Some analytic results on generalised Seiberg Witten equations

Guanheng Chen

Abstract

The purpose of this note is to generalise several known results for Seiberg Witten equations to generalised Seiberg Witten equations. The results include the following three parts: Firstly, we establish the Kuranishi charts for the moduli space of generalised Seiberg Witten equations. Secondly, we study the sectional curvature of the part of the moduli space where is smooth. Finally, under certain assumptions, we establish a compactness result for the generalised harmonic spinors. The harmonic spinors are solutions to the generalised Dirac equation, which is a special case of the generalised Seiberg Witten equations. Moreover, we show that the blow-up locus lies inside zero set of a function. This function comes from the limit of the hyperKähler potential along a sequence of harmonic spinors.

1 Introduction

Let \((X, g_X)\) be a Riemannian closed 4-manifold. Fix a \(Spin^c\) structure \(Q \rightarrow X\), the Seiberg Witten equations are introduced by E.Witten \[15\]. Latter, C. H. Taubes and V. Y. Pidstrygach generalise the equations to more general settings \[11\], \[8\]. Such equations are called generalised Seiberg Witten equations, abbreviated as GSW.

In the classical case, a solution to the Seiberg Witten equations consists of a pair \((A, u)\), where \(A\) is a \(Spin^c\) connection and \(u\) is a section of the associated bundle \(Q \times_{Spin^c} \mathbb{H}\). Here \(\mathbb{H}\) is space of quaternions. The idea behind the generalisation is shown in the following two aspects. Firstly, the \(Spin^c\) group is replaced by a more general Lie group, which is so-called \(Spin^G\) group, here \(G\) can be any compact Lie group. Secondly,
the fiber \( \mathbb{H} \) of the associated bundle is replaced by a hyperKähler manifold with certain symmetries. Such a manifold is called target manifold. In particular, \( u \) is a section of a fiber bundle and the fiber is not necessary to be vector space.

By suitable choice of \( G \) and \( M \), the GSW recovers various known equations in gauge theory. (Cf. Section 5.2 of [4]) In the cases that \( M \) are \( \mathbb{H} \) modules, based on Taubes’ method in [12], several compactness results are established by many authors, eg. [7], [18], [13], etc. For the general cases, other aspects of GSW have been studied by many mathematicians as well, eg. [6], [2], [14], etc.

The purpose of this note is to generalise several known results for Seiberg Witten equations to GSW. The main results include the following three parts:

Firstly, we establish the Kuranishi charts for the moduli space of GSW. The proof of this part is essentially the same as the classical case.

Secondly, we study the Riemannian geometry near the smooth points of the moduli space. Near the smooth points, the moduli space admits a natural metric which is defined by \( L^2 \) norm. In addition, there is a torsion-free connection compatible with this metric. We give a description of the sectional curvature, which is a generalisation of the results in [1].

Finally, under certain curvature bound assumptions and we assume that the Lie group \( G \) is zero dimension, we study the behavior of a sequence of solutions to GSW. Note that under these assumptions, the GSW is reduced to a single generalised Dirac equation. The method in [17] can be applied to this case directly. Furthermore, we show that the blow-up locus is contained in zero set of a Hölder continuous function. In fact, this function comes from the limit of the hyperKähler potential along the sequence of harmonic spinors. The proof borrows the technique of frequency function, which is introduced by C. H. Taubes [12]. (Also see [7] and [13].)

2 Preliminaries

Before we state the main results, let us introduce some essential definitions in this section. Most of what follows here paraphrase parts of the accounts in [10], [3] and [4].
2.1 Spin$^G$ group and Spin$^G$ structure

Let $G$ be a compact Lie group and $\varepsilon$ be a central element of $G$ satisfying $\varepsilon^2 = 1$. The Spin$^G$ group is defined by

$$\text{Spin}^G_\varepsilon(m) = \frac{\text{Spin}(m) \times G}{\langle -1, \varepsilon \rangle}.$$ 

Here are some examples of Spin$^G$ group: $\text{Spin}^U_{-1}(1) = \text{Spin}^c(m)$, $\text{Spin}^{Z_2}_{-1}(m) = \text{Spin}(m)$ and $\text{Spin}\{e\}_{-1}(m) = \text{SO}(m)$. We focus on the cases that $m = 3$ or $m = 4$, and we denote the Spin$^G_\varepsilon(m)$ group by $H$.

**Definition 2.1.** Let $P_{SO(4)}$ be the frame bundle of $X$ and $P_{\bar{G}} \to X$ be a principal $\bar{G}$ bundle, where $\bar{G} = \{G, 1, \varepsilon\}$. A Spin$^G_\varepsilon(4)$ structure is a principal Spin$^G_\varepsilon(4)$ bundle $Q \to X$ which is an equivariant double cover of $P_{SO(4)} \times X P_{\bar{G}} \to X$ with respective to the double cover in the following exact sequence

$$1 \to \mathbb{Z}_2 \to \text{Spin}^G_\varepsilon(4) \to SO(4) \times \bar{G} \to 1.$$ 

2.2 HyperKähler manifold and permuting action

A hyperKähler manifold is a Riemannian manifold $(M, g_M)$ endowed with a triple of complex structures $\{I_i\}_{i=1}^3$ which satisfy the quaternionic relations. Also, the metric and these complex structures form a triple of Kähler structures. Define the scalar product by

$$I : \mathbb{H} \to \text{End}TM$$

$$\zeta = h_0 + h_1i + h_2j + h_3k \to I_\zeta = h_0Id_{TM} + h_1I_1 + h_2I_2 + h_3I_3.$$ 

Then we can think of the tangent bundle $TM$ as a bundle of $\mathbb{H}$-modules. Observe that $I_\zeta$ is still a complex structure whenever $|\zeta| = 1$.

**Definition 2.2.** Let $(M, g_M, I_1, I_2, I_3)$ be a hyperKähler manifold with isometric $Sp(1)$ action. The $Sp(1)$ action is called permuting if

$$dqI_\zeta dq^{-1} = I_{q\zeta q},$$

for any $q \in Sp(1)$ and $\zeta \in \text{Im} \mathbb{H}$ with $|\zeta| = 1$.

**Convention 1.** The hyperKähler form $\omega \in \Omega^2(M, sp(1)^*)$ is defined by $\omega_\zeta = g_M(\cdot, I_\zeta \cdot)$.

Assume that $M$ admits a hyperKähler $G$-action, i.e., it preserves the metric and complex structures. Then a hyperKähler moment map is a $G$-equivariant map $\mu : M \to sp(1)^* \otimes \mathfrak{g}^*$ such that

$$<d\mu, \zeta \otimes \xi> = \iota_{K_{\mu, G}\omega_\zeta},$$

(2)
where $\zeta \otimes \xi \in \mathfrak{sp}(1) \otimes \mathfrak{g}$ and $K^{M,G}_\xi |_m = \frac{d}{dt} \exp(t\xi) \cdot m |_{t=0}$ is the fundamental vector field.

Now $(M, g_M, I_1, I_2, I_3)$ admits a permuting $Sp(1)$-action and a hyperKähler $G$-action. We hope that the action $Sp(1) \times G$ can descend to a $Spin^G$ action on $M$. To this end, we make the following assumptions. Firstly, the $G$-action commutes with the $Sp(1)$ action. Secondly, let $\varepsilon$ be a central element of $G$ satisfying $\varepsilon^2 = 1$ as before, we require that the element $(-1, \varepsilon) \subset Sp(1) \times G$ acts trivially on $M$. Under these assumptions, the $Sp(1) \times G$ action descends to a $Spin^G$ action. A $Spin^G$ action is called permuting if it is induced by a permuting action of $Spin^G(3)$ via the homomorphism $Spin^G(3) \rightarrow Spin^G(4) / Sp_-(1) \cong Spin^G(3)$.

**Convention 2.** In the rest part of this note, we always assume that the hyperKähler manifold $(M, g_M, I_1, I_2, I_3)$ admits a permuting $Spin^G(4)$ action.

### 2.3 HyperKähler potential

Let $(M, g_M, I_1, I_2, I_3)$ be a hyperKähler manifold with permuting $Spin^G(4)$ action as before. We define a map $\chi : \mathfrak{sp}(1) \otimes \mathfrak{sp}(1) \rightarrow \Gamma(M, TM)$ by

$$\zeta \otimes \zeta' \rightarrow -I_\zeta \cdot K^{M,Sp(1)}_{\zeta}.$$ 

We decompose $\chi$ into $\chi_0 + \chi_1 + \chi_2$, where $\chi_0 = -\frac{1}{3} \sum_{l=1}^3 I_l K^{M,Sp(1)}_{\zeta_l}$ is its diagonal, $\chi_1$ is its antisymmetric part and $\chi_2$ is its trace-free symmetric part.

A function $\rho \in C^\infty(M, \mathbb{R})$ is called hyperKähler potential if it satisfies $dI_\zeta d\rho = 2\omega_\zeta$ for any $\zeta \in \mathfrak{sp}(1)$ with $|\zeta| = 1$. The following lemma gives a sufficient condition of the existence of hyperKähler potential.

**Lemma 2.3** (Lemma 3.2.3 of [10]). Let $M$ be a hyperKähler manifold with permuting $Sp(1)$-action. Suppose that $\chi_2 = 0$, then there is a unique hyperKähler potential $\rho_0$ such that

$$\rho_0 = \frac{1}{2} g_M(\chi_0, \chi_0), \text{ and } |\text{grad}\rho_0| = 2\rho_0.$$ 

**Convention 3.** The choice of hyperKähler potential is not unique. We fix the choice provided by the above lemma throughout.

