise to vastly different expressive capabilities.

In the cooperative abstract Tile Assembly Model, square tiles attach to each other using multi-sided cooperation of one, two or more sides. This precise control of tile binding is directly exploited for algorithmic tasks including growth of specified shapes using very few tile types, as well as simulation of Turing machines and even self-simulation of self-assembly systems. But are cooperative bindings required for these computational tasks? The definitionally simpler noncooperative (or Temperature 1) model has poor control over local binding events: tiles stick if they bind on at least one side. This has led to the conjecture that it is impossible for it to exhibit precisely controlled growth of computationally-defined shapes.

Here, we prove such an impossibility result. We show that any planar noncooperative system that attempts to grow large algorithmically-controlled tile-efficient assemblies must also grow infinite non-algorithmic (pumped) structures with a simple closed-form description, or else suffer blocking of intended algorithmic structures. Our result holds for both directed and nondirected systems, and gives an explicit upper bound of $(8|T|)^{4|T|+1}(5|\sigma|+6)$, where $|T|$ is the size of the tileset and $|\sigma|$ is the size of the seed assembly, beyond which any path of tiles is pumpable or blockable.

[^0]
## 1 Introduction

The main challenge of molecular programming is to understand, build and control matter at the molecular level. The dynamics of molecules can embed algorithms 42 and the theory of algorithmic self-assembly [13, 34, 43] is one formal way to think about the computational capabilities of autonomic self-assembling molecular systems. That theory, and more broadly the theory of models of computation, guides advances in experimental work to this day: the self-assembling binary counter of Winfree and Rothemund [37] was later implemented using tiles made of DNA [17], as were bit-copying systems [2, 3, 39] and discrete self-similar fractals [20, 38]. More recently, twenty-one self-assembly algorithms were implemented using DNA single-stranded tiles [44, including a tile-based implementation [7] of von Neuman's fair-bit-from-an-unfair-coin and a 3-bit instance of the computationally universal cellular automata Rule 110 [9, 32]. Besides guiding experiment, the theory itself has undergone significant developments, with the long-term vision of understanding the kinds of structure-building capabilities and computational mechanisms that are implementable and permitted by molecular processes.

Perhaps the most studied model of algorithmic self-assembly is the abstract Tile Assembly Model (aTAM), introduced by Winfree [42] as a computational model of DNA tile-based selfassembly. The model is an algorithmic version of Wang tilings 41, can be thought of as an asynchronous cellular automaton [5 and has features seen in other distributed computing models. In each instance of the model, we have a finite set of unit square tile types, with colours on their four sides, and an infinite supply of each type. Starting from a small connected arrangement of tiles on the $\mathbb{Z}^{2}$ plane, called the seed assembly, we attach tiles to that assembly asynchronously and nondeterministically based on a local rule depending only on the colour of the sides of the newly placed tile and of the sides of the assembly that are adjacent to the attachment position.

This model can simulate Turing machines [42], self-assemble squares with few tile types [36, 37], assemble any finite spatially-scaled shape using a small, Kolmogorov-efficient, tile set 40], and there is an intrinsically universal tile set capable of simulating the behaviour (produced shapes and growth dynamics) of any other tile set, up to spatial rescaling [14].

However, these results have all been proven using the so-called cooperative tile assembly model. In the cooperative, or temperature 2, model there are two kinds of bonds: strong and weak. A tile can attach to an assembly by one side if that side forms a strong ("strength 2") bond with the assembly, or it can attach if two of its sides each match with a weak ("strength 1") bond. Intuitively, the cooperative model exploits weak bonds to create a form of synchronisation. The attachment of a tile by two weak glues sticking to two neighbour tiles can only occur after both neighbour tiles are present, allowing the system to wait rather than (say) proceeding with potentially inaccurate or incomplete information.

But what happens if we allow only one kind of bond? We get a simple model called the non-cooperative, or temperature 1, model. In the non-cooperative model, tiles may attach to the assembly whenever at least one of their sides' colour matches the colour of a side of the assembly adjacent to the position where they attach. Intuitively, they need not wait for more bonds to appear adjacent to their attachment position. In this model it seems non-obvious how to implement synchronisation; we have no obvious programmable feature that enables one growth process to wait until another is complete. Our attempts to build such things typically lead to rampant uncontrolled growth.

The question of whether the non-cooperative (or "non-waiting") model has any non-trivial
computational abilities has been open since the beginning of the field [37]. Perhaps a reason for this is that actually proving that one can not synchronise growth is tricky; maybe noncooperative self-assembly can somehow simulate synchronisation using some complicated form of in-plane geometric blocking? Restrictions of the model have been shown to be extremely weak [26,37], generalisations shown to be extremely powerful 4, $\mathbf{6}, 10,12,15,18,19,23,25,33,35,36$, and, to further deepen the mystery, the model has been shown capable of some (albeit limited) efficient tile reuse [27,30.

### 1.1 Main result

Our main result is stated in Theorem 1.1, although a number of notions have yet to be formally defined (see Section 2 for definitions). Intuitively if a noncooperative tile assembly system produces a large assembly, it is capable of also producing any path of tiles in that assembly. Our statement says that if the tile assembly system can produce a long enough path $P$, then it must also produce assemblies where either an infinite ultimately periodic path appears ( $P$ is "pumpable"), or else the path cannot appear in all terminal assemblies (because some other tiles can be placed to block the growth of $P$ ), in which case we say that $P$ is fragile. Let $T$ be a set of tile types, and let $|\sigma|$ denote the number of tiles in the (seed) assembly $\sigma$.

Theorem 1.1. Let $\mathcal{T}=(T, \sigma, 1)$ be any tile assembly system in the abstract Tile Assembly Model (aTAM), and let $P$ be a path producible by $\mathcal{T}$. If $P$ has vertical height or horizontal width at least $(8|T|)^{4|T|+1}(5|\sigma|+6)$, then $P$ is pumpable or fragile.

Our result rules out the kind of Turing machine simulations, and other kinds of computations, that have appeared in the literature to date and execute precisely controlled growth patterns [4, [6, 10-12, 15, 18, 19, 23-26, 33, 35, 36. We do so by showing that any attempt to carry out long computations such as these, which provably require large assemblies and thus long paths, will result in unbounded pumped growth or the blocking of such paths.

The essence of algorithmic self-assembly is tile reuse: growing structures that are larger than the number of available tile types [13, 34, 37, 43]. Meunier and Regnault [30] show that some noncooperative systems are capable of tile reuse in the following sense: there is a tile assembly system with multiple terminal assemblies, all of finite size, such that each of them contains the same long path $P$, where $P$ is of width $O(|T| \log |T|$ ) (i.e. larger than $|T|)$. In that construction, $P$ is neither pumpable (all assemblies are finite) nor fragile ( $P$ appears in all terminal assemblies, hence no assembly or path can block it). Their result should be contrasted with ours since here we show that any attempt to generalise such a construction beyond our exponential-in- $|T|$ bound will fail - thus we give a limitation of the amount of tile reuse possible in such constructions. Analogous tile reuse limitations do not appear in cooperative systems [37], due to their ability to run arbitrary algorithms.

Our theorem statement is quite similar to the pumpability conjecture of Doty, Patitz and Summers [16] (Conjecture 6.1). In that work [16] under the assumption that the conjecture is true, they achieve a complete characterisation of the producible assemblies. Our result is slightly different from that conjecture, being stronger in two ways, and weaker in one:

- First, their conjecture was stated for directed systems (that produce a single terminal assembly), but here we prove the result for both directed and undirected systems (systems that produce many terminal assemblies) ${ }^{1]}$ In the directed case, our result shows that any attempt

[^1]to simulate computations by growing longer and longer paths is doomed to also produce a terminal assembly littered with more and more infinite pumped paths.

- Second, we give an explicit bound (exponential in $|T|$ ) on the length a path can reach before it is pumpable or fragile.
- Our result is weaker in one way: indeed, while our result only applies to paths grown all the way from the seed, the conjecture is that arbitrary paths are pumpable, regardless of their position relative to the seed.
However, we conjecture that our result is sufficient to achieve the same characterisation of producible assemblies, using the same techniques and arguments as [16.
Our result can be applied to other models. After the aTAM, another well-studied model in the theory of algorithmic self-assembly is the hierarchical, or two-handed, model (2HAM) [6, 8, 12, 15]. There is no seed assembly in the 2HAM: in the noncooperative (temperature 1) 2HAM tiles stick together if glues match on one tile side, forming a collection of assemblies, and those assemblies can in turn stick to each other if they can be translated to touch without overlapping and with adjacent matching glues between them. As an almost direct corollary of Theorem 1.1 we get:

Corollary 1.2. Let $\mathcal{H}=(T, 1)$ be any tile assembly system in the Two-Handed Assembly Model (2HAM), and let $P$ be a path producible by $\mathcal{H}$. If $P$ has vertical height or horizontal width at least $(88|T|)^{4|T|+1}$, then $P$ is pumpable or fragile.

Intuitively, the corollary comes from the fact that aTAM-like growth is permitted in the 2HAM. In fact, if we fix a tile set $T$ and a temperature of 1 , the set of producible assemblies in a 2 HAM system over $T$ is a superset (sometimes a strict superset [6]) of those in the aTAM over $T$. A brief proof sketch is given in Appendix A,

### 1.2 Relationship with other prior work

Perhaps due to the difficulty of analysing the standard noncooperative model (2D, square tiles, tiles attach one at a time), researchers have looked at different variants of that model.

The first restriction studied was where we permit only terminal assemblies that are "fully connected" meaning all tiles are fully bound to all of their neighbour tiles): Rothemund and Winfree [37] showed that for each large enough $n \in \mathbb{N}$ there does not exist a noncooperative system that builds a fully-connected $n \times n$ square in a tile-efficient way (using $<n^{2}$ tile types). Since embedding algorithms in tiles are essentially our best (and perhaps only) way to exhibit efficient tile reuse, our result shuts the door on a wide class of algorithmic approaches. Other restrictions proven weak are where we disallow adjacent mismatching colours [26], or even force any pair of adjacent tiles to bind to each other [37].

Another, quite productive, approach has been to study generalisations of the noncooperative model (e.g. 3D, non-square tiles, multi-tile assembly steps, more complicated 'active' tiles, etc.): it turns out that these generalisations and others are powerful enough to simulate Turing machines [4, 6, 10-12, 15, 18, 19, 21, $26,33,35,36]$. Each such result points to a specific feature or set of features in a generalised model that provably needs to be exploited in order to avoid our negative result.

Since Cook, Fu, and Schweller [10] have shown that for any Turing machine there is an undirected tile assembly system, whose seed encodes an input, and where the largest producible

[^2]terminal assembly (which is possibly infinite) simulates the Turing machine computation on that input. However, in that construction, "blocking errors" can occur where growth is prematurely blocked and is stopped before the simulation, or computation, is completed (hence their result is stated in a probabilistic setting). Indeed their tile assembly systems that simulate Turing machines will produce many such erroneous assemblies. Our result shows that this kind of blocking is unavoidable.

Assemblies that cannot be "blocked" have the opposite issue, where it seems there is always a part of the assembly that can be repeated forever, which led Doty, Patitz and Summers [16] to their pumpability conjecture. They go on to show that, assuming the pumpability conjecture holds, projections to the vertical/horizontal axes of assemblies produced by directed noncooperative systems have a straightforward closed-form description (as the union of semi-linear sets).

In the direction of negative results on Temperature 1, reference [31] showed that the noncooperative planar aTAM is not capable of simulating - in the sense used in intrinsic universality 43] - other noncooperative aTAM systems. In other words intrinsic universality is not possible for the planar noncooperative model. The Temperature 2 (or, cooperative) model is capable of such simulations [14], hence the main result of [31] shows a difference in the self-simulation capabilities of the two models. Prior to that work, another result showed that Temperature 1 cannot simulate Temperature 2 intrinsically [28], and hence the former is strictly weaker than the later in this setting (where we ignore spatial scaling). However, to obtain both of those results, the use of simulation and intrinsic universality permitted a technique where we choose a particular class of shapes we want to simulate, and restrict the analysis of produced assemblies to (scaled versions of) these shapes. The proofs [28, 31] then involved forcing certain paths to grow outside of these pre-determined shapes. This paper makes use of a number of tools from [31. Here, however, the setting is significantly more challenging as we have no geometric hypotheses whatsoever on producible assemblies and therefore can not directly leverage 31, although we do make use of the tools of visibility and the notion of right/left priority exploited in that prior work. As already noted, positive constructions have been found that some limited form of efficient reuse of tile types is possible in the standard 2D noncooperative model [27,30]. This paper also builds on extensive previous work by two of the authors [29.

### 1.3 New tools and future work

We develop a collection of new tools to reason about paths in $\mathbb{Z}^{2}$. In order to carry out computation in tile-assembly, a key idea is to reuse tile types (analogous to how a Boolean circuit reuses gates of a given type, or how a computer program reuses instructions via loops). Our main technical lemma, which we term the "shield" lemma, shows that if a path $P$ has a certain form that reaches so far to the east that it reuses some tile types, then we can use $P$ to construct a curve in $\mathbb{R}^{2}$ that is an almost-vertical cut $c$ of the plane. We use this cut of the plane to show one of two things must happen: either that iterations of a pumping of $P$ are separated from one another, and hence that the pumping is simple, which means that $P$ is pumpable, or else that a path can be grown that blocks the growth of $P$.

This cut, and our subsequent argument can be thought of as a kind of "Window Movie Lemma" [28], or pumping tool, but targeted specifically at noncooperative self-assembly.

The shield lemma can only be applied when $P$ is of a certain form. Our second tool is a combinatorial argument on the height and width of a path. We begin by applying some straight-froward transformations to put any wide enough or tall enough path (i.e., that meets
the hypothesis of Theorem 1.1) into a form that its last tile is also its eastern-most tile. Then, for any such path $P$, our combinatorial argument shows that we can always find a cut that satisfies the hypothesis of the shield lemma. We hope that the techniques developed in this paper can be applied to other self-assembly models - as an example we apply them to the 2HAM (Corollary 1.2).

Although we answer one of the main unresolved questions on noncooperative self-assembly, our result does not close all questions on the model. First, there is still a big gap between the best known lower bounds on the size of assemblies (which is $O(|T| \log |T|)$ ), and the exponential bound $(8|T|)^{4|T|+1}(5|\sigma|+6)$ we prove here. It remains as future work to reduce that gap. We also conjecture that our result can be used to characterise the assemblies producible by directed systems, using the same argument as [16]. A number of decidability questions are also still open such as: can we decide whether a planar nondirected tile assembly system is directed (i.e. produces exactly one terminal assembly)? An important part of self-assembly is related to building shapes (as opposed to decidability questions). In this direction, can we build $n \times n$ squares any more efficiently than the best known result of $2 n-1$ tile types for noncooperative systems? For this common benchmark of shape-building, cooperative systems achieve a tileset size as low as $\Theta(\log n / \log \log n)$ [1,22, 37].

### 1.4 Structure of the paper

Section 2 contains key definitions and notions required for the paper. Section 3 proves our main technical lemma (Lemma 3.1), which we call the Shield lemma. The section begins with the definition of a shield of a path (a triple of indices of tiles along the path) and then gives some high-level intuition for the proof of Lemma 3.1. The section proceeds to prove quite a number of claims (Claims 3.2 to 3.15) that provide an arsenal of technical tools to reason about paths that have a shield. The section ends with an inductive argument that proves the Shield lemma, making use of the previous claims. Finally, Section 4 proves our main result, Theorem 1.1, using a combinatorial argument to show that every wide enough path has a shield. It begins with Subsection 4.1 which contains the Intuition behind the proof of Theorem 1.1 - some may find it helpful to begin reading there.

Appendix A proves the 2HAM result (Corollary (1.2) and Appendix B states a particular version of the Jordan curve theorem for infinite polygonal curves and states related definitions (one curve turning from another, left-/right-hand side of the plane).

## 2 Definitions and preliminaries

As usual, let $\mathbb{R}$ be the set of real numbers, let $\mathbb{Z}$ be the integers, and let $\mathbb{N}$ be the natural numbers including 0 . The domain of a function $f$ is denoted $\operatorname{dom}(f)$, and its range (or image) is denoted $f(\operatorname{dom}(f))$.

### 2.1 Abstract tile assembly model

The abstract tile assembly model was introduced by Winfree [42]. In this paper we study a restriction of the abstract tile assembly model called the temperature 1 abstract tile assembly model, or noncooperative abstract tile assembly model. For definitions of the full model, as well as intuitive explanations, see for example [36, 37].

A tile type is a unit square with four sides, each consisting of a glue type and a nonnegative integer strength. Let $T$ be a a finite set of tile types. In any set of tile types used in this paper, we assume the existence of a well-defined total ordering which we call the canonical ordering of the tile set. The sides of a tile type are respectively called north, east, south, and west, as shown in the following picture:

An assembly is a partial function $\alpha: \mathbb{Z}^{2} \rightarrow T$ where $T$ is a set of tile types and the domain of $\alpha($ denoted $\operatorname{dom}(\alpha))$ is connected ${ }^{2}$ We let $\mathcal{A}^{T}$ denote the set of all assemblies over the set of tile types $T$. In this paper, two tile types in an assembly are said to bind (or interact, or are stably attached), if the glue types on their abutting sides are equal, and have strength $\geq 1$. An assembly $\alpha$ induces an undirected weighted binding graph $G_{\alpha}=(V, E)$, where $V=\operatorname{dom}(\alpha)$, and there is an edge $\{a, b\} \in E$ if and only if the tiles at positions $a$ and $b$ interact, and this edge is weighted by the glue strength of that interaction. The assembly is said to be $\tau$-stable if every cut of $G_{\alpha}$ has weight at least $\tau$.

A tile assembly system is a triple $\mathcal{T}=(T, \sigma, \tau)$, where $T$ is a finite set of tile types, $\sigma$ is a $\tau$-stable assembly called the seed, and $\tau \in \mathbb{N}$ is the temperature. Throughout this paper, $\tau=1$.

Given two $\tau$-stable assemblies $\alpha$ and $\beta$, we say that $\alpha$ is a subassembly of $\beta$, and write $\alpha \sqsubseteq \beta$, if $\operatorname{dom}(\alpha) \subseteq \operatorname{dom}(\beta)$ and for all $p \in \operatorname{dom}(\alpha), \alpha(p)=\beta(p)$. We also write $\alpha \rightarrow_{1}^{\mathcal{T}} \beta$ if we can obtain $\beta$ from $\alpha$ by the binding of a single tile type, that is: $\alpha \sqsubseteq \beta$, $|\operatorname{dom}(\beta) \backslash \operatorname{dom}(\alpha)|=1$ and the tile type at the position $\operatorname{dom}(\beta) \backslash \operatorname{dom}(\alpha)$ stably binds to $\alpha$ at that position. We say that $\gamma$ is producible from $\alpha$, and write $\alpha \rightarrow^{\mathcal{T}} \gamma$ if there is a (possibly empty) sequence $\alpha_{1}, \alpha_{2}, \ldots, \alpha_{n}$ where $n \in \mathbb{N} \cup\{\infty\}, \alpha=\alpha_{1}$ and $\alpha_{n}=\gamma$, such that $\alpha_{1} \rightarrow_{1}^{\mathcal{T}} \alpha_{2} \rightarrow_{1}^{\mathcal{T}} \ldots \rightarrow_{1}^{\mathcal{T}} \alpha_{n}$. A sequence of $n \in \mathbb{Z}^{+} \cup\{\infty\}$ assemblies $\alpha_{0}, \alpha_{1}, \ldots$ over $\mathcal{A}^{T}$ is a $\mathcal{T}$-assembly sequence if, for all $1 \leq i<n$, $\alpha_{i-1} \rightarrow_{1}^{\mathcal{T}} \alpha_{i}$.

The set of productions, or producible assemblies, of a tile assembly system $\mathcal{T}=(T, \sigma, \tau)$ is the set of all assemblies producible from the seed assembly $\sigma$ and is written $\mathcal{A}[\mathcal{T}]$. An assembly $\alpha$ is called terminal if there is no $\beta$ such that $\alpha \rightarrow_{1}^{\mathcal{T}} \beta$. The set of all terminal assemblies of $\mathcal{T}$ is denoted $\mathcal{A}_{\square}[\mathcal{T}]$.

### 2.2 Paths and non-cooperative self-assembly

This section introduces quite a number of key definitions and concepts that will be used extensively throughout the paper.

Let $T$ be a set of tile types. A tile is a pair $((x, y), t)$ where $(x, y) \in \mathbb{Z}^{2}$ is a position and $t \in T$ is a tile type. Intuitively, a path is a finite or one-way-infinite simple (non-selfintersecting) sequence of tiles placed on points of $\mathbb{Z}^{2}$ so that each tile in the sequence interacts with the previous one, or more precisely:

Definition 1 (Path). A path is a (finite or infinite) sequence $P=P_{0} P_{1} P_{2} \ldots$ of tiles $P_{i}=$ $\left(\left(x_{i}, y_{i}\right), t_{i}\right) \in \mathbb{Z}^{2} \times T$, such that:

[^3]- for all $P_{j}$ and $P_{j+1}$ defined on $P$, their positions $\left(x_{j}, y_{j}\right)$ and $\left(x_{j+1}, y_{j+1}\right)$ are adjacent nodes in the grid graph of $\mathbb{Z}^{2}$, moreover $t_{j}$ and $t_{j+1}$ interact (have matching glues on their abutting sides), and
- for all $P_{j}, P_{k}$ such that $j \neq k$ it is the case that $\left(x_{j}, y_{j}\right) \neq\left(x_{k}, y_{k}\right)$.

By definition, paths are simple (or self-avoiding), and this fact will be repeatedly used throughout the paper. For a tile $P_{i}$ on some path $P$, its x -coordinate is denoted $\mathrm{x}_{P_{i}}$ and its y -coordinate is denoted $\mathrm{y}_{P_{i}}$. The concatenation of two paths $P$ and $Q$ is the concatenation $P Q$ of these two paths as sequences, and $P Q$ is a path if and only if (1) the last tile of $P$ interacts with the first tile of $Q$ and (2) $P$ and $Q$ do not intersect each other.

For a path $P=P_{0} \ldots P_{i} P_{i+1} \ldots P_{j} \ldots$, we define the notation $P_{i, i+1, \ldots, j}=P_{i} P_{i+1} \ldots P_{j}$, i.e. "the subpath of $P$ between indices $i$ and $j$, inclusive". Whenever $P$ is finite, i.e. $P=$ $P_{0} P_{1} P_{2} \ldots P_{n-1}$ for some $n \in \mathbb{N}, n$ is termed the length of $P$ and denoted by $|P|$. In the special case of a subpath where $i=0$, we say that $P_{0,1, \ldots, j}$ is a prefix of $P$ and that $P$ is an extension of $P_{0,1, \ldots, j}$. The prefix or extension are said to be strict if $j<|P|-1$. Else, when $j=|P|-1$, we say that $P_{i, \ldots,|P|-1}$ is a suffix of $P$, and is a strict suffix of $P$ if $i>0$.

For any path $P=P_{0} P_{1} P_{2}, \ldots$ and integer $i \geq 0$, we write $\operatorname{pos}\left(P_{i}\right) \in \mathbb{Z}^{2}$, or $\left(\mathrm{x}_{P_{i}}, \mathrm{y}_{P_{i}}\right) \in \mathbb{Z}^{2}$, for the position of $P_{i}$ and type $\left(P_{i}\right)$ for the tile type of $P_{i}$. Hence if $P_{i}=\left(\left(x_{i}, y_{i}\right), t_{i}\right)$ then $\operatorname{pos}\left(P_{i}\right)=\left(\mathrm{x}_{P_{i}}, \mathrm{y}_{P_{i}}\right)=\left(x_{i}, y_{i}\right)$ and type $\left(P_{i}\right)=t_{i}$. A "position of $P$ " is an element of $\mathbb{Z}^{2}$ that appears in $P$ (and therefore appears exactly once), and an index $i$ of a path $P$ of length $n \in \mathbb{N}$ is a natural number $i \in\{0,1, \ldots, n-1\}$. For a path $P=P_{0} P_{1} P_{2} \ldots$ we write $\operatorname{pos}(P)$ to mean "the sequence of positions of tiles along $P$ ", which is $\operatorname{pos}(P)=\operatorname{pos}\left(P_{0}\right) \operatorname{pos}\left(P_{1}\right) \operatorname{pos}\left(P_{2}\right) \ldots$.

Although a path is not an assembly, we know that each adjacent pair of tiles in the path sequence interact implying that the set of path positions forms a connected set in $\mathbb{Z}^{2}$ and hence every path uniquely represents an assembly containing exactly the tiles of the path, more formally: for a path $P=P_{0} P_{1} P_{2} \ldots$ we define the set of tiles asm $(P)=\left\{P_{0}, P_{1}, P_{2}, \ldots\right\}$ which we observe is an assembly $\sqrt{3}$ and we call asm $(P)$ a path assembly. Given a tile assembly system $\mathcal{T}=(T, \sigma, 1)$ the path $P$ is a producible path of $\mathcal{T}$ if $\operatorname{asm}(P)$ does not intersect ${ }^{4}$ the seed $\sigma$ and the assembly $(\operatorname{asm}(P) \cup \sigma)$ is producible by $\mathcal{T}$, i.e. $(\operatorname{asm}(P) \cup \sigma) \in \mathcal{A}[\mathcal{T}]$, and $P_{0}$ interacts with a tile of $\sigma$. As a convenient abuse of notation we sometimes write $\sigma \cup P$ as a shorthand for $\sigma \cup \operatorname{asm}(P)$. Given a tile assembly system $\mathcal{T}=(T, \sigma, 1)$ we define the set of producible paths of $\mathcal{T}$ to be ${ }^{5}$

$$
\mathbf{P}[\mathcal{T}]=\{P \mid P \text { is a path that does not intersect } \sigma \text { and }(\operatorname{asm}(P) \cup \sigma) \in \mathcal{A}[\mathcal{T}]\}
$$

So far, we have defined paths of tiles (Definition (1). In our proofs, we will also reason about (untiled) binding paths in the binding graph of an assembly.

Definition 2 (Binding path). Let $G=(V, E)$ be a binding graph. A binding path $q$ in $G$ is a sequence $q_{0,1, \ldots,|q|-1}$ of vertices from $V$ such that for all $i \in\{0,1, \ldots,|q|-2\},\left\{q_{i}, q_{i+1}\right\} \in E$ ( $q$ is connected) and no vertex appears twice in $q$ ( $q$ is simple).

[^4]Observation 2.1. Let $\mathcal{T}=(T, \sigma, 1)$ be a tile assembly system and let $\alpha \in \mathcal{A}[\mathcal{T}]$. For any tile $((x, y), t) \in \alpha$ either $((x, y), t)$ is a tile of $\sigma$ or else there is a producible path $P \in \mathbf{P}[\mathcal{T}]$ that for some $j \in \mathbb{N}$ contains $P_{j}=((x, y), t)$.
Proof. If $((x, y), t)$ is a tile of $\sigma$ we are done. Assume otherwise for the rest of the proof.
Since $\operatorname{dom}(\alpha)$ is a connected subset of $\mathbb{Z}^{2}$ there is an integer $n \geq 0$ and a binding path $p_{0,1, \ldots, n}$ in the binding graph of $\alpha$ where $p_{0} \in \operatorname{dom}(\sigma)$ and $p_{n}=(x, y)$. Let $i_{0}$ be the largest integer such that $p_{i_{0}} \in \operatorname{dom}(\sigma)$. We can then define $P$ as the path:

$$
P=P_{0,1, \ldots, n-\left(i_{0}+1\right)}=\left(p_{i_{0}+1}, \alpha\left(p_{i_{0}+1}\right)\right)\left(p_{i_{0}+2}, \alpha\left(p_{i_{0}+2}\right)\right) \ldots\left(p_{n}, \alpha\left(p_{n}\right)\right)
$$

By definition of binding graph, for all $i \in\left\{i_{0}+1, i_{0}+2, \ldots, n-1\right\}$, the tiles $\left(p_{i}, \alpha\left(p_{i}\right)\right)=P_{i-\left(i_{0}+1\right)}$ and $\left(p_{i+1}, \alpha\left(p_{i+1}\right)\right)=P_{i+1-\left(i_{0}+1\right)}$ on $P$ are adjacent in $\mathbb{Z}^{2}$ and interact on their abutting sides. Moreover, by the definition of $i_{0}, P$ does not intersect $\sigma$ and the tile $\left(p_{i_{0}+1}, \alpha\left(p_{i_{0}+1}\right)\right)=P_{0}$ (the first tile of $P$ ) interacts with a tile of $\sigma$, meaning that $P \in \mathbf{P}[\mathcal{T}]$, thus proving the statement.

For $A, B \in \mathbb{Z}^{2}$, we define $\overrightarrow{A B}=B-A$ to be the vector from $A$ to $B$, and for two tiles $P_{i}=\left(\left(x_{i}, y_{i}\right), t_{i}\right)$ and $P_{j}=\left(\left(x_{j}, y_{j}\right), t_{j}\right)$ we define $\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{j}\right)-\operatorname{pos}\left(P_{i}\right)$ to mean the vector from $\operatorname{pos}\left(P_{i}\right)=\left(x_{i}, y_{i}\right)$ to $\operatorname{pos}\left(P_{j}\right)=\left(x_{j}, y_{j}\right)$. The translation of a path $P$ by a vector $\vec{v} \in \mathbb{Z}^{2}$, written $P+\vec{v}$, is the path $Q$ such that $|P|=|Q|$ and for all indices $i \in\{0,1, \ldots,|P|-1\}$, $\operatorname{pos}\left(Q_{i}\right)=\operatorname{pos}\left(P_{i}\right)+\vec{v}$ and type $\left(Q_{i}\right)=\operatorname{type}\left(P_{i}\right)$. We always use parentheses for scoping of translations when necessary, i.e. $P(Q+\vec{v})$ is the sequence containing the path $P$ followed by the translation of the entire path $Q$ by vector $\vec{v}$. The translation of an assembly $\alpha$ by a vector $\vec{v}$, written $\alpha+\vec{v}$, is the assembly $\beta$ defined for all $(x, y) \in(\operatorname{dom}(\alpha)+\vec{v})$ as $\beta(x, y)=\alpha((x, y)-\vec{v})$.