A typical example of hyperKähler manifold with permuting $Sp(1)$-action and vanishing $\chi_2$ is the Swann bundles $\mathcal{U}(N)$, where $\mathcal{U}(N)$ is a fiber bundle over $N$ and $N$ is a quaternionic Kähler manifold with positive scalar curvature. The fiber of $\mathcal{U}(N)$ is $\mathbb{H}^*/\mathbb{Z}_2$. In this case, the hyperKähler potential is $\rho_0 = \frac{1}{2} r^2$, where $r$ is the radial coordinate of $\mathbb{H}^*$. We remind the reader that the Swann bundles $\mathcal{U}(N)$ usually is not complete. For more details about the construction of $\mathcal{U}(N)$ and its properties, we refer the reader to [9] and Section 3.5 of [10].
2.4 Clifford multiplication

In dimension four, there are two $\text{Spin}^G$ spaces, denoted by $E^\pm$. They are respectively analogy of the $\text{Spin}^c$ bundles $S_+$ and $S_-$. Both of them are a copy of $TM$ while admitting different $\text{Spin}^G(4)$ actions. Let $[q_+, q_-, g] \in \text{Spin}^G(4)$ and $v \in TM$. The $\text{Spin}^G$ action on $E^+$ is given by

$$[q_+, q_-, g] \cdot v = (q_+) \ast g \ast (v).$$

On the other hand, the $\text{Spin}^G$ action over $E^-$ is

$$[q_+, q_-, g] \cdot v = I_{q_-} I_{q_+} (q_+) \ast g \ast (v).$$

The Clifford multiplication is a $\text{Spin}^G(4)$-equivariant map $c_4 : \mathbb{R}^* \simeq \mathbb{H} \to \text{End}(E^+ \oplus E^-)$

$$g_{\mathbb{R}^*}(h, \cdot) \to \begin{pmatrix} 0 & -I_h \\ I_h & 0 \end{pmatrix}. \quad (3)$$

2.5 Generalised Dirac operator

Recall that we set $H = \text{Spin}^G(4)$. Let $N = C^\infty(Q, M)^H$ be the space of $H$-equivariant maps from $Q$ to $M$. Note that this is nothing but just the space of sections of the associated bundle $M = Q \times_H M$. An element of $N$ is referred to as spinor.

Note that the Lie algebra of $\text{Spin}^G$ group can be decomposed as $\text{Lie} H = so(m) \oplus g$. Let $A$ denote the space of connections on $\pi : Q \to X$ whose $so(m)$ component is induced by Levi-Civita connection, i.e.,

$$A = \{ A \in \mathcal{A}(Q) | pr_{so(m)} \circ A = \pi^*_{SO(m)} \varphi_X \},$$

where $\varphi_X$ denotes the Levi-Civita connection of $P_{SO(m)} \to Z$. This is an affine space over $\Omega^1(Q, g)^H_{\text{hor}} = \Omega^1(X, Adg)$, where $Adg$ is the associated bundle $Q \times_{Ad} g$.

Fix a connection $A \in A$, for any $u \in N$, the covariant derivative $d_A : N \to C^\infty(Q, (\mathbb{R}^4)^* \otimes TM)^H$ is defined by

$$< d_A u, w > |_p = du(\tilde{w}(p)),$$

where $w \in \mathbb{R}^4$, $\tilde{w}$ is any horizontal lift of $w$. Besides, we also define a variant of the covariant derivative as follows:

$$d^T_A : C^\infty(Q, TM)^H \to C^\infty(Q, (\mathbb{R}^4)^* \otimes TM)^H$$

$$< d^T_A v, w > |_p = \mathcal{K} \circ dv(\tilde{w}(p)),$$ \quad (4)

where $\mathcal{K} : TTM \to TM$ is the connector induced by Levi-Civita connection. When we restrict our attention to a spinor $u$, then $d^T_A$ descends to a covariant derivative (still
denoted by $d_A^{TM}$ on the vector bundle $\pi^! u^* TM = u^* TM/H$ in the usual sense. (Cf. Remark 4.3.3 of [4])

Similar to the usual case, the generalised Dirac operator is defined by the composition of the Clifford multiplication $c_4$ and the covariant derivative, i.e., $D_A u = c_4 \circ d_A u$.

**Definition 2.4.** A spinor $u \in \Gamma(X, M)$ such that $D_A u = 0$ is called harmonic spinor.

### 2.6 Generalised Seiberg Witten equations

Let $(X, g_X)$ be a closed 4-manifold and $Q \to X$ be a $\text{Spin}^G$ structure. Let $(M, g_M, I_1, I_2, I_3)$ be a hyperKähler manifold with permuting $\text{Spin}^G$ action and $\mu : M \to \mathfrak{sp}(1) \otimes g^*$ be the moment map.

We define a map $\Phi : \mathcal{N} \to C^\infty(Q, \Lambda^{2+} \mathbb{R}^4 \otimes g)^H$ by

$$< \Phi(u), \eta \otimes \xi >_{g_X \otimes g_\mathfrak{g}} = < \mu(u), \zeta \otimes \xi >,$$

where $\{\eta\}_{l=1}^{3}$ and $\{\zeta\}_{l=1}^{3}$ are respectively orthonormal basis of $\Lambda^{2+} \mathbb{R}^4$ and $\mathfrak{sp}(1)^*$. Let $C = A \times \mathcal{N}$, it is called configuration space. Let $\mathcal{G} = C^\infty(Q, G)^H$ be the gauge group. For any $g \in \mathcal{G}$, the gauge action is defined by

$$g \cdot (A, u) = (g^* A, L_{g^{-1}} u) = (Ad_{g^{-1}} p)(A|_p) + g^* \eta|_p, \ L_{g^{-1}} u),$$

where $\eta \in \Omega^1(G, g)^G$ is the left-invariant Maurer-Cartan form on $G$ and $L_g$ denotes the left $G$-action. In most of the time, we write $L_{g^{-1}} u$ as $g^{-1} \cdot u$. A configuration $(A, u)$ is solution to GSW if it satisfies the following equations

$$\begin{cases}
D_A u = 0, \\
F_a^+ + \Phi(u) = \eta,
\end{cases}$$

where $\eta \in \Omega^{2+}(X, \text{Ad}_3)$ is a perturbation and $3$ is the fixed point set of the adjoint action of $G$ on $g$. By Proposition 4.2.8 of [3], the GSW is gauge invariant.

**Convention 4.** We fix a $G$-invariant metric $g_\mathfrak{g}$ over the Lie algebra $\mathfrak{g}$ throughout.

### 3 Main results

Now we introduce the main results of this note.

**Theorem 1.** Assume that the moduli space of the GSW, $\mathfrak{M}$, is a smooth manifold of expected dimension. Then $\mathfrak{M}$ admits natural quotient $L^2$ metric. The sectional curvature of those metrics is explicitly given in terms of Riemannian curvature of $M$, the Green operators of the deformation complex of GSW and the Hessian of nonlinear Dirac operator and moment map.
Remark 1. In fact, the conclusion of Theorem 1 is local. If $\mathcal{M}$ is not a smooth manifold, but $\mathcal{M}$ contains a smooth point. Then the statement is still true for a small neighbourhood of the smooth point.

The following two theorems concern the behavior of a sequence of harmonic spinors $\{u_n\}_{n=1}^{\infty}$ with uniform bound $\int_X \rho_0 \circ u_n \leq c_0$. When $M = \mathbb{H}^n$, this condition is equivalent to a uniform bound on the $L^2$-norm of harmonic spinors. (Cf. Example 3.2.8 of [3].)

Theorem 2. Suppose that the Lie group $G$ is zero dimension and $(M, g_M, I_1, I_2, I_3)$ is a hyperKähler manifold with $\chi_2 = 0$. Let $\rho_0$ be the unique hyperKähler potential. Let $\{u_n\}_{n=1}^{\infty}$ be a sequence of harmonic spinors, i.e., $D_A u_n = 0$. Assume that there exists a sequence of uniform positive constant $\{c_k\}_{k \in \mathbb{N}}$ such that

1. The images of $\{u_n\}_{n=1}^{\infty}$ are contained in a compact subset of $M$.
2. $|Rm_M| u_n |C^k \leq c_k$, $|K^{M,H}_{F_A}| u_n |C^k \leq c_k$ and $\int_X \rho_0 \circ u_n \leq c_0$.

Then there exists a subsequence of $\{u_n\}_{n=1}^{\infty}$ (Still denoted by $\{u_n\}_{n=1}^{\infty}$) and a subset $S \subset X$ with the following significations:

1. The set $S$ is closed and the 2-dimensional Hausdorff measure of $S$ is finite, i.e. $\mathcal{H}^2(S) < \infty$.
2. The subsequence $\{u_n\}_{n=1}^{\infty}$ converges $C^\infty_{\text{loc}}$ to $u$ over $X - S$.
3. The set $S$ is minimal in the following sense: If there is a subset $S' \subset X$ such that a subsequence of $\{u_n\}_{n=1}^{\infty}$ in $C^\infty_{\text{loc}}$ over $X - S'$, then $S \subset S'$.
4. If $\lim_{n \to \infty} \int_X \rho_0 \circ u_n = 0$, then $S = \emptyset$. Let $u$ denote the limit of the sequence, then it is a parallel harmonic spinor, i.e., $d_A u = 0$. Moreover, $\rho_0 \circ u = 0$.

Remark 2. For any orthonormal frame $\{e_i\}_{i=1}^{4}$ of $X$, $K^{M,H}_{F_A(e_i,e_j)} u$ is a vector field over $M$. The $C^k$-norm in the assumptions is defined by

$$|K^{M,H}_{F_A}| u |C^k = \sup_{i,j} \sum_{l=0}^{k} \sum_{p=0}^{l} (\sum ((\nabla^M)^p K^{M,H}_{(\nabla^A)^l-p F_A(e_i,e_j)} |u|),$$

where $\nabla^M$ is the Levi-Civita connection of $(M, g_M)$.

Remark 3. As our $X$ is closed, if the images of $\{u_n\}_{n=1}^{\infty}$ are contained in a compact subset of $M$, then the curvature conditions on $|Rm_M| u_n |C^k$ and $|K^{M,H}_{F_A}| u_n |C^k$ are true. The reason why we keep these assumptions is as follows: When $M$ is a Swann bundle, we can still get a convergence result under the curvature bound assumptions.
\[ |\text{Rm}_M u_n|_{C^k} \leq c_k \text{ and } |K_{F_A}^{M,H} u_n|_{C^k} \leq c_k, \] without any assumption on the images of \( \{ u_n \}_{n=1}^\infty \). See Remarks \( 6 \) and \( 8 \).