Let $P$ be a path, let $i \in\{1,2, \ldots,|P|-2\}$, and let $A \neq P_{i+1}$ be a tile such that $P_{0,1, \ldots, i} A$ is a path. Let also $\rho$ be the clockwise rotation matrix defined as $\rho=\left(\begin{array}{cc}0 & 1 \\ -1 & 0\end{array}\right)$, and let $\Delta=$ $\left(\rho \overrightarrow{P_{i} P_{i-1}}, \rho^{2} \overrightarrow{P_{i} P_{i-1}}, \rho^{3} \overrightarrow{P_{i} P_{i-1}}\right)$ (intuitively, $\Delta$ is the vector of possible steps after $P_{i}$, ordered clockwise). We say that $P_{0,1, \ldots, i} A$ turns right (respectively turns left) from $P_{0,1, \ldots, i+1}$ if $\overrightarrow{P_{i} A}$ appears after (respectively before) $\overrightarrow{P_{i} P_{i+1}}$ in $\Delta$.
Definition 3 (The right priority path of a set of paths or binding paths). Let $P$ and $Q$ be two paths, where $P \neq Q$ and moreover neither is a prefix of the other, and with $\operatorname{pos}\left(P_{0}\right)=\operatorname{pos}\left(Q_{0}\right)$ and $\operatorname{pos}\left(P_{1}\right)=\operatorname{pos}\left(Q_{1}\right)$. Let $i$ be the smallest index such that $i \geq 0$ and $P_{i} \neq Q_{i}$. We say that $P$ is the right priority path of $P$ and $Q$ if either (a) $P_{0,1, \ldots, i}$ is a right turn from $Q$ or (b) $\operatorname{pos}\left(P_{i}\right)=\operatorname{pos}\left(Q_{i}\right)$ and the type of $P_{i}$ is smaller than the type of $Q_{i}$ in the canonical ordering of tile types.

Similarly, let $p$ and $q$ be two binding paths, where $p \neq q$ and moreover neither is a prefix of the other, and with $p_{0}=q_{0}$ and $p_{1}=q_{1}$. Let $i$ be the smallest index such that $i \geq 0$ and $p_{i} \neq q_{i}$. We say that $p$ is the right priority path of $p$ and $q$ if $p_{0,1, \ldots, i}$ is a right turn from $q$.

For any finite set $S$ of paths, or of binding paths, we extend this definition as follows: let $p_{0} \in \mathbb{Z}^{2}, p_{1} \in \mathbb{Z}^{2}$ be two adjacent positions. If for all $s \in S$, we have $s_{0}=p_{0}$ and $s_{1}=p_{1}$, we call the right-priority path of $S$ the path that is the right-priority path of all other paths in $S$.

For all $i \in\{0,1, \ldots,|P|-2\}$, we define glue $\left(P_{i} P_{i+1}\right)=(g, i)$, where $g$ is the shared glue type between consecutive tiles $P_{i}$ and $P_{i+1}$ on the path $P$. Similarly, when we say "glue" in the context of a path $P$, we mean a pair of the form (glue type, path index). We define type(glue $\left.\left(P_{i} P_{i+1}\right)\right)=$ $g$ to denote the glue type of glue $\left(P_{i} P_{i+1}\right)$. The position of the glue glue $\left(P_{i} P_{i+1}\right)$ is the midpoint of the unit-length line segment $\left[\operatorname{pos}\left(P_{i}\right), \operatorname{pos}\left(P_{i+1}\right)\right]$ and is written as $\operatorname{pos}\left(\right.$ glue $\left.\left(P_{i} P_{i+1}\right)\right)$. We
say that glue $\left(P_{i} P_{i+1}\right)$ is pointing to the north (or points to the north, for short) if $\overrightarrow{P_{i} P_{i+1}}=\binom{0}{1}$, pointing to the west if $\overrightarrow{P_{i} P_{i+1}}=\binom{-1}{0}$, pointing to the south if $\overrightarrow{P_{i} P_{i+1}}=\binom{0}{-1}$, and pointing to the east if $\overrightarrow{P_{i} P_{i+1}}=\binom{1}{0}$.

### 2.3 Fragile paths

If two paths, or two assemblies, or a path and an assembly, share a common position we say that they intersect at that position. Furthermore, we say that two paths, or two assemblies, or a path and an assembly, agree on a position if they both place the same tile type at that position and conflict if they place a different tile type at that position. We say that a path $P$ is fragile to mean that there is a producible assembly $\alpha$ that conflicts with $P$ (intuitively, if we grow $\alpha$ first, then there is at least one tile that $P$ cannot place), or more formally:

Definition 4 (Fragile). Let $\mathcal{T}=(T, \sigma, 1)$ be a tile assembly system and $P \in \mathbf{P}[\mathcal{T}]$. We say that $P$ is fragile if there exists a producible assembly $\alpha \in \mathcal{A}[\mathcal{T}]$ and a position $(x, y) \in$ $(\operatorname{dom}(\alpha) \cap \operatorname{dom}(\operatorname{asm}(P)))$ such that $\alpha((x, y)) \neq \operatorname{asm}(P)((x, y)) \underbrace{6}$

### 2.4 Pumping a path

Next, for a path $P$ and two indices $i, j$ on $P$, we define a sequence of points and tile types (not necessarily a path) called the pumping of $P$ between $i$ and $j$ :
Definition 5 (Pumping of $P$ between $i$ and $j$ ). Let $\mathcal{T}=(T, \sigma, 1)$ be a tile assembly system and $P \in \mathbf{P}[\mathcal{T}]$. We say that the "pumping of $P$ between $i$ and $j$ " is the sequence $\bar{q}$ of elements from $\mathbb{Z}^{2} \times T$ defined by:

$$
\bar{q}_{k}= \begin{cases}P_{k} & \text { for } 0 \leq k \leq i \\ \left.P_{i+1+((k-i-1)} \bmod (j-i)\right)+\left\lfloor\frac{k-i-1}{j-i}\right\rfloor \overrightarrow{P_{i} P_{j}} & \text { for } i<k,\end{cases}
$$

Intuitively, $\bar{q}$ is the concatenation of a finite path $P_{0,1, \ldots, i}$ and an infinite periodic sequence of tile types and positions (possibly intersecting $\sigma \cup P_{0,1, \ldots, i}$, and possibly intersecting itself). We formalise this intuition in Lemma B. 2 ,

The following definition gives the notion of pumpable path used in our proofs. It is followed by a less formal but more intuitive description.

Definition 6 (Pumpable path). Let $\mathcal{T}=(T, \sigma, 1)$ be a tile assembly system. We say that a producible path $P \in \mathbf{P}[\mathcal{T}]$, is infinitely pumpable, or simply pumpable, if there are two integers $i<j$ such that the pumping of $P$ between $i$ and $j$ is an infinite producible path, i.e. formally: $\bar{q} \in \mathbf{P}[\mathcal{T}]$.

In this case, we say that the pumping vector of $\bar{q}$ is $\overrightarrow{P_{i} P_{j}}$, and that $P$ is pumpable with pumping vector $\overrightarrow{P_{i} P_{j}}$.

For a path $P$ to be pumpable between $i$ and $j$ implies that $P_{i+1}+\overrightarrow{P_{i} P_{j}}$ interacts with $P_{j}$. It also implies that $\bar{q}$ is self-avoiding and that in particular, for any positive integers $s \neq t$, the path $P_{i+1, \ldots, j}+s \overrightarrow{P_{i} P_{j}}$ does not intersect with the path $P_{i+1, \ldots, j}+t \overrightarrow{P_{i} P_{j}}$. Lemma B.1 shows that a sufficient condition for this is that $P_{i+1, \ldots, j}$ does not intersect $P_{i+1, \ldots, j}+\overrightarrow{P_{i} P_{j}}$.

[^5]
### 2.5 2D plane

### 2.5.1 Column, glue column, row, glue row

When referring to sets of positions, we use the term "the column $x$ " for some fixed $x \in \mathbb{Z}$ to mean the set $\{(x, y) \mid y \in \mathbb{Z}\}$, and the term "the row $y$ " for some fixed $y \in \mathbb{Z}$ to mean the set $\{(x, y) \mid x \in \mathbb{Z}\}$. The glue column $x$, for some fixed $x \in \mathbb{Z}$, is the set of 2 D half-integer positions $\{(x+0.5, y) \mid y \in \mathbb{Z}\}$. The glue row $y$, for some fixed $y \in \mathbb{Z}$, is the set of 2 D half-integer positions $\{(x, y+0.5) \mid x \in \mathbb{Z}\}$.

Using the canonical embedding of $\mathbb{Z}^{2}$, the definition of a glue column $x$ can also be defined as the set of edges of the grid graph of $\mathbb{Z}^{2}$ between column $x$ and column $x+1$, and the glue row $y$ is the set of edges of the grid graph of $\mathbb{Z}^{2}$ between row $x$ and row $x+1$. Which definition we use will always be clear from the context.

### 2.5.2 Curves

A curve $c: I \rightarrow \mathbb{R}^{2}$ is a function from an interval $I \subset \mathbb{R}$ to $\mathbb{R}^{2}$, where $I$ is one of a closed, open, or half-open. All the curves in this paper are polygonal, i.e. unions of line segments and rays.

For a finite path $P$, we call the embedding $\mathfrak{E}[P]$ of $P$ the curve defined for all $t \in[0,|P|-1] \subset$ $\mathbb{R}$ by:

$$
\mathfrak{E}[P](t)=\operatorname{pos}\left(P_{[t]}\right)+(t-\lfloor t\rfloor) \xrightarrow[{P_{[t]} P_{[t\rfloor+1}}]{ }
$$

Similarly, for a finite binding path $p$, the embedding $\mathfrak{E}[p]$ of $p$ is the curve defined for all $t \in$ $[0,|p|-1] \subset \mathbb{R}$ by:

$$
\mathfrak{E}[p](t)=p_{\lfloor t\rfloor}+(t-\lfloor t\rfloor) \overrightarrow{p_{\lfloor t\rfloor} p_{\lfloor t\rfloor+1}}
$$

The ray of vector $\vec{v}$ from (or, that starts at) point $A \in \mathbb{R}$ is defined as the curve $r:[0,+\infty[\rightarrow$ $\mathbb{R}^{2}$ such that $r(t)=A+t \vec{v}$. The vertical ray from a point $A$ to the south (respectively to the north) is the ray of vector $(0,-1)$ (respectively $(0,1)$ ) from $A$, and the horizontal ray from a point $A$ to the west (respectively to the east) is the ray of vector $(-1,0)$ (respectively $(1,0)$ ) from $A$.

If $C$ is a curve defined on some real interval of the form $[a, b]$ or $] a, b]$, and $D$ is a curve defined on some real interval of the form $[c, d]$ or $[c, d[$, and moreover $C(b)=D(c)$, then the concatenation concat $(C, D)$ of $C$ and $D$ is the curve defined on $\operatorname{dom}(C) \cup(\operatorname{dom}(D)-(c-b))$ by ${ }^{7}$

$$
\operatorname{concat}(C, D)(t)=\left\{\begin{array}{l}
C(t) \text { if } t \leq b \\
D(t+(c-b)) \text { otherwise }
\end{array}\right.
$$

A curve $c$ is said to be simple or self-avoiding if all its points are distinct, i.e. if for all $x, y \in \operatorname{dom}(c), c(x)=c(y) \Rightarrow x=y$.

For $a, b \in \mathbb{R}$ with $a \leq b$, the notation $[a, b]$ denotes a closed real interval, $] a, b[$ an open real interval, and $[a, b[$ and $] a, b]$ are open on one end and closed on the other. The reverse $c^{\leftarrow}$ of a curve $c$ defined on some interval $[a, b]$ (respectively $[a, b[] a, b],,] a, b[$ ) is the curve defined on $[-b,-a]$ (respectively $]-b,-a],\left[-b,-a[]-b,,-a[)\right.$ as $c^{\leftarrow}(t)=c(-t)$.

If $A=\left(x_{a}, y_{a}\right) \in \mathbb{R}^{2}$ and $B=\left(x_{b}, y_{b}\right) \in \mathbb{R}^{2}$, the segment $[A, B]$ is defined to be the curve $s:[0,1] \rightarrow \mathbb{R}^{2}$ such that for all $t \in[0,1], s(t)=\left((1-t) x_{a}+t x_{b},(1-t) y_{a}+t y_{b}\right)$. We sometimes

[^6]abuse notation and write $[A, B]$ even if $A$ or $B$ (or both) is a tile, in which case we mean the position of that tile instead of the tile itself.

For a curve $c: \mathbb{R} \rightarrow \mathbb{R}^{2}$ we write $c(\mathbb{R})$ to denote the range of $c$ (whenever we use this notation the curve $c$ has all of $\mathbb{R}$ as its domain). When it is clear from the context, we sometimes write $c$ to mean $c(\mathbb{R})$, for example

For a path or binding path, $p_{0,1, \ldots, k}$ of length $\geq 1$, for $0 \leq i<k$ the notation $\operatorname{mid}\left(p_{i} p_{i+1}\right)$ denotes the midpoint of the unit-length line segment $\mathfrak{E}\left[p_{i, i+1}\right]$. For a path $P$, we have $\operatorname{mid}\left(p_{i} p_{i+1}\right)=$ $\operatorname{pos}\left(\right.$ glue $\left.\left(P_{i} P_{i+1}\right)\right)$, hence this notation is especially useful for binding paths, since they do not have glues.

### 2.5.3 Cutting the plane with curves; left and right turns

In this paper we use finite and infinite polygonal curves to cut the $\mathbb{R}^{2}$ plane into two pieces. The finite polygonal curves we use consist of a finite number of concatenations of vertical and horizontal segments of length 1 or 0.5 . If the curve is simple and closed we may apply the Jordan Curve Theorem to cut the plane into connected components.

Theorem 2.2 (Jordan Curve Theorem). Let c be a simple closed curve, then c cuts $\mathbb{R}^{2}$ into two connected components.

Here, we have stated the theorem in its general form, although for our results the (easier to prove) polygonal version suffices.

The second kind of curve we use is composed of one or two infinite rays, along with a finite number of length 0.5 or length 1 segments. For such infinite polygonal curves we also state and prove a slightly different version of the polygonal Jordan Curve Theorem, as Theorem B. 3 ,

In Section B. 1 we define what it means for one curve to turn left or right from another, as well as left hand side and right hand side of a cut of the real plane.

### 2.5.4 Visibility

Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$, and let $i \in\{0,1, \ldots,|P|-$ $2\}$ be such that glue $\left(P_{i} P_{i+1}\right)$ points east or west. We say that glue $\left(P_{i} P_{i+1}\right)$ is visible from the south if and only if the ray $\ell^{i}$ of vector $(0,-1)$ starting at $\ell^{i}(0)=\left(\frac{\mathrm{x}_{P_{i}}+\mathrm{x}_{P_{i+1}}}{2}, \mathrm{y}_{P_{i}}\right)$ does not intersect $\mathfrak{E}[P]$ nor $\sigma{ }^{8}$

We define the terms visible from the east, visible from the west and visible from the north similarly.

In many of our proofs, we will use curves, in particular curves that include visibility ray(s), to define connected components. For example, consider the curve $e$, where we have a path $P_{i+1, i+2, \ldots, j, j+1}$ with $i<j$ and two glues glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$ which are visible from the south with respective visibility rays $l^{i}$ and $l^{j}$ :

$$
e=\operatorname{concat}\left(l^{i \leftarrow},\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right], \mathfrak{E}\left[P_{i+1, \ldots, j}\right],\left[\operatorname{pos}\left(P_{j}\right), l^{j}(0)\right], l^{j}\right)
$$

The curve $e$ is defined on $]-\infty,+\infty[=\mathbb{R}$.

[^7]We will use the following lemma about visibility, which was stated in [31] (it is the fusion of Lemmas 5.2 and 6.3 in that paper). For the sake of completeness, we prove this result again, with slightly different notation.
Lemma 2.3. Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$ such that the last glue of $P$ is visible from the north. Let $i, j \in\{0,1, \ldots,|P|-2\}$ be two integers. If both glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$ are visible from the south and glue $\left(P_{i} P_{i+1}\right)$ points to the east (respectively to the west), and $\mathrm{x}_{P_{i}}<\mathrm{x}_{P_{j}}$ (respectively $\mathrm{x}_{P_{i}}>\mathrm{x}_{P_{j}}$ ), then $i<j$ and glue $\left(P_{j} P_{j+1}\right)$ points to the east (respectively to the west).
Proof. We first assume that glue $\left(P_{i} P_{i+1}\right)$ points to the east and $\mathrm{x}_{P_{i}}<\mathrm{x}_{P_{j}}$ : indeed by taking the vertical symmetric of each tile in $T$, of $\sigma$, and of $P$, we get the "respective" version of this statement, where glue $\left(P_{i} P_{i+1}\right)$ points to the west and $\mathrm{x}_{P_{i}}>\mathrm{x}_{P_{j}}$. In particular, this flip about a vertical line does not change the visibility hypotheses.

Let $l^{i}$ and $l^{j}$ be the respective visibility rays of glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$. Additionally, let $m_{i}$ and $m_{j}$ be two real numbers such that $l^{i}\left(m_{i}\right) \in \mathbb{R}^{2}$ and $l^{j}\left(m_{j}\right) \in \mathbb{R}^{2}$ have the same y -coordinate, and are below all the points of $\sigma \cup \operatorname{asm}(P)$. Moreover, let $t_{i}=i+0.5 \in \mathbb{R}$, $t_{j}=j+0.5 \in \mathbb{R}$ and $t_{k}=|P|-1.5 \in \mathbb{R}$, and note that $\mathfrak{E}[P]\left(t_{i}\right)=\operatorname{pos}\left(\right.$ glue $\left.\left(P_{i} P_{i+1}\right)\right), \mathfrak{E}[P]\left(t_{j}\right)=$ $\operatorname{pos}\left(\operatorname{glue}\left(P_{j} P_{j+1}\right)\right)$ and $\mathfrak{E}[P]\left(t_{k}\right)=\operatorname{pos}\left(\right.$ glue $\left.\left(P_{|P|-2} P_{|P|-1}\right)\right)$.

Now, assume for the sake of contradiction that $i>j$, which means that $t_{i}>t_{j}$. We define a curve $c$ as the concatenation of $l^{i}\left(\left[0, m_{i}\right]\right),\left[l^{i}\left(m_{i}\right), l^{j}\left(m_{j}\right)\right], l^{j}\left(\left[0, m_{j}\right]\right)^{\leftarrow}$ and the restriction to the interval $\left[t_{j}, t_{i}\right]$ of $\mathfrak{E}[P]$.

By the Jordan Curve Theorem (Theorem [2.2), $c$ cuts the plane $\mathbb{R}^{2}$ into two connected components. Let $\mathcal{C}$ be the connected component inside $c$. We claim that $\mathfrak{E}[P]\left(\left[t_{i}, t_{k}\right]\right)$ has at least one point inside $\mathcal{C}$ : indeed, the translation by a distance 0.1 to the east of $l^{i}$, i.e. $l^{i}+(0.1,0)$, which starts at $\mathfrak{E}[P]\left(t_{i}+0.1\right)$, does not intersect $\mathfrak{E}\left[P_{j, j+1, \ldots, i}\right]$ (by visibility of $l^{i}$ ), does not intersect $l^{i}$ nor $l^{j}$, and intersects $\left[l^{i}\left(m_{i}\right), l^{j}\left(m_{j}\right)\right]$ exactly once (since $\left.\mathrm{x}_{P_{i}}<\mathrm{x}_{P_{j}}\right)$. Therefore, $\mathfrak{E}[P]\left(t_{i}+0.1\right)$ is inside $\mathcal{C}$.

However, glue $\left(P_{|P|-2} P_{|P|-1}\right)$, the last glue of $P$, is visible from the north, hence cannot be in $\mathcal{C}$, since there is at least one glue of $P_{j, j+1, \ldots, i}$ to the north of any glue inside $\mathcal{C}$. Therefore, $\mathfrak{E}[P]\left(\left[t_{i}, t_{k}\right]\right)$ starts in $\mathcal{C}$ and has at least one point outside $\mathcal{C}$. But $\mathfrak{E}\left[P_{i+1, i+2, \ldots,|P|-1}\right]$ cannot cross $l^{i}$ nor $l^{j}$ (because of visibility), nor $\mathfrak{E}[P]\left(\left[t_{j}, t_{i}\right]\right)$ (because $P$ is simple), nor $\left[l^{i}\left(m_{i}\right), l^{j}\left(m_{j}\right)\right]$ (because $\left[l^{i}\left(m_{i}\right), l^{j}\left(m_{j}\right)\right]$ is strictly below all points of $P$ ). This is a contradiction, and hence $t_{i}<t_{j}$ and $i<j$.

Finally, we claim that glue $\left(P_{j} P_{j+1}\right)$ points to the east. We first redefine $c$ to be the concatenation of $l^{j}\left(\left[0, m_{j}\right]\right),\left[l^{j}\left(m_{j}\right), l^{i}\left(m_{i}\right)\right], l^{i}\left(\left[0, m_{i}\right]\right)^{\leftarrow}$, and the restriction to interval $\left[t_{i}, t_{j}\right]$ of $\mathfrak{E}[P]^{9}$. Assume, for the sake of contradiction that glue $\left(P_{j} P_{j+1}\right)$ points to the west. This means that $\mathfrak{E}[P]\left(t_{j}+0.1\right)$ is inside $\mathcal{C}$, since by the same argument as above, $l^{j}-(0.1,0)$ starts at $\mathfrak{E}[P]\left(t_{j}+0.1\right)$ and intersects $c$ exactly once. But $\mathfrak{E}[P]\left(\left[t_{j}, t_{k}\right]\right)$ has at least one point inside $\mathcal{C}$ and ends outside $\mathcal{C}$, yet cannot cross $c$ (for the same reasons as before). This is a contradiction, and hence glue $\left(P_{j} P_{j+1}\right)$ points to the east.

We will sometimes use this lemma when the last tile of $P$ is the unique easternmost tile of $\sigma \cup \operatorname{asm}(P)$, in this case the last glue of $P$ is visible from the south and from the north.

[^8]
## 3 Shield lemma

The goal of this section is to prove Lemma 3.1, which is the main technical tool we prove in this paper. The following definition is crucial to the lemma statement and defines notation used throughout this section. It is illustrated in Figure 3.1.
Definition 7 (A shield $(i, j, k)$ for $P$ ). Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$. We say that the triple ( $i, j, k$ ) of integers is a shield for $P$ if $0 \leq i<j \leq k<|P|-1$, and the following three conditions hold:

1. glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$ are both of the same type, visible from the south relative to $P$ and pointing east; and
2. glue $\left(P_{k} P_{k+1}\right)$ is visible from the north relative to $P$, for notation let $l^{k}$ be the visibility ray to the north of glue $\left(P_{k} P_{k+1}\right)$; and
3. $\mathfrak{E}\left[P_{i, i+1, \ldots, k}\right] \cap\left(l^{k}+{\overrightarrow{P_{j} P}}_{i}\right) \subseteq\left\{l^{k}(0)+{\overrightarrow{P_{j} P}}_{i}\right\}$. In other words, if $\mathfrak{E}\left[P_{i, i+1, \ldots, k}\right]$ intersects $l^{k}+{\overrightarrow{P_{j} P}}_{i}$ (which may not be the case), there is exactly one intersection, which is at the start-point of the ray $l^{k}+\overrightarrow{P_{j} P_{i}}$.

It should be noted that $x_{\overrightarrow{P_{i} P_{j}}}>0$, i.e. the x-component of the vector $\overrightarrow{P_{i} P_{j}}$ is strictly positive, which follows from $i<j$ together with the contrapositive of Lemma 2.3] indeed, the contrapositive of Lemma 2.3, with $i$ and $j$ swapped, is $i \leq j \Rightarrow x_{P_{i}} \leq x_{P_{j}}$, and since here $P$ is simple, we also have $i<j \Rightarrow x_{P_{i}}<x_{P_{j}}$ ). Throughout the paper, $l^{i}$ and $l^{j}$ denote the vertical (visibility) rays to the south that start at $\operatorname{pos}\left(\right.$ glue $\left.\left(P_{i} P_{i+1}\right)\right)$ and $\operatorname{pos}\left(\right.$ glue $\left.\left(P_{j} P_{j+1}\right)\right)$, respectively.
Definition 8 (The cut $c$ and workspace $\mathcal{C}$ of shield $(i, j, k)$ ). Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$, and let $(i, j, k)$ be a shield for $P$. We say that the cut of the shield $(i, j, k)$ is the curve $c$ defined by:

$$
c=\operatorname{concat}\left(l^{i \leftarrow},\left[l^{i}(0), P_{i+1}\right], \mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right],\left[P_{k}, l^{k}(0)\right], l^{k}\right)
$$

By Claim 3.2 below, $c$ cuts the plane into the two connected components defined in the conclusion of Theorem B. 3 the left-hand side and right-hand side of $c$. The right-hand side of $c$ is the connected component $\mathcal{C}$ that is intuitively to the east of $l^{i}$ and $l^{k}$, and includes $c$ itself. We say that $\mathcal{C}$ is the workspace of shield $(i, j, k)$ (see Figure 3.2 for an example).

Lemma 3.1 (Shield lemma). Let $P$ be a path producible by some tile assembly system $\mathcal{T}=$ $(T, \sigma, 1)$, such that $(i, j, k)$ is a shield for $P$ (see Definition(7). Then $P$ is pumpable with pumping vector $\overrightarrow{P_{i} P_{j}}$, or $P$ is fragile.

Moreover, if $P$ is fragile, there is a path $Q$, entirely contained in the workspace of shield $(i, j, k)$ (see Definition 8), such that $P_{0,1, \ldots, i Q} Q$ is a producible path and conflicts with $P_{i+1, i+2, \ldots, k}$.

We prove Lemma 3.1 in Section 3.3, First, we state a simplifying assumption on $P$ (that we show is without loss of generality), then give an intuition for the overall proof strategy. The section then proceeds with a number of technical claims followed by the actual proof of Lemma 3.1. In this section, for the sake of brevity, claims are stated without repeating the hypotheses on $P$ and related notation.

Assumption on $P$ used throughout this section. Observe that if we prove that any prefix of $P$ is pumpable or fragile, this means that $P$ is also pumpable or fragile. Therefore,

Figure 3.1: A suffix $P_{i, i+1, \ldots, k+1}$ of a path $P$. Tiles $P_{i}, P_{j}$ and $P_{k}$ are shown along with the four rays and the three glues (at ray starting points) of Hypotheses $1 / 3$ of Definition 7 thus $(i, j, k)$ is a shield for $P$. The goal of this section is to prove Lemma 3.1showing that such a path is pumpable or fragile.
without loss of generality, for the remainder of this section (including the proof of Lemma 3.1) we suppose that the last tile of $P$ is $P_{k+1}$, i.e. that $P=P_{0,1, \ldots, k+1}$.

Intuition for the proof of Lemma 3.1. Starting from a producible path $P$ with the properties described in Definition 7, we define three indices on $P$ (called a "shield") which in turn are used to define an infinite curve $c$ that partitions $\mathbb{R}^{2}$. Then to build a path $R$ that stays on the right hand side of $c$, and that will ultimately allow us to reason about $P$ and show that $P$ is pumpable or fragile. Since the proof is rather involved, we split it up into parts, each containing one or more Claims:

- Using Definition 7, in Subsection [3.1 we define a bi-infinite curve $c$ using the ray $l^{i}$, the path $P_{i+1, i+2, \ldots, k}$ and the ray $l^{k}$. By Definition 12, and Theorem B.3, $c$ cuts $\mathbb{R}^{2}$ into two pieces: the left-hand and right-hand side of $c$. In the rest of the proof, we will use the right-hand side $\mathcal{C} \subset \mathbb{R}^{2}$ of $c$ as a "workspace" where we can edit paths freely (hence the name of that connected component in Definition (8). The intuition is that $c$ "shields our edits" from $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$, which is entirely in the left-hand side of $c$, and thus prevents $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ from blocking these paths in the workspace $\mathcal{C}$.
- We then reason by induction on the length of $P$. The initial setup for the inductive argument is given in Subsection 3.2, and goes as follows (in a number of places we may reach the early conclusion that $P$ is fragile, in which case we are done with the entire proof of Lemma 3.1):
- In Subsection 3.2.1, we define a tile $P_{m_{0}}$ of $P$ called a dominant tile, which means that $P_{m_{0}}$ is such that for all integers $n \geq 0, P_{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}$.
- Then, in Subsection 3.2.3, we define a binding path $r$ in $\mathbb{Z}^{2}$ and prove a number of key properties about about it and it's translation $r+\overrightarrow{P_{j} P}$. We then use $r$ as a sequence of locations along which we we can either tile a producible path $R$, or else show that $P$ is fragile. The path $R$ is built in such a way that both $R$ and $R+\vec{P}_{j} P_{i}$ are producible
and in $\mathcal{C}$.
- To complete the setup for the inductive argument, in Subsection 3.2.4 we use $R$ and $m_{0}$ to define the initial inductive indices $u_{0}$ and $v_{0}$. To define these indices, we use a ray $L^{m_{0}}$ that starts from the tile $P_{m_{0}}$ and splits the component $\mathcal{C}$ into two parts (called $\mathcal{C}^{+}$ and $\mathcal{C}^{-}$), which guarantees that $u_{0} \leq m_{0} \leq v_{0}$, which in turn means that the pumping of $P$ between $u_{0}$ and $v_{0}$ is well-defined (i.e. $u_{0}<v_{0}$ ) and has pumping vector $\overrightarrow{P_{i} P_{j}}$. (note that the pumping is not a simple path until the last step of the induction, where we eventually find a simple pumping of $P$ ).

The inductive step is then defined in Subsection 3.3, where we show that either $P$ is pumpable or fragile, or else we can use $R$ again, along with inductive indices $u_{n}, m_{n}, v_{n}$, to find new indices $u_{n+1}, m_{n+1}$ and $v_{n+1}$, but with $m_{n+1}>m_{n}$. Since $P$ is of finite length, we will eventually run out of new indices (values for $m_{n+1}$, in particular), leading to the conclusion that $P$ is either pumpable or fragile.

### 3.1 Reasoning about the curve $c$ and the workspace $\mathcal{C}$

Claim 3.2. Let $(i, j, k)$ be a shield for $P$. The cut of shield $(i, j, k)$, called curve $c$ Definition [8, is simple and cuts the plane $\mathbb{R}^{2}$ into two connected components. Moreover, these two components are defined in the conclusion of Theorem B.3.
Proof. We first claim that $c$ is a simple curve. Indeed, $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ intersects neither $l^{i}{ }^{\leftarrow}$ nor $l^{k}$ (by visibility of glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{k} P_{k+1}\right)$, respectively). The half-line $l^{i \leftarrow}$ (from the south) and the ray $l^{k}$ (to the north) do not intersect by Definition 7 and in particular by the visibility of glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{k} P_{k+1}\right)$ and since $i \neq k$. Moreover, the length- $1 / 2$ segments $\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right]$ (that joins the ray $l^{i \leftarrow}$ to $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ ), and $\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right]$ (that joins $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ to $\left.l^{k}\right)$ are horizontal, and only intersect $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ and those rays at their respective endpoints. Hence, $c$ is a simple curve. Moreover, $c$ is connected since the endpoints of the five connected curves that define it are equal in the order given.

Hence $c$ satisfies Definition [12, Then, by Theorem B.3, $c$ cuts the plane $\mathbb{R}^{2}$ into the two connected components defined in its conclusion.

By definition, $\operatorname{dom}\left(\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)\right)$ is a subset of $\mathbb{Z}^{2}$. The following claim captures the intuition that allows us to think of $\mathcal{C}$ as a "workspace" that is "shielded" from $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ :
Claim 3.3. Let $(i, j, k)$ be a shield for $P$ and let $\mathcal{C}$ be the workspace of shield $(i, j, k)$. Then $\operatorname{dom}\left(\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)\right)$ is a subset of $\mathbb{R}^{2} \backslash \mathcal{C}$.

Proof. By the definition of $c$, since glue $\left(P_{i} P_{i+1}\right)$ points east, $\operatorname{pos}\left(P_{i}\right)$ is on the left-hand side of $c$, hence $\operatorname{pos}\left(P_{i}\right)$ is not in $\mathcal{C}$. Moreover, since $P$ is a producible path, $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ is a connected assembly. We claim that $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ has no tile in $\mathcal{C}$, since otherwise one or both of (a) $\mathfrak{E}\left[P_{0,1, \ldots, i}\right]$ or (b) some of the tile positions of $\sigma$, or glue positions of abutting tiles of $\sigma$, would have to intersect $c$ to reach that tile. If that were the case, the intersection would be on one of the five curves used to define $c$ :

- If $\mathfrak{E}\left[P_{0,1, \ldots, i}\right]$ intersects any of $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right],\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right]$, or $\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right]$, this contradicts the fact that $P$ is simple.
- If $\operatorname{dom}(\sigma)$ intersects $\operatorname{dom}\left(\operatorname{asm}\left(P_{i+1, i+2, \ldots, k}\right)\right)$, this contradicts the fact that $P$ is a producible path.

Figure 3.2: The path and shield triple $(i, j, k)$ from Figure 3.1 annotated with curve $c$ and component $\mathcal{C}$. The border of the shaded region is the curve $c$ (from Definition 8), and the shaded region itself is the component $\mathcal{C}$ (Definition 8).

- If $\operatorname{dom}\left(\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)\right)$ has a glue positioned on $l^{i}$ or $l^{k}$, this contradicts the fact that glue $\left(P_{i} P_{i+1}\right)$ is visible from the south, and glue $\left(P_{k} P_{k+1}\right)$ is visible from the north, relative to $P$.
In all cases, we get a contradiction, and hence $\operatorname{dom}\left(\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)\right)$ is disjoint from $\mathcal{C}$, and thus contained in $\mathbb{R}^{2} \backslash \mathcal{C}$.

The following claim restates Hypothesis 3 of Definition 7 to be in a form more suited to our proofs. Specifically, Claim 3.4 states that $l^{k}(0)+\overrightarrow{P_{j} P_{i}}$ is the only position of the ray $l^{k}+\overrightarrow{P_{i} P_{j}}$ that may be in $\mathcal{C}$ and if this is the case then $l^{k}(0)+\vec{P}_{j} P_{i}$ is also a point of $c$.
Claim 3.4. $\left(\left(l^{k}+{\overrightarrow{P_{j} P}}_{i}\right) \cap \mathcal{C}\right)=\left(\left(l^{k}+\vec{P}_{j} P_{i}\right) \cap c\right) \subseteq\left\{l^{k}(0)+\overrightarrow{P_{j} P_{i}}\right\}$.
Proof. First, we prove that if there is an intersection between $l^{k}+\vec{P}_{j} P_{i}$ and the curve $c$ then this happens only at the point $l^{k}(0)+\overrightarrow{P_{j} P_{i}}$, by analysing the five curves used to define $c$ (Definition (8)):

- since $x_{\overrightarrow{P_{j} P_{i}}}$ is a non-zero integer then $l^{k}+\vec{P}_{j} P_{i}$ does not intersect $l^{k} \operatorname{nor}\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right]$;
- by Hypothesis 3 of Definition 7 the point $l^{k}(0)+\vec{P}_{j} P_{i}$ is the only intersection permitted between the ray $l^{k}+{\overrightarrow{P_{j} P}}_{i}$ and either of the curves $\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right]$ or $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$;
- since $l^{i}$ is a ray to the south, if $l^{k}+\overrightarrow{P_{j} P_{i}}$ intersects $l^{i}$ then $l^{k}+\vec{P}_{j} P_{i}$ also intersects $\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right]$ which means, by the previous case, that $l^{k}(0)+\overrightarrow{P_{j} P_{i}}=l^{i}(0)$ is the only permitted intersection between these two rays.
Thus $l^{k}(0)+\overrightarrow{P_{j} P_{i}}$ is the only possible intersection of $l^{k}+\overrightarrow{P_{j} P_{i}}$ with $c$, which shows the second part of our claim, i.e. $\left(\left(l^{k}+\overrightarrow{P_{j} P_{i}}\right) \cap c\right) \subseteq\left\{l^{k}(0)+\overrightarrow{P_{j} P_{i}}\right\}$.

We now show the first part of our claim, i.e. $\left(\left(l^{k}+\vec{P}_{j} \vec{P}_{i}\right) \cap \mathcal{C}\right)=\left(\left(l^{k}+\vec{P}_{j} P_{i}\right) \cap c\right)$. First, since $l^{k}$ is a ray to the north, there exists $z \in \mathbb{R}, z \geq 0$ such that $l^{k}(z)$ is strictly to the north
of all positions of concat $\left(l^{i \leftarrow},\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right], \mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right],\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right]\right)$. Also, since $x_{\overrightarrow{P_{j} P_{i}}}<0$, the point $l^{k}(z)+\overrightarrow{P_{j} P_{i}}$ is to the west of all positions of $l^{k}$. Thus, $l^{k}(z)+\overrightarrow{P_{j} P_{i}}$ is on the strict left-hand side of $c$, that is, in $\mathbb{R}^{2} \backslash \mathcal{C}$.

Therefore, if there were a $z^{\prime}>0$ such that $l^{k}\left(z^{\prime}\right)+\overrightarrow{P_{j} P_{i}} \in \mathcal{C}$ (the right hand side of $c$ ), and since $\left\{l^{k}(z)+\overrightarrow{P_{j} P_{i}}\right\}$ is not in the right hand side of $c$, there would be at least one real number $z^{\prime \prime} \in\left[z^{\prime}, z\left[\right.\right.$ such that $l^{k}\left(z^{\prime \prime}\right)+\vec{P}_{j} P_{i}$ is on $c$, contradicting the first part of this proof. Therefore, $\left(\left(l^{k}+\overrightarrow{P_{j} P_{i}}\right) \cap \mathcal{C}\right)=\left(\left(l^{k}+\overrightarrow{P_{j} P_{i}}\right) \cap c\right)$.

### 3.2 The first dominant tile $P_{m_{0}}$ and the path $R$

In this subsection, we define a tile $P_{m_{0}}$ of $P$, and a path $R$, that will be used in the inductive argument in Section 3.3.

### 3.2.1 The ray $\rho$ used to define the first dominant tile $P_{m_{0}}$

Let $\rho$ be the lowest (southernmost) ray of vector $\overrightarrow{P_{i} P_{j}}$ that starts on $l^{i}$ and intersects at least one tile of $P_{i+1, i+2, \ldots, k}$. Such a ray exists because in particular, the ray of vector $\overrightarrow{P_{i} P_{j}}$ starting on $l^{i}$ and going through $\operatorname{pos}\left(P_{i+1}\right)$ intersects $\operatorname{pos}\left(P_{j+1}\right)$ (these two positions are positions of tiles of $P_{i+1, i+2 \ldots, k}$ because $\left.i<j \leq k\right)$, and since $P_{i+1, i+2, \ldots, k}$ is of finite length there is one ray that is the southernmost ray (meaning that out of all such rays, $\rho$ is the ray whose start position $\rho(0)$ is the southernmost on $\left.l^{i}\right)$.

Then, let $m_{0} \in\{i+1, i+2, \ldots, k\}$ be the index such that $P_{m_{0}}$ is positioned on $\rho$, and is the easternmost tile of $P_{i+1, i+2, \ldots, k}$ that is positioned on $\rho$. See Figure 3.3 for an example.

Figure 3.3: The ray $\rho$ and tile $P_{m_{0}}$. We define $\rho$ as the southernmost ray of vector $\overrightarrow{P_{i} P_{j}}$ that starts on $l^{i}$ and intersects the position of at least one tile of $P_{i+1, i+2, \ldots, k}$. The easternmost such intersection is then defined to be $\operatorname{pos}\left(P_{m_{0}}\right)$, and $P_{m_{0}}$ is called the dominant tile.

Claim 3.5. $m_{0}>i+1$.
Proof. By its definition, we know that $m_{0} \geq i+1$. If we had $m_{0}=i+1$, then $P_{j+1}$ would also be on $\rho$, and hence since $\mathrm{x} \overrightarrow{P_{i} P_{j}}>0$ (i.e., $\overrightarrow{P_{i} P_{j}}$ has positive x-component, a consequence of Definition 7 and Lemma (2.3), we would have $m_{0} \geq j+1$, contradicting the fact that $i<j$.

Claim 3.6. Let $L^{m_{0}}$ be a vertical ray from $\operatorname{pos}\left(P_{m_{0}}\right)$ to the south. Then $L^{m_{0}}$ only intersects $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ at $\operatorname{pos}\left(P_{m_{0}}\right)$, and for all integers $n>0, L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ does not intersect $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$.

Proof. Remember that $m_{0} \in\{i+1, i+2, \ldots, k\}$. Thus, by definition of $L^{m_{0}}, L^{m_{0}}$ intersects $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ at $\operatorname{pos}\left(P_{m_{0}}\right)$. If there were another intersection point then that intersection would be strictly lower (strictly to the south) on $L^{m_{0}}$ and that intersection would define a ray of vector $\overrightarrow{P_{i} P_{j}}$ that intersects $P_{i, i+1, \ldots, k}$ strictly lower than $\rho$ thus contradicting the definition of $\rho$ as the lowest such ray. Thus $L^{m_{0}}$ only intersects $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ at $\operatorname{pos}\left(P_{m_{0}}\right)$.

For the second conclusion of this lemma, suppose, for the sake of contradiction, that there is an integer $n>0$ such that $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ and $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ intersect. Then that intersection is either:

- At $L^{m_{0}}(0)+n \overrightarrow{P_{i} P_{j}}$. Since $n>0$, that intersection is on $\rho$ (since $\rho$ is of vector $\overrightarrow{P_{i} P_{j}}$ and goes through $\operatorname{pos}\left(P_{m_{0}}\right)=L^{m_{0}}(0)$ for $\left.n=0\right)$ and strictly to the east of $P_{m_{0}}\left(\right.$ because $\left.\mathrm{x} \overrightarrow{P_{i} P_{j}}>0\right)$, contradicting the definition of $P_{m_{0}}$ as the easternmost tile of $P$ whose position is on $\rho$.
- Or else strictly lower (more southern) on $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ than $L^{m_{0}}(0)+n \overrightarrow{P_{i} P_{j}}$. Since $L^{m_{0}}+$ $n \overrightarrow{P_{i} P_{j}}$ is on a column (vertical line of integer positions), that intersection happens between $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ and a tile of $P_{i+1, i+2, \ldots, k}$, which contradicts the definition of $\rho$ as the lowest ray of vector $\overrightarrow{P_{i} P_{j}}$ through the position of a tile of $P_{i+1, i+2, \ldots, k}$.

Claim 3.7. $L^{m_{0}}$ is entirely in $\mathcal{C}$.
Proof. By Claim 3.6, $L^{m_{0}}$ only intersects $P_{i+1, i+2, \ldots, k}$ at $L^{m_{0}}(0)=\operatorname{pos}\left(P_{m_{0}}\right)$, which is on the border $c$ of $\mathcal{C}$ since $m_{0} \in\{i+1, i+2, \ldots, k\}$. Also, $L^{m_{0}}$ does not otherwise intersect $c$ since $l^{i}$ and $l^{k}$ are both on glue columns (half-integer x-coordinate) and $L^{m_{0}}$ is on a column (integer xcoordinate). Finally, $L^{m_{0}}$ is strictly to the east of $l^{i}$ (by definition of $\rho$ ), and hence by Definition 8, $L^{m_{0}}$ is entirely in $\mathcal{C}$.

Claim 3.8. Recall that $L^{m_{0}}$ and $l^{j}$ are vertical rays to the south starting at $\operatorname{pos}\left(P_{m_{0}}\right)$ and $\operatorname{pos}\left(\right.$ glue $\left.\left(P_{j} P_{j+1}\right)\right)$, respectively. If $m_{0}>j$, the vertical ray to the south $L^{m_{0}}$ is strictly to the east of the ray $l^{j}$, and $L^{m_{0}}+\overrightarrow{P_{j} P_{i}} \cap \mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right] \subseteq\left\{L^{m_{0}}(0)+\vec{P}_{j} P_{i}\right\}$.

Proof. The proof has four cases, depending on the glues around $P_{m_{0}}$. We show that cases 1 and 2 below cannot occur, and that cases 3 and 4 yield the conclusion of this claim:

1. If glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ is pointing south, the ray of vector $\overrightarrow{P_{i} P_{j}}$ through $\operatorname{pos}\left(P_{m_{0}+1}\right)$ is strictly lower than $\rho$, contradicting the definition of $\rho$.
2. If glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ is pointing west, then we claim that glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ would be visible from the south relative to $P$. Indeed, by Claim 3.7, $L^{m_{0}} \in \mathcal{C}$, and since $L^{m_{0}}$ is on a tile column, $L^{m_{0}}-(0.5,0)$ is on a glue column, and at x -coordinate at least $\mathrm{x}_{\mathrm{pos}\left(\operatorname{glue}\left(P_{i} P_{i+1}\right)\right)}$.

That, together with the fact that $L^{m_{0}}$ intersects $P_{i+1, i+2, \ldots, k}$ only at $\operatorname{pos}\left(P_{m_{0}}\right)$, implies that no glue of $P$ can be positioned on the line defined as $L^{m_{0}}(z)-(0.5,0)$ for $z>0, z \in \mathbb{R}$ (i.e. on line $L^{m_{0}}-(0.5,0)$ and strictly below glue $\left.\left(P_{m_{0}} P_{m_{0}+1}\right)\right)$. Thus glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ is visible from the south. But, since $m_{0}>j$ and glue $\left(P_{j} P_{j+1}\right)$ points east, glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ pointing west and being visible from the south contradicts Lemma 2.3,
3. If glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ is pointing east, then glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ is visible from the south relative to $P$ (by the same argument as in the previous case, with $L^{m_{0}}+(0.5,0)$ instead of $L^{m_{0}}-(0.5,0)$ ). Therefore by Claim 3.5 and Lemma [2.3, $L^{m_{0}}$ is strictly to the east of $l^{i}$, and if $m_{0}>j$, then $L^{m_{0}}$ is strictly to the east of $l^{j}$ too.
Furthermore, if $m_{0}>j$ and if $L^{m_{0}}+{\overrightarrow{P_{j} P}}_{i}$ intersected $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ other than at $L^{m_{0}}(0)+$ $\overrightarrow{P_{j} P_{i}}$, we could find a ray of vector $\overrightarrow{P_{i} P_{j}}$ through a tile of $P_{i+1, i+2, \ldots, k}$ strictly lower (strictly to the south) than $\rho$, which is a contradiction. Hence, if $m_{0}>j$, then $L^{m_{0}}+\vec{P}_{j} P_{i}$ does not intersect $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ except possibly at $L^{m_{0}}(0)+\overrightarrow{P_{j} P_{i}}$.
4. If glue $\left(P_{m_{0}} P_{m_{0}+1}\right)$ is pointing north, we consider all possibilities for glue $\left(P_{m_{0}-1} P_{m_{0}}\right)$ :
(a) If glue $\left(P_{m_{0}-1} P_{m_{0}}\right)$ points north, this contradicts the definition of $\rho$, since the ray of vector $\overrightarrow{P_{i} P_{j}}$ going through $P_{m_{0}-1}$ is strictly lower than $\rho$.
(b) If glue $\left(P_{m_{0}-1} P_{m_{0}}\right)$ points west, then glue $\left(P_{m_{0}-1} P_{m_{0}}\right)$ is visible relative to $P$ (by Claim[3.6), and this contradicts Lemma 2.3 since $m_{0}>i$.
(c) glue $\left(P_{m_{0}-1} P_{m_{0}}\right)$ pointing south contradicts $P$ being simple: indeed, this would mean that $\operatorname{pos}\left(P_{m_{0}-1}\right)=\operatorname{pos}\left(P_{m_{0}+1}\right)$.
(d) Therefore, glue $\left(P_{m_{0}-1} P_{m_{0}}\right)$ points east, and is therefore visible from the south relative to $P_{i+1, i+2, \ldots, k}$ (by Claim 3.6). By Lemma 2.3, since $m_{0}>i$, the visibility ray of glue $\left(P_{m_{0}-1} P_{m_{0}}\right)$ is strictly to the east of $l^{i}$, and hence $L^{m_{0}}$ is strictly to the east of $l^{i}$. If $m_{0}>j$, then $L^{m_{0}}$ is also strictly to the east of $l^{j}$, hence $L^{m_{0}}+{\overrightarrow{P_{j} P_{i}}}^{\text {does not intersect }}$ $P_{i+1, i+2, \ldots, k}$, except possibly at $L^{m_{0}}(0)+\overrightarrow{P_{j} P_{i}}$, by the same argument as in Case 3 above.

### 3.2.2 Splitting $\mathcal{C}$ into two components, $\mathcal{C}^{-}$and $\mathcal{C}^{+}$, using $P_{m_{0}}$

By Claim 3.7, $L^{m_{0}}$ is entirely in $\mathcal{C}$. Moreover, by Claim 3.6, $L^{m_{0}}$ intersects $c$ only at $\operatorname{pos}\left(P_{m_{0}}\right)$. Therefore, we use $L^{m_{0}}$ to split $\mathcal{C}$ into two components: let $c^{m_{0}}$ be the curve defined as

$$
c^{m_{0}}=\operatorname{concat}\left(L^{m_{0} \leftarrow}, \mathfrak{E}\left[P_{m_{0}, m_{0}+1, \ldots, k}\right],\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)
$$

Since $c^{m_{0}}$ starts and ends with vertical rays, and is otherwise made of a finite concatenation of horizontal and vertical segments, $c^{m_{0}}$ splits $\mathbb{R}^{2}$ into two connected components by Theorem B. 3 , Moreover, since $c^{m_{0}}$ is in $\mathcal{C}$ (because the four curves that define $c^{m_{0}}$ are in $\mathcal{C}$ ), let $\mathcal{C}^{+} \subseteq \mathcal{C}$ be the right-hand side of $c^{m_{0}}$ (including $\left.c^{m_{0}}\right)$, and let $\mathcal{C}^{-}=\left(\mathcal{C} \backslash \mathcal{C}^{+}\right) \cup L^{m_{0}}(\mathbb{R}) \sqrt{10}$. See Figure 3.4 for an illustration.

Moreover, $P_{i+1, i+2, \ldots, m_{0}}$ is entirely in $\mathcal{C}^{-}$(and on the border of $\mathcal{C}^{-}$, by definition of $\mathcal{C}$ ) and $P_{m_{0}, m_{0}+1, \ldots, k}$ is entirely in $\mathcal{C}^{+}$(and on the border of $\mathcal{C}^{+}$, by definition of $\mathcal{C}$ ).

[^9]

Figure 3.4: The components $\mathcal{C}^{+}$and $\mathcal{C}^{-}$. In Subsection 3.2.1 $\mathcal{C}^{+}$and $\mathcal{C}^{-}$were defined so that $\mathcal{C}^{+} \cup \mathcal{C}^{-}=\mathcal{C}$ and $\mathcal{C}^{+} \cap \mathcal{C}^{-}=L^{m_{0}}$.

Claim 3.9. For any integer $n>0, L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}^{+}$.
Proof. Let integer $n>0$. By Claim 3.6, $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ does not intersect $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$. Moreover, since $\mathrm{x}_{P_{i} P_{j}}>0$ we know that $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ is strictly to the east of $L^{m_{0}}$, and $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ does not intersect $l^{k}$ (because $L^{m_{0}}$ is on a tile column, and $l^{k}$ on a glue column) nor $\left[P_{k}, l^{k}(0)\right]$ (because that would mean that $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ intersects $P_{k}$ ).

Therefore, $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ does not intersect the border of $\mathcal{C}^{+}$, and starts to the east of $L^{m_{0}}$ (which is on the border of $\mathcal{C}^{+}$). Therefore, $L^{m_{0}}+n \overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{C}^{+}$.

### 3.2.3 A path $R$ that can grow in two different translations

The goal of this subsection is to define a path $R$ that can grow in two possible translations (respectively, $R$ that starts at $\operatorname{pos}\left(P_{i+1}\right)$ and $R+\overrightarrow{P_{i} P_{j}}$ that starts at $\left.\operatorname{pos}\left(P_{j+1}\right)\right)$. We proceed in two steps: the first step is to specify a binding path called $r$ below (from Definition 2, a binding path is a simple sequence of adjacent positions in $\mathbb{Z}^{2}$, i.e. a path but without tiles), and the second step is to "tile" that binding path to get the path $R$.

The binding path $r$. The definition of $r$ is illustrated in Figure 3.5, Let $G$ be the binding graph $G=(V, E)$ where:

$$
\begin{aligned}
V= & \left\{\operatorname{pos}\left(P_{n}\right) \mid n \in\{i+1, i+2, \ldots, k\}\right\} \cup\left\{\operatorname{pos}\left(P_{n}\right)+\vec{P}_{j} P_{i} \mid n \in\{j+1, j+2, \ldots, k\}\right\} \\
E= & \left\{\left\{\operatorname{pos}\left(P_{n}\right), \operatorname{pos}\left(P_{n+1}\right)\right\} \mid n \in\{i+1, i+2, \ldots, k-1\}\right\} \\
& \cup\left\{\left\{\operatorname{pos}\left(P_{n}\right)+\overrightarrow{P_{j} P_{i}}, \operatorname{pos}\left(P_{n+1}\right)+\overrightarrow{P_{j} P_{i}}\right\} \mid n \in\{j+1, j+2, \ldots, k-1\}\right\}
\end{aligned}
$$

We define the set $\overline{\mathbb{S}}$ of all binding paths in the graph $G^{\prime}=\left(V \cup\left\{\operatorname{pos}\left(P_{i}\right)\right\}, E \cup\left\{\operatorname{pos}\left(P_{i}\right), \operatorname{pos}\left(P_{i+1}\right)\right\}\right)$ such that $q \in \overline{\mathbb{S}}$ if and only if:

Figure 3.5: Left: Following from Figure $3.2 \mathfrak{E}\left[P_{i+1, i+2, \ldots, k+1}\right]$ is shown in brown and $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k+1}\right]+$ $\overrightarrow{P_{j} P_{i}}$ is shown in green. Right: The route traced by (the embedding of) the binding path $r$ defined in Subsection 3.2.3] red indicates when $r$ takes positions from $P_{i+1, i+2, \ldots, k}$ only, and brown indicates when $r$ takes positions from $P_{j+1, j+2, \ldots, k}+{\overrightarrow{P_{j} P}}$ and/or $P_{i+1, i+2, \ldots, k}$.

- $q$ starts with $q_{0} q_{1}=\operatorname{pos}\left(P_{i}\right) \operatorname{pos}\left(P_{i+1}\right)$ and has its final vertex $q_{|q|-1}$ being a vertex of $G$ that is "adjacent" to $l^{k}$; more precisely there exists $z \in \mathbb{R}, z \geq 0$ such that $l^{k}(z) \in\left\{q_{|q|-1}-\right.$ $\left.(0.5,0), q_{|q|-1}+(0.5,0)\right\}$; and
- the curve concat $\left(\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right], \mathfrak{E}\left[q_{1,2, \ldots, q_{|q|-1}}\right],\left[q_{|q|-1}, l^{k}(z)\right]\right)$ is entirely in $\mathcal{C}$.

We now define the set $\mathbb{S} \subseteq \overline{\mathbb{S}}$ of all paths $q \in \overline{\mathbb{S}}$ such that for all $q^{\prime} \in \overline{\mathbb{S}}$ that is a strict prefix or a strict extension of $q$, the last tile of $q^{\prime}$ is strictly lower than the last tile of $q$, i.e. $y_{q_{\left|q^{\prime}\right|-1}^{\prime}}<y_{q_{|q|-1}}$.

Let $q^{\prime}$ be the most right priority binding path of $\mathbb{S}$ (see Definition (3). We claim that $q^{\prime}$ is well-defined. First, we claim that $\mathbb{S}$ is nonempty: indeed, $\overline{\mathbb{S}}$ is nonempty as there is at least one binding path $q$ that starts with $q_{0} q_{1}=\operatorname{pos}\left(P_{i}\right) \operatorname{pos}\left(P_{i+1}\right)$, ends with a vertex adjacent to $l^{k}$, and stays in $\mathcal{C}$, since $\operatorname{pos}\left(P_{i, i+1, \ldots, k}\right)$ satisfies the first and second conditions. Second, either $P$ or one of its strict prefixes is in $\mathbb{S}$. Third, since all binding paths $q \in \mathbb{S}$ have their first two vertices $q_{0} q_{1}=\operatorname{pos}\left(P_{i}\right) \operatorname{pos}\left(P_{i+1}\right)$ in common, the right priority path of $\mathbb{S}$ is well-defined. Thus $q^{\prime}$ is well-defined. Finally, let $r=r_{0,1, \ldots,|r|-1}=q_{1,2, \ldots,\left|q^{\prime}\right|-1}^{\prime}$, i.e. $r$ is the same binding path as $q^{\prime}$ but without its the first vertex $q_{0}^{\prime}$.

Thus, by definition, $r$ is entirely in $\mathcal{C}$. We now go on to prove some properties about $r$. The proof of Claim 3.10 is illustrated in Figures 3.6 and 3.7.

Claim 3.10. Let $a$ and $b$ be two integers such that $0 \leq a<b \leq|r|-1$. If there are indices $d, e \in\{i+1, i+2, \ldots, k\}$ such that $\operatorname{pos}\left(P_{d}\right)=r_{a}$ and $\operatorname{pos}\left(P_{e}\right)=r_{b}$, then $d<e$.

Proof. Assume, for the sake of contradiction, that there are two indices $d$ and $e$ such that $\operatorname{pos}\left(P_{d}\right)=r_{a}, \operatorname{pos}\left(P_{e}\right)=r_{b}$ and $d \geq e$. Because $r$ and $P$ are simple and $a \neq b$, we also have $d>e$. Note that $e>i+1$ (since $r_{0}=\operatorname{pos}\left(P_{i+1}\right), b>a \geq 0$ and $r$ is simple). We assume without loss of generality that $e$ is the smallest integer satisfying the hypotheses of this claim. (See Figure 3.6 for an example.)

Figure 3.6: Initial setup for the proof Claim 3.10. We assume, for the sake of contradiction, that there are two indices $a<b$ such that $r_{a}=\operatorname{pos}\left(P_{d}\right), r_{b}=\operatorname{pos}\left(P_{e}\right)$, for some $d$ and $e$ such that $d>e$. Here the brown path is $\operatorname{pos}\left(P_{i+1, i+2, \ldots, k+1}\right)$, and the red path is $r$.