When \( \dim G = 0 \), the connection \( A \) is determined by the Levi-Civita connection of \( (X, g_X) \). If \( (X, g_X) \) is flat, then \( K_{F_A}^{M,H} u = 0 \). The curvature conditions \( |K_{F_A}^{M,H} u_n|_{C^k} \leq c_k \) are automatically true.

**Remark 4.** When \( M = U(N) \) is a Swann bundle, then the last statement of Theorem 2 doesn’t make sense in general, as \( \rho_0^{-1}(0) \) may not be well defined. From the proof, we still know that \( \{|d_A u_n|\}_{n=1}^\infty \) is uniformly bounded.

**Theorem 3.** Let \( \{ u_n \}_{n=1}^\infty \) be a sequence of harmonic spinors. Under the assumptions in Theorem 2 then there exists a constant \( 0 < \gamma < 1 \) such that the sequence \( \{ \rho_0 \circ u_n \}_{n=1}^\infty \) converges to a nonnegative function \( \rho : X \to \mathbb{R} \) in \( C^{0,\gamma} \) sense. Moreover, \( S \subset \rho^{-1}(0) \).

**Remark 5.** In general, we cannot expect that \( S = \rho^{-1}(0) \). For example, in the case that \( M = \mathbb{H} \), then \( \{ u_n \}_{n=1}^\infty \) are harmonic spinors in the classical sense. Hence, \( S = \emptyset \).

However, \( \rho^{-1}(0) = \emptyset \) if and only if the limit harmonic spinor nowhere vanishes.

**Remark 6.** When \( M = U(N) \) is a Swann bundle and \( N \) is compact, the assumption on the image of \( \{ u_n \}_{n=1}^\infty \) can be removed. The second conclusion of Theorem 3 can be restated as follows. The sequence \( \{ u_n \}_{n=1}^\infty \) converges \( C_0^\infty \) to a harmonic spinor over \( X - \rho^{-1}(0) \). Please see Remark \( 8 \) as well.

### 4 Local structure of the moduli space

In this section, the goal is to establish the deformation complex and Kuranishi structure for the moduli space of GSW.

#### 4.1 Sobolev completion

Let \( \mathcal{M} = Q \times_H M \) be the associated bundle. Embed \( M \hookrightarrow \mathbb{R}^N \) for some positive integer \( N \). Then for any section \( u \in \Gamma(X, \mathcal{M}) \), we can define the Sobolev norm \( |u|_{W^{k,p}} \) via the embedding. Under the identification \( \mathcal{N} = \Gamma(X, \mathcal{M}) \), we define the Sobolev norm for elements in \( \mathcal{N} \). Let \( \mathcal{N}^{k,p} \) be the completion of \( \mathcal{N} \) with respect to the norm \( |\cdot|_{W^{k,p}} \).

Alternatively, \( \mathcal{N}^{k,p} \) is the subspace of \( W^{k,p}(Q, M) \) that consists of the \( H \)-equivariant maps. Similarly, we define the Sobolev completion for the gauge group, denoted by \( \mathcal{G}^{k,p} \). For more details on the Sobolev completion of maps between manifolds, we refer the reader to Appendix B of [15].

**Convention 5.** We denote the Sobolev completion of \( H \)-equivariant maps between manifolds by \( W^{k,p} \). The Sobolev completion of \( H \)-equivariant, horizontal \( \mathfrak{g} \)-valued \( q \) forms is denoted by \( \Omega^q_H(Q, \mathfrak{g})^{k,p}_{\text{hor}} \). We assume that \( kp > 4 \) throughout.
By the assumption that $kp > 4$, $N^{k,p}$ is a Banach manifold and the tangent bundle $TN^{k,p}$ is given by $T_uN^{k,p} = W^{k,p}_H(Q, u^*TM)$. (The completeness of $(M, g_M)$ is required here.) The Lie algebra of $G^{k,p}$ is $W^{k,p}_H(Q, g) \cong \Omega^0(X, Adg)^{k,p}$.

Fix a reference connection $A_0$, identify $A$ with $\Omega^1(Q, g)^k_T \cong \Omega^1(X, Adg)$. Define $A^{k,p} \cong \Omega^1(X, Adg)^{k,p}$. Let $C^{k,p} = N^{k,p} \times A^{k,p}$. The gauge group $G^{k+1,p}$ acts smoothly on $C^{k,p}$. Let $B^{k,p} = C^{k,p}/G^{k+1,p}$, the usual bootstrapping argument in gauge theory shows that $B^{k,p}$ is a Hausdorff space provided that $kp > 4$.

### 4.2 Slice of quotation space

Follow from the definition of gauge action and Lemma 2.1.45 of [3], the linearisation of the gauge action at $(e, (A, u))$ is

$$D_{(A,u)}\xi = (d_u\xi, -K_{\xi}^{M,G}|_u).$$

Here $D_{(A,u)}$ is a map $D_{(A,u)} : W^{k+1,p}_H(Q, g) \to \Omega^1_{H}(Q, g)_{hor}^{k,p} \oplus W^{k,p}_H(Q, u^*E^+)$. It is easy to check that its formal $L^2$ adjoint is $D^*_{(A,u)} : \Omega^1_{H}(Q, g)^{k,p} \oplus W^{k,p}(Q, u^*E^+) \to W^{k-1,p}_H(Q, g)$,

$$D^*_{(A,u)}(b, v) = d^*_ub + d_u\mu^\# \xi(I_\xi(v)), \quad (7)$$

where $\xi \in \mathfrak{sp}(1)$ with $|\xi| = 1$ and $\mu^\#$ is $g_\xi$-dual of $\mu$. Note that the term $d_u\mu^\# \xi(I_\xi(v))$ is independent of $\xi$.

Let $Stab_{(A,u)}$ denote the stabiliser of the gauge group at $(A, u)$, i.e., $Stab_{(A,u)} = \{g \in G | g \cdot (A, u) = (A, u)\}$.

**Lemma 4.1.** $KerD_{(A,u)} = \{\xi \in W^{k+1,p}_H(Q, g) : d_u\xi = 0, K_{\xi}^{M,G}|_u = 0\}$. Moreover, dim$KerD_{(A,u)}$ is finite and $D_{(A,u)}$ has closed range. If $Stab_{(A,u)} = \{e\}$, then $KerD_{(A,u)} = 0$.

**Proof.** By the definition, $D_{(A,u)}\xi = 0$ if and only if $d_u\xi = 0$ and $K_{\xi}^{M,G}|_u = 0$.

To show that dim$KerD_{(A,u)}$ is finite and $D_{(A,u)}$ has closed range. It suffices to show that $D_{(A,u)}$ satisfies the following inequality

$$|\xi|_{W^{k+1,p}} \leq c_0 |D_{(A,u)}\xi|_{W^{k,p}} + c_0 |\xi|_{L^p}. \quad (8)$$

Note that $d_u : W^{k,p}(X, Adg) \to \Omega^1(X, Adg)^{k-1,p}$ is elliptic, thus it satisfies the similar inequality as [3]. Therefore, inequality (3) is automatically true for $D_{(A,u)}$.

For the last statement, we argue by contradiction. Assume that $Stab_{(A,u)} = \{e\}$ and $KerD_{(A,u)} \neq 0$. For any $p \in Q$ and $\xi \neq 0 \in KerD_{(A,u)}$, then

$$\frac{d}{ds} \exp(-s\xi(p))u(p) = K_{\xi}^{M,G}(\exp(-s\xi(p)))\xi(p)|_{\exp(-s\xi(p))u(p)} = 0$$

$$\frac{d}{ds} \exp(s\xi(p))^*A = Ad_{\exp(-s\xi(p))}(d_\xi = 0).$$
Therefore, \( \exp(s\xi) \cdot (A,u) = (A,u) \) and this contradicts with the assumption. 

**Definition 4.2.** Let \( S_{(A,u)}^{k,p} = \{(A + b, \exp_u(v)) \mid (b,v) \in \text{Ker}D^*_{(A,u)}\} \). It is called the local slice at \((A,u)\).

As the metric \(g_M\) is \(G\)-invariant, the exponential map is \(G\)-equivariant. Using this fact, it is easy to check that \(S_{(A,u)}^{k,p}\) is invariant under the action of \(\text{Stab}(A,u)\).

**Lemma 4.3.** Let \( U \subset S_{(A,u)}^{k,p} \) be a neighbourhood of \((A,u)\). If \( U \) is sufficiently small, then \( \mathcal{F} : U \times_{\text{Stab}(A,u)} G^{k+1,p} \to \mathcal{C}^{k,p} \) is diffeomorphic onto its image, where \( \mathcal{F} \) is defined by

\[
\mathcal{F}((A + b, \exp_u(v)), g) = g \cdot (A + b, \exp_u(v)),
\]

\(U \times_{\text{Stab}(A,u)} G^{k+1,p}\) is the product \(U \times G^{k+1,p}\) which mods out the action \(h \cdot ((A + b, \exp_u(v)), g)\) for \((h \cdot (A + b, \exp_u(v)), h^{-1}g)\).

**Proof.** The proof is the same as the usual case. Here we only sketch the main points. Note that \(\mathcal{F}\) is \(G\)-equivariant and \(\text{Stab}(A,u)\)-invariant, turn out the map \(\mathcal{F}\) is well defined.

The differential of \(\mathcal{F}\) at \((A,u,e)\) is \(d_{((A,u),e)}\mathcal{F}((b,v),\xi) = D_{(A,u)}\xi + (b,v)\), which is bijective. By implicit function theorem, \(\mathcal{F}\) is a local diffeomorphism.

If \(\mathcal{F} : U \times_{\text{Stab}(A,u)} G^{k+1,p} \to \mathcal{C}^{k,p}\) is not diffeomorphic onto its image for any small \(U\), then we can find two distinct sequences of \((\{A_n, u_n\}, g_n)\) and \((\{A'_n, u'_n\}, g'_n)\) such that \(\mathcal{F}(\{A_n, u_n\}, g_n(g'_n)^{-1}) = \mathcal{F}(\{A'_n, u'_n\}, e)\) for \((A_n, u_n), (A'_n, u'_n)\) tend to \((A,u)\). The bootstrapping argument implies that \([(\{A_n, u_n\}, g_n(g'_n)^{-1})] = [(\{A'_n, u'_n\}, e)]\) lie inside a small neighbourhood of \([(A,u), e]\) (Cf. Lemmas B.5, B.9 of [16]), which contradicts with the fact that \(\mathcal{F}\) is a local diffeomorphism. 

**Corollary 4.4.** If \(\text{Stab}(A,u) = \{e\}\), then a small neighbourhood of \([(A,u)] \in \mathcal{B}\) can be identified with a neighbourhood \(U\) of \(S_{(A,u)}^{k,p}\). In particular, \(\mathcal{T}_{[(A,u)]}\mathcal{B} = \text{Ker}D^*_{(A,u)}\).

### 4.3 Linearisation of GSW

Let \(\pi_\mathcal{E} : \mathcal{E}^{k-1,p} \to \mathcal{C}^{k,p}\) be a vector bundle defined by \(\mathcal{E}_{(A,u)}^{k,p} = W_{H}^{k-1,p}(Q, u^*E^-) \oplus \Omega^2_{H}(Q, \theta)^{k-1,p}_{\text{hor}}\). Furthermore, note that the vector bundle \(\mathcal{E}\) is \(G^{k+1,p}\)-equivariant. Let \(\mathcal{F}_{sw}(A,u) = (D_{A}u, F_{\theta}^+ + \Phi_4(u))\), then it is a section of the bundle \(\pi_\mathcal{E} : \mathcal{E}^{k,p} \to \mathcal{C}^{k,p}\).

The linearisation of \(\mathcal{F}_{sw}\) at \((A,u)\) is

\[
D_{(A,u)}\mathcal{F}_{sw}(b,v) = \begin{pmatrix}
D_{\text{lin}_u}^A v + c_4(K^M)_{b} |_{u} \\
d^*_a b + d_u \Phi_4(v)
\end{pmatrix},
\]

where \((b,v) \in T_{(A,u)}\mathcal{C}^{(k,p)} = \Omega^1_{H}(Q, \theta)^{k,p}_{\text{hor}} \oplus W_{H}^{k,p}(Q, u^*E^+)\) and \(D_{\text{lin}_u}^A v = c_4 \circ d^T_M v\).
Definition 4.5. The deformation operator of GSW at \((A, u)\) is a map

\[ \mathcal{D}_{(A, u)} : \Omega^2_H(Q, \mathfrak{g})_{\text{hor}} + W^k_{H^+}(Q, u^* E^+) \to W^{k-1, p}_{H^+}(Q, u^* E^-) + \Omega^1_H(Q, \mathfrak{g})_{\text{hor}} + W^{k-1, p}_{H^+}(Q, \mathfrak{g}) \]

defined by

\[ \mathcal{D}_{(A, u)}(b, v) = \begin{cases} 
D_{\text{lin}, u}^b v + c_4(K^M_G|_u) \\
\partial^b_t v + d_u \Phi_1(v) \\
\partial^{\#}_u v + d_u \mu^{\#}_\xi(I_\xi(v)).
\end{cases} \tag{10} \]

Note that \(\mathcal{D}_{(A, u)}\) is an elliptic operator. In particular, it is Fredholm. We denote the index of this operator by \(\text{ind}\mathcal{D}_{(A, u)}\).

Lemma 4.6. We have Fredholm complex

\[
0 \to W^{k+1, p}_{H^+}(Q, \mathfrak{g}) \overset{D_{(A, u)}}{\longrightarrow} \Omega^0_H(Q, \mathfrak{g})_{\text{hor}} + W^k_{H^+}(Q, u^* E^+) \overset{D_{(A, u)}\mathcal{F}_{sw}}{\longrightarrow} \Omega^1_H(Q, \mathfrak{g})_{\text{hor}} + W^{k-1, p}_{H^+}(Q, \mathfrak{g}) \to 0.
\]

This complex is called deformation complex. Its Euler number is \(-\text{ind}\mathcal{D}_{(A, u)}\).

Proof. It is easy to check that \(D_{(A, u)}\) and \(D_{(A, u)}\mathcal{F}_{sw}\) has closed range. The cohomology of the complex is

\[ H^0_{(A, u)} = \text{Ker}D_{(A, u)}, H^1_{(A, u)} = \frac{\text{Ker}D_{(A, u)}\mathcal{F}_{sw}}{\text{Im}D_{(A, u)}} \text{ and } H^2_{(A, u)} = \text{Coker}D_{(A, u)}\mathcal{F}_{sw}. \]

By Lemma 4.11, \(H^0_{(A, u)}\) is finite dimension. The decomposition \(\Omega^0(X, Adg)^{k, p} = \text{Im}D_{(A, u)} \oplus \text{Ker}D^*_{(A, u)}\) implies that \(H^1_{(A, u)} = \text{Ker}\mathcal{D}_{(A, u)}\). Thus \(H^1_{(A, u)}\) is finite dimension as well. Note that \(\text{Coker}\mathcal{D}_{(A, u)} = \text{Coker}D_{(A, u)}\mathcal{F}_{sw} \oplus \text{Coker}D^*_{(A, u)}\), hence \(H^2_{(A, u)}\) is also finite dimension.

The remaining task is to prove that \(D_{(A, u)}\mathcal{F}_{sw} \circ D_{(A, u)} = 0\). This follows from differentiate the GSW acting by \(g = \exp(t\xi) \in \mathfrak{g}^{k+1, p}\). To differentiate the Dirac equation, we have

\[
0 = \mathcal{K} \circ \frac{d}{dt} D_{\exp(t\xi)\ast A}(\exp(-t\xi)u)|_{t=0} = \mathcal{K} \circ \frac{d}{dt} D_A(\exp(-t\xi)u)|_{t=0} + \mathcal{K} \circ \frac{d}{dt} c_4(K^M_G|_{\exp(t\xi)\ast A- A}|_{\exp(-t\xi)u})|_{t=0} \tag{12}
\]

The last equality follows from the fact that \(c_4\) is parallel. Let \(a(t) = (\exp(t\xi)\ast A - A)(X)\) for any horizontal tangent vector \(X\) with respect to \(A\). Then \(a'(0) = d_a\xi(X)\). By
\[
\frac{d}{dt} K_{u(t)}^{M,G}|_{t=0} = \frac{d}{dt} \frac{d}{ds} \exp(sa(t))u|_{s=0, t=0} \\
= \kappa_M \frac{d}{ds} \frac{d}{dt} \exp(sa(t))u|_{t=0, s=0} \\
= \kappa_M \frac{d}{ds} \left( d_{\exp(sa(0))} L_u(\dot{s}) \right) |_{s=0} \\
= \kappa_M \left( d_{\exp(sa(0))} \dot{L}_u(0) \right) = \kappa_M \frac{d}{ds} \exp(sa(0))u|_{s=0} \\
= \kappa_M \circ K_{a,0}^{M,G},
\]

where \( L_u \) denotes the left \( G \) action along \( u \), i.e., \( L_u g = g \cdot u \), and \( \kappa_M : TTM \rightarrow TTM \) denotes the canonical flip. By Theorem 2.1.39 of [3], \( \kappa_M \circ K = K \). Hence, \( K \circ \frac{d}{dt} K_{\exp(t\xi)A}|_{t=0} = K_{d_s \xi}|_u \).

The moment \( \mu \) is \( G \)-equivariant implies that \( \Phi_4(g \cdot u) = Ad_g \Phi_4(u) \). Take \( g = \exp(t\xi) \), then

\[
\frac{d}{dt} \Phi_4(\exp(t\xi)u)|_{t=0} = \frac{d}{dt} Ad_{\exp(t\xi)} \Phi_4(u)|_{t=0}.
\]

By definition, the left hand side is \( d_u \Phi_4(K_{\xi}^{M,G}|_u) \), while the right side is \( ad_{\xi} \Phi_4(u) = [\xi, \Phi_4(u)] \). Therefore,

\[
d_u^* d_u \xi + d_u \Phi_4(-K_{\xi}^{M,G}|_u) = [F_3^+, \xi] - [\xi, \Phi_4(u)] = 0.
\]

In sum, \( D_{(A,u)} F_{sw} \circ D_{(A,u)} = 0 \) follows from equations (12), (13) and (15).

\[ \square \]

The following lemma establish the Kuranishi chart of the moduli space.

**Lemma 4.7.** There is a \( Stab(A,u) \) equivariant map \( \kappa : U \subset H_1^{1}(A,u) \rightarrow H_2^{1}(A,u) \) such that \( \kappa^{-1}(0)/Stab(A,u) \) is homeomorphic to a neighbourhood of \( [(A,u)] \) in \( \mathfrak{M} \).

**Proof.** Without loss of generality, we identify a neighbourhood of \( [(A,u)] \) in \( \mathcal{B} \) is \( S_{(A,u)}/Stab(A,u) \). Fix a trivialisation of the bundle \( \pi_1 \mathcal{E}^{k-1,p} \) over this neighbourhood and the fiber is \( \mathcal{E}^{k-1,p}_{(A,u)} \). Under these identifications, \( F_{sw} : S_{(A,u)}^{k,p} \rightarrow \mathcal{E}^{k-1,p}_{(A,u)} \) is well-defined.

Let \( \Pi_{(A,u)} : \mathcal{E}^{k-1,p}_{(A,u)} \rightarrow Coker D_{(A,u)} \), \( F_{sw} \) be the \( L^2 \) projection. Then the linearisation of the map \((1-\Pi_{(A,u)}) \circ F_{sw} \) at \( (A,u) \) is surjective with kernel \( H_1^{1}(A,u) \). By implicit function theorem, there is a diffeomorphism \( \Phi : U \subset H_1^{1}(A,u) \rightarrow \{(1-\Pi_{(A,u)}) \circ F_{sw}(0)\}^{-1}(0) \subset S_{(A,u)}^{k,p} \) onto its image. The map \( \Phi \) is \( Stab(A,u) \)-equivariant.