Let $s$ be the curve defined by:

$$
s=\operatorname{concat}\left(l^{i \leftarrow},\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right], \mathfrak{E}\left[P_{i+1, i+2, \ldots, e}\right], \mathfrak{E}\left[r_{b, b+1, \ldots,|r|-1}\right],\left[r_{|r|-1}, l^{k}(z)\right], l_{z}^{k}\right)
$$

where $l^{k}(z) \in \mathbb{R}^{2}$ is the point of $l^{k}$ at the same y -coordinate as $r_{|r|-1}$ and $l_{z}^{k}$ is the ray to the north starting at $l^{k}(z)$. The curve $s$ is entirely in $\mathcal{C}$ because the six curves used to define $s$ are in $\mathcal{C}$. The six curves used to define $s$ only intersect pairwise at their endpoints meaning that $s$ is simple (in particular by the minimality of $e, P_{i+1, i+2, \ldots, e-1}$ does not intersect $r_{b, b+1, \ldots,|r|-1}$ ). Therefore, since $s$ starts and ends with vertical rays, and is otherwise made of a finite number of horizontal and vertical segments, $s$ cuts the plane into two connected components, by Theorem B. 3 . We claim that $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ does not turn right from $s$, by looking at each part of $s$ :

- glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{k} P_{k+1}\right)$ are visible relative to $P$, hence $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ does not intersect $l^{i \leftarrow}$ nor $l^{k}$.
- $P$ is simple, hence $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ cannot intersect $\mathfrak{E}\left[P_{i+1, i+2, \ldots, e-1}\right]$.
- If $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ turns right from a point of $\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right]$, then $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ must intersect $P_{i}$ or $l^{i}(0)$ (or both), which is already covered by the two previous points.
- $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ (which is in $\mathcal{C}$ ) does not turn right from $\mathfrak{E}\left[r_{b, b+1, \ldots,|r|-1}\right]$. There are two subcases:
- If that right turn happens on a point of $r$ strictly before $|r|-1$, then this contradicts the definition of $r$ as a most right-priority path.
- Else, that right turn happens at $r_{|r|-1}=\operatorname{pos}\left(P_{f}\right)$ for some integer $f$, which means that $f<k$. This means that $\mathfrak{E}[P]$ also turns right from the curve defined as $\rho=$ concat $\left(l^{i \leftarrow},\left[l^{i}(0), \operatorname{pos}\left(r_{0}\right)\right], \mathfrak{E}[r],\left[r_{|r|-1}, l^{k}(z)\right], l_{z}^{k}\right)$. However, $P_{k}$ is not in the connected component on the right-hand side of $\rho$, since $f<k$. Therefore, $P$ must intersect $\rho$, and that can only happen on $r$. However, this implies that not all of $r$ is on the same side of $P$, contradicting the definition of $r$ as being in $\mathcal{C}$.

Figure 3.7: Illustration for the proof of Claim 3.10, $\operatorname{pos}\left(P_{i+1, i+2, \ldots, k+1}\right)$ is in brown, $r$ is in red, and we assume that there are two indices $a<b$ such that $r_{a}=\operatorname{pos}\left(P_{d}\right)$ and $r_{b}=\operatorname{pos}\left(P_{e}\right)$ and such that (for the sake of contradiction) we have $d>e$. If we draw $r_{b, b+1, \ldots,|r|-1}$ after $r_{a, a+1, \ldots, b}$, then since $r$ is simple, then although $r_{0,1, \ldots, a}$ must enter the grey zone where $r_{a}$ is, any attempt by $r_{0,1, \ldots, a}$ to do so leads it having position(s) outside $\mathcal{C}$ (contradicting that $\mathfrak{E}[r]$ stays in $\mathcal{C}$ by definition) or $r$ intersecting itself (contradicting that $r$ is a simple binding path - a situation shown by the dashed curve).

- if $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ turns right from a point of $\left[r_{|r|-1}, l^{k}(z)\right]$ then this can only occur at one of the two endpoints of this segment (which is a horizontal line segment of length 0.5 ) which is already covered in the first or fourth point above.
This means that $\mathfrak{E}\left[P_{e, e+1, \ldots, k}\right]$ does not turn right from $s$, and therefore, $r_{a}=\operatorname{pos}\left(P_{d}\right)$ is either on $s$, or in the component of $\mathbb{R}^{2}$ that is on the left-hand side of $s$.

If $r_{a}$ is on $s$, then since $d>e$ and $P$ is simple, $r_{a}$ cannot be on $P_{i+1, i+2, \ldots, e}$. But $r_{a}$ cannot be on $r_{b, b+1, \ldots,|r|-1}$ either, since $r$ is simple and $a<b$. Therefore, $r_{a}$ is not on $s$, and since $r_{0}=\operatorname{pos}\left(P_{i+1}\right)$, this implies that $\mathfrak{E}\left[r_{0,1, \ldots, a}\right]$ turns left from $\mathfrak{E}[s]$. The position of that left turn from $\mathfrak{E}[s]$ must be on one of the six curves used to define $s$ (see Figure 3.7 for an example):

- If the left turn is from a point on $\mathfrak{E}\left[r_{b, b+1, \ldots,|r|-1}\right]$, this contradicts that $r$ is simple.
- If the left turn is from a point on $l^{i \leftarrow},\left[l^{i}(0), \operatorname{pos}\left(P_{i+1}\right)\right], \mathfrak{E}\left[P_{i+1, i+2, \ldots, e}\right],\left[r_{|r|-1}, l^{k}(z)\right]$ or $l_{z}^{k}$, then either we are also in the previous case (i.e. the left turn is on $\mathfrak{E}\left[r_{b, b+1, \ldots,|r|-1}\right]$, or we contradict the definition of $\mathfrak{E}[r]$ as being in $\mathcal{C}$.
In all cases, we get a contradiction. Therefore, $d<e$.

Next we show that if $(i, j, j)$ is a shield for $P$, then $P$ is pumpable with pumping vector $\overrightarrow{P_{i} P_{j}}$.
Claim 3.11. Let $(i, j, k)$ be a shield for $P$ (as in Definition (7). If $j=k$ then $P$ is pumpable.
Proof. Since $j=k$, the ray $l^{k}+\overrightarrow{P_{j} P_{i}}=\operatorname{pos}\left(\right.$ glue $\left.\left(P_{k} P_{k+1}\right)\right)+\overrightarrow{P_{j} P_{i}}=\operatorname{pos}\left(\right.$ glue $\left.\left(P_{j} P_{j+1}\right)\right)+\overrightarrow{P_{j} P_{i}}=$ $\operatorname{pos}\left(\operatorname{glue}\left(P_{i} P_{i+1}\right)\right)=l^{i}(0)$, and thus, by Definition 7 glue $\left(P_{i} P_{i+1}\right)$ is visible from both the north and the south. Moreover, glue $\left(P_{i} P_{i+1}\right)$ points east (Definition 7), hence all positions of $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ are strictly to the west of the vertical line through $\operatorname{pos}\left(\operatorname{glue}\left(P_{i} P_{i+1}\right)\right)$.

Since $j=k$, then $l^{j}(0)=l^{k}(0)$ and by Definition 7 glue $\left(P_{k} P_{k+1}\right)$ is visible from both the north and the south. Moreover, by the visibility of glue $\left(P_{i} P_{i+1}\right)$, the path $P_{i+1, i+2, \ldots, k}$ is entirely positioned between the two vertical lines that run through glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{k} P_{k+1}\right)$. As noted after Definition 7, $\mathrm{x}_{\overrightarrow{P_{i} P_{j}}}=\mathrm{x}_{\overrightarrow{P_{i} P_{k}}}>0$. Hence, for all $n \in \mathbb{N}$, the path $P_{i+1, i+2, \ldots, k}+$ $(n+1) \overrightarrow{P_{i} P_{j}}$ is strictly to the east of $P_{i+1, i+2, \ldots, k}+n \overrightarrow{P_{i} P_{j}}$. Moreover, for all $n \in \mathbb{N}$, the pair of tiles $P_{k}+n \overrightarrow{P_{i} P_{j}}$ and $P_{i+1}+(n+1) \overrightarrow{P_{i} P_{j}}$ interact, hence the pumping of $P$ between $i$ and $k$ is simple and producible (Definition (5). Hence $P$ is a pumpable path (Definition (6) with pumping vector $\overrightarrow{P_{i} P_{j}}$.

From now on, we assume that $j<k$, otherwise $P$ is pumpable by the previous claim. We use this to define a second connected component $\mathcal{D} \subseteq \mathcal{C}$ (see Figure 3.8 for an example), since $j<k$ makes the following curve simple:

Definition 9. Let $d$ be the curve defined as the concatenation of five curves:

$$
d=\operatorname{concat}\left(l^{j^{\leftarrow}},\left[l^{j}(0), \operatorname{pos}\left(P_{j+1}\right)\right], \mathfrak{E}\left[P_{j+1, j+2, \ldots, k}\right],\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)
$$

By a similar argument to Claim 3.2 for curve $c$ (Definition 8), here $d$ is a simple connected curve starting with a vertical ray to the south $\left(l^{j}\right)$ and ending with a vertical ray to the north $\left(l^{k}\right)$. Therefore, by Theorem B.3, $d$ cuts $\mathbb{R}^{2}$ into two infinite connected components. Let $\mathcal{D} \subsetneq \mathbb{R}^{2}$ be the connected component on the right-hand side of $d$ (intuitively, the component connected to the east of $l^{i}$ and $l^{k}$ ), including $d$ itself.

Moreover, since each of the five curves used to define $d$ are in $\mathcal{C}$ (Definition [8) we get that $d$ is entirely in $\mathcal{C}$. Hence $\mathcal{D}$ is a subset of $\mathcal{C}$.

The following two claims are illustrated in Figure 3.8.

Figure 3.8: The component $\mathcal{D} \subset \mathbb{R}^{2}$ (shaded) and the embedded binding path $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$. Claim 3.12 asserts that no tile of $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, j}\right)$ is in $\mathcal{D}$ and Claim 3.13]asserts that $\mathfrak{E}[r]+{\overrightarrow{P_{i} P}}_{j}$ is entirely contained in $\mathcal{D}$.

Claim 3.12. $\operatorname{dom}\left(\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, j}\right)\right) \subset\left(\mathbb{R}^{2} \backslash \mathcal{D}\right)$.
Proof. Similar argument to Claim 3.3, but respectively substitute $j, d, \mathcal{D}$ for $i, c, \mathcal{C}$ in the proof of Claim 3.3.
Claim 3.13. $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{D}$.
Proof. Assume otherwise, for the sake of contradiction. Since $r_{0}+\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{j+1}\right)$ is on the border $d$ of $\mathcal{D}$ and thus in $\mathcal{D}$, this would mean that $\mathfrak{E}[r]+{\overrightarrow{P_{i} P}}_{j}$ turns left from $d$ (see Definition 14 for one curve turning from another). That left turn is on one of the five curves that define $d$ (Definition 9), which we handle in four cases:

1. $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$ at a position on $l^{j}$ : But since glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$ are both visible relative to $P$, and $r$ is made of positions taken from $P_{i+1, i+2, \ldots, k}$ and $P_{j+1, j+2, \ldots, k}+$ $\vec{P}_{j} P_{i}$, this implies $\mathfrak{E}[r]$ does not intersect the visibility ray $l^{i}$ of glue $\left(P_{i} P_{i+1}\right)$, and hence $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ does not intersect $l^{j}$. Thus having the left turn be from $l^{j}$ is a contradiction.
2. $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$ at a position on $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}\right]$. Since this case is rather involved, we split it into a number of paragraphs, and each paragraph header gives the core argument being proven in the paragraph. We first define the curve $\rho$ as:

$$
\rho=\operatorname{concat}\left(l^{i},\left[l^{i}(0), r_{0}\right], \mathfrak{E}[r],\left[r_{|r|-1}, l_{z}^{k}(0)\right], l_{z}^{k}\right)
$$

where $l_{z}^{k}=l^{k}\left(\left[z,+\infty[)\right.\right.$ is the ray to the north starting at $l_{z}^{k}(0)=l^{k}(z) \in \mathbb{R}^{2}$ which is the point of $l^{k}$ at the same y -coordinate as $r_{|r|-1}$.

Setup: Indices $a$ and $b$ such that $\operatorname{pos}\left(P_{a}\right)=r_{b}+\overrightarrow{P_{i} P_{j}}$ and $\mathfrak{E}\left[r_{0,1, \ldots, b+1}\right]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$. First, $\mathfrak{E}[r]$ turns left from $d+{\overrightarrow{P_{j} P}}_{i}$ at a position on $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$. The curve $\rho$ is a simple infinite almost-vertical polygonal curve (Definition (12) - in particular, it is simple because its five component curves intersect each other only at their endpoints in the order given. Using Definition 13 , let $\mathcal{R} \subsetneq \mathbb{R}$ be the right-hand side of $\rho$, and let $\mathcal{R} \backslash \rho(\mathbb{R})$ denote the strict right-hand side of $\rho$.
Since we are in Case 2, $\mathfrak{E}[r]$ has a point in the strict left hand side (Definition [13) of the simple infinite almost-vertical polygonal curve $d+\vec{P}_{j} P_{i}$, with the left turn being on $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}\right]$. Hence, let $b \in\{0,1, \ldots,|r|-1\}$ be the smallest integer such that there is an $a \in\{j+1, j+2, \ldots, k\}$ where $r_{b}+\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{a}\right)$ and $\mathfrak{E}\left[r_{0,1, \ldots, b+1}\right]+\overrightarrow{P_{i} P_{j}}$ has a point on the strict left hand side of curve $d$. Hence, $r_{0,1, \ldots, b}$ is entirely in the right hand side of $d+\vec{P}_{j} P_{i}$, and the point $\operatorname{mid}\left(r_{b} r_{b+1}\right)$ is in the strict left hand side of $d+\overrightarrow{P_{j} P_{i}}$.

We claim that $a<k$. Suppose for the sake of contradiction that $a=k$. Then $r_{b}=$ $\operatorname{pos}\left(P_{k}\right)+\overrightarrow{P_{j} P_{i}}$. Since $\mathfrak{E}[r]$ makes a left turn from $d+\vec{P}_{j} P_{i}$ at $\operatorname{pos}\left(P_{k}\right)+{\overrightarrow{P_{j} P}}_{i}$, and since $\mathfrak{E}\left[r_{0,1, \ldots, b}\right]$ is on the right hand side of $d+\overrightarrow{P_{j} P_{i}}, \mathfrak{E}[r]$ makes a left turn from the curve

$$
\rho^{\prime}=\operatorname{concat}\left(l^{i},\left[l^{i}(0), r_{0}\right], \mathfrak{E}\left[r_{0,1, \ldots, b}\right],\left[\operatorname{pos}\left(P_{k}\right)+\overrightarrow{P_{j} P_{i}}, l^{k}(0)+\overrightarrow{P_{j} P_{i}}\right], l^{k}+\overrightarrow{P_{j} P_{i}}\right)
$$

at the position $r_{b}$. By the definition of $r$, we know that $r_{b+1, b+2, \ldots,|r|-1}$ has its last point within horizontal distance $\pm 0.5$ of the ray $l^{k}$. But any such position is in the strict right
hand side of $\rho^{\prime}$ because: (a) since $i<j, l^{k}$ is at least distance 1 to the east of $l^{k}+\vec{P}_{j} P_{i}$, (b) since $i<k$ (because $i<j \leq k$ ), and by visibility, $l^{k}$ does not intersect $l^{i}$, and (c) $\mathfrak{E}[r]$ does not intersect $l^{k}$ by definition of $r$. Hence $\mathfrak{E}\left[r_{b+1, b+2, \ldots,|r|-1}\right]$ intersects $\rho^{\prime}$, but that intersection can not happen along $l^{i}$ (by its definition $\mathfrak{E}[r]$ does not intersect $l^{i}$ ) nor along $\mathfrak{E}\left[r_{0,1, \ldots, b}\right]$ (because $r$ is simple), nor at $l^{k}(z)+\vec{P}_{j} P_{i}$ for all $z \in \mathbb{R}, z>0$ (because, by Definition 7, the curves $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ and $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}\right]+{\overrightarrow{P_{j} P}}$ from which $\mathfrak{E}[r]$ is composed do not touch $\left.l^{k}(z)+\overrightarrow{P_{j} P_{i}}\right)$, nor $\left[\operatorname{pos}\left(P_{k}\right)+\overrightarrow{P_{j} P_{i}}, l^{k}(0)+\overrightarrow{P_{j} P_{i}}\right]$ because $r$ turns left from $d+\overrightarrow{P_{j} P_{i}}$ at $r_{b}=\operatorname{pos}\left(P_{k}\right)+\overrightarrow{P_{j} P_{i}}$. Thus we get a contraction. Hence $a<k$ as claimed.

We claim that $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ has a point in $\mathcal{R} \backslash \rho(\mathbb{R})$ (the strict right hand side of $\rho$ ). We first treat the case $b=0$ as a special case: in this case, $r_{b}=r_{0}=\operatorname{pos}\left(P_{j+1}\right)+\overrightarrow{P_{j} P_{i}}$ and, by the statement of the case we are in (Case (2), the point $\operatorname{mid}\left(P_{j+1} P_{j+2}\right)+\vec{P}_{j} P_{i}$ is in the right hand side of $\rho$. The point $\operatorname{mid}\left(P_{j+1} P_{j+2}\right)+\overrightarrow{P_{j} P_{i}}$ is not on $\rho$, because $\operatorname{mid}\left(r_{0} r_{1}\right) \neq$ $\operatorname{mid}\left(P_{j+1} P_{j+2}\right)+\vec{P}_{j} P_{i}$ (because of the turn at $r_{0}$ ) and because if it were $r$ would not be simple (there would be an intersection of $r_{1,2, \ldots,|r|-1}$ with $r_{0}$ ). Hence $\operatorname{mid}\left(P_{j+1} P_{j+2}\right)+\vec{P}_{j} P_{i}$ is in the strict right hand side of $\rho$. Thus if $b=0$, we are done with our current argument, i.e. $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ has a point in $\mathcal{R} \backslash \rho(\mathbb{R})$.

Else $b>0$. There are two possibilities for $r_{b-1}$. First, suppose $r_{b-1}=\operatorname{pos}\left(P_{a-1}\right)+\vec{P}_{j} P_{i}$. Since $r_{b-1, b}=\operatorname{pos}\left(P_{a-1, a}\right)+{\overrightarrow{P_{j} P}}_{i}$, we get that $r_{b-1, b, b+1}$ turns left from $\operatorname{pos}\left(P_{a-1, a, a+1}+\vec{P}_{j} P_{i}\right)$ and thus the point $\operatorname{mid}\left(P_{a} P_{a+1}\right)+\vec{P}_{j} P_{i}$ is in $\mathcal{R} \backslash \rho(\mathbb{R})$ and we are done with our current argument, i.e. that $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ has a point in $\mathcal{R} \backslash \rho(\mathbb{R})$.
Otherwise, we have $r_{b-1} \neq \operatorname{pos}\left(P_{a-1}\right)+\vec{P}_{j} P_{i}$, which we split into two cases:

- $r_{b-1} \neq \operatorname{pos}\left(P_{a+1}\right)+\overrightarrow{P_{j} P_{i}}$.

In this case, the four positions around $P_{a}+\overrightarrow{P_{j} P_{i}}=r_{b}$ are each occupied by one of the following tiles $P_{a-1}+\overrightarrow{P_{j} P_{i}}, P_{a+1}+\vec{P}_{j} P_{i}, r_{b-1}$ and $r_{b+1}$ (since $r$ and $P$ are simple and by the hypothesis of this case). Consider the enumeration of these four tiles around $P_{a}+\overrightarrow{P_{j} P_{i}}=r_{b}$ in clockwise order starting with $P_{a-1}+\overrightarrow{P_{i} P_{j}}$. By definition of $b, r_{b+1}$ comes before $P_{a+1}+\vec{P}_{j} P_{i}$ and by minimality of $b, r_{b-1}$ cannot come before $P_{a+1}+\overrightarrow{P_{i} P_{j}}$, then the four tiles are ordered as follow:

$$
P_{a-1}+\vec{P}_{j} \vec{P}_{i}, r_{b+1}, P_{a+1}+\overrightarrow{P_{j} P_{i}}, r_{b-1}
$$

which means that $P_{a-1, a, a+1}+{\overrightarrow{P_{j} P}}_{i}$ turns right form $r$ at $P_{a}+\vec{P}_{j} P_{i}=r_{b}$.
Then, the point $\operatorname{mid}\left(P_{a} P_{a+1}\right)+\vec{P}_{j} P_{i}$ is on the strict right hand side of $\rho$ (note in particular that $\operatorname{mid}\left(P_{a} P_{a+1}\right)+\vec{P}_{j} P_{i}$ is not on $l_{z}^{k}$, for else we would get an extension of $r$ that would be in $\overline{\mathbb{S}}$ and end higher than $r$, contradicting the fact that by definition, $r \in \mathbb{S}$ ). Thus $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ has a point in $\mathcal{R} \backslash \rho(\mathbb{R})$, which is the claim of this paragraph.

- $r_{b-1}=\operatorname{pos}\left(P_{a+1}\right)+\overrightarrow{P_{j} P_{i}}$. There are two cases:

[^10]* $b-(k-a)>0$. We claim that $\operatorname{pos}\left(P_{a, a+1, \ldots, k}+\vec{P}_{j} P_{i}\right)=r_{b, b-1, \ldots, b-(k-a)}$ (intuitively, we are claiming that $r_{b, b-1, \ldots, b-(k-a)}$ tracks "backwards" along $\operatorname{pos}\left(P_{a, a+1, \ldots, k}+\vec{P}_{j} P_{i}\right)$, without either turning from the other). Since $r_{0,1, \ldots b}$ is on the right hand side of $d+\overrightarrow{P_{j} P_{i}}, \mathfrak{E}\left[r_{b, b-1, \ldots, b-(k-a)}\right]$ has all its points on the right hand side of $d+{\overrightarrow{P_{j} P}}_{i}$ (and none on the strict left hand side of $d+\vec{P}_{j} P_{i}$ ). Hence if $\mathfrak{E}\left[r_{b, b-1, \ldots, b-(k-a)}\right]$ turns from $d+{\overrightarrow{P_{j} P}}_{i}$, it turns to the right from $d+\overrightarrow{P_{j} P_{i}}$ (and in particular has points in the strict right hand side of $d+\vec{P}_{j} P_{i}$ ).
But this means that $d+\overrightarrow{P_{j} P_{i}}$ has points on the strict left hand side of $\rho^{\leftarrow}$, or in other words $d+\vec{P}_{j} P_{i}$ has points on the strict right hand side of $\rho$. This yields the claim of this paragraph.
* $b-(k-a) \leq 0$. There are two cases, depending on whether or not $r_{b, b-1, \ldots, 0}$ turns from $\operatorname{pos}\left(P_{a, a+1, \ldots, k}+{\overrightarrow{P_{j} P}}_{j}\right)$. First, if $r_{b, b-1, \ldots, 0}$ turns (right or left) from $\operatorname{pos}\left(P_{a, a+1, \ldots, k}+\right.$ $\overrightarrow{P_{j} P_{i}}$ ), then by using the same argument as the previous bullet, we get the claim of this paragraph.
Finally, assume for the sake of contradiction, that $r_{b, b-1, \ldots, 0}$ does not turn from $\operatorname{pos}\left(P_{a, a+1, \ldots, k}+\vec{P}_{j} P_{i}\right)$. We have $r_{0}=P_{m}+\vec{P}_{P_{i}}$ for some $m \in\{a, a+1, \ldots, k\}$. Since we are in a case where $b>0$, we also get ${ }^{111}$ that $j+1<a$, hence $j+1 \neq m$. But, by the definition of $r, r_{0}=\operatorname{pos}\left(P_{j+1}\right)+\overrightarrow{P_{j} P_{i}}$, hence $j+1=m$, which is a contradiction, hence $r_{b, b-1, \ldots, 0}$ must turn from $\operatorname{pos}\left(P_{a, a+1, \ldots, k}+{\overrightarrow{P_{j} P}}_{i}\right)$ we get a contradiction.
Hence we have proven that $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ has a point in $\mathcal{R} \backslash \rho(\mathbb{R})$.
$P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}$ does not intersect $\rho$ again after entering $\mathcal{R} \backslash \rho(\mathbb{R})$, yielding a contradiction. We have already proven that $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ has a point in $\mathcal{R} \backslash \rho(\mathbb{R})$ (previous paragraph). Using that fact, let $a^{\prime} \in\{j+1, j+2, \ldots, k-1\}, b^{\prime} \in\{0,1, \ldots,|r|-1\}$ be so that $b^{\prime}$ is the smallest integer such that $r_{b^{\prime}}=\operatorname{pos}\left(P_{a^{\prime}}\right)+\overrightarrow{P_{j} P_{i}}$ and $\operatorname{pos}\left(P_{j+1, j+2, \ldots, a^{\prime}+1}\right)+\overrightarrow{P_{j} P_{i}}$ turns right from $\rho$ at position $r_{b^{\prime}}$. Hence $\operatorname{pos}\left(\operatorname{glue}\left(P_{a^{\prime}} P_{a^{\prime}+1}\right)+\vec{P}_{j} P_{i}\right)$ is in $\mathcal{R} \backslash \rho(\mathbb{R})$ (since $\mathfrak{E}\left[P_{j+1, j+2, \ldots, a^{\prime}+1}\right]+\vec{P}_{j} P_{i}$ cannot intersect with $l^{i}$ and $\left.l^{k}\right)$.
Claim [3.4, states that $\left(\left(l^{k}+{\overrightarrow{P_{j} P}}_{i}\right) \cap \mathcal{C}\right)=\left(\left(l^{k}+\overrightarrow{P_{j} P_{i}}\right) \cap c\right) \subseteq\left\{l^{k}(0)+{\overrightarrow{P_{j} P}}\right\}$ which in turn implies that the point $\operatorname{pos}\left(\operatorname{glue}\left(P_{k} P_{k+1}\right)\right)+\overrightarrow{P_{j} P_{i}}=l^{k}(0)+\overrightarrow{P_{j} P_{i}}$ is not in $\mathcal{C} \backslash c$, and therefore not in $\mathcal{R} \backslash c$ (recall that $\mathcal{R} \subset \mathcal{C}$ ). Therefore, $\mathfrak{E}\left[P_{a^{\prime}, a^{\prime}+1, \ldots, k+1}+{\overrightarrow{P_{j} P}}_{i}\right]$ intersects $\rho$ for some real number $t>0$ at a point $Z=\mathfrak{E}\left[P_{a^{\prime}, a^{\prime}+1, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right](t) \in \mathbb{R}^{2}$. 12 We analyse where such an intersection point $Z$ might occur on $\rho$ :
- $Z$ is not on $l^{i}$ nor $\left[l^{i}(0), r_{0}\right]$ : Since $j+1 \leq a^{\prime}$, the curve $\mathfrak{E}\left[P_{a^{\prime}, a^{\prime}+1, \ldots, k}\right]$ does not intersect $l^{j}$ by visibility, and thus $\mathfrak{E}\left[P_{a^{\prime}, a^{\prime}+1, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ does not intersect $l^{i}$. Also, $Z$ is not on $\left[l^{i}(0), r_{0}\right]=\left[l^{i}(0), \operatorname{pos}\left(P_{j+1}+\overrightarrow{P_{j} P_{i}}\right)\right]$, since $j+1 \leq a^{\prime}, t>0$ and $P$ is simple.
- If the first such intersection point $Z$ along $\mathfrak{E}\left[P_{a^{\prime}, a^{\prime}+1, \ldots, k}+\vec{P}_{j} P_{i}\right]$ (i.e., smallest $t>0$ ) is with $l^{k}$ or $\left[r_{|r|-1}, l_{z}^{k}(0)\right]$, then let $r^{\prime}=r_{0,1, \ldots, b^{\prime}} \operatorname{pos}\left(P_{a^{\prime}+1, a^{\prime}+2, \ldots, g}+\vec{P}_{j} P_{i}\right)$ where the index

[^11]$g \in\left\{a^{\prime}+1, a^{\prime}+2, \ldots, k\right\}$ is defined such that $\left[\operatorname{pos}\left(P_{g}\right), \operatorname{pos}\left(P_{g+1}\right)\right]+{\overrightarrow{P_{j} P}}$ intersects $\left[\operatorname{pos}\left(P_{k}\right), l^{k}(z)\right] \cup l^{k}$.
Then, by the definition of $a^{\prime}$ and $b^{\prime}$, either $r$ is a prefix of the binding path $r^{\prime}$ (if $b^{\prime}=|r|-1$ ) or $r^{\prime}$ turns right from $r$ at $r_{b^{\prime}}=\operatorname{pos}\left(P_{a^{\prime}}+\overrightarrow{P_{j} P_{i}}\right)$ (if $b^{\prime}<|r|-1$ ). In the former case, this contradicts the definition of $r$, since then $r^{\prime} \in \mathbb{S}$ and $r \notin \mathbb{S}$. In the latter case, this contradicts that $r$ is the most right-priority path of $\mathbb{S}$, since $r^{\prime} \in \mathbb{S}$ is more right-priority.

- Else, the first (i.e., smallest $t>0$ ) such intersection point $Z$ along $\mathfrak{E}\left[P_{a^{\prime}, a^{\prime}+1, \ldots, k}+\overrightarrow{P_{j} P_{i}}\right]$ is on $\mathfrak{E}[r]$, in other words $P_{a^{\prime}+1, a^{\prime}+2, \ldots, k}+{\overrightarrow{P_{j} P}}^{\prime}$ has a position on $r$. Since $\operatorname{pos}\left(P_{a^{\prime}}\right)+\overrightarrow{P_{j} P_{i}}=$ $r_{b^{\prime}}$, we know that $P_{a^{\prime}+1, a^{\prime}+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}$ does not intersect $r_{b^{\prime}}$, and we have two subcases:
- If $P_{a^{\prime}+1, a^{\prime}+2, \ldots, k}+{\vec{P} P_{j}}$ intersects $r_{b^{\prime}+1, b^{\prime}+2, \ldots,|r|-1}$, let $g \in\left\{a^{\prime}+1, a^{\prime}+2, \ldots, k\right\}$ be the smallest index such that $\operatorname{pos}\left(P_{g}+\overrightarrow{P_{j} P_{i}}\right)=r_{h}$ for some $h \in\left\{b^{\prime}+1, b^{\prime}+2, \ldots,|r|-1\right\}$. Then $r^{\prime}=r_{0,1, \ldots, b^{\prime}} \operatorname{pos}\left(P_{a^{\prime}+1, a^{\prime}+2, \ldots, g-1}+\vec{P}_{j} P_{i}\right) r_{h, h+1, \ldots,|r|-1}$ turns right from $r$ by definition of $a^{\prime}$ and $b^{\prime}{ }^{13}$ This right turn contradicts the definition of $r$ as the most right-priority binding-graph path that starts at $r_{0}$, ends adjacent to $l^{k}\left(r_{|r|-1}\right.$ is horizontal distance $\pm 0.5$ from $l^{k}$ ), and whose embedding stays entirely in $\mathcal{C}$.
- If $P_{a^{\prime}+1, a^{\prime}+2, \ldots, k}+\vec{P}_{j} P_{i}$ intersects $r_{0,1, \ldots, b^{\prime}-1}$, then let $g \in\left\{a^{\prime}+1, a^{\prime}+2, \ldots, k\right\}$ be the smallest index such that $\operatorname{pos}\left(P_{g}+\overrightarrow{P_{j} P_{i}}\right)=r_{h}$ for some index $h \in\left\{0,1, \ldots, b^{\prime}-1\right\}$, and let $r^{\prime}=r_{0,1, \ldots, h} \operatorname{pos}\left(\left(P_{a^{\prime}+1, a^{\prime}+2, \ldots, g-1}+\overrightarrow{P_{j} P_{i}}\right)^{\leftarrow}\right) r_{b^{\prime}, b^{\prime}+1, \ldots,|r|-1} 1415$
Since $\operatorname{pos}\left(\right.$ glue $\left.\left(P_{a^{\prime}} P_{a^{\prime}+1}\right)+\vec{P}_{j} P_{i}\right) \in \mathcal{R} \backslash \mathfrak{E}[r]$, then $r^{\prime}$ turns right from $r$. Also, $\mathfrak{E}\left[r^{\prime}\right]$ is in $\mathcal{R} \subseteq \mathcal{C}$, since $\mathfrak{E}\left[P_{a^{\prime}+1, a^{\prime}+2, \ldots, g-1}+\overrightarrow{P_{j} P_{i}}\right] \leftarrow$ does not intersect $\mathfrak{E}[r]$ and all other points of $\mathfrak{E}\left[r^{\prime}\right]$ are in $\mathcal{R}$ since they are taken from $\mathfrak{E}[r]$ (plus two length 1 line segments that are in $\mathcal{R}$ ). Moreover, $r^{\prime}$ starts and ends at the same positions as $r$ does, which contradicts the definition of $r$ as the most right priority such path.
In all cases we contradict the existence of the intersection point $Z$ on $\rho$, and hence $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ does not turn left from $d$ at a position on $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}\right]$.

3. $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$ at a position on $\left[l^{j}(0), \operatorname{pos}\left(P_{j+1}\right)\right]$ : since $r$ is a binding path in graph $G$, this can only happen at a tile position, i.e., at $\operatorname{pos}\left(P_{j+1}\right)$, and this case was already covered in Case 2.
4. $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$ at a position on concat $\left(\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$. If $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$ at $\operatorname{pos}\left(P_{k}\right)$ this was already covered in Case 2. By Hypothesis 3 of Definition 7, $P$ may only intersect $l^{k}+\vec{P}_{j} P_{i}$ at $l^{k}(0)+\overrightarrow{P_{j} P_{i}}$, and by Hypothesis 2 of Definition 78 may only intersect $l^{k}$ at $l^{k}(0)$. Therefore, $P$ and $P+\overrightarrow{P_{j} P_{i}}$
${ }^{13}$ In the special case of $g=a^{\prime}+1$, although $\operatorname{pos}\left(P_{a^{\prime}+1, a^{\prime}+2, \ldots, g-1}+\vec{P}_{j} P_{i}\right)$ is empty, the segment $\left[r_{b^{\prime}}, r_{h}\right]$ is not entirely on $\mathfrak{E}[r]$ (only its endpoints are). This follows from the fact that $b^{\prime}<h$, i.e., $b^{\prime} \neq h$ (due to the existence of the turn from $r$ at $r_{b^{\prime}}$ ). Moreover, $\left[r_{b^{\prime}}, r_{h}\right]$ is entirely in $\mathcal{R} \subset \mathcal{C}$ since $r_{b^{\prime}-1, b^{\prime}, h}$ is a right turn from $r$ at $r_{b^{\prime}}$.
${ }^{14}$ Here the "reverse arrow" notation applied to a path denotes the path in reverse order, i.e. $\left(P_{a^{\prime}, a^{\prime}+1, \ldots, g-1}\right)^{\leftarrow}+$ $\overrightarrow{P_{j} P_{i}}=P_{g-1} P_{g-2} \ldots P_{a^{\prime}+1} P_{a^{\prime}}+\overrightarrow{P_{j} P_{i}}$.
${ }^{15}$ In the special case of $g=a^{\prime}+1$, although $\operatorname{pos}\left(\left(P_{a^{\prime}+1, a^{\prime}+2, \ldots, g-1}+\vec{P}_{j} P_{i}\right)^{\leftarrow}\right)$ is empty, the segment $\left[r_{h}, r_{b}\right]$ is not entirely on $\mathfrak{E}[r]$ (although its endpoints are). This follows from the fact that $h<b^{\prime}$, i.e., $h \neq b^{\prime}$ (due to the existence of the turn from $r$ at $r_{h}$ ). Moreover, the segment $\left[r_{h}, r_{b^{\prime}}\right]$ is entirely in $\mathbb{R} \subset \mathbb{C} \operatorname{since} r_{h-1, h, b^{\prime}}$ is a right turn from $r$ at $r_{h}$.
can only intersect $l^{k}+\overrightarrow{P_{j} P_{i}}$ at $l^{k}(0)+\overrightarrow{P_{j} P_{i}}$, and $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ can only intersect $l^{k}$ at $l^{k}(0)$, thus for all $z \in \mathbb{R}, z>0$ the left turn does not occur at $l^{k}(z)$.
It remains to handle the case of the left turn of $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ from $d$ being along the half-open segment $\left(\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right]$. Since $r$ is a binding path in graph $G$, an intersection of $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ and $l^{k}(0)=\operatorname{pos}\left(\operatorname{glue}\left(P_{k} P_{k+1}\right)\right)$ can only occur if $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ contains exactly one of the unit-length horizontal line segments $\left[\operatorname{pos}\left(P_{k+1}\right), \operatorname{pos}\left(P_{k}\right)\right]$ or $\left[\operatorname{pos}\left(P_{k}\right), \operatorname{pos}\left(P_{k+1}\right)\right]$. There are two cases.

- If glue $\left(P_{k} P_{k+1}\right)$ points to the east, then $\left[\operatorname{pos}\left(P_{k+1}\right), \operatorname{pos}\left(P_{k}\right)\right]$ is not (does not contain) a left turn from concat $\left(\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$, and $\left[\operatorname{pos}\left(P_{k}\right), \operatorname{pos}\left(P_{k+1}\right)\right]$ is a right turn, from concat $\left(\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$. Thus, in this case we contradict that $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$ at a point on concat $\left(\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$.
- Else glue $\left(P_{k} P_{k+1}\right)$ points to the west. Since $\left[\operatorname{pos}\left(P_{k+1}\right), \operatorname{pos}\left(P_{k}\right)\right]$ is not (does not contain) a left turn from concat $\left(\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$ and since $\left[\operatorname{pos}\left(P_{k}\right), \operatorname{pos}\left(P_{k+1}\right)\right]$ is a left turn from concat $\left(\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$, we know that $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ contains $\left[\operatorname{pos}\left(P_{k}\right), \operatorname{pos}\left(P_{k+1}\right)\right]$. Thus $\mathfrak{E}[r]$ contains the segment $s=\left[\operatorname{pos}\left(P_{k}\right), \operatorname{pos}\left(P_{k+1}\right)\right]+\vec{P}_{j} P_{i}$. The segment $s$ is entirely in $\mathcal{C}$ because $\mathfrak{E}[r]$ is (by definition of $r$ ). We also claim that the segment $s$ has no points in $\mathcal{C} \backslash c$ : By Claim 3.4, the midpoint of $s$ is not in $\mathcal{C} \backslash c$, and hence that midpoint is on $c$. The segment $s$ is not on $l^{i}$ nor $l^{k}$ (because $\mathfrak{E}[r]$ does not intersect $l^{i}$ nor $\left.l^{k}\right)$. Hence the midpoint of $s$ is on $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$, a curve whose unit length horizontal segments start and end at integer coordinates and thus $s$ has all of its points on $c$. By Claim [3.10, $s$ (a segment of $\mathfrak{E}[r]$ ) and $\mathfrak{E}\left[P_{i+1, \ldots, k}\right]$ have the same curve-direction (points along both curves occur in the same order).
We claim that $s$ being a segment of $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ yields a contradiction: Since $s$ is a horizontal segment "pointed" to the west, $l^{k}+\overrightarrow{P_{j} P_{i}}$ is a right turn from $s$. But $l^{k}(z)+\vec{P}_{j} P_{i}$, for all $z \in \mathbb{R}, z>0$ is on the left hand side of $c$, and thus $l^{k}+{\overrightarrow{P_{j} P}}$ is a left turn from $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$, yielding the claimed contradiction. Thus $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ does not turn left from $d$ at a point on concat $\left(\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$.
Each of the four cases contradicts the claim that $\mathfrak{E}[r]+\overrightarrow{P_{i} P_{j}}$ turns left from $d$.
The path $R$. We now define a path $R$ capable of growing in two translations, as stated in the following claim:

Claim 3.14. There is a path $R$ such that all of the following hold:

- $P_{0,1, \ldots, i} R$ is a producible path, and
- $P_{0,1, \ldots, j}\left(R+\overrightarrow{P_{i} P_{j}}\right)$ is a producible path, and
- Exactly one of the following is the case:
$-\operatorname{pos}(R)=r$, and $R$ does not conflict with $P_{i+1, i+2, \ldots, k}$ nor $P_{j+1, j+2, \ldots, k}+{\overrightarrow{P_{j} P}}_{i}$.
- $\operatorname{pos}(R)$ is a strict prefix of $r$ and $R$ or $R+\overrightarrow{P_{i} P_{j}}$ (or both) conflict with $P$, meaning in particular that $P$ is fragile.
Proof. We first define the length $s_{0}$ of $R$. If there is an integer $s \in\{0,1, \ldots,|r|-1\}$ such that $r_{s}=\operatorname{pos}\left(P_{a}\right)=\operatorname{pos}\left(P_{b}+\overrightarrow{P_{j} P_{i}}\right)$ for some $a \in\{i+1, i+2, \ldots, k\}$ and $b \in\{j+1, j+2, \ldots, k\}$, and type $\left(P_{a}\right) \neq \operatorname{type}\left(P_{b}\right)$, then let $s_{0}$ be the smallest such $s$ (and note that, in this case $s_{0}$ is an index on $r$ and $r_{s_{0}}$ is the position of the conflict). Else, we simply let $s_{0}=\mid r 16$.

We next define $R$ to be of length $s_{0}$, and for all $s \in\left\{0,1, \ldots, s_{0}-1\right\}$, we define the tile $R_{s}$ as follows:

- If there is an index $a \in\{i+1, i+2, \ldots, k\}$ such that $r_{s}=\operatorname{pos}\left(P_{a}\right)$ then we let $R_{s}=P_{a}$.
- Else, by definition of $r$, there is an index $a$ such that $r_{s}=\operatorname{pos}\left(P_{a}\right)+\overrightarrow{P_{j} P_{i}}$. In this case, we let $R_{s}=P_{a}+\overrightarrow{P_{j} P_{i}}$.

Regardless of whether or not $s_{0}<|r|$, we prove the following two claims:

- First, we claim that $P_{0,1, \ldots, i} R$ is a producible path:
- We claim that the glues along $R$ match: indeed, by definition of the graph $G$ in which $r$ is a path, for any $a \in\{0,1, \ldots,|r|-2\}$, there is an edge $\left\{r_{a}, r_{a+1}\right\}$ in $G$. Moreover, since $\operatorname{asm}\left(P_{i+1, i+2, \ldots, k}\right)$ and $\operatorname{asm}\left(P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}\right)$ agree on all tiles that happen to share positions of $r_{0,1, \ldots, s_{0}-1}$ the glues along $R$ match.
- Moreover, we claim that $P_{0,1, \ldots, i} R$ is simple and producible: indeed, by definition of $r$, and since the positions of $R$ are exactly $r$ (i.e., $\operatorname{pos}(R)=r$ ), $R$ is entirely in $\mathcal{C}$, and since neither $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ has no tile in $\mathcal{C}$ (Claim (3.3), $\sigma \cup P_{0,1, \ldots, i}$ does not conflict with $R$. Finally, since $P_{i}$ and $R_{0}=P_{i+1}$ interact, $P_{0,1, \ldots, i} R$ is a producible path.
- Next, we claim that $P_{0,1, \ldots, j}\left(R+\vec{P}_{i} P_{j}\right)$ is also a producible path. First, we already proved in the previous bullet that $R$ has matching glues and is simple. By Claim 3.13, $R$ is in $\mathcal{D}$ (note that if $\mathcal{D}$ is not correctly defined, i.e. $j=k$, then $P$ is pumpable by lemma 3.11), and since $\sigma \cup P_{0,1, \ldots, j}$ is in $\mathbb{R}^{2} \backslash \mathcal{D}$ (Claim 3.12), $R+\overrightarrow{P_{i} P_{j}}$ does not intersect $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, j}\right)$. Moreover this implies that $P_{0,1, \ldots, j}\left(R+\overrightarrow{P_{i} P_{j}}\right)$ is simple. Finally, since $P_{j}$ and $R_{0}+\overrightarrow{P_{i} P_{j}}=P_{j+1}$ interact, $P_{0,1, \ldots, j}\left(R+\overrightarrow{P_{i} P_{j}}\right)$ is producible.
- Finally, $R$ conflicts with neither $P_{i+1, i+2, \ldots, k}$ and $P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}$ since by the definition of $R$ the index $s_{0}$ (the first index of a potential tile conflict along the positions of $r$ ) is not an index on $R$.

Then, there are two cases, depending on whether $s_{0}=|r|$ or $s_{0}<|r|$ :

- If $s_{0}=|r|$, we are done, since in this case $\operatorname{pos}(R)=r$, and we have already proved the other three conclusions of this lemma for the case where we are not showing $P$ to be fragile.
- Else $s_{0}<|r|$, and we claim that $P$ is fragile. By the definition of $r_{s}$ we have that $P_{i+1, i+2, \ldots, k}$ and $P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}$ have a conflict at position $r_{s_{0}}$. There are two cases:

1. $r_{s_{0}-1}=\operatorname{pos}\left(P_{a}\right)+\overrightarrow{P_{j} P_{i}}$ for some $a \in\{j+1, j+2, \ldots, k\}$ (an example is shown in Figure 3.9). In this case, we first grow $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i} R\right)$ (we have already proved that $P_{0,1, \ldots, i} R$ is a producible path). We claim we can producibly place the tile $P_{a+1}+\vec{P}_{j} P_{i}$ :

[^12]

Figure 3.9: We are in the case where $s_{0}<|r|$ and $r_{s_{0}-1}=\operatorname{pos}\left(P_{a}\right)+\vec{P}_{j} P_{i}$. To show that $P$ is fragile, we first produce $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ (not shown), then produce $R$ (red tiles) and then we place the tile $P_{a+1}+\vec{P}_{j} P_{i}($ marked $\times)$ at the position $r_{s_{0}}$. The path $P$, shown in brown, can not be grown from this assembly due to the conflict at $\times$.
$-\operatorname{pos}\left(P_{a+1}+\overrightarrow{P_{j} P_{i}}\right)=r_{s_{0}}$, and thus $P_{a+1}+\vec{P}_{j} P_{i}$ interacts (has a matching abutting glue) with $P_{a}+\overrightarrow{P_{j} P_{i}}=R_{|R|-1}$ which is at position $r_{s_{0}-1}$,
$-P_{a+1}+\vec{P}_{j} P_{i}$ conflicts with $P_{i+1, i+2, \ldots, k}$ and hence does not share any position of a tile of $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ (since $P_{i+1, i+2, \ldots, k}$ does not intersect $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ by the definition of producible path), and

- since $r$ is simple that position is not occupied by any other tile of $R$.

By the definition of $s_{0}$, the tile $P_{a+1}+\vec{P}_{j} P_{i}$ conflicts with $P_{i+1, i+2, \ldots, k}$, which shows that $P$ is fragile.
2. Else, $r_{s_{0}-1}=\operatorname{pos}\left(P_{a}\right)$ for some $a \in\{i+1, i+2, \ldots, k\}$ (an example is shown in Figure 3.10). We first grow $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, j}\left(R+\overrightarrow{P_{i} P_{j}}\right)\right)$ (which we have shown is producible). We claim we can then producibly place the tile $P_{a+1}+\overrightarrow{P_{i} P_{j}}$ :
$-\operatorname{pos}\left(P_{a+1}+\overrightarrow{P_{i} P_{j}}\right)=r_{s_{0}}+\overrightarrow{P_{i} P_{j}}$ and thus $P_{a+1}+\overrightarrow{P_{i} P_{j}}$ interacts (has a matching abutting glue) with $P_{a}+\overrightarrow{P_{i} P_{j}}=R_{|R|-1}+\overrightarrow{P_{i} P_{j}}$ which is at position $r_{s_{0}-1}$,
$-P_{a+1}+\overrightarrow{P_{i} P_{j}}$ conflicts with $P_{j+1, j+2, \ldots, k}$ and hence does not share any position of a tile of $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, j}\right)$, (since $P_{j+1, j+2, \ldots, k}$ does not intersect $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, j}\right)$ by the definition of a producible path), and

- since $r$ is simple $\operatorname{pos}\left(P_{a+1}\right)+\overrightarrow{P_{i} P_{j}}$ is not occupied by any other tile of $R+\overrightarrow{P_{i} P_{j}}$.

By the definition of $s_{0}$, the tile $P_{a+1}$ conflicts with $P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}$ thus $P_{a+1}+\overrightarrow{P_{i} P_{j}}$ conflicts with $P_{j+1, j+2, \ldots, k}$, which shows that $P$ is fragile.

In either Case 1 or 2, $P$ is fragile.

Figure 3.10: Left: We are in the case where $s_{0}<|r|$ and $r_{s_{0}-1}=\operatorname{pos}\left(P_{a}\right)$. Right: We first grow $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ (not shown), then we grow $\operatorname{asm}\left(P_{i+1, i+2, \ldots, j}\left(R+\overrightarrow{P_{i} P_{j}}\right)\right)$ (red tiles), and then $P_{a+1}+\overrightarrow{P_{i} P_{j}}$ (marked with a $\times$ ). $P_{j+1, j+2, \ldots, k}$ is shown in brown and can not grow from this assembly due to the conflict at $\times$.

### 3.2.4 Using $m_{0}$ and $R$ to define $u_{0}$ and $v_{0}$

Using the index $m_{0}$ from Subsection 3.2.1, and the path $R$ from Subsection 3.2 .3 we prove the following claim (illustrated with an example in Figure 3.11):

Claim 3.15. If $|R|=|r|$ (i.e. if $R$ does not conflict with $P_{i, i+1, \ldots, k}$ nor with $P_{j, j+1, \ldots, k}+\overrightarrow{P_{i} P_{j}}$ ), there are two indices $u_{0}$ and $v_{0}$ satisfying all of the following conditions:

1. $i+1 \leq u_{0} \leq m_{0} \leq v_{0}$, and
2. $P_{u_{0}}=P_{v_{0}}+\vec{P}_{j} P_{i}$, and
3. $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{C}^{+}$, and
4. $\left(P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}\right) \cap P_{i+1, i+2, \ldots, k}=\left\{P_{v_{0}}\right\}$.

Proof. We first claim that $P_{m_{0}}$ is a tile of $R$, and moreover that $\mathfrak{E}[R] \cap L^{m_{0}}=\left\{L^{m_{0}}(0)\right\}=$ $\left\{\operatorname{pos}\left(P_{m_{0}}\right)\right\}$. By definition of $R, R_{0}=P_{i+1}$, and since $l^{i}$ is strictly to the west of $L^{m_{0}}$ (by Claim 3.8 and since $x \xrightarrow[P_{i} P_{j}]{ }>0$ meaning $l^{i}$ is to the west of $l^{j}$ ), since $m_{0}>i+1$ (Claim 3.5), and by the definition of $\mathcal{C}^{+}$(Subsection 3.2.2), $\operatorname{pos}\left(P_{i+1}\right) \notin \mathcal{C}^{+}$. By definition of $r, \operatorname{pos}\left(R_{|R|-1}\right) \in \mathcal{C}$.

We also claim that $\operatorname{pos}\left(R_{|R|-1}\right) \in \mathcal{C}^{+}$. Indeed, assume for the sake of contradiction that $\operatorname{pos}\left(R_{|R|-1}\right) \in \mathcal{C}^{-}$. However, $l^{k}$ is in $\mathcal{C}^{+}$, and $\operatorname{pos}\left(R_{|R|-1}\right)$ is at a horizontal distance 0.5 to the east or to the west of $l^{k}$ and is in $\mathcal{C}$ (by definition of $r$ ). Then the horizontal segment from $R_{|R|-1}$ to $l^{k}$ crosses $L^{m_{0}}$, and since $L^{m_{0}}$ is on a tile column, the only position where that can happen is at $R_{|R|-1}$, contradicting our assumption. Therefore, $R_{|R|-1} \in \mathcal{C}^{+}$.

Now, since $\mathfrak{E}[R]$ is entirely in $\mathcal{C}$ (by definition of $r$ ) and has a position in $\mathcal{C}^{-}$and another one in $\mathcal{C}^{+}, R$ intersects the border of $\mathcal{C}^{+}$. Moreover, that intersection happens on $L^{m_{0}}$ since $L^{m_{0}}$ partitions $\mathcal{C}$ into $\mathcal{C}^{-}$and $\mathcal{C}^{+}$(Subsection 3.2.2). However, since $R$ is composed only of segments of $P_{i+1, i+2, \ldots, k}$ and $P_{j+1, j+2, \ldots, k}+{\overrightarrow{P_{j} P}}, \mathfrak{E}[R]$ cannot intersect $L^{m_{0}}$ strictly below $L^{m_{0}}(0)=\operatorname{pos}\left(P_{m_{0}}\right)$, because by Claim 3.6, $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ can only intersect $L^{m_{0}}$ at $L^{m_{0}}(0)$, and $\mathfrak{E}\left[P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}\right]$ does not intersect $L^{m_{0}}$ (because by Claim 3.6, $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$ does not intersect $\left.L^{m_{0}}+\overrightarrow{P_{i} P_{j}}\right)$. Therefore, $R$ intersects $L^{m_{0}}$ at position $L^{m_{0}}(0)$, and hence $P_{m_{0}}$ is also a tile of $R$. Let $b \in\{0,1, \ldots,|R|-1\}$ be the index such that $R_{b}=P_{m_{0}}$.

We now define the index $v_{0}$ to be used in the statement of this claim: let $a \in\{0,1, \ldots, b-1\}$ be the largest index such that there is an index $v_{0} \in\{i+1, i+2, \ldots, k\}$ such that $R_{a}+\overrightarrow{P_{i} P_{j}}=P_{v_{0}}$. Indices $a$ and $v_{0}$ exist because with $a=0$ and $v_{0}=j+1$, we have $R_{0}+\overrightarrow{P_{i} P_{j}}=P_{i+1}+\overrightarrow{P_{i} P_{j}}=P_{j+1}$ (this equality holds by the definition of $R$ at the beginning of the proof of Claim 3.14, and by the final conclusion of Claim 3.14 which states that there are no conflicts between $R$ and $P_{i+1, i+2, \ldots, k}$, and no conflicts between $R$ and $P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}$ ).

Next, we define the index $u_{0}$ to be used in the statement of this claim: $R_{a+1, a+2, \ldots, b}+\overrightarrow{P_{i} P_{j}}$ does not intersect $P_{i+1, i+2, \ldots, k}$ (by definition of $a$ and $b$ ), therefore $R_{a+1, a+2, \ldots, b}$ does not intersect $P_{j+1, j+2, \ldots, k}+\vec{P}_{j} P_{i}$ either. Hence, $R_{a+1, a+2, \ldots, b}$ is a segment of $P$ (because $R$ is only composed of segments of $P_{i+1, i+2, \ldots, k}$ and segments of $P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}$ ), and moreover $R_{a}$ is both a tile of $P_{i+1, i+2, \ldots, k}$ and a tile of $P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}$. We then define $u_{0} \in\{i+1, i+2, \ldots, k\}$ to be the index such that $R_{a}=P_{u_{0}}$. By Claim 3.10, since $a<b$ and $R_{b}=P_{m_{0}}$, this means that $u_{0}<m_{0}$, and we get Conclusion 2,

Figure 3.11: Definition of $u_{0}$ and $v_{0}$. The path $R_{a, a+1, \ldots, b}+\overrightarrow{P_{i} P_{j}}$ is shown in red and shares its start position $\operatorname{pos}\left(R_{a}\right)$ with the tile $P_{v_{0}}$. Also, in the example, it can be seen that $\operatorname{pos}\left(P_{u_{0}}\right)=\operatorname{pos}\left(R_{a}\right)$. In the proof of Claim 3.15 we find that $R_{a, a+1, \ldots, b}=P_{u_{0}, u_{0}+1, \ldots, m_{0}}$, and we go on to show that $u_{0} \leq m_{0} \leq v_{0}$, $P_{u_{0}}=P_{v_{0}}+\overrightarrow{P_{j} P_{i}}$, and $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}^{+}$.

Then, we claim that $v_{0} \geq m_{0}$ and that $R_{a, a+1, \ldots, b}+\overrightarrow{P_{i} P_{j}}=P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}^{+}$. There are two cases:

- If $m_{0}>j, L^{m_{0}}$ is entirely in $\mathcal{D}$, since $L^{m_{0}}$ is then a right turn from curve $d$. Therefore, $\mathcal{C}^{+} \subseteq \mathcal{D}$. By Claim 3.6, $P_{m_{0}}+\overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}^{+}$. Moreover, by Claim 3.8, $L^{m_{0}}+{\overrightarrow{P_{j} P}}^{\prime}$ does not intersect $P_{i+1, i+2, \ldots, k}$, except possibly at $L^{m_{0}}(0)+{\overrightarrow{P_{j} P} P_{i}}$, hence $L^{m_{0}}$ does not intersect $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$, except possibly at $L^{m_{0}}(0)=\operatorname{pos}\left(P_{m_{0}}\right)$ (and in this case, $\operatorname{pos}\left(P_{m_{0}}\right)=$ $\operatorname{pos}\left(P_{u_{0}}\right)+\overrightarrow{P_{i} P_{j}}$ and $\left.m_{0}=v_{0}\right)$. Thus, $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ does not turn left from $L^{m_{0}}$.
Therefore, since by Claim 3.13, $R_{a, a+1, \ldots, b}+\overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{D}$, then $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{D}$. Then, $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ does not turn left from $\mathfrak{E}\left[P_{m_{0}, m_{0}+1, \ldots, k}\right]$ or from $l^{k}$. This implies that $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ is inside $\mathcal{C}^{+}$and that $P_{v_{0}}$ is a tile of $P_{m_{0}, m_{0}+1, \ldots, k}$ (which
is the only part of $P$ on the border of $\mathcal{C}^{+}$), and hence that $v_{0} \geq m_{0}$, showing Conclusions $\mathbb{1}$ and 3. Since $v_{0}$ was chosen as a largest index, we also get Conclusion 4 .
- If $m_{0} \leq j$, then $\mathcal{D} \subseteq \mathcal{C}^{+}$. Similarly as the previous case, by Claim 3.13, $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ is inside $D \subset \mathcal{C}^{+}$, hence we have Conclusion 3. In particular, $\operatorname{pos}\left(P_{u_{0}}+\overrightarrow{P_{i} P_{j}}\right)=\operatorname{pos}\left(P_{v_{0}}\right)$ is in $\mathcal{D}$. Since the only part of $P_{i+1, i+2, \ldots, k}$ that is in $\mathcal{D}$ is $P_{j+1, j+2, \ldots, k}$, this means that $v_{0} \geq j+1>m_{0}$ showing Conclusion 1. Since $v_{0}$ was chosen as a largest index, we also get Conclusion 4

### 3.3 Proof of Lemma 3.1

We restate Lemma 3.1 and give its proof.
Lemma 3.1, Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$, such that $(i, j, k)$ is a shield for $P$ (see Definition (7). Then $P$ is pumpable with pumping vector $\overrightarrow{P_{i} P_{j}}$, or $P$ is fragile.

Moreover, if $P$ is fragile, there is a path $Q$, entirely contained in the workspace of shield $(i, j, k)$ (see Definition (8) , such that $P_{0,1, \ldots, i} Q$ is a producible path and conflicts with $P_{i+1, i+2, \ldots, k}$.
Proof. As noted at the beginning of Section 3, without loss of generality, we suppose that the last tile of $P$ is $P_{k+1}$, i.e. that $P=P_{0,1, \ldots, k+1}$. We prove this lemma by induction on a triple ( $u_{n}, m_{n}, v_{n}$ ) of indices of $P$ and a curve $f_{n}$.

We first apply Claim 3.14 to $P$ and shield $(i, j, k)$. If $|R|<|r|$, this yields the conclusion that $P$ is fragile, with a path that satisfies the conclusion of this lemma and we are done with the proof. Otherwise, we assume until the end of this proof that $|R|=|r|$, and $R$ conflicts with neither $P_{i+1, i+2, \ldots, k}$ nor with $P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}$.