Define \( \kappa = \Pi_{(A,u)} \circ F_{sw} \circ \Phi : U \subset H_1^{1}(A,u) \rightarrow H_2^{1}(A,u) \). Then \( \Phi(b,v) \) satisfies the GSW if and only if \( (b,v) \in \kappa^{-1}(0) \). Therefore, \( \kappa^{-1}(0)/Stab(A,u) \) is homeomorphic to a neighbourhood of \( [(A,u)] \) in \( \mathfrak{M} \).

\[ \square \]
Definition 4.8. A solution \((A, u)\) to GSW is called regular if \(H^2_{(A, u)} = 0\). A point \([A, u]\) in moduli space \(\mathcal{M}\) is called smooth if it contains a regular representative \((A, u)\) such that \(\text{Stab}_{(A, u)}\) is trivial.

If \([A, u]\) is a smooth point in the moduli space, then a small neighbourhood of \(\mathcal{M}\) can be given the structure of a smooth manifold of dimension \(\text{ind} D_{(A, u)}\).

5 Riemannian geometry of the moduli space

In this section, we study the Riemannian curvature of the moduli space. The moduli space may not be smooth manifold in general, thus we only compute the curvature tensor near the smooth points.

Assume that \(C^k,p\) is a codimension zero \(G^k+1,p\)-invariant submanifold of \(C^k,p\) such that \(\text{Stab}_{(A, u)} = \{e\}\) for any \((A, u) \in C^k,p\). For example, we can take \(C^k,p\) to be the image of \(F\big|_{U \times \text{Stab}_{(A, u)}}\) in Lemma 4.3 and \((A, u)\) has trivial stabiliser. Note that \(G^k+1,p\) acts freely on \(C^k,p\). Define \(B^k,p = C^k,p / G^k+1,p\), then this is a Banach manifold. By Corollary 4.4, the tangent space at \([A, u]\) \(\in B^k,p\) is \(\text{Ker} D_{(A, u)}\). Let \(\mathcal{M}_s = (F^{-1}_{sw}(0) \cap C^k,p) / G^{k+1,p}\) denote the corresponding moduli space.

We briefly summarise the idea here, it is the same as [1] and [5]. Over \(C\), there is a natural metric defined by \(L^2\) norm. Then \(B_s\) inherits a quotient metric such that the projection \(C_s \to B_s\) is a Riemannian submersion. We use the O'Neill formula for Riemannian submersions to derive a formula for the sectional curvature of this quotient metric on \(B_s\). The metric over \(\mathcal{M}_s\) is induced from the embedding \(\mathcal{M}_s \hookrightarrow B_s\). We compute the second fundamental form of this embedding and apply Gauss formula to get the curvature formula for \(\mathcal{M}_s\).

5.1 \(L^2\) metric and connection

The natural metric over \(C\) is given by

\[
g^C((a, v), (b, w))|_{(A, u)} = \int_X g_M(v, w) + < a \wedge b, g >,
\]

where \((a, v), (b, w) \in T_{(A, u)}C = \Omega^1(Q, \mathfrak{g})^H_{\text{hor}} \oplus C^\infty_H(Q, u^* E^+)\). The connection \(\nabla^C\) on \(C\) is product of the canonical connection on \(A\) and the connection on \(N\). It are defined as follows. Let \(V = (b, v)\) and \(W = (c, w)\) be a vector fields over \(C\). Let \(\gamma(t)\) be a path in \(A\) such that \(\gamma(0) = A\) and \(\gamma'(0) = c\). Then

\[
\nabla^C_{\gamma'(0)} V = \left( \frac{d}{dt} b(\gamma(t))|_{t=0}, \mathcal{K} \circ d_u v(w) \right).
\]
This connection is torsion-free and compatible with the metric \( g^C \). When we restrict \( \nabla^C \) to subbundle \( TN \), it is torsion-free and metric compatible as well, we denote it by \( \nabla^N \). For more details, please refer to Appendix of [3].

The gauge action on \( TC \) is given by \( g : (b, v) = (Ad_g^{-1}(b), (L_g^{-1})_*(v)) \). As the metric \( g_M \) and \( < \cdot, \cdot >_g \) are \( G \)-invariant, the metric \( g^C \) is gauge invariant. Therefore, \( g^C \) descends to a unique Riemannian metric \( g^B^* \) such that the projection \( C_* \to B_* \) is a Riemannian submersion. The metric \( g^\mathfrak{m}_* \) over \( \mathfrak{m}_* \) is induced by the natural embedding \( \mathfrak{m}_* \hookrightarrow B_* \). The curvature over \( C, B_* \) and \( \mathfrak{m}_* \) are respectively denoted by \( Rm^C, Rm^{B_*} \) and \( Rm^{\mathfrak{m}_*} \).

5.2 Riemannian curvature of \( C \) and \( B^* \)

In this section, we compute \( Rm^C \) and \( Rm^{B_*} \).

Lemma 5.1. Let \( V = (a, v), W = (b, w) \) and \( X = (c, x) \) be vector fields over \( C \). Then

\[
Rm^C(V, W)X|_{(A,u)} = (0, Rm_M(v_u, w_u)x_u). \tag{18}
\]

In particular, \( < Rm^C(V, W)X, Y >|_{(A,u)} = \int_X g_M(Rm_M(v_u, w_u)x_u, y_u). \tag{19} \)

Proof. The tangent bundle of \( C^{k,p} \) is \( TC = TA^{k,p} \oplus TN^{k,p} \). Obverse that \( TA^{k,p} \) is a trivial bundle with fiber \( \Omega^1_{H}(Q, \mathfrak{g})_{\text{hor}}^{k,p} \).

Since the curvature is a tensor, it only depends on the values of \( V, W, X \) at \((A, u)\). Thus we can assume that \( a, b, c \) are constant sections over the trivial bundle \( TA^{k,p} \).

By definition, \( \nabla^C_V \nabla^C_W X|_{(A,u)} = (0, K \circ dK \circ d_{(u,w)}(dx)(d_u w(v))). \) Therefore,

\[
\nabla^C_V \nabla^C_W X - \nabla^C_W \nabla^C_V X - \nabla^C_{[V,W]} X|_{(A,u)} = (0, K \circ dK \circ d_{(u,w)}(dx)(d_u w(v))) - K \circ dK \circ d_{(u,v)}(dx)(d_u v(w)) - K \circ d_u x([v, w]))
\]

\[
= (0, [\nabla^M_v, \nabla^M_w] x - \nabla^M_{[v,w]} x)|_{u} = (0, Rm_M(v_u, w_u)x_u).
\]

By O’Neil formula, we have

\[
< Rm^{B_*}(V, W)W, V >|_{(A,u)} = < Rm^{C^*}(\tilde{V}, \tilde{W})\tilde{W}, \tilde{V} >|_{(A,u)} + \frac{3}{4}[\tilde{V}, \tilde{W}]_{\text{vert}}|_{(A,u)}^2, \tag{19}
\]

where \( \tilde{V}, \tilde{W} \) are horizontal lifts of \( V, W \).

The following lemma introduces a \( \text{LieG} \) valued two form over \( N \).
Lemma 5.2. Define a two form $\Omega \in \Omega^2(\mathcal{N}^{k,p}, W^{k,p}_H(Q, g))$ by the following relation

$$<\Omega_u(w_u, v_u), \xi>_g = g_M(\nabla^M_{w_u} K^{M,G}_\xi|_{u}, v_u),$$

where $u$ is any map in $\mathcal{N}^{k,p}$ and $v_u, \ w_u \in T_u \mathcal{N}^{k,p} = W^{k,p}_H(Q, u^* TM)$.

Proof. Using the fact that $g_M$ is $H$-invariant, then it is easy to check that $\Omega$ is $H$-equivariant, i.e. $\Omega_{h^{-1}u}(dL_{h^{-1}}(v_u), dL_{h^{-1}}(w_u)) = Ad_{h^{-1}}(\Omega_u(v_u, w_u))$ for any $h \in H$. $\Omega_u(v_u, w_u) \in W^{k,p}$ follows from Sobolev multiplication theorem. Hence, the definition makes sense.

Again use the fact that $g_M$ is $G$ invariant, we have $\mathcal{L}_{K^{M,G}_\xi} g_M = 0$. By the definition of Lie derivative, we have $g_M(-\nabla^M_w K^{M,G}_\xi, v) = g_M(\nabla^M_v K^{M,G}_\xi, w)$. Hence, $\Omega$ is antisymmetric and it is a two form.

Lemma 5.3. $[\tilde{V}, \tilde{W}]^{vert}|_{(\mathcal{A}, u)} = 2D_{(\mathcal{A}, u)} G^{0}_{(\mathcal{A}, u)}(*[a \wedge *b] + \Omega_u(w, v))$, where $G^{0}_{(\mathcal{A}, u)} : W^{k-1,p}_H(Q, g) \rightarrow W^{k+1,p}_H(Q, g)$ is the Green operator of $D_{(\mathcal{A}, u)} D_{(\mathcal{A}, u)}$.

Proof. Let $\tilde{V} = (b, v), \tilde{W} = (c, w)$ be horizontal lifts of $V, W$. Let $\gamma(t) = (A(t), u(t)) = (A + tc, exp_u(tw))$ be a path in $\mathcal{C}$ such that $\gamma(0) = (A, u)$ and $\gamma'(0) = \tilde{W}|_{(\mathcal{A}, u)}$. By definition, $\nabla_C V|_{(\mathcal{A}, u)} = (Id \otimes K) \frac{d}{dt} \tilde{V}_{\gamma(t)|t=0}$.