Induction hypothesis. The induction hypothesis is that for all natural numbers $n \geq 0$, the following four conditions are satisfied (we recall some notation: $i, j, k, l^{k}$ were defined in Definition 7 and $l^{i}, l^{j}$ immediately after it; $c$ and $\mathcal{C}$ were defined in Definition 娄 $P_{m_{0}}, L^{m_{0}}$ were introduced in Subsection 3.2):
H1 $f_{n}$ is a simple curve, and is the concatenation of: (a) $L^{m_{0} \leftarrow}+s_{n} \overrightarrow{P_{i} P_{j}}$ for some natural number $s_{n} \geq 0$, and (b) a curve that is the concatenation of embeddings of translations of segments ${ }^{17}$ of $P_{i+1, i+2, \ldots, k}$ and that connects $L^{m_{0}}(0)+s_{n} \overrightarrow{P_{i} P_{j}}$ to $\operatorname{pos}\left(P_{m_{n}}\right)$.
H2 $f_{n}$ is entirely in $\mathcal{C}$ and intersects $c$ exactly once, at the endpoint $\operatorname{pos}\left(P_{m_{n}}\right)$ of $f_{n}$.
H 3 for all integers $u>0, f_{n}+u \overrightarrow{P_{i} P_{j}}$ intersects neither $f_{n}$ nor $c$.
H4 $u_{n} \leq m_{n} \leq v_{n}$ and $\mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, m_{n}}\right]+\vec{P}_{i} P_{j}$ intersects $c$ exactly once, at $\operatorname{pos}\left(P_{u_{n}}\right)+\overrightarrow{P_{i} P_{j}}=$ $\operatorname{pos}\left(P_{v_{n}}\right)$, and intersects $g_{n}$ only at that position, where $g_{n}$ is the curve defined by:

$$
g_{n}=\operatorname{concat}\left(f_{n}, \mathfrak{E}\left[P_{m_{n}, m_{n}+1, \ldots, k}\right],\left[P_{k}, l^{k}(0)\right], l^{k}\right)
$$

Special case. Sometimes, we need to consider some cases whereH1, H2, H3 and $u_{n} \leq m_{n} \leq$ $v_{n}$ hold, but where $v_{n}=k, P_{u_{n}}+\overrightarrow{P_{i} P_{j}}=P_{k}$ and $\operatorname{pos}\left(P_{u_{n+1}}\right)+\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{k+1}\right)$ (which can

[^13]occur only if glue $\left(P_{k} P_{k+1}\right)$ points to the east) and in this case, $P_{u_{n}, u_{n}+1, \ldots, m_{n}}+\overrightarrow{P_{i} P_{j}}$ intersects $c$ only at $\left[P_{k}, l^{k}(0)\right]$. We now prove that $P$ is pumpable in such a case by considering the curve:
$$
\rho=\operatorname{concat}\left(f_{n}, \mathfrak{E}\left[P_{u_{n}+1, u_{n}+2, \ldots, m_{n}}\right]^{\leftarrow},\left[P_{u_{n}+1}, l^{k}(0)+\overrightarrow{P_{j} P_{i}}\right], l^{k}+\overrightarrow{P_{i} P_{j}}\right)
$$

By Theorem B.3, $\rho$ partitions the plane $\mathbb{R}^{2}$ into two connected components. Note that for all $t \geq 0, \rho+t \overrightarrow{P_{i} P_{j}}$ does not intersect $\rho+(t+1) \overrightarrow{P_{i} P_{j}}$. Moreover, since $l^{k}$ does not intersect $\rho$ then $l^{k}$ is in the right hand-side of this curve (and then in particular $l^{k}(0)$ and $P_{k}$ ). Thus $P_{u_{n+1}, u_{n+2}, \ldots, v_{n}}$ is in the right-hand side of $\rho$. Now note that for all $t>0$, the right-hand side of $\rho+t \overrightarrow{P_{i} P_{j}}$ is included into $\mathcal{C}$ and $\sigma \cup P$ has no tile in the right-hand side of $\rho+t \overrightarrow{P_{i} P_{j}}$. In particular, for $t=1$ this means that $P_{u_{n+1}, u_{n+2}, \ldots, v_{n}}$ is in the strict left-hand side of $\rho+\overrightarrow{P_{i} P_{j}}$. Thus for all $t, P_{u_{n+1}, u_{n+2}, \ldots, v_{n}}+t \overrightarrow{P_{i} P_{j}}$ is in the right hand-side of $\rho$ and in the strict left-hand side of $\rho+(t+1) \overrightarrow{P_{i} P_{j}}$. Since $P_{v_{n}}+t \overrightarrow{P_{i} P_{j}}$ and $P_{u_{n+1}+(t+1) \overrightarrow{P_{i} P_{j}}}$ interact, this means that $P$ is pumpable.

Initialisation $(n=0)$. We initialise the induction by applying Claim 3.15 to $P$ to get $i+1 \leq u_{0} \leq m_{0} \leq v_{0}$, and by letting $f_{0}=L^{m_{0} \leftarrow}$. We show that the induction hypothesis is indeed satisfied for $\left(u_{0}, m_{0}, v_{0}\right)$ and $f_{0}$.

H1 $f_{0}$ is indeed equal to $L^{m_{0}} \leftarrow$ (i.e. $s_{0}=0$ ) concatenated with a zero length segment of $P_{i+1, i+2, \ldots, k}$ (i.e. $\operatorname{pos}\left(P_{m_{0}}\right)$ ), and $f_{0}$ ends at $\operatorname{pos}\left(P_{m_{0}}\right)$.
H2 By Claim 3.7, $f_{0}$ is indeed entirely in $\mathcal{C}$. By Claim 3.6 and the fact that $L^{m_{0}}$ is on a column and $l^{i}, l^{k}$ are on glue columns, $f_{0}$ intersects $c$ exactly once, at $\operatorname{pos}\left(P_{m_{0}}\right)$ (which is on $c$ since $\left.i+1 \leq m_{0} \leq k\right)$.
H3 Let $u>0$ be an integer. Since $\mathrm{x}_{\overrightarrow{P_{i} P_{j}}}>0, f_{0}+u \overrightarrow{P_{i} P_{j}}=L^{m_{0}}+u \overrightarrow{P_{i} P_{j}}$ does not intersect $f_{0}=L^{m_{0} \leftarrow}$. Claim 3.6 shows that $L^{m_{0}}+u \overrightarrow{P_{i} P_{j}}$ does not intersect $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$, and since $L^{m_{0}}+u \overrightarrow{P_{i} P_{j}}$ does not intersect $l^{k}$ nor $l^{i}$ (because $L^{m_{0}}+u \overrightarrow{P_{i} P_{j}}$ is on a tile column, and $l^{k}$, $l^{i}$ are on glue columns) we get that $L^{m_{0}} \leftarrow+u \overrightarrow{P_{i} P_{j}}$ does not intersect $c$.
H4 By Claim 3.15, $u_{0} \leq m_{0} \leq v_{0}$ and $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ intersects $P$ exactly once, at $P_{u_{0}}+$ $\overrightarrow{P_{i} P_{j}}=P_{v_{0}}$. Since $m_{0} \leq v_{0} \leq k, P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ intersects $c$ and $g_{0}$ at $\operatorname{pos}\left(P_{v_{0}}\right)$.
We claim that this is the only intersection between $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ and $g_{0}$ : indeed, by Hypothesis 3 of Definition 7, $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ cannot intersect $l^{k}$ or $\left[P_{k}, l^{k}(0)\right]$ (or we are in the special case where $P$ is pumpable). Moreover, by definition of $L^{m_{0}}, P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ can only intersect $f_{0}=L^{m_{0}}$ at position $\operatorname{pos}\left(P_{m_{0}}\right)$, and by the previous argument, this can only happen if $m_{0}=v_{0}$.
Therefore, there is exactly one intersection between $g_{0}$ and $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$, and that intersection is at $\operatorname{pos}\left(P_{v_{0}}\right)$.
Finally, by Claim 3.15, $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{C}^{+}$. Therefore, $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ cannot intersect $l^{i}$ either, which shows that the only intersection between $P_{u_{0}, u_{0}+1, \ldots, m_{0}}+\overrightarrow{P_{i} P_{j}}$ and $c$ is at position $\operatorname{pos}\left(P_{v_{0}}\right)$.

Restricting $\mathcal{C}$. We start by defining a connected component $\mathcal{H}_{n} \subset \mathcal{C}$, so that at least one translation of $P_{u_{n}, u_{n}+1, \ldots, m_{n}}$ by a multiple of $\overrightarrow{P_{i} P_{j}}$ must intersect the border of $\mathcal{H}_{n}$. Let $h_{n}$ be

Figure 3.12: Definition of $u_{n} \leq m_{n} \leq v_{n}$. We have $P_{u_{n}}=P_{v_{n}}+\vec{P}_{j} P_{i}$. The curve $f_{n}$ ends in $m_{n}$ which is the only intersection between $f_{n}$ and $c$.
the curve defined as:

$$
h_{n}=\operatorname{concat}\left(f_{n}+\overrightarrow{P_{i} P_{j}}, \mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, m_{n}}\right]^{\leftarrow}+\overrightarrow{P_{i} P_{j}}, \mathfrak{E}\left[P_{v_{n}, v_{n}+1, \ldots, k}\right],\left[P_{k}, l^{k}(0)\right], l^{k}\right)
$$

The endpoints of the successive parts of that concatenation are equal. Moreover, by H1 $f_{n}$ is a curve, hence $h_{n}$ is also a curve. We now claim that $h_{n}$ is simple, by considering each of its parts in the order of the concatenation, and checking each time that that part does not intersect the remaining parts. First, by $\left[\mathbf{H 2}\right.$, concat $\left(f_{n}+\overrightarrow{P_{i} P_{j}}, \mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, m_{n}}\right]^{\leftarrow}+\overrightarrow{P_{i} P_{j}}\right)=$ $\operatorname{concat}\left(f_{n}, \mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, m_{n}}\right]^{\leftarrow}\right)+\overrightarrow{P_{i} P_{j}}$ is a simple curve. Moreover, by H3 $f_{n}+\overrightarrow{P_{i} P_{j}}$ does not intersect $c$, hence intersects neither $\mathfrak{E}\left[P_{v_{n}, v_{n}+1, \ldots, k}\right],\left[P_{k}, l^{k}(0),\right]$ nor $l^{k}$. And finally, by H4 , the only intersection between $\mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, m_{n}}\right]+\overrightarrow{P_{i} P_{j}}$ and $c$ is at $\operatorname{pos}\left(P_{u_{n}}\right)+\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{v_{n}}\right)$. Finally, since $c$ is a simple curve (by Claim [3.2), so is concat $\left(\mathfrak{E}\left[P_{v_{n}, v_{n}+1, \ldots, k}\right],\left[P_{k}, l^{k}(0)\right], l^{k}\right)$, and therefore, $h_{n}$ is simple.

Also, we claim that $h_{n}$ is entirely in $\mathcal{C}$. Indeed, $\mathfrak{E}\left[P_{v_{n}, v_{n}+1, \ldots, k}\right],\left[P_{k}, l^{k}(0)\right], l^{k}$ are on $c$, the border of $\mathcal{C}$. Moreover, since $f_{n}$ is in $\mathcal{C}(\overline{\mathrm{H} 2})$, and $f_{n}+\overrightarrow{P_{i} P_{j}}$ is to the east of of $f_{n}$ and does not intersect $c$ (H3), we get that $f_{n}+\overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}$. Finally, $f_{n}(0)+\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{m_{n}}\right)+\overrightarrow{P_{i} P_{j}}$ (H2) is in $\mathcal{C}$ and since the only intersection between $\mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, m_{n}}\right]^{\leftarrow}+\overrightarrow{P_{i} P_{j}}$ and $c$ is $\operatorname{pos}\left(P_{u_{n}}\right)+\overrightarrow{P_{i} P_{j}}$ (H4), we get that $\mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, m_{n}}\right]^{\leftarrow}+\overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}$.

Since $h_{n}$ is a simple curve, entirely in $\mathcal{C}$, that begins and ends with a vertical ray, $h_{n}$ partitions $\mathcal{C}$ into two connected components. Let $\mathcal{H}_{n}$ be the connected component on the right-hand side

Figure 3.13: The component $\mathcal{H}_{n}$, whose border $h_{n}$ is defined as the concatenation of $f_{n}+\overrightarrow{P_{i} P_{j}}$, $P_{u_{n}, u_{n}+1, \ldots, m_{n}}+\overrightarrow{P_{i} P_{j}}, P_{v_{n}, v_{n}+1, \ldots, k}$ and $l^{k}$ (and a half-length segment between $P_{k}$ and $\left.l^{k}(0)\right)$.
of $h_{n}$, including $h_{n}$ itself, as shown in Figure 3.13,
Finding $m_{n+1}$ and $f_{n+1}$. Let $a \in\left\{u_{n}, u_{n}+1, \ldots, m_{n}\right\}$ and $t \geq 1$ be the two integers such that $(a, t)$ is the largest pair (ordered first by largest $a$, then by largest $t$ ) such that $\operatorname{pos}\left(P_{a}\right)+t \overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{m_{n+1}}\right)$ for some integer $m_{n+1} \in\{i+1, i+2, \ldots, k\}$. These indices exist because by H4, with $a=u_{n}, m_{n+1}=v_{n}$ and $t=1$, we have $\operatorname{pos}\left(P_{u_{n}}\right)+\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{v_{n}}\right)$.

Using $a$ and $t$, we set $f_{n+1}=\operatorname{concat}\left(f_{n}, \mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]^{\leftarrow}\right)+t \overrightarrow{P_{i} P_{j}}$ (see Figure 3.14).
We claim that for all $s>1, P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{H}_{n}$. Suppose for the sake of contradiction that this is not the case, and let $s>1$ be the smallest integer such that $P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ is not entirely in $\mathcal{H}_{n}$.

We first claim that $f_{n}+s{\overrightarrow{P_{i} P}}_{j}$ is entirely in $\mathcal{H}_{n}$. Indeed, by H3, for all $u \geq 1, f_{n}+u \overrightarrow{P_{i} P_{j}}$ intersects neither $f_{n}$ nor $c$. Therefore, since $s \geq 2, f_{n}+s \overrightarrow{P_{i} P_{j}}$ intersects neither $f_{n}+\overrightarrow{P_{i} P_{j}}$ nor $c+\overrightarrow{P_{i} P_{j}}$ nor $c$, and therefore doesn't intersect $h_{n}$ (since $h_{n}$ is entirely composed of parts of $f_{n}+\overrightarrow{P_{i} P_{j}}, c+\overrightarrow{P_{i} P_{j}}$ and $c$. By H1, the beginning of $f_{n}$ is $L^{m_{0}}+s_{n} \overrightarrow{P_{i} P_{j}}$ for $s_{n} \geq 0$, and hence the beginning of $f_{n}+s \overrightarrow{P_{i} P_{j}}$ is $L^{m_{0}}+\left(s_{n}+s\right) \overrightarrow{P_{i} P_{j}}$, which starts on the right-hand side of $h_{n}$ (because $\mathrm{x}_{\overrightarrow{P_{i} P_{j}}}>0$ ), and doesn't intersect $h_{n}$. Hence, $f_{n}+s \overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{H}_{n}$, as claimed.

Then, we claim that $P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ intersects $h_{n}$. Indeed, since $f_{n}+s \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{H}_{n}$, then $f_{n}(0)+s \overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{m_{n}}\right)+s \overrightarrow{P_{i} P_{j}}$ is also in $\mathcal{H}_{n}$. Therefore, since we assumed $P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$

Figure 3.14: Finding $m_{n+1}$ and $f_{n+1}$ : we let $(a, t)$ be the largest pair of integers such that $\operatorname{pos}\left(P_{a}\right)+$ $t \overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{m_{n+1}}\right)$ for some integer $m_{n+1} \in\{i+1, i+2, \ldots, k\}$, and let $f_{n+1}$ be equal to $f_{n}+t \overrightarrow{P_{i} P_{j}}$, plus $P_{a, a+1, \ldots, m_{n}}+t \overrightarrow{P_{i} P_{j}}$. Here, $t=2$ and $a=u_{n}+3$.
is not completely in $\mathcal{H}_{n}$, this means that $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}\right]$ intersects $h_{n}$. That intersection can only happen on one of the five parts of $h_{n}$ :

1. if $P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ intersects $l^{k}$ at some $l^{k}(z)$ with $z \geq 0$ then we claim that $P_{a, a+1, \ldots, m_{n}}+$ $(s-1) \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{H}_{n}$ : if $s=2$, this is because $P_{a, a+1, \ldots, m_{n}}+\overrightarrow{P_{i} P_{j}}$ is actually part of the border $h_{n}$ of $\mathcal{H}_{n}$, else, $s>2$, and this is because $s$ is minimal.
Moreover, by maximality of $a, P_{a+1}+(s-1) \overrightarrow{P_{i} P_{j}}$ is not on $P_{v_{n}, v_{n}+1, \ldots, k}$. Therefore, $l^{k}(z)+\overrightarrow{P_{j} P_{i}}$ is inside $\mathcal{H}_{n}$ and is not on $\mathfrak{E}\left[P_{v_{n}, v_{n}+1, \ldots, k}\right]$. Since $\mathcal{H}_{n} \subset \mathcal{C}$ and since the only part of $P$ that is in $\mathcal{H}_{n}$ is $\mathfrak{E}\left[P_{v_{n}, v_{n}+1, \ldots, k}\right]$, this means that $l^{k}(z)+{\overrightarrow{P_{j}}}_{j}$ is inside $\mathcal{C}$ and is not on $\mathfrak{E}\left[P_{i+1, i+2, \ldots, k}\right]$. This contradicts Claim 3.4.
2. If $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}\right]^{\leftarrow}$ intersects $P_{v_{n}, v_{n}+1, \ldots, k}$, then $P_{a+1, a+2, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ intersects $P_{v_{n}, v_{n}+1, \ldots, k}$ (because $\operatorname{pos}\left(P_{m_{n}}\right)+s \overrightarrow{P_{i} P_{j}}=f_{n}(0)+s \overrightarrow{P_{i} P_{j}}$ is in $\left.\mathcal{H}_{n}\right)$. However, this contradicts the definition of $a$ as the largest integer such that $\operatorname{pos}\left(P_{a}\right)+t \overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{m_{n+1}}\right)$ for some $m_{n+1}$.
3. If $P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ intersects $f_{n}+\overrightarrow{P_{i} P_{j}}$ then $P_{a, a+1, \ldots, m_{n}}+(s-1) \overrightarrow{P_{i} P_{j}}$ intersects $f_{n}$. We have argued in Point 1 that $P_{a, a+1, \ldots, m_{n}}+(s-1) \overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{H}_{n}$. However, the only point of $f_{n}$ that can be in $\mathcal{H}_{n}$ is $f_{n}(0)=\operatorname{pos}\left(P_{m_{n}}\right)$, which happens only when $m_{n}=v_{n}$.
If $s=2$, this means that $P_{a, a+1, \ldots, m_{n}}+{\overrightarrow{P_{i} P}}_{j}$ intersects $f_{n}$, but the only place where that can happen is at $\operatorname{pos}\left(P_{a}\right)=f_{n}(0)$, which means that $a=u_{n}$. However, by maximality of $a$, this means that for all $t>1, P_{a+1, a+2, \ldots, m_{n}}+t \overrightarrow{P_{i} P_{j}}$ does not intersect $h_{n}$, contradicting our
assumption.
If $s=3, P_{a, a+1, \ldots, m_{n}}+(s-2) \overrightarrow{P_{i} P_{j}}$ intersects $P_{u_{n}}$, which is not in $\mathcal{H}_{n}$, contradicting that $P_{a, a+1, \ldots, m_{n}}+\overrightarrow{P_{i} P_{j}}$ is on the border $h_{n}$ of $\mathcal{H}_{n}$.
Else, $s>3$, and $P_{a, a+1, \ldots, m_{n}}+(s-2) \overrightarrow{P_{i} P_{j}}$ intersects $P_{u_{n}}$, which is not in $\mathcal{H}_{n}$, contradicting the minimality of $s$.
4. If $P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ intersects $P_{u_{n}, u_{n}+1, \ldots, v_{n}}+\overrightarrow{P_{i} P_{j}}$ then $P_{a, a+1, \ldots, m_{n}}+(s-1) \overrightarrow{P_{i} P_{j}}$ intersects $P_{u_{n}, u_{n}+1, \ldots, m_{n}}$.
However, by minimality of $s, P_{a, a+1, \ldots, m_{n}}+(s-1) \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{H}_{n}$, and the only position of $P_{u_{n}, u_{n}+1, \ldots, m_{n}}$ that may be in $\mathcal{H}_{n}$ is $\operatorname{pos}\left(P_{m_{n}}\right)=f_{n}(0)$. Therefore $P_{m_{n}}+s \overrightarrow{P_{i} P_{j}}$ intersects $f_{n}(0)+\overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{m_{n}}\right)+\overrightarrow{P_{i} P_{j}}$, and this case is already covered in Point 3 above.
This shows that for all $s>1, P_{a, a+1, \ldots, m_{n}}+s \overrightarrow{P_{i} P_{j}}$ is entirely in $\mathcal{H}_{n}$ as claimed.
Now, remember that $\operatorname{pos}\left(P_{m_{n+1}}\right)=\operatorname{pos}\left(P_{a}\right)+t \overrightarrow{P_{i} P_{j}}$. This means that $P_{m_{n+1}}$ is in $\mathcal{H}_{n}$. However, the only part of $P$ that is inside $\mathcal{H}_{n}$ is $P_{v_{n}, v_{n}+1, \ldots, k}$, hence $m_{n+1} \geq v_{n} \geq m_{n}$.

Satisfying the induction hypotheses for step $n+1$. Our final step is to prove that either $P$ is pumpable, or we can find two indices $u_{n+1}$ and $v_{n+1}$ (we have already specified the index $m_{n+1}$ and the curve $f_{n+1}$ ) to move on to the next step of the induction. There are two cases:
A If $m_{n+1}=m_{n}$ then we claim that $P$ is pumpable.
Since $P_{a, a+1, \ldots, m_{n}}+t \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{H}_{n}, \operatorname{pos}\left(P_{a}+t \overrightarrow{P_{i} P_{j}}\right)=\operatorname{pos}\left(P_{m_{n+1}}\right)=\operatorname{pos}\left(P_{m_{n}}\right)$ is in $\mathcal{H}_{n}$. However, by definition of $\mathcal{H}_{n}$, the only position of $P_{m_{n}, m_{n}+1, \ldots, v_{n}}$ in $\mathcal{H}_{n}$ is $P_{v_{n}}$, hence $m_{n}=v_{n}$. In this case, $P_{u_{n}, u_{n}+1, \ldots, v_{n}}=P_{u_{n}, u_{n}+1, \ldots, m_{n}}$ and the only position of $P_{u_{n}, u_{n}+1, \ldots, v_{n}}$ that is in $\mathcal{H}_{n}$ is $\operatorname{pos}\left(P_{v_{n}}\right)$. Moreover, $\mathfrak{E}\left[P_{u_{n}, u_{n}+1, \ldots, v_{n}}\right]+\vec{P}_{i} P_{j}$ is on the border of $\mathcal{H}_{n}$, which implies that the only intersection between $P_{u_{n}, u_{n}+1, \ldots, v_{n}}$ and $P_{u_{n}, u_{n}+1, \ldots, v_{n}}+\overrightarrow{P_{i} P_{j}}$ is $\operatorname{pos}\left(P_{v_{n}}\right)=$ $\operatorname{pos}\left(P_{u_{n}}\right)+\overrightarrow{P_{i} P_{j}}$. By Lemma B.1, this means that for all $s>2, P_{u_{n}, u_{n}+1, \ldots, v_{n}}+s{\overrightarrow{P_{i} P_{j}}}^{\text {does }}$ not intersect $P_{u_{n}, u_{n}+1, \ldots, v_{n}}$. Therefore, $t=1$ and $a=u_{n}$.
By definition of $a$, we have for all $s \geq 1, P_{u_{n}, u_{n}+1, \ldots, v_{n}}+s \vec{P}_{i} P_{j}$ is in $\mathcal{H}_{n} \subset \mathcal{C}$, this means that the pumping of $P$ between $u_{n}$ and $v_{n}$ is simple (since $\sigma \cup \operatorname{asm}\left(P_{0,1, \ldots, i}\right)$ is not in $\mathcal{C}$ and by Lemma B.1), and hence that $P$ is pumpable, and we are done: indeed, that is one of the conclusions of this lemma.
B Else $m_{n+1}>m_{n}$. We already defined $f_{n+1}=\operatorname{concat}\left(f_{n}, \mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]^{\leftarrow}\right)+t \overrightarrow{P_{i} P_{j}}$. We let $s_{n+1}=s_{n}+t$. We will define $u_{n+1}$ and $v_{n+1}$, and prove that the induction hypothesis holds for ( $u_{n+1}, m_{n+1}, v_{n+1}$ ) and $f_{n+1}$ :
H1 $f_{n+1}=\operatorname{concat}\left(f_{n}, \mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right\}^{\leftarrow}\right)+t \overrightarrow{P_{i} P_{j}}$ is indeed the concatenation of $f_{n}+t \overrightarrow{P_{i} P_{j}}$ and a finite curve made of the concatenation of embeddings of translations of segments of $P_{i+1, i+2, \ldots, k}$ (we have merely added the reverse of one such segment). Since $\operatorname{pos}\left(P_{a}\right)+$ $t \overrightarrow{P_{i} P_{j}}=\operatorname{pos}\left(P_{m_{n+1}}\right)$ we get that $f_{n+1}$ connects $L^{m_{0}}(0)+s_{n+1} \overrightarrow{P_{i} P_{j}}$ to $\operatorname{pos}\left(P_{m_{n+1}}\right)$. Moreover, by $\boxed{H 2}$ the only intersection between $f_{n}$ and $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]$ is $\operatorname{pos}\left(P_{m}\right)$ and thus $f_{n+1}$ is simple.
H2 $f_{n+1}$ is entirely in $\mathcal{H}_{n} \subset \mathcal{C}$ and intersects $c$ exactly once at $\operatorname{pos}\left(P_{m_{n+1}}\right)$ : indeed, $f_{n}+t \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{C}$ and does not intersect $c$ at all by $\# 3$, and $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n+1}}\right]+t \overrightarrow{P_{i} P_{j}}$ starts at $f_{n+1}(0) \in \mathcal{C}$, and intersects $c$ exactly once by definition of $a$.
H3 We claim that for all $u>0, f_{n+1}+u \overrightarrow{P_{i} P_{j}}$ does not intersect $c$ : indeed, by H3, $f_{n}+(t+$
$u) \overrightarrow{P_{i} P_{j}}$ does not intersect $c$. Moreover, since $t$ is maximal, then $P_{a, a+1, \ldots, m_{n}}+(t+u) \overrightarrow{P_{i} P_{j}}$ does not intersect $c$. Moreover, we show that $f_{n+1}+u \overrightarrow{P_{i} P_{j}}$ does not intersect $f_{n+1}$, by considering the two parts of $f_{n+1}+u \overrightarrow{P_{i} P_{j}}$, namely $f_{n}+(t+u) \overrightarrow{P_{i} P_{j}}$ and $P_{a, a+1, \ldots, m_{n}}+$ $(t+u) \overrightarrow{P_{i} P_{j}}$ :

- By H3, $f_{n}+(t+u) \overrightarrow{P_{i} P_{j}}$ intersects neither $f_{n}+t \overrightarrow{P_{i} P_{j}}$ nor $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+\overrightarrow{P_{i} P_{j}}$ (which is a segment of $c+\overrightarrow{P_{i} P_{j}}$ ), nor $c$.
- We claim now that $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+(t+u) \overrightarrow{P_{i} P_{j}}$ does not intersect $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+$ $t \overrightarrow{P_{i} P_{j}}$, or equivalently, that $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+u \overrightarrow{P_{i} P_{j}}$ does not intersect $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]$. We showed above that $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+u \overrightarrow{P_{i} P_{j}}$ is in $\mathcal{H}_{n}$. However, the only point of $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]$ that may be in $\mathcal{H}_{n}$ if $P_{m_{n}}$, which happens if and only if $v_{n}=m_{n}$. Moreover, if $u>1$, then $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+(u-1) \overrightarrow{P_{i} P_{j}}$ intersects $P_{u_{n}}$, which is not in $\mathcal{H}_{n}$, and this is a contradiction. Therefore, if $u=1$, we also have $a=u_{n}$ and $m_{n}=m_{n+1}$, which was already handled in Case A. Finally, if $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+(t+u) \overrightarrow{P_{i} P_{j}}$ intersects $f_{n}+t \overrightarrow{P_{i} P_{j}}$, then $\mathfrak{E}\left[P_{a, a+1, \ldots, m_{n}}\right]+u \overrightarrow{P_{i} P_{j}}$ intersects $f_{n}$. Therefore, by H4, $m_{n}=v_{n}$ and $a=u_{n}$, which means that $m_{n+1}=m_{n}$, and this was already handled in Case A.
Therefore, $f_{n+1}+u \overrightarrow{P_{i} P_{j}}$ does not intersect $f_{n+1}$.
H4 We first define the curve $g_{n+1}=\operatorname{concat}\left(f_{n+1}, \mathfrak{E}\left[P_{m_{n+1}, m_{n+1}+1, \ldots, k}\right],\left[\operatorname{pos}\left(P_{k}\right), l^{k}(0)\right], l^{k}\right)$.

Figure 3.15: Finally, we find $u_{n+1}$ and $v_{n+1}$ by translating $f_{n+1}$ by $\overrightarrow{P_{i} P_{j}}$, and looking at the first intersection between $P_{i, i+1, \ldots, m_{n+1}}+\overrightarrow{P_{i} P_{j}}$ and $P$. In order to find such an intersection, we define the infinite curve $g_{n+1}$, which cuts $\mathbb{R}^{2}$ into two connected components by Theorem B. 3

To conclude, we proceed as in Section 3.2.4 by using $R$ to find $u_{n+1}$ and $v_{n+1}$. The path $R$ starts on the left-hand side of $g_{n+1}$ (at $\operatorname{pos}\left(P_{i+1}\right)$, which is not on $f_{n+1}$ since by Claim 3.5 $m_{0}>i+1$ ) and ends on the right-hand side of $g_{n+1}$ or on $g_{n+1}$ (at a position within
horizontal distance 0.5 of $l^{k}$, and possibly at $\left.\operatorname{pos}\left(P_{k}\right)\right)$. Therefore, $R$ must intersect $g_{n+1}$. Now, $f_{n+1}$ only intersects $P_{i+1, i+2, \ldots, k}$ at $\operatorname{pos}\left(P_{m_{n+1}}\right)$, and $f_{n+1}+\vec{P}_{i} P_{j}$ does not intersect $c$ (by H3), and hence does not intersect $P_{i+1, i+2, \ldots, k}$. Therefore, $f_{n+1}$ does not intersect $P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}$. Therefore, $R$ intersects $P_{m_{n+1}}$. Let $b$ be the integer such that $R_{b}=P_{m_{n+1}}$, and let $d \leq b$ be the largest integer such that $R_{d}+\overrightarrow{P_{i} P_{j}}$ is on $P_{i+1, i+2, \ldots, k}$ (at least $i+1 \leq b$ has that property, hence $d$ is well-defined).
Since $d$ is maximal, $R_{d, d+1, \ldots, b}$ is a segment of $P$. Let $u_{n+1}$ be such that $R_{d}=P_{u_{n+1}}$. Since $d \leq b$, by Claim 3.10, $u_{n+1} \leq m_{n+1}$. Let $v_{n+1}$ be such that $R_{d}+\overrightarrow{P_{i} P_{j}}=P_{v_{n+1}}$. These tiles have the same type by Claim 3.14.
We claim that $v_{n+1} \geq m_{n+1}$. By Hypothesis [3] of Definition $7 \mathfrak{E}\left[P_{u_{n+1}, u_{n+1}+1, \ldots, m_{n+1}}+\overrightarrow{P_{i} P_{j}}\right]$ can only intersect $l^{k}$ at $\operatorname{pos}\left(\right.$ glue $\left.\left(P_{k} P_{k+1}\right)\right)$, and can only intersect $\left[P_{k}, l^{k}(0)\right]$ at $\operatorname{pos}\left(P_{k}\right)$, in which case $k=v_{n+1}$. Moreover, we have already argued that $\mathfrak{E}\left[P_{u_{n+1}, u_{n+1}+1, \ldots, m_{n+1}}+\overrightarrow{P_{i} P_{j}}\right]$ can only intersect $f_{n+1}$ at $\operatorname{pos}\left(P_{m_{n+1}}\right)$ (only in the case where $\left.m_{n+1}=v_{n+1}\right)$. Therefore, $\mathfrak{E}\left[P_{u_{n+1}, u_{n+1}+1, \ldots, m_{n+1}}+\overrightarrow{P_{i} P_{j}}\right]$ intersects $g_{n}$ exactly once, at $\operatorname{pos}\left(P_{v_{n+1}}\right)$ (or we are in the special case where $P$ is pumpable).
Finally, since $\mathfrak{E}\left[P_{u_{n+1}, u_{n+1}+1, \ldots, m_{n+1}}+\overrightarrow{P_{i} P_{j}}\right]$ starts on the right-hand side of $g_{n+1}$, and intersects $g_{n+1}$ only at $\operatorname{pos}\left(P_{u_{n+1}}\right)+\overrightarrow{P_{i} P_{j}}, \mathfrak{E}\left[P_{u_{n+1}, u_{n+1}+1, \ldots, m_{n+1}}+\overrightarrow{P_{i} P_{j}}\right]$ is entirely on the right-hand side of $g_{n+1}$, which means that $v_{n+1} \geq m_{n+1}$.

Conclusion of the inductive argument. Since for all $n \geq 0, m_{n+1}>m_{n}$, and since $P$ is of finite length $(|P|=k+2)$ we eventually run out of indices along $P$. This implies that at some point end up in Case $\mathbf{A}$ above, where $m_{n+1}=m_{n}$, which implies that $P$ is pumpable with pumping vector $\overrightarrow{P_{i} P_{j}}$. This completes the proof of Lemma 3.1.

## 4 Proof of main theorem

### 4.1 Intuition and roadmap for the proof of Theorem 1.1

To prove Theorem 1.1, we need to find three indices $i, j, k \in\{0,1, \ldots,|P|-1\}$ of $P$ that satisfy the hypotheses of the Shield Lemma (Lemma 3.1, Definition 7) on $P$, the conclusion of which is that $P$ is pumpable or fragile. Throughout the proof we apply the Shield Lemma in several different ways. We proceed in three steps:

1. First, in the proof of Theorem 1.1, we make some trivial modifications to $P$ (a rotation and translation of our frame of reference, and a truncation) so that $P$ is in a canonical form where, intuitively, it reaches far to the east ( $P$ 's final tile is to the east of the seed $\sigma$ ). We then invoke Theorem 4.6, the combinatorial-based proof of which goes through the following steps.
2. In Lemma 4.3, we use Lemma 4.2 to show that either $P$ is pumpable or fragile (in turn, by applying Lemma 3.1), or else that at most $|T|+1$ glues of $P$ that are visible from the south or from the north can be pointing west (the remaining $\geq(4|T|)^{(4|T|+1)}(4|\sigma|+6)-|T|-|\sigma|$ glues visible from the south are pointing east).
3. Then, using the notion of spans (Definitions 10 and 11, intuition in Figure 4.1) we show (Lemma 4.5) that if we find two spans $S=(s, n)$ and $S^{\prime}=\left(s^{\prime}, n^{\prime}\right)$ of the same orientation and type, and such that $s<s^{\prime}$ and the height of $S^{\prime}$ is at least the height of $S$, then we can

Figure 4.1: The seed is in blue, and $P$ is in brown. Three example spans are shown in this figure, $S=(s, n), S^{\prime}=\left(s^{\prime}, n^{\prime}\right)$ and $S^{\prime \prime}=\left(s^{\prime \prime}, n^{\prime \prime}\right)$. A span $(s, n)$ is a pair of indices such that glue $\left(P_{s} P_{s+1}\right)$ is visible from the south, glue $\left(P_{n} P_{n+1}\right)$ is visible from the north, and glue $\left(P_{s} P_{s+1}\right)$ and glue $\left(P_{n} P_{n+1}\right)$ are on the same glue column. Here, both $S$ and $S^{\prime}$ have both of their glues pointing east, hence we say that the span is pointing east. Moreover, since $s<n$ and $s^{\prime}<n^{\prime}, S$ and $S^{\prime}$ are "up spans". On the other hand, $S^{\prime \prime}$ has its south glue pointing east, and its north glue pointing west, hence $S^{\prime \prime}$ is not pointing in any particular direction. Moreover, $n^{\prime \prime}<s^{\prime \prime}$, hence $S^{\prime \prime}$ is a "down span". Span $S$ has height 6 , and spans $S^{\prime}$ and $S^{\prime \prime}$ have height 8. If the spans $(s, n)$ and ( $s^{\prime}, n^{\prime}$ ) happen to be of the same type (meaning type $\left(\right.$ glue $\left.\left(P_{s} P_{s+1}\right)\right)=\operatorname{type}\left(\right.$ glue $\left.\left(P_{s^{\prime}} P_{s^{\prime}+1}\right)\right)$ ), since the height of $S^{\prime}$ is at least the height of $S$, we could apply Lemma 3.1 directly to prove that $P$ is pumpable or fragile.
apply Lemma 3.1 to $P$, proving that $P$ is pumpable or fragile.
4. Finally, the proof of Theorem 4.6 uses a combinatorial argument, showing that if the path is long enough, there are enough spans that we can always find two spans of the same type and orientation, and of increasing height.

### 4.2 First step: Putting $P$ into a canonical form

We first restate Theorem [1.1, the short proof of which merely contains some initial setup to put $P$ in a canonical form and finishes by invoking Theorem 4.6, where the main heavy lifting happens.

Theorem 1.1. Let $\mathcal{T}=(T, \sigma, 1)$ be any tile assembly system in the abstract Tile Assembly Model (aTAM), and let $P$ be a path producible by $\mathcal{T}$. If $P$ has vertical height or horizontal width at least $(8|T|)^{4|T|+1}(5|\sigma|+6)$, then $P$ is pumpable or fragile.

Proof. Since the vertical height or horizontal width of $P$ is strictly greater than $|\sigma|$ (the number of tiles in $\sigma$ ) for all $|T| \geq 1$, we know that $P$ extends beyond the bounding box of $\sigma$.

Let $B$ be a square in $\mathbb{Z}^{2}$ (its four sides are parallel to the x and y axes) whose center is at the origin, and where each side is distance $(4|T|)^{(4|T|+1)}(4|\sigma|+6)+|\sigma|$ from the origin. Without loss of generality, we translate $P \cup \sigma$ so that $\operatorname{pos}\left(P_{0}\right)=(0,0) \in \mathbb{Z}^{2}$. Then we let $b \in\{0,1, \ldots,|P|-1\}$ be the smallest index so that tile $P_{b}$ is positioned on $B$. Note that $b$ is correctly defined since either the width or height of $P$ (which is at least $(8|T|)^{(4|T|+1)}(5|\sigma|+6)$ ) is greater than the length of the side of $B$ (which is less than $\left.(8|T|)^{(4|T|+1)}(4|\sigma|+6)+2|\sigma|+1\right)$ ). From now on we redefine $P$ to be its own prefix up to $P_{b}$, i.e., $P \stackrel{\text { def }}{=} P_{0,1, \ldots, b}$ (since proving the theorem conclusion on any prefix of $P$ implies that conclusion also holds for $P$ ).

Without loss of generality, we assume that the last tile $P_{b}=P_{|P|-1}$ of $P$ is the unique easternmost tile of $P \cup \sigma$ (if it is not, we simply rotate all tiles of $T$, and the seed assembly $\sigma$, to make it so - thus redefining $P$ again). Note that, $\operatorname{pos}\left(P_{0}\right)$ is still $(0,0)$ after this rotation. Uniqueness follows from the fact that $\sigma$ does not reach to $B$ for all $|T| \geq 1$, and that we assumed that $P$ places exactly one tile on $B$.

Finally, we also assume, without loss of generality, that the westernmost tile of $\sigma \cup \operatorname{asm}(P)$ is at x-coordinate 0 and that the southernmost tile of $\sigma \cup \operatorname{asm}(P)$ is at y-coordinate 0 (we translate $P \cup \sigma$ if this is not the case - thus redefining $P$ again). Since we have $\operatorname{pos}\left(P_{0}\right)=(0,0)$ before the translation, then $\sigma \cup P$ is translated to the east. Moreover, since $P_{0}$ and the seed interacted then the last tile of $P$ is at least $(4|T|)^{(4|T|+1)}(4|\sigma|+6)$ to the east of the easternmost tile of $\sigma$. $P$ now satisfies the hypotheses of Theorem 4.6, thus $P$ is pumpable or fragile.

### 4.3 Second step: $P$ has many visible glues pointing east, or else is pumpable or fragile

For the remainder of this section, we define $X \in \mathbb{Z}$ to be the x-coordinate of the easternmost glue column, i.e. $X$ is the largest integer such that $P$ has a glue with x-coordinate $X+0.5$. Recall (Section 2.2) that for a tile $P_{i}$, its x-coordinate is denoted $\mathrm{x}_{P_{i}}$.

We will need the following lemma, which uses a similar proof technique as Lemma 2.3:
Lemma 4.1. Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$ such that the last tile of $P$ is the unique easternmost tile of $\sigma \cup \operatorname{asm}(P)$. Either (a) all glues visible from the north relative to $P$ point to the east or (b) all glues visible from the south relative to $P$ point to the east.

Proof. Suppose, for the sake of contradiction, that for some integer $i$, glue $\left(P_{i} P_{i+1}\right)$ is visible from the south relative to $P$ and points west, and for some integer $j$, glue $\left(P_{j} P_{j+1}\right)$ is visible from the north relative to $P$ and points west.

Assume without loss of generality that $i<j$, and let $l^{i}$ and $l^{j}$ be the respective visibility rays of glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$. We define a curve $c$ as

$$
c=\operatorname{concat}\left(l^{i \leftarrow},\left[l^{i}(0), P_{i+1}\right], \mathfrak{E}\left[P_{i+1, i+2, \ldots, j}\right],\left[P_{j}, l^{j}(0)\right], l^{j}\right)
$$

By Theorem B.3, $c$ cuts $\mathbb{R}^{2}$ into two connected components. Observe that the last tile of $P$ is on the right-hand side of $c$, yet $P_{j+1}$ is on the left-hand side of $c$. Therefore, $\mathfrak{E}\left[P_{j+1, j+2, \ldots,|P|-1}\right]$ must intersect $c$. However:

- That intersection is not be on $l^{i \leftarrow}$ or on $l^{j}$, by visibility of glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$.
- That intersection is not be on $\mathfrak{E}\left[P_{i+1, i+2, \ldots, j}\right]$, because $P$ is simple.
- That intersection is not be on $\left[l^{i}(0), P_{i+1}\right]$ nor $\left[P_{j}, l^{j}(0)\right]$, since $P$ can only intersect these segments at the endpoints of these segments, and we have already handled this case.
Therefore, we get a contradiction, hence either all glues visible from the north relative to $P$ point to the east, or all glues visible from the south relative to $P$ point to the east.

Lemma 4.2. Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$ such that the last tile of $P$ is the unique easternmost tile of $P \cup \sigma$. If more than $|T|+1$ glues of $P$ are visible from the south and are pointing to the west then $P$ is fragile or pumpable.

Proof. We claim that the hypotheses of Definition 7 are satisfied, and establishing that claim will in turn allow us to apply Lemma 3.1. Since there are $|T|+1$ glues visible from the south relative to $P$ and pointing west, then by the pigeonhole principle, there are two indices $i<j$ such that glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$ are visible from the south, pointing west and of the same glue type. Since the last tile $P_{|P|-1}$ of $P$ is the unique easternmost tile of $P \cup \sigma$, then for $k=|P|-2$, glue $\left(P_{k} P_{k+1}\right)$ is visible from the north relative to $P$. Hence, let $l^{k}$ be the visibility ray of glue $\left(P_{k} P_{k+1}\right)$ (this means that $l^{k}$ is the vertical ray from glue $\left(P_{k} P_{k+1}\right)$ to the north). By Lemma 2.3, we have $x_{P_{i}}>x_{P_{j}}$. Therefore, $l^{k}+\overrightarrow{P_{j} P_{i}}$ is strictly to the east of $l_{k}$, and hence does not intersect $P$.

We claim that the three hypotheses of Definition 7 are satisfied by the horizontal mirror flip of $\mathcal{T}$ and of $P$ : In the mirror-flip of $P$ we (still) have $0 \leq i<j<k<|P|-1$, also glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$ are visible to the south (with respect to the mirror-flip of $P \cup \sigma$ ), point to the east, and are of the same type (Hypothesis (1); glue $\left(P_{k} P_{k+1}\right)$ is visible to the north (Hypothesis 2); and $\mathfrak{E}\left[P_{i, i+1, \ldots, k}\right] \cap\left(l^{k}+\overrightarrow{P_{j} P_{i}}\right)=\emptyset$ (Hypothesis 3). Thus for the mirror-flip of $P$ and of $\mathcal{T}$, the mirror-flip of $P$ is pumpable or fragile, hence $P$ is pumpable or fragile as claimed.

### 4.4 Third step: repeated spans imply $P$ is pumpable or fragile

We need two key definitions that are illustrated in Figure 4.1.
Definition 10 (span). Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$, whose last glue is the unique easternmost (respectively highest) glue of $P \cup \sigma$. A span (respectively horizontal span) of $P$ is a pair $(s, n) \in\{0,1, \ldots,|P|-2\}^{2}$ of indices of tiles of $P$ such that, at the same time:

- $\mathrm{x}_{\text {glue }\left(P_{n} P_{n+1}\right)}=\mathrm{x}_{\operatorname{glue}\left(P_{s} P_{s+1}\right)}\left(\right.$ respectively $\left.\mathrm{y}_{\text {glue }\left(P_{n} P_{n+1}\right)}=\mathrm{y}_{\operatorname{glue}\left(P_{s} P_{s+1}\right)}\right)$, and
- glue $\left(P_{n} P_{n+1}\right)$ is visible from the north (respectively from the east), and
- glue $\left(P_{s} P_{s+1}\right)$ is visible from the south (respectively from the west).

Remark on Definition (10. Notice that $P$ has exactly one span on each glue column that does not have seed glues $\sqrt{18}$ and on which $P$ has at least one glue. Hence in the rest of the proof we will use terms such as "the span of $P$ on glue column $x$ ".

The following properties of spans will be useful.
Definition 11 (span properties: orientation, pointing direction, type and height). The orientation of a span (respectively of a horizontal span) $(s, n)$ is $u p$ (respectively right) if $s \leq n{ }^{19}$ or down (respectively left) if $s>n$.

A span (respectively horizontal span) ( $s, n$ ) points east (respectively points north) if both glue $\left(P_{s} P_{s+1}\right)$ and glue $\left(P_{n} P_{n+1}\right)$ point east (respectively point north), and that ( $s, n$ ) points west (respectively points south) if both glue $\left(P_{s} P_{s+1}\right)$ and glue $\left(P_{n} P_{n+1}\right)$ point west (respectively point south 20 .

The type of a span or horizontal span $(s, n)$ is the type of its first glue in the growth order of $P$, i.e. the type of glue $\left(P_{s} P_{s+1}\right)$ if $s \leq n$ and the type of glue $\left(P_{n} P_{n+1}\right)$ otherwise.

[^14]The height (respectively width) of a span (respectively horizontal span) ( $s, n$ ) is $\mathrm{y}_{P_{n}}-\mathrm{y}_{P_{s}}$ (respectively $\mathrm{x}_{P_{n}}-\mathrm{x}_{P_{s}}$ ).
Lemma 4.3. Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$ such that the last tile of $P$ is the unique easternmost tile of $\sigma \cup \operatorname{asm}(P)$. Either $P$ is pumpable or fragile or else there is a glue column $x_{0} \leq|T|+|\sigma|$ such that for all $x \in\left\{x_{0}, x_{0}+1, \ldots, X\right\}$, the span of $P$ on glue column $x$ is pointing east.

Proof. First, by Lemma 4.1, we can assume without loss of generality (by vertical mirror-flip) that all glues visible from the north relative to $P$ are pointing east.

Then, since $P_{|P|-1}$ is the unique easternmost tile of $P$, glue $\left(P_{|P|-2} P_{|P|-1}\right)$ is pointing east and visible both from the south and from the north. Therefore, the span of $P$ on glue column $X$ is pointing east. Let $x_{0} \in \mathbb{Z}$ be the westernmost glue column on which the glue visible from the south relative to $P$ is pointing east. By Lemma 2.3, for all $x \in\left\{x_{0}, x_{0}+1, \ldots, X\right\}$, the glue visible from the south relative to $P$ on column $x$ is also pointing east. If $x_{0}>|T|+|\sigma|$ then there are at least $|T|+|\sigma|+1$ columns on which either $P$ has no visible glue (meaning that $\sigma$ has glues on these columns), or on which the glue visible from the south relative to $P$ is pointing west. Since the size of the seed is $|\sigma|$, this means that at least $|T|+1$ glues visible from the south relative to $P$ are pointing west, and we can conclude using Lemma 4.2 that $P$ is pumpable or fragile.

In all other cases, the span of $P$ on glue column $x$ is pointing east.
In the final theorem, we need the following corollary of Lemma 4.3, whose statement is about horizontal spans instead of spans. The corollary statement is simply a rotation of the statement of Lemma 4.3 along with Y substituted for X in the latter, hence the proof is immediate.

Corollary 4.4. Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$ such that the last tile of $P$ is the unique northernmost (respectively southernmost) tile of $\sigma \cup \operatorname{asm}(P)$, let $Y$ be the largest integer such that $P$ or $\sigma$ has a glue on glue row $Y+0.5$ and let $y$ be the smallest integer such that $P$ or $\sigma$ has a glue on glue row $y+0.5$. Either $P$ is pumpable or fragile or else there is a glue row $y_{0} \leq y+|T|+|\sigma|$ (respectively $y_{0} \geq Y-|T|-|\sigma|$ ) such that for all $z \in\left\{y_{0}, y_{0}+1, \ldots, Y\right\}$ (respectively $z \in\left\{y, y+1, \ldots, y_{0}\right\}$ ), the horizontal span of $P$ on glue row $z$ is pointing north (respectively south).

The following simple but powerful lemma shows how to exploit spans in order to apply Lemma 3.1:

Lemma 4.5. Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$ such that the last tile of $P$ is the unique easternmost tile of $P \cup \sigma$. If there are two spans $S=(s, n)$ and $S^{\prime}=\left(s^{\prime}, n^{\prime}\right)$ on $P$, both pointing east, of the same orientation and type, and such that $\mathrm{x}_{P_{s}}<\mathrm{x}_{P_{s^{\prime}}}$ and the height of $S^{\prime}$ is at least the height of $S$, then $P$ is pumpable or fragile.

Proof. Without loss of generality, since $S$ and $S^{\prime}$ have the same orientation, we assume that $S$ and $S^{\prime}$ both have the "up" orientation (i.e. $s \leq n$ and $s^{\prime} \leq n^{\prime}$ ). We claim that we can apply Lemma 3.1 by setting $i=s, j=s^{\prime}$ and $k=n^{\prime}$.

Indeed, both glue $\left(P_{s} P_{s+1}\right)$ and glue $\left(P_{s^{\prime}} P_{s^{\prime}+1}\right)$ are visible from the south and pointing east. Since $S$ and $S^{\prime}$ are of the same type, glue $\left(P_{s} P_{s+1}\right)$ and glue $\left(P_{s^{\prime}} P_{s^{\prime}+1}\right)$ are also of the same type. Moreover, since $\mathrm{x}_{P_{s}}<\mathrm{x}_{P_{s^{\prime}}}$, applying Lemma 2.3 shows that $i<j$. By definition of a span, glue $\left(P_{n^{\prime}} P_{n^{\prime}+1}\right)$ is visible from the north, and since $S^{\prime}$ has the up orientation, $s^{\prime}<n^{\prime}$, hence $j \leq k$.

Finally, let $l^{n^{\prime}}$ be the visibility ray from glue $\left(P_{n^{\prime}} P_{n^{\prime}+1}\right)$ to the north. Note that $\operatorname{pos}\left(\operatorname{glue}\left(P_{s^{\prime}} P_{s^{\prime}+1}\right)\right)+$ $\overrightarrow{P_{s^{\prime}} P_{s}}=\operatorname{pos}\left(\operatorname{glue}\left(P_{s} P_{s+1}\right)\right)$, and since the height of $S$ is smaller than or equal to the height of $S^{\prime}, \mathfrak{E}[P]$ may only intersect $l^{n^{\prime}}+\overrightarrow{P_{s^{\prime}} P_{s}}$ at $l^{n^{\prime}}(0)+\overrightarrow{P_{s^{\prime}} P_{s}}$, which on the same column, and at least as high as glue $\left(P_{n} P_{n+1}\right){ }^{21}$

We can therefore conclude by applying Lemma 3.1 which shows that $P$ is pumpable or fragile.

### 4.5 Fourth step: proof of the main theorem

Theorem 4.6. Let $P$ be a path producible by some tile assembly system $\mathcal{T}=(T, \sigma, 1)$ where the final tile $P_{|P|-1}$ is the easternmost one and it is positioned at distance at least $(4|T|)^{(4|T|+1)}(4|\sigma|+$ 6) to the east of the easternmost tile of $\sigma$. Then $P$ is pumpable or fragile.

Proof. We first apply Lemma 4.3, yielding one of two possible conclusions: (1) either $P$ is pumpable or fragile, in which case we are done, or (2) there is an integer $x_{0} \leq|T|+|\sigma|$ such that for all $x \in\left\{x_{0}, x_{0}+1, \ldots, X\right\}$, the span of $P$ on glue column $x$ is pointing east.

Let $x_{0}<x_{1}<\ldots<x_{n}$ be the sequence of glue columns such that, both of the following hold:

- for all $a \neq b$, the spans of $P$ on glue columns $x_{a}$ and $x_{b}$ have different orientations or different types (or both); and
- for all $x \in\left\{x_{0}, x_{0}+1, \ldots, X\right\}$, there is an integer $a \in\{0,1, \ldots, n\}$ such that $x_{a} \leq x$ and the spans of $P$ on glue columns $x_{a}$ and $x$ have the same orientation and the same type.
In other words, the sequence $x_{0}, x_{1}, \ldots, x_{n}$ is the sequence of the first occurrences, in increasing x-coordinate order, of each span type and orientation. That sequence has at least one element ( $x_{0}$ ), and since that sequence contains at most one occurrence of each span type and orientation, $n<2|T|{ }^{22}$ Moreover, as a consequence of our use of Lemma 4.3 in the beginning of this proof, all the spans of $P$ on glue columns $x_{0}, x_{1}, \ldots, x_{n}$ point east.

We extend the sequence by one point, by letting $x_{n+1}=X$ (i.e. we add the easternmost possible span), and for all $i \in\{0,1, \ldots, n\}$, we let $h_{i}$ be the height of the span of $P$ on glue column $x_{i}$.

Intuitively, we consider a "cone" from $\sigma$ to the east (see Figure 4.2), and consider two cases, depending on whether all spans are within the cone. The only difference with an actual geometric cone is that the y-coordinate of spans might not be aligned.

There are two cases:

1. If there is an integer $c \in\{0,1, \ldots, n+1\}$ such that $h_{c}>4|T|^{2}\left(x_{c}+4|\sigma|+6\right)$, then we claim that $P$ is pumpable or fragile.
Indeed, without loss of generality, we assume that the span $\left(s_{c}, n_{c}\right)$ of $P$ on glue column $x_{c}$ has the "up" orientation (i.e. $s_{c} \leq n_{c}$ ). Let $X^{\prime}$ be the easternmost glue column reached by $Q=P_{0,1, \ldots, n_{c}+1}$. See Figure 4.3. There are two subcases, depending on the relative sizes of $h_{c}$ and $X^{\prime}$ :
(a) If $h_{c}<4|T|\left(X^{\prime}+2\right)+3|\sigma|+1$, we first claim that $X^{\prime}>|T|\left(x_{c}+3\right)+|\sigma|+1$. See Figure 4.4

[^15]

Figure 4.2: $P$ is drawn schematically in brown. This proof has two cases: if the height of the spans are increasing no more than proportionally to their x -coordinate, which we represent by a cone here (even though the spans are not actually in a cone, since the spans might not be vertically aligned), we are in Case 2, Else, if we can find at least one $c$ such that $h_{c}$ gets out of the cone, i.e. such that $h_{c}>4|T|^{2}\left(x_{c}+4|\sigma|+6\right)$, we are in Case 1

Indeed, we have $h_{c}>4|T|^{2}\left(x_{c}+4|\sigma|+6\right)$, and hence:

$$
\begin{aligned}
4|T|\left(X^{\prime}+2\right)+3|\sigma|+1 & >4|T|^{2}\left(x_{c}+4|\sigma|+6\right) \\
X^{\prime} & >\frac{4|T|^{2}\left(x_{c}+4|\sigma|+6\right)-3|\sigma|-1}{4|T|}-2 \\
X^{\prime} & >\frac{4|T|^{2}\left(x_{c}+3\right)}{4|T|}+\frac{4|T|^{2}(4|\sigma|+3)-3|\sigma|-1-8|T|}{4|T|} \\
X^{\prime} & >|T|\left(x_{c}+3\right)+|\sigma| \frac{16|T|^{2}-3}{4|T|}+\frac{12|T|^{2}-1-8|T|}{4|T|}
\end{aligned}
$$

Finally, since $|T| \geq 1, \frac{16|T|^{2}-3}{4|T|} \geq 3$, and $\frac{12|T|^{2}-1-8|T|}{4|T|} \geq \frac{3|T|-2}{2}-\frac{1}{4|T|} \geq \frac{1}{2}-\frac{1}{4} \geq 0$, and therefore (ignoring the last term, and since $|\sigma| \geq 1$ ):

$$
X^{\prime}>|T|\left(x_{c}+3\right)+3|\sigma| \geq|T|\left(x_{c}+3\right)+|\sigma|+2
$$

thus proving the claim that $X^{\prime}>|T|\left(x_{c}+3\right)+|\sigma|+1$.
Let $k=n_{c}$ and $l^{k}$ be the ray from glue $\left(P_{k} P_{k+1}\right)$ to the north. By Lemma 2.3, we have $s_{0} \leq$ $s_{c}$, and since span ( $s_{c}, n_{c}$ ) has the "up" orientation then $s_{0} \leq n_{c}$. Then glue $\left(Q_{s_{0}} Q_{s_{0}+1}\right)$ is visible from the south relative to $Q$, and pointing east, hence by Lemma 2.3, all the glues visible from the south relative to $Q$ and to the east of glue $\left(P_{s_{0}} P_{s_{0}+1}\right)$ also point east. And since $X^{\prime} \geq|T|\left(x_{c}+3\right)+|\sigma|+1$, there are at least $X^{\prime}-x_{0} \geq X^{\prime}-(|T|+|\sigma|) \geq|T|\left(x_{c}+2\right)+1$ of them.
By the pigeonhole principle, at least $x_{c}+2$ of these glues share the same type. Let $i \in \mathbb{N}$ be the index on $Q$ of the westernmost of these glues, and let $j$ be the index on $Q$ of the easternmost one. By Lemma 2.3, this means that $i \leq j$.
Moreover, $\overrightarrow{P_{j} P_{i}}$ is at least $x_{c}+1$ columns wide (and $\overrightarrow{P_{j} P_{i}}$ is to the west), since there are at least $x_{c}+1$ glue columns between glue $\left(P_{i} P_{i+1}\right)$ and glue $\left(P_{j} P_{j+1}\right)$. Therefore, $l^{k}+\vec{P}_{j} P_{i}$ is

Figure 4.3: $P$ is drawn schematically in brown. In Case 1, at least one span, at column $x_{c}$, gets out of the cone, i.e. is of height $h_{c}>4|T|^{2}\left(x_{c}+4|\sigma|+6\right)$. We define $X^{\prime}$, the rightmost column reached by $P_{0,1, \ldots, n_{c}}$, and split this case into two Cases, 1a and 1b, depending on the relative values of $h_{c}$ and $X^{\prime}$.
to the west of $x_{c}+0.5-\left(x_{c}+1\right) \leq-0.5$, and hence cannot intersect $P$ (since we assumed in the beginning of this section that the westernmost tile of $P \cup \sigma$ has x-coordinate 0 ). We can therefore apply Lemma 3.1, using $(i, j, k)$, as a shield, to $P$ thus proving that $P$ is pumpable or fragile.
(b) Else, $h_{c} \geq 4|T|\left(X^{\prime}+2\right)+3|\sigma|+1$. See Figure 4.5.