Since $\tilde{V}_{\gamma(t)} = (b(t), v(t))$ is horizontal, we have $D^*_{\gamma(t)} \tilde{V}_{\gamma(t)} = 0$. We differentiate this equation. The differentiation of the first term $d^*_{a(t)} b(t)$ is given as follows:

$$\frac{d}{dt} d^*_{a(t)} b(t)|_{t=0} = d^*_{a(t)} b'(0) - *[a'(0) \wedge *b]. \quad (20)$$

For any $\xi \in W^{k,p}_H(Q, g)$, then

$$<\frac{d}{dt} d^*_{a(t)} \mu^\#(I_\xi(v(t)))|_{t=0}, \xi>_g$$

$$= \frac{d}{dt} \omega_\xi(I^M_G|_{u(t)}, I_\xi v(t))|_{t=0} = - \frac{d}{dt} g_M(K^{M,G}_\xi|_{u(t)}, v(t))|_{t=0}$$

$$= g_M(-\nabla^M_w K^{M,G}_\xi, v) + g_M(-K^{M,G}_\xi, \nabla^M_v v)$$

$$= g_M(-\nabla^M_w K^{M,G}_\xi, v) + <d^*_a \mu^\#(I_\xi(\nabla^M_v v)), \xi>_g$$

$$= -\Omega_u(w, v) + d^*_a \mu^\#(I_\xi(\nabla^M_v v)), \xi>_g.$$

Therefore, $\frac{d}{dt} d^*_{a(t)} \mu^\#(I_\xi(v(t)))|_{t=0} = -\Omega_u(w, v) + d^*_a \mu^\#(I_\xi(\nabla^M_v v))$.

According to the above discussion, we have

$$D^*_{(\mathcal{A}, u)}(\nabla_C V|_{(\mathcal{A}, u)}) = *[c \wedge *b] + \Omega_u(w, v).$$

Therefore, $\nabla_C V|_{(\mathcal{A}, u)} = D_{(\mathcal{A}, u)} G^{0}_{(\mathcal{A}, u)}(*[a \wedge *b] + \Omega_u(w, v)) + r$, where $r \in Ker D^*_{(\mathcal{A}, u)}$.

Note that the term $D_{(\mathcal{A}, u)} G^{0}_{(\mathcal{A}, u)}(*[c \wedge *b] + \Omega_u(w, v))$ is antisymmetric. Therefore, we have

$$[\tilde{V}, \tilde{W}]^{vert}|_{(\mathcal{A}, u)} = 2D_{(\mathcal{A}, u)} G^{0}_{(\mathcal{A}, u)}(*[c \wedge *b] + \Omega_u(w, v)).$$

$\square$
5.3 Riemannian curvature on \( \mathfrak{M}_* \)

Since we already compute the Riemannian curvature of \( \mathcal{B}_* \), it suffices to compute the second fundamental form of \( \mathfrak{M}_* \). The second fundamental form is denoted by \( \Pi \). Let \( V, W \in T\mathfrak{M}_* \subset T\mathcal{B}_* \). Let \( \tilde{V} = (b, v), \tilde{W} = (c, w) \in TC \) be horizontal lifts and they lie inside \( \text{Ker} \mathfrak{D}_{(A,u)} \). By Gauss formula,

\[
< Rm^{\mathfrak{M}_*}(V, W)W, V > |_{(A,u)} = < Rm^{\mathcal{B}_*}(V, W)W, V > |_{(A,u)} - g^{\mathcal{B}_*}(\Pi(V, V), \Pi(W, W))|_{(A,u)} + g^{\mathcal{B}_*}(\Pi(V, W))\Pi(V, W))|_{(A,u)}.
\]

Before we compute the second fundamental form, let us introduce the Hessian of the nonlinear Dirac operator and the map \( \Phi_4 \).

**Definition 5.4.**
1. Regards \( D_A \) as a section of the vector bundle \( W_H^{k-1,p}(Q, E^-) \rightarrow W_H^{k,p}(Q, M) \), the Hessian of \( D_A \) at \( u \) is defined by \( \text{Hess}_u D_A = (\nabla^N)^2 D_A|_u \).
2. Let \( \nabla^{\Omega^{2+}} \) denote the canonical connection over the trivial bundle \( W_H^{k,p}(Q, M) \times \Omega_H^{2+}(Q, \mathfrak{g})_{\text{hor}} \rightarrow W_H^{k,p}(Q, M) \). More precisely, \( \nabla^{\Omega^{2+}} \) is defined by

\[
\nabla^{\Omega^{2+}} \eta|_u = \frac{d}{dt} \eta(u(t))|_{t=0},
\]

where \( u(t) \) is any path passing through \( u \) and \( u'(0) = v \). Regards \( \Phi_4 \) as a section of the trivial bundle, the Hessian of \( \Phi_4 \) is defined by \( \text{Hess}_u \Phi_4 = (\nabla^{\Omega^{2+}})^2 \Phi_4|_u \).

**Remark 7.** By Lemma 4.6.1 of [10], \( D_A^{lin,u} v = (\nabla^N D_A)|_u \).

The Hessian of \( D_A \) and \( \Phi_4 \) here are not symmetric in general. However, they are symmetric along the solutions of GSW.

**Lemma 5.5.** If \( (A, u) \) is a solution to GSW, then \( \text{Hess}_u D_A \) and \( \text{Hess}_u \Phi_4 \) are symmetric.

**Proof.** For any \( v, w \in W_H^{k,p}(Q, TM) \), we have \( \text{Hess}_u D_A(w, v) = \nabla^N v \nabla^N D_A|_u - \nabla^N \nabla^N v D_A|_u \).

Therefore,

\[
\text{Hess}_u D_A(w, v) - \text{Hess}_u D_A(v, w) = [\nabla^N v, \nabla^N w] D_A|_u - \nabla^N [v, w] D_A|_u = R^{\nabla^N}(w|_u, v|_u) D_A u = 0,
\]

where \( R^{\nabla^N} \) is curvature of the connection \( \nabla^N \).

Similarly, we have

\[
\text{Hess}_u \Phi_4(v, w) - \text{Hess}_u \Phi_4(w, v) = R^{\nabla^{\Omega^{2+}}}(v, w) \Phi_4(u) - R^{\nabla^{\Omega^{2+}}}(w, v) \Phi_4(u) \]

Since the curvature \( R^{\nabla^{\Omega^{2+}}} \) is a tensor and \( F^+_a \) can extend to be a constant section over the trivial bundle \( W_H^{k,p}(Q, M) \times \Omega_H^{2+}(Q, \mathfrak{g})_{\text{hor}} \rightarrow W_H^{k,p}(Q, M) \), \( R^{\nabla^{\Omega^{2+}}}(v, w) F_+^a = 0 \) by definition. \( \square \)
Lemma 5.6. $\Pi(V, W)|_{[(A, u)]} = -D_{(A, u)}F_{sw}^* G_{(A, u)} \left( Hess_u D_A(w, v) + c_4(\nabla^M_w K^M_{b,G}) + c_4(\nabla^M_v K^M_{c,G}) \right)$, where

$$G_{(A, u)} : W_H^{k-2,p}(Q, u^* E^-) \oplus \Omega^2_H(Q, \mathfrak{g})_{hor}^{k-2,p} \to W_H^{k,p}(Q, u^* E^-) \oplus \Omega^2_H(Q, \mathfrak{g})_{hor}^{k,p}$$

is the Green function of $D_{(A, u)}F_{sw} \circ D_{(A, u)}F_{sw}^*$.

Proof. Let $\gamma(t) = (A(t), u(t))$ be a path in $F_{sw}^{-1}(0)$ with $\gamma(0) = (A, u)$ and $\gamma'(0) = \tilde{W}|_{(A, u)}$. Without loss of generality, assume that $\gamma(t) = (A + tc, exp_u(tw))$. Let $(b(t), v(t)) = \tilde{V}|_{\gamma(t)}$. Then we have $D_{(A(t), u(t))}F_{sw}(\tilde{V}|_{\gamma(t)}) = 0$ for any $t$. We differentiate this equation. First of all,

$$K \frac{d}{dt} D^{lin, u(t)}_{A^{+} + tc} v(t)|_{t=0} = K \frac{d}{dt} D^{lin, u(t)}_{A} v(t)|_{t=0} + c_4(\nabla^M_w K^M_{c,G}).$$

(25)

Recall that $D_A$ is a section of vector bundle $W^{k-1,p}_H(Q, E^-) \to W^{k,p}_H(Q, M)$. The linear Dirac operator $D^{lin, u(t)}_{A} v(t)$ is $(\nabla^N_{\gamma(t)} D_A)|_{u(t)}$. Therefore,

$$K \frac{d}{dt} D^{lin, u(t)}_{A} v(t)|_{t=0} = \nabla^N_{u(t)}(\nabla^N_{\gamma(t)} D_A)|_{u(t)}|_{t=0} = \nabla^N_{w} \nabla^N_{v} D_A|_{u(t).}$$

(26)

By the fact that $c_4$ is parallel, we have

$$K \frac{d}{dt} c_4(K^M_{b,G} |_{u(t)})|_{t=0} = c_4(Id_{(\mathbb{R}^4)^*} \otimes K)(\frac{d}{dt} K^M_{b,G} |_{u(t)})|_{t=0} = c_4(K^M_{b,G}(0) |_{u}) + c_4(\nabla^M_w K^M_{c,G}).$$

(27)

The differentiation of the second equation is given as follows:

$$\frac{d}{dt} d^{+}_{a + tc} b(t)|_{t=0} = d^{+}_{a} b'(0) + [c \wedge b]^+.$$  

(28)

According to the definition, $d_A \Phi_4(v) = \nabla^2_{v} \Phi_4$ and

$$\frac{d}{dt} d_{u(t)} \Phi_4(v(t))|_{t=0} = \nabla^2_{w} \nabla^2_{v} \Phi_4|_{u} = Hess_u \Phi_4(w, v) + Hess_u \Phi_4(w, v) = Hess_u \Phi_4(v, w) + Hess_u \Phi_4(v, w).$$

(29)

In sum,

$$D_{(A, u)} F_{sw}(\nabla^C_{W} \tilde{V}) + \left( Hess_u D_A(w, v) + c_4(\nabla^M_w K^M_{b,G}) + c_4(\nabla^M_v K^M_{c,G}) \right) = 0.$$ 

(30)

Let $B(\tilde{V}, \tilde{W})$ denote the second term of equation (30). Then $DF_{sw}(\nabla^C_{W} \tilde{V} + D_{(A, u)} F_{sw}^* G_{(A, u)} B(\tilde{V}, \tilde{W})) = 0$. Note that $D^*_{(A, u)} \circ D_{(A, u)} F_{sw}^* = 0$ because of the Fredholm complex, we can write

$$\nabla^S_{W} V = -D_{(A, u)} F_{sw}^* G_{(A, u)} B(\tilde{V}, \tilde{W}) + r,$$  

(31)
where \( r \in \text{Ker} D_{(A,u)} \). Thus the second fundamental form is
\[
\Pi(V, W) = -D_{(A,u)} F^*_{sw} \circ G_{(A,u)} B(\tilde{V}, \tilde{W}).
\]
By Lemma 5.5 the second fundamental form \( \Pi \) is symmetric.

Proof of Theorem 7. Theorem 7 follows from Lemmas 5.1, 5.3, 5.6, and equations (22), (19).

6 A compactness result for harmonic spinors

In this section, we assume that \( G \) is a zero dimensional Lie group. Then the GSW is reduced to a single nonlinear Dirac equation \( D_A u = 0 \), where \( A \) is the pullback of the Levi-Civita connection of \( X \). Note that the elliptic regularity implies that the harmonic spinor is smooth. (Cf. Theorem 5.3.2 of [10]) Besides, we assume that \( \chi_2 = 0 \). Then \( M \) admits a unique hyperKähler potential \( \rho_0 \). Finally, we assume that there is a uniform constant \( c_0 > 0 \) such that
\[
2 \int_X \rho_0 \circ u = \int_X |\chi_0 \circ u|^2 \leq c_0.
\]

Convention 6. In this section, we use \( c_0 \) to denote the uniform constant which only depends on geometric data. It may be different from line to line.

Under the assumption that \( \chi_2 = 0 \), keep in mind that we have
\[
d_A u = d^{TM}_A \chi_0 \circ u.
\]
This is an important property which helps us to reduce the nonlinear differential to linear differential. For the proof of this formula, please refer to Corollary 4.6.2 of [10].

Now we start to prove Theorems 2 and 3. To this end, let us recall the Weizenböck formula firstly.

Theorem 6.1 (Theorem 4.7.1 of [10]). The Weizenböck formula for the generalized Dirac operator:
\[
D_A^{lin,u} D_A u = d^{TM,u}_A d_A u + \frac{s_X}{4} \chi_0 \circ u + \mathcal{Y}_u(F^+_A),
\]
where \( \mathcal{Y}_u(F^+_A) = \sum_{i=1}^3 I_i K_{F^+_A, \eta_i} |u \) and \( \{ \eta_i \}_{i=1}^3 \) are basis of \( \mathfrak{sp}(1) \).

Lemma 6.2. There exists a constant \( c_0 > 0 \) such that \( \int_X |d_A u|^2 \leq c_0 \) and \( |\chi_0 \circ u| \leq c_0 \).
Proof. By the assumptions that \( g = \{0\} \) and \( \chi_2 = 0 \), then \( \mathcal{V}_u(F^+_A) = 0 \). The Weizenböck formula becomes

\[
0 = d_A^{TM} \cdot d_A^{TM} \chi_0 \circ u + \frac{s X}{4} \chi_0 \circ u.
\]  

(34)

Take inner product of the equation (34) with \( \chi_0 \circ u \), then we have

\[
\frac{1}{2} d^* d |\chi \circ u|^2 + |d_A^{TM} \chi_0 \circ u|^2 = -\frac{s X}{4} |\chi_0 \circ u|^2.
\]  

(35)

Integrate the equation (35), then we get

\[
\int_X |d_A u|^2 = \int_X |d_A^{TM} \chi_0 \circ u|^2 = \int_X -\frac{s X}{4} |\chi_0 \circ u|^2 \leq c_0.
\]  

(36)

Assume that \( |\chi_0 \circ u|^2 \) attends its maximum at \( p \in X \). Let \( G_p \) be the Green function of \( d^* d \) with pole at \( p \), then

\[
|\chi_0 \circ u|^2(p) \leq c_0 \int_{B_r} G_p |\chi_0 \circ u|^2 + c_0 \int_{X-B_r} G_p |\chi_0 \circ u|^2 + \frac{1}{\text{vol}(X)} \int_X |\chi_0 \circ u|^2
\]

\[
\leq c_0 r^2 |\chi_0 \circ u|^2(p) + \left( \frac{c_0}{r^2} + \frac{1}{\text{vol}(X)} \right) \int_X |\chi_0 \circ u|^2.
\]

Take \( r > 0 \) such that \( c_0 r^2 = \frac{1}{2} \), then we get the sup-norm bound on \( |\chi_0 \circ u| \).

The proof of Theorem 2 is essentially the same as in [17], we will sketch the proof latter. The key point is to use the Heinz trick to deduce a uniform bound on \( |d_A u| \). The Heinz trick that we need is summarised as follows. For more details about the Heinz trick and its proof, we refer the reader to Appendix A of [17].

**Proposition 6.3** (Heinz trick). Let \( f : X \to [0, \infty) \) be a nonnegative function. Suppose that there exists a constant \( c_0 > 0 \) such that \( f \) satisfies the following properties:

1. \( d^* d f \leq c_0 (f^2 + 1) \).

2. If \( B_s(y) \subset B_{\frac{r}{2}}(x) \), then \( s^{-2} \int_{B_s(y)} f \leq c_0 r^{-2} \int_{B_r(x)} f + c_0 r^2 \).

Then there exist constants \( \epsilon_0 > 0 \) and \( \delta_1 > 0 \) such that for all \( r \leq \delta_1 \) and \( B_r(x) \) with

\[
\epsilon = r^{-2} \int_{B_r(x)} f \leq \epsilon_0,
\]

we have

\[
\sup_{B_{\frac{r}{2}}(x)} f \leq c_0 r^{-2} \epsilon + c_0 r^2.
\]

**Convention 7.** Let \( \delta_0 \) denote the injective radius of \((X, g_X)\). In order to simplify the notation, we assume that \( \delta_1 = \delta_0 \) all time.
The following two lemmas verify the conditions in Proposition 6.3. They are respectively counterparts of Propositions 2.1 and 3.4 of [17].

**Lemma 6.4.** Let \( u \) be a harmonic spinor. Define a function \( F_r(r) = r^{-2} \int_{B_r(x)} |d_A u|^2 \) for \( r \leq \delta_0 \). Then

\[
\frac{\partial F}{\partial r} \geq \frac{2}{r^2} \int_{\partial B_r} |d_{A,r} u|^2 - c_0 (|K^{M,H}_{F_A}|_u + 1)^2 F(r) - c_0 r^2. \tag{37}
\]

In particular, if \( |K^{M,H}_{F_A}|_u \leq c_0 \), then \( e^{c_0 r} F(r) + c_0 r^3 \) is non-decreasing.

**Proof.** By definition,

\[
\frac{\partial F}{\partial r} = \frac{2}{r^3} \int_{B_r} |d_A u|^2 + \frac{1}{r^2} \int_{\partial B_r} |d_A u|^2. \tag{38}
\]

Define a symmetric 2-tensor \( T = T_{ij} dx^i \otimes dx^j \) by

\[
T_{ij} = \langle d_{A,i} u, d_{A,j} u \rangle - \frac{1}{2} (g_X)_{ij} |d_A u|^2. \tag{39}
\]

Assume that the \( \{x^i\} \) is normal coordinate at \( p \), then the divergence of \( T \) at \( p \) is

\[
T_{ij} = \langle d_{A,j}^T d_{A,i} u, d_{A,j} u \rangle + \langle d_{A,i} u, d_{A,j}^T d_{A,j} u \rangle - \delta_{ij} \langle d_{A,j}^T d_{A,k} u, d_{A,k} u \rangle
\]

\[
= \langle d_{A,j}^T d_{A,i} u, d_{A,j} u \rangle - \langle d_{A,i} u, d_{A,j}^T d_{A,k} u \rangle - \langle d_{A,i}^T d_{A,k} u, d_{A,k} u \rangle
\]

\[
= \langle K^{M,H}_{F_A} |u| \rangle_{u, d_{A,i} u} + \langle \frac{S^X}{4} \chi_{0} \circ u, d_{A,i} u \rangle.
\]

The last step follows from the curvature formula Lemma 2.4.2 of [10]. Therefore,

\[
|\text{div} T| \leq c_0 (1 + |K^{M,H}_{F_A}|_u) |d_A u|.
\tag{40}
\]

Let \( r(p) = \text{dist}(p, x) \) denote the distance function, the divergence theorem implies that

\[
\int_{B_r(x)} \text{div} T \left( \frac{1}{2} \nabla r^2 \right) = r \int_{\partial B_r} T_{ij} r_i r_j - \int_{B_r} < T, \frac{1}{2} \nabla^2 r^2 > .
\]

Note that \( \frac{1}{2} \nabla^2 r^2 = g_X + O(r) \). Hence

\[
\int_{B_r(x)} \text{div} T, \frac{1}{2} \nabla r^2 > = r \int_{\partial B_r} T(\partial_r, \partial_r) - \int_{B_r} \text{tr} g_X T + O(r) \int_{B_r} |T|
\]

\[
= r \int_{\partial B_r} (|d_{A,r} u|^2 - \frac{1}{2} |d_A u|^2) + \int_{B_r} |d_A u|^2 + O(r) \int_{B_r} |d_A u|^2.
\tag{41}
\]

Combine (40) and (41), then we get

\[
\frac{\partial F}{\partial r} = \frac{2}{r^3} \int_{B_r(x)} \text{div} T \left( \frac{1}{2} \nabla r^2 \right) + \frac{2}{r^2} \int_{\partial B_r} |d_{A,r} u|^2 + O(1) F(r)
\]

\[
\geq \frac{2}{r^2} \int_{\partial B_r} |d_{A,r} u|^2 - c_0 (|K^{M,H}_{F_A}|_u + 1)^2 F(r) - c_0 r^2.
\tag{42}
\]

\( \square \)
Lemma 6.5. Let $u$ be a harmonic spinor, then

\[
\frac{1}{2} d^*d|d_Au|^2 + |d^A_Md_Au|^2 \leq c_0|d_Au|^4 + c_0(1 + |K_{F_A}^{M,H}|^2). \tag{43}
\]