Therefore, there is a tile of $Q$ at least $\left[\frac{h_{c}-|\sigma|}{2}\right\rceil \geq 2|T|\left(X^{\prime}+2\right)+|\sigma|+1$ to the north of all the tiles of $\sigma$, or to the south of all the tiles of $\sigma$.
If the highest tile of $Q$ is at least $2|T|\left(X^{\prime}+2\right)+|\sigma|+1$ rows to the north (respectively to the south) of all the tiles of $\sigma$, then let $Q^{\prime}$ be the shortest prefix of $Q$ whose highest tile is $2|T|\left(X^{\prime}+2\right)+|\sigma|+1$ rows to the north (respectively to the south) of all the tiles of $\sigma$.
By Corollary 4.4, either $Q$ is pumpable or fragile or at least $2|T|\left(X^{\prime}+1\right)$ horizontal spans of $Q$ point north (respectively south), and by the pigeonhole principle, at least $X^{\prime}+1$ of these spans have the same orientation and type. Since the width of all these horizontal spans is bounded by $X^{\prime}$ (because $X^{\prime}$ is by definition the easternmost column reached by $Q$ ), at least two of them have the same width, and hence by Lemma 4.5, $Q$ is fragile or pumpable, and so is $P$ (because $Q$ is a prefix of $P$ ).
2. Otherwise, $h_{c} \leq 4|T|^{2}\left(x_{i}+4|\sigma|+6\right)$ for all $c \in\{0,1, \ldots, n\}$, i.e. intuitively, just like in Figure 4.2, all the spans are inside the "cone".
We first claim that at least one of the $x_{c}$ (for $c \in\{0,1, \ldots, n+1\}$ ) must be "large enough", specifically we claim there is an $x_{c}>x_{0}+\sum_{d=0}^{c-1} h_{d}$. Indeed, suppose, for the sake of contradiction, that for all $c \in\{0,1, \ldots, n+1\}, x_{c} \leq x_{0}+\sum_{d=0}^{c-1} h_{d}$. We prove that the

Figure 4.4: $P$ is drawn schematically in brown. In Case 1 a $X^{\prime}$ is large enough that we can find two glue spans between $x_{0}$ and $X^{\prime}$ that have the same type and orientation, and are at least $x_{c}$ columns apart. We can therefore apply Lemma 3.1 by letting $i$ and $j$ be the indices of the south glues of these spans on $P$, and letting $k$ be the index of $P_{n_{c}}$.
following inequality holds by induction on $c \in\{0,1, \ldots, n+1\}$ :

$$
x_{0}+\sum_{d=0}^{c-1} h_{d} \leq(4|T|)^{2 c+1}(4|\sigma|+6)-2
$$

First, the induction hypothesis holds for $c=0$, since $x_{0}+\sum_{d=0}^{c-1} h_{d}=x_{0} \leq 4|T|(4|\sigma|+6)-2$. Then, if the induction hypothesis holds for any $c \in\{0,1, \ldots, n\}$, i.e. if $x_{c} \leq x_{0}+\sum_{d=0}^{c-1} h_{d} \leq$ $(4|T|)^{2 c+1}(4|\sigma|+6)-2$, then:

$$
\begin{aligned}
h_{c} & \leq 4|T|^{2}\left(x_{c}+4|\sigma|+6\right) \\
x_{0}+\sum_{d=0}^{c-1} h_{d}+h_{c} & \leq(4|T|)^{2 c+1}(4|\sigma|+6)-2+4|T|^{2}\left(x_{c}+4|\sigma|+6\right) \\
& \leq(4|T|)^{2 c+1}(4|\sigma|+6)+4|T|^{2} x_{c}+4|T|^{2}(4|\sigma|+6)-2 \\
& \leq(4|T|)^{2 c+1}(4|\sigma|+6)+4|T|^{2}(4|T|)^{2 c+1}(4|\sigma|+6)+4|T|^{2}(4|\sigma|+6)-2 \\
& \leq\left((4|T|)^{2 c+1}+4|T|^{2}(4|T|)^{2 c+1}+4|T|^{2}\right)(4|\sigma|+6)-2 \\
& \leq(4|T|)^{2 c+1}\left(1+4|T|^{2}+\frac{4|T|^{2}}{(4|T|)^{2 c+1}}\right)(4|\sigma|+6)-2 \\
& \leq(4|T|)^{2 c+1}\left(4|T|^{2}+|T|+1\right)(4|\sigma|+6)-2 \\
& \leq(4|T|)^{2 c+1}\left(16|T|^{2}\right)(4|\sigma|+6)-2 \\
& \leq(4|T|)^{2 c+3}(4|\sigma|+6)-2
\end{aligned}
$$

This proves the induction hypothesis for $c+1$, and hence by induction, the induction hypothesis holds for all $c \in\{0,1, \ldots, n+1\}$.

Figure 4.5: $P$ is drawn schematically in brown. In Case 1b $h_{c}$ is large enough, and $X^{\prime}$ is small enough that if we consider all horizontal spans of $P$ (there are at least $h_{c}$ of them), two of them will have the same width, and we can apply Lemma 4.5.

However, $x_{n+1}=X \geq(4|T|)^{4|T|+1}(4|\sigma|+6)-1>x_{0}+\sum_{d=0}^{n} h_{d}$, which is a contradiction. Therefore, there is at least one $c \in\{0,1, \ldots, n\}$ such that $x_{c}>x_{0}+\sum_{d=0}^{c-1} h_{d}$.
Let $c_{0}$ be the smallest such $c$. There is at least one $d<c_{0}$ such that the type and orientation of the span of $P$ on $x_{d}$ is repeated strictly more than $h_{d}$ times between $x_{d}$ (included) and $x_{c_{0}}$ (excluded).
There are two cases:

- There is a glue column $x$, such that $x_{d}<x<c_{0}$ and the spans of $P$ on glue columns $x_{d}$ and $x$ have the same type and orientation, and furthermore the height of the span of $P$ on $x$ is at least $h_{d}$. Since by definition, the height of the span on glue column $x_{d}$ is $h_{d}$, we conclude immediately setting $S$ and $S^{\prime}$ to be the spans on $x_{d}$ and $x$, respectively, in Lemma 4.5. Thus $P$ is pumpable or fragile.
- Otherwise, at least $h_{d}+1$ spans of the same type and orientation as the span of $P$ on $x_{d}$, have height at most $h_{d}$. By the pigeonhole principle, two of them have the same height and we can also apply Lemma 4.5 setting $S$ to be the more western of the two spans, and $S^{\prime}$ being the more eastern. Thus $P$ pumpable or fragile.

## A The 2HAM is pumpable or blockable: proof sketch

This section contains a proof sketch of Corollary 1.2; an application of our main result to the two-handed, or hierarchical, tile assembly model (2HAM). A full proof requires using formal $2 H A M$ definitions, and making some notions below more precise. We restate the Corollary here, see [6, 8, 15] for 2HAM definitions.

Corollary 1.2, Let $\mathcal{H}=(T, 1)$ be any tile assembly system in the Two-Handed Assembly Model $(2 \mathrm{HAM})$, and let $P$ be a path producible by $\mathcal{H}$. If $P$ has vertical height or horizontal width at
least $(88|T|)^{4|T|+1}$, then $P$ is pumpable or fragile.
Proof sketch of Corollary 1.2, Let $\mathcal{H}=(T, 1)$ be a temperature 12 HAM system with tile set $T$ that grows a (tile) path $P$ of horizontal or vertical width $(88|T|)^{4|T|+1}$. Then redefine $P$ to be a shortest segment of $P$ that has horizontal or vertical width exactly $(88|T|)^{4|T|+1}$ (it is always possible to remove a prefix of $P$ and a suffix of $P$ so that this is the case). If necessary, redefine $\mathcal{H}$ by rotating all tiles $T$ by $90^{\circ}$ so that $P$ has horizontal width $(88|T|)^{4|T|+1}$. We define an aTAM system $\mathcal{T}=(T, \sigma, 1)$ by setting $T=H$ and by choosing the westernmost (smallest xcoordinate) tile $t$ of $P$, setting $\sigma=t$. Since $P$ is a producible in $\mathcal{H}$, and since $\sigma$ is a tile of $P, P$ is also producible by $\mathcal{T}$ (note that $\operatorname{asm}(P)=\sigma \cup \operatorname{asm}(P)$, and $P$ is simple, and all adjacent glues along $P$ match $)$. Since $(8|T|)^{4|T|+1}(5|\sigma|+6) \leq(88|T|)^{4|T|+1}$ for $|\sigma|=1$, we apply Theorem 1.1 to $\mathcal{T}$, and $P$, and thus $P$ is pumpable or fragile in $\mathcal{T}$. Specifically, this means that there is a producible assembly $\alpha \in \mathcal{A}[\mathcal{T}]$ such that either (i) $\alpha$ contains exactly $\sigma=t$, a prefix $P_{0,1, \ldots, i}$ of $P$, and then infinitely many repetitions of a segment $P_{i+1, i+2, \ldots, j}$, each translated by a unique vector $d \cdot \overrightarrow{P_{i} P_{j}}$ for all $d \in \mathbb{N}$, or (ii) $\alpha$ is an assembly that places a tile that conflicts with $P$ (prevents $P$ from growing). Since assemblies that are producible in the aTAM (i.e. in $\mathcal{T}$ ) are producible in the 2 HAM (i.e. in $\mathcal{H}$ ), we get that $\alpha$ is producible in $\mathcal{H}$. Hence $P$ is pumpable or fragile in $\mathcal{H}$.

## B Wee lemmas and left/right turns for curves

Lemma B. 1 (Lemma 6.3 of [11]). Consider a two-dimensional, bounded, connected, regular closed set $S$, i.e. $S$ is equal to the topological closure of its interior points. Suppose $S$ is translated by a vector $v$ to obtain shape $S_{v}$, such that $S$ and $S_{v}$ do not overlap. Then the shape $S_{c * v}$ obtained by translating $S$ by $c * v$ for any integer $c \neq 0$ also does not overlap $S$.

The following lemma [31] formalises the intuition behind Definition 5.
Lemma B. 2 (Lemma 2.5 of [31]). Let $P$ be a path with tiles from some tileset $T, i<j$ be two integers, and $\bar{q}$ be the pumping of $P$ between $i$ and $j$. Then for all integers $k \geq i$, $\bar{q}_{k+(j-i)}=\bar{q}_{k}+{\overrightarrow{P_{i} P_{j}}}$.

Proof. By the definition of $\bar{q}$ (and using the fact that $(j-i) \bmod (j-i)=0)$ :

$$
\begin{aligned}
\bar{q}_{k+(j-i)} & \left.=P_{i+1+((k+(j-i)-i-1)} \bmod (j-i)\right)+\left\lfloor\frac{k+(j-i)-i-1}{j-i}\right\rfloor \overrightarrow{P_{i} P_{j}} \\
& =P_{i+1+((k-i-1) \bmod (j-i))}+\left\lfloor\frac{k-i-1}{j-i}\right\rfloor \overrightarrow{P_{i} P_{j}}+\overrightarrow{P_{i} P_{j}} \\
& =\bar{q}_{k}+\overrightarrow{P_{i} P_{j}}
\end{aligned}
$$

## B. 1 Jordan curve theorem for infinite polygonal curves and left/right turns

The line $\ell:(-\infty,+\infty) \rightarrow \mathbb{R}^{2}$ of vector $\vec{w}=(u, v)$ passing through a point $(a, b) \in \mathbb{R}^{2}$ is defined as $\{(x, y) \mid-v(x-a)+u(y-b)=0\}$. This line cuts the 2 D plane $\mathbb{R}^{2}$ into two connected components: the right-hand side $R=\{(x, y) \mid-v(x-a)+u(y-b) \leq 0\}$ and the left-hand side $L=\{(x, y) \mid-v(x-a)+u(y-b) \geq 0\}$. We say that a curve $c$ turns right (respectively left)
of $\ell$ if there exist $\epsilon>0$ and $t \in \mathbb{R}$ such that $c(t)$ is a point of $\ell$ and for all $t<z \leq t+\epsilon, c(z)$ belongs to $R$ (respectively $L$ ) and is not on $\ell$. Moreover, we say that $c$ crosses $\ell$ from left to right (respectivelyfrom right to left) if there exist $t$ and $\epsilon>0$ such that $c$ turns right (respectively left) of $\ell$ at $c(t)$, for all $t-\epsilon \leq z \leq t, c(t) \in L$ (respectively $c(t) \in R$ ) and $c(t-\epsilon)$ is not on $\ell{ }^{23}$ We say that $c$ crosses $\ell$ if $c$ crosses $\ell$ either from left to right or from right to left. Now, we generalise these notions to a specific class of polygonal curves:

Definition 12. A simple infinite almost-vertical polygonal curve is a simple curve that is a concatenation of an (infinite) vertical ray from the south, a finite curve made of horizontal and vertical segments of lengths 1 or 0.5 , and an (infinite) vertical ray to the north.

Examples of simple infinite almost-vertical polygonal curves appear throughout this paper, including: the curve $c$ in Definition 8 and shown as the border of $\mathcal{C}$ in Figure 3.2, $e$ in Subsection 2.5.4, $c^{m_{0}}$ in Subsection 3.2.2, and $d$ in Definition 9 ,

Let $w_{0}, w_{1} \in \mathbb{R}^{2}$ and let $c$ be a curve. We say that $w_{0}$ is connected to $w_{1}$ while avoiding $c$ if there is a curve $d:[0,1] \rightarrow \mathbb{R}^{2}$ with $d(0)=w_{0}$ and $d(1)=w_{1}$ and $d$ does not intersect $c$.
Theorem B.3. Let $c: \mathbb{R} \rightarrow \mathbb{R}^{2}$ be a simple infinite almost-vertical polygonal curve, and let $x_{\text {min }}$ and $x_{\text {max }}$ be the respective minimum and maximum $x$-coordinates of $c(\mathbb{R})$.

Then c cuts $\mathbb{R}^{2}$ into two connected components:

1. the left-hand side of $c: c(\mathbb{R}) \cup\left\{w \mid w \in \mathbb{R}^{2}\right.$ is connected to ( $x_{\text {min }}, 0$ ) while avoiding $\left.c\right\}$,
2. the right-hand side of $c: c(\mathbb{R}) \cup\left\{w \mid w \in \mathbb{R}^{2}\right.$ is connected to ( $x_{\max }, 0$ ) while avoiding $\left.c\right\}$.

Proof. The proof is similar to the proof of the Jordan Curve Theorem for polygonal curves.
For each point $(x, y) \in \mathbb{R}^{2}$ we define $\ell(x, y)$ to be the line of vector $(1,1)$ through $(x, y)$, $\ell^{+}(x, y)$ to be the ray of vector $(1,1)$ from $(x, y)$, and $\ell^{-}(x, y)$ to be the ray of vector $(-1,-1)$ from ( $x, y$ ).

Since $c$ is made only of two vertical rays and a finite number of horizontal and vertical segments, for all $(x, y) \in \mathbb{R}^{2}, \ell^{-}(x, y)$ and $\ell^{+}(x, y)$ intersects $c$ at a finite number of points. Moreover, because $\ell(x, y)$ cuts the plane into two connected components, $\ell(x, y)$ crosses $c$ an odd number of times,

Let $L$ be the subset of $\mathbb{R}^{2}$ such that for all $(x, y) \in L, c$ crosses ${ }^{\sqrt{23}} \ell^{+}(x, y)$ an odd number of times ${ }^{24}$ and let $R$ be the subset of $\mathbb{R}^{2}$ such that for all $(x, y) \in R, c$ crosses $\ell^{-}(x, y)$ an odd number of times. Note that $L \cap R=c(\mathbb{R})$ (where $c(\mathbb{R})$ is the range of $c$ ), or in other words the intersection of $L$ and $R$ is the set of all points of $c$.

We claim that $L$ (respectively $R$ ) is a connected component: indeed, since $c$ is connected, if $\left(x_{0}, y_{0}\right)$ and $\left(x_{1}, y_{1}\right)$ are both in $L$ (respectively both in $\left.R\right)$, let $t_{0}, t_{1} \in \mathbb{R}$ be the smallest real numbers such that $\ell^{+}\left(x_{0}, y_{0}\right)\left(t_{0}\right)$ (respectively $\left.\ell^{-}\left(x_{0}, y_{0}\right)\left(t_{0}\right)\right)$ is on $c$, and $\ell^{+}\left(x_{1}, y_{1}\right)\left(t_{1}\right)$ (respectively $\left.\ell^{-}\left(x_{1}, y_{1}\right)\left(t_{1}\right)\right)$ is on $c$. We know there is at least one such intersection because $\ell^{+}\left(x_{0}, y_{0}\right)$ and $\ell^{+}\left(x_{1}, y_{1}\right)$ (respectively $\ell^{-}\left(x_{0}, y_{0}\right)$ and $\left.\ell^{-}\left(x_{1}, y_{1}\right)\right)$ cross $c$ an odd number of times, hence at least once. Without loss of generality we suppose that $\ell^{+}\left(x_{0}, y_{0}\right)\left(t_{0}\right)$ (respectively $\ell^{-}\left(x_{0}, y_{0}\right)\left(t_{0}\right)$ ) is before $\ell^{+}\left(x_{1}, y_{1}\right)\left(t_{1}\right)$ (respectively $\left.\ell^{-}\left(x_{1}, y_{1}\right)\left(t_{1}\right)\right)$ according to the order of positions along $c$.

Let $d$ be the curve defined as the concatenation of:

[^16]- $\ell^{+}\left(x_{0}, y_{0}\right)$ (respectively, $\left.\ell^{-}\left(x_{0}, y_{0}\right)\right)$ from $\left(x_{0}, y_{0}\right)$ up to $\ell^{+}\left(x_{0}, y_{0}\right)\left(t_{0}\right)$ (respectively, $\left.\ell^{-}\left(x_{0}, y_{0}\right)\left(t_{0}\right)\right)$,
- $c$ from $\ell^{+}\left(x_{0}, y_{0}\right)\left(t_{0}\right)$ to $\ell^{+}\left(x_{1}, y_{1}\right)\left(t_{1}\right)$ (respectively, from $\ell^{-}\left(x_{0}, y_{0}\right)\left(t_{0}\right)$ to $\left.\ell^{-}\left(x_{1}, y_{1}\right)\left(t_{1}\right)\right)$,
- $\ell^{+}\left(x_{1}, y_{1}\right)^{\leftarrow}$ (respectively, $\left.\ell^{-}\left(x_{1}, y_{1}\right)^{\leftarrow}\right)$ from $\ell^{+}\left(x_{1}, y_{1}\right)\left(t_{1}\right)$ (respectively, $\left.\ell^{-}\left(x_{1}, y_{1}\right)\left(t_{1}\right)\right)$ to $\left(x_{1}, y_{1}\right)$.
The curve $d$ is entirely in $L$ (respectively in $R$ ), starts at ( $x_{0}, y_{0}$ ) and ends at ( $x_{1}, y_{1}$ ), which proves that $L$ (respectively $R$ ) is indeed a connected component.

We claim that $L \cup R=\mathbb{R}^{2}$ : indeed, for all $(x, y) \in \mathbb{R}^{2}$, since $\ell(x, y)$ crosses $c$ an odd number of times, $\ell^{+}(x, y)$ crosses $c$ an even number of times if and only if $\ell^{-}(x, y)$ crosses $c$ an odd number of times (and vice-versa), hence ( $x, y$ ) is in at least one of $L$ and $R$, and only the points of $c$ are in both.

As a conclusion, $c$ cuts the plane into two disjoint connected components: $L \backslash c(\mathbb{R})$ which we call the strict left-hand side of $c$ and $R \backslash c(\mathbb{R})$ which we call the strict right-hand side of $c$.

Let $(x, 0)$ be a point so far to the east of $c$ that $\ell^{+}(x, 0)$ intersects $c$ exactly once, along $c$ 's horizontal ray to the north. $(x, 0)$ is in $L$, and since $L$ is connected, we get Conclusion 1. Let $(x, 0)$ be a point so far to the west of $c$ that $\ell^{-}(x, 0)$ intersects $c$ exactly once, along $c$ 's horizontal ray to the north. $(x, 0)$ is in $R$, and since $R$ is connected, we get Conclusion 2 ,

Using the technique in the proof of Theorem B.3, the definitions of turning right and left can be extended from a line to an infinite polygonal curve.

Definition 13 (left-hand and right-hand side of a curve). The conclusion of Theorem B. 3 defines the left-hand side $\mathcal{L} \subsetneq \mathbb{R}^{2}$, and right-hand side $\mathcal{R} \subsetneq \mathbb{R}^{2}$ of a simple infinite almostvertical polygonal curve $c$. The strict left-hand side of an infinite almost-vertical polygonal curve $c: \mathbb{R} \rightarrow \mathbb{R}^{2}$ is the set $\mathcal{L} \backslash c(\mathbb{R})$. Likewise the strict right-hand side of an infinite almost-vertical polygonal curve $c$ is the set $\mathcal{R} \backslash c(\mathbb{R})$, where $\mathcal{R}$ is the right-hand side of $c$.

We have already defined what ti means for a curve to cross a line. Theorem B. 3 enables us to generalise that definition to one curve turning from another simple infinite almost-vertical polygonal curve.
Definition 14 (One curve turning left or right from another). Let $d$ be a curve and let $c: \mathbb{R} \rightarrow$ $\mathbb{R}^{2}$ be a simple infinite almost-vertical polygonal curve. We say that $d$ turns left (respectively, right) from curve $c$ at the point $d(z)=c(w)$, for some $z, w \in \mathbb{R}$, if there is an $\epsilon>0$ such that $d(z+\epsilon)$ is in the strict left-hand (respectively, right-hand) side of $d$ and $d\left(z^{\prime}\right)$ is not on $c$, for all $z^{\prime}$ where $z<z^{\prime}<z+\epsilon$.

Definition 14 is consistent with the definition of one path turning left/right from another (Section (2.2) in the following sense. Consider two paths $P$ and $Q$ such that $Q$ turns right (respectively, left) of $P$ and consider a curve $c$ which contains $\mathfrak{E}[P]$ (with the same orientation) then $\mathfrak{E}[Q]$ turns right (respectively, left) of $c$. However, not all curves are the embedding of some path, hence the reverse implication does not hold. Also, the curve turning definition has no requirement analogous to the orientation requirement for path turns (implied by $i>0$ and the definition of $\Delta$ in the path turning definition).

Throughout the article, we will use the following fact several times. First, let $c$ be a simple infinite almost-vertical polygonal curve (Definition (12), and let $\ell^{1}$ and $\ell^{2}$ be two vertical rays from the south such that $\ell^{1}$ is the vertical ray from the south used to define $c$, and $\ell^{2}$ is strictly to the east (respectively, west) of $\ell^{1}$ and does not intersect $c$, then $\ell^{2}$ belongs to the right-hand side (respectively, left-hand side) of $c$. The same conclusion holds if $\ell^{1}$ and $\ell^{2}$ go to the north, with $\ell^{1}$ being the vertical ray from the north used to define $c$.

[^1]:    ${ }^{1}$ Directed systems do not have fragile paths, hence for directed systems the conclusion of the theorem statement

[^2]:    systems simply reads "... then $P$ is pumpable".

[^3]:    ${ }^{2}$ Intuitively, an assembly is a positioning of unit-sized tiles, each from some set of tile types $T$, so that their centers are placed on (some of) the elements of the discrete plane $\mathbb{Z}^{2}$ and such that those elements of $\mathbb{Z}^{2}$ form a connected set of points.

[^4]:    ${ }^{3}$ I.e. asm $(P)$ is a partial function from $\mathbb{Z}^{2}$ to tile types, and is defined on a connected set.
    ${ }^{4}$ Formally, non-intersection of a path $P=P_{0} P_{1}, \ldots$ and a seed assembly $\sigma$ is defined as: $\forall t$ such that $t \in \sigma, \nexists i$ such that $\operatorname{pos}\left(P_{i}\right)=\operatorname{pos}(t)$.
    ${ }^{5}$ Intuitively, although producible paths are not assemblies, any producible path $P$ has the nice property that it encodes an unambiguous description of how to grow $\operatorname{asm}(P)$ from the seed $\sigma$, in path $(P)$ order, to produce the assembly $\operatorname{asm}(P) \cup \sigma$.

[^5]:    ${ }^{6}$ Here, it might be the case that $\alpha$ and $P$ conflict at only one position by placing two different tile types $t$ and $t^{\prime}$, but that $t$ and $t^{\prime}$ may place the same glues along $P$. In this case $P$ is not producible when starting from the assembly $\alpha$ because one of the tiles along the positions of $P$ is of the wrong type.

[^6]:    ${ }^{7} \operatorname{dom}(D)-(c-b)$ means $[b, d-(c-b)]$ if $\operatorname{dom}(D)=[c, d]$, and $[b, d-(c-b)[$ if $\operatorname{dom}(D)=[c, d[$

[^7]:    ${ }^{8}$ For a glue ray (whose range has half-integer x-coordinate), to not intersect $\sigma$ (whose tiles are on integer points), we mean that the glue ray does not intersect any segment between two adjacent tiles of $\sigma$ (even if these adjacent tiles do not interact).

[^8]:    ${ }^{9}$ this new definition of $c$ follows the same points as the previous one, but some parts are reversed because now we know that $i<j$.

[^9]:    ${ }^{10}$ Recall that $L^{m_{0}}(\mathbb{R})$ is the set of all points in the range of of $L^{m_{0}}$

[^10]:    ${ }^{11}$ We've already shown that $a<k$, hence the tile $P_{a+1}+{\overrightarrow{P_{j} P}}$ is a tile of $P_{j+1, j+2, \ldots, k}+{\overrightarrow{P_{j} P}}$ and thus is well-defined. Also, $b>0$ implies $a \neq j+1$ which in turn implies $a>j+1$, hence $P_{a-1}+\overrightarrow{P_{j} P_{i}}$ is a tile of $P_{j+1, j+2, \ldots, k}+\overrightarrow{P_{j} P_{i}}$ and thus is well-defined.

[^11]:    ${ }^{12}$ Remember that $\mathfrak{E}\left[P_{a^{\prime}, a^{\prime}+1, \ldots, k+1}+\overrightarrow{P_{j} P_{i}}\right]$ has domain $\left[0, k+1-a^{\prime}\right]$.

[^12]:    ${ }^{16}$ Note that, in particular, $s_{0}$ is not an index on $r$ (nor $R$ ) since the maximum index on $R$ is $|r|-1$

[^13]:    ${ }^{17}$ We are intentionally not fully describing where these segments appear on $P$; that is one of the goals of the remainder of the proof.

[^14]:    ${ }^{18}$ Seed glues are glues that are located on tiles belonging to the seed $\sigma$. Thus, in particular, the $\geq 1$ glue(s) on $\sigma$ that are abutting to tile $P_{0}$ of $P$ are seed glues.
    ${ }^{19}$ In the case where $s=n, P$ has only one glue on the glue column of glue $\left(P_{s} P_{s+1}\right)$, and $(s, n)$ is an up span.
    ${ }^{20}$ If glue $\left(P_{s} P_{s+1}\right)$ and glue $\left(P_{n} P_{n+1}\right)$ point to different direction, the span has no direction.

[^15]:    ${ }^{21} S$ and $S^{\prime}$ have the same height if and only if $l^{n^{\prime}}(0)+\overrightarrow{P_{s^{\prime}} P_{s}}=\operatorname{pos}\left(\operatorname{glue}\left(P_{n} P_{n+1}\right)\right)$
    ${ }^{22}$ There are 2 orientations, and $\leq|T|$ glue types that appear as the east glue of some tile in $T$, and the indexing up to $n$ begins at 0 .

[^16]:    ${ }^{23}$ The definition of " $c$ crosses $\ell$ from left to right" ensures that certain kinds of intersections between $c$ and $\ell$ are not counted as crossing, those include: coincident intersection between two straight segments of length $>0$, and "glancing" of a line "tangentially" to a corner.
    ${ }^{24}$ The term "crosses" was defined with respect to a line $\ell(x, y)$. This definition is easily generalised to the (coincident) ray $\ell^{+}(x, y)$, by considering only those crossings at locations that are simultaneously on both $\ell$ and the ray. Likewise for the ray $\ell^{-}(x, y)$.