Proof. By Lemmas 2.4.1 and 2.4.2 of [10], we have

\[
d^A_Md^A_Md_A,iu = d^A_Md^A_Md_A,iu + K \circ K_{F_A}^{TM,H} |d_A,iu| + Rm_M(d_{A,j}u, d_A,iu)d_A,iu
\]
\[
= d^A_Md_A,iu + K_{F_A}^{M,H} |d_A,iu| + K \circ K_{F_A}^{TM,H} |d_A,iu| + Rm_M(d_{A,j}u, d_A,iu)d_A,iu
\]
\[
= -d^A_Md^A_Md_A,iu + d^A_M(K_{F_A}^{M,H} |d_A,iu| + K \circ K_{F_A}^{TM,H} |d_A,iu| + Rm_M(d_{A,j}u, d_A,iu)d_A,iu
\]

Lemma 2.4.3 of [10] implies that $K \circ K_{F_A}^{TM,H} |d_A,iu| = \nabla^M d_A,iu (K_{F_A}^{M,H} |d_A,iu|)$. By definition, $d^A_M(K_{F_A}^{M,H} |d_A,iu|) = \nabla^M d_A,iu (K_{F_A}^{M,H} |d_A,iu|) + K_{\nabla^M F_A}^{M,H} |d_A,iu|$. Therefore,

\[
d^A_Md_A,iu = d^A_Md^A_Md_A,iu + 2\nabla^M d_A,iu (K_{F_A}^{M,H} |d_A,iu|) + K_{\nabla^M F_A}^{M,H} |d_A,iu| + Rm_M(d_{A,j}u, d_A,iu)d_A,iu.
\]

By Weizenböck formula,

\[
d^A_Md^A_Md_A,iu = -\frac{1}{4}(s_X)_j\chi_0 \circ u - \frac{s_X}{4}d_A,iu
\]
\[
+ 2\nabla^M d_A,iu (K_{F_A}^{M,H} |d_A,iu|) + K_{\nabla^M F_A}^{M,H} |d_A,iu| + Rm_M(d_{A,j}u, d_A,iu)d_A,iu.
\]

Take inner product of equation (44) with $d_Au$, then we get

\[
\frac{1}{2} d^*d|d_Au|^2 + |d^A_Md_Au|^2 \leq c_0(1 + |\nabla^M K_{F_A}^{M,H} |u|)|d_Au|^2 + |K_{\nabla^M F_A}^{M,H} |u||d_Au| + |Rm_M||d_Au|^4 + c_0|\chi_0 \circ u|^2.
\]

The conclusion follows from Cauchy Schwarz inequality. \(\square\)

Proof of Theorem 2. By Lemmas 6.4, 6.5 and the Heinz trick (Proposition 6.3), we can find a constant $\epsilon_0 > 0$ such that if

\[
\frac{1}{r^2} \int_{B_r(x)} |d_{A}u_n|^2 \leq \epsilon_0,
\]

then $\sup_{B_r\frac{1}{4}(x)} |d_{A}u_n| \leq c_0(r^{-2}\epsilon_0 + 1)$.

For each $n$ and $0 < r \leq r_0$, define a set $S_{n,r} = \{x \in X, e^{\epsilon_0 r}F_{n,x}(r) + c_0r^3 \geq \frac{1}{2}\epsilon_0\}$, where $F_{n,x}$ is $u_n$-version of $F_x$. Roughly speaking, the blow-up locus $S$ is defined by taking limit of $S_{n,r}$ as $n \to \infty$ and $r \to 0$. For more details, please refer to [17].

For any compact set $K \subset X - S$, follows from definition of $S$, there exists $r_K > 0$ such that $F_x(r) \leq \epsilon_0$ for $r \leq r_K$ and $x \in K$. Thus we deduce a uniform bound $|d_{A}u_n| \leq C_K$. By Arzela-Ascoli theorem, $\{u_n\}_{n=1}^{\infty}$ converges $C^0$ to $u$. Also, $\{u_n|K\}_{n=1}^{\infty}$ converges weakly $W^{1,p}$ to $u$ for any $p$. In particular, $u$ satisfies the Dirac equation and it.
is smooth. For $n \gg 1$, we can write $u_n = \exp_h(v_n)$ for some $v_n \in W^{1,p}(X, \pi!u^*TM)$. By elliptic regularity (Cf. Theorem 5.3.2 of [10]), $v_n$ converges $C^\infty$ to zero.

To see why $S$ has finite Hausdorff measure. Given $0 < \delta < \delta_0$, we cover $S$ by balls \( \{ B_{4r_j}(x) \} \) with $x_j \in S$, $r_j \leq \delta$ and \( \{ B_{2r_j}(x) \} \) pairwise disjoint. Fix a large $k$ such that $2^{-k}\delta_0 < \min_j \{ r_j \}$. According to the construction of $S$, for sufficiently large $n$, we can find $x'_j \in S_{n,2^{-k}\delta_0}$ with $d(x'_j, x_j) \leq r_j$. Then $S$ is covered by \( \{ B_{5r_j}(x'_j) \} \) while the smaller balls \( \{ B_{r_j}(x'_j) \} \) are pairwise disjoint. By the definition of $S_{n,2^{-k}\delta_0}$,

$$
\sum_j r_j^2 \leq \sum_j \left( \frac{2c_0r_j}{\epsilon_0} \int_{B_{r_j}(x'_j)} |d_A u_n|^2 + c_0 r_j^3 \right) \leq \frac{2c_0 \rho_0}{\epsilon_0} \int_X |d_A u_n|^2 + c_0 r_j^3 \sum_j r_j^2.
$$

Take a small $r_0 > 0$, we deduce a uniform bound for $\sum_j r_j^2$. In particular, we have $\mathcal{H}^2(S) \leq c_0$.

Moreover, one can follow Proposition 4.1 of [17] to show that $S$ is minimal.

\[\square\]

### 6.1 Small energy case

The following two lemmas assert that if the $L^2$ norm of $\chi_0 \circ u_n$ tends to zero, then the blow-up locus $S$ is empty. Also, the limit of the sequence is a parallel harmonic spinor.

**Lemma 6.6.** Suppose that $\int_X |d_A u|^2 \leq \delta_0^2 \epsilon_0$, then $\sup_X |d_A u| \leq c_0(\delta_0^{-2} \epsilon_0 + c_0 \delta_0^2)$.

**Proof.** Suppose that $|d_A u|$ attains its maximum at $x$. By our assumption,

$$
\frac{1}{\delta_0^2} \int_{B_{\delta_0}(x)} |d_A u|^2 \leq \frac{1}{\delta_0^2} \int_X |d_A u|^2 \leq \epsilon_0.
$$

By Proposition 6.3 we have $|d_A u|^2(x) \leq c_0(\delta_0^{-2} \epsilon_0 + c_0 \delta_0^2)$.

\[\square\]

**Lemma 6.7.** Let $\{ u_n \}_{n=1}^\infty$ be the sequence of harmonic spinors in Theorem 2. Assume additionally that $\lim_{n \to 0} \int_X |\chi_0 \circ u_n|^2 = 0$. Then there exists a subsequence of $\{ u_n \}_{n=1}^\infty$ converges $C^\infty$ to a parallel harmonic spinor $u$, i.e. $d_A u = 0$. Moreover, $\rho_0 \circ u = 0$.

**Proof.** According to the assumptions and formula (35), there exists an integer $n_0 > 0$ such that for any $n \geq n_0$, we have $\int_X |d_A u_n|^2 \leq \delta_0^2 \epsilon_0$. Lemma 6.6 gives an uniform bound on $|d_A u_n|$. Follow from the standard elliptic regularity and Arzela-Ascoli theorem, we can find a subsequence of $\{ u_n \}_{n=1}^\infty$ converges to $u$ in $C^\infty$ sense. The assumptions and formula (35) also implies that $\int_X |d_A u|^2 = 0$. Hence, $u$ is parallel. $\rho_0 \circ u = 0$ is obvious.

\[\square\]
6.2 Frequency function

In this subsection, we follow the technique in [7] and [13] to show that the sequence \( \{u_n\}_{n=1}^\infty \) is convergence outside the zero set of a certain function. Assume that for any \( k \in \mathbb{N} \), there exists constant \( c_k > 0 \) such that \( |K_{FA}^{M,H} u|_{C^k} \leq c_k \).

**Definition 6.8.** Let \( \epsilon_0 > 0 \) be the constant given by Heinz trick. For any \( x \in X \), define the critical radius at \( x \) by

\[
    r(x) = \sup \{ r \in (0, \delta_0] \mid \frac{1}{r^2} \int_{B_r(x)} |d_A u|^2 \leq \epsilon_0 \}. \tag{45}
\]

**Lemma 6.9.** Let \( f_x(r) = \int_{\partial B_r(x)} |\chi_0 \circ u|^2 \), then

\[
    f'(r) = \frac{3}{r} f(r) + 2r^2 F + 2 \int_{B_r} \left( \frac{8X}{4} |\chi_0 \circ u|^2 \right) + O(r)f(r).
\]

**Proof.** Note that

\[
    f'(r) = \frac{3}{r} f(r) + \int_{\partial B_r} \partial_r |\chi_0 \circ u|^2 + O(r)f(r).
\]

The term \( O(r)f(r) \) comes from the nonflatness of the metric \( g_X \). By divergence theorem,

\[
    \int_{\partial B_r} \partial_r |\chi_0 \circ u|^2 = \int_{B_r} \text{div}(|\chi_0 \circ u|^2) = 2 \int_{B_r} -d_A^{TM^*}d_A u, \chi_0 \circ u > + |d_A u|^2
\]

By Weizenböck formula (34),

\[
    \int_{\partial B_r} \partial_r |\chi_0 \circ u|^2 = 2r^2 F + 2 \int_{B_r} \frac{8X}{4} |\chi_0 \circ u|^2
\]

**Corollary 6.10.** For any \( 0 < s < r \leq \delta_0 \), we have

\[
    e^{c_0s^2} \frac{f(s)}{s^3} \leq e^{c_0r^2} \frac{f(r)}{r^3}. \tag{46}
\]

Also, \( \int_{B_r} |\chi_0 \circ u|^2 \leq c_0 r f(r) \).

**Proof.** For any function \( h \), we have \( \int_{B_r} h^2 \leq c_0 (r^2 \int_{B_r} |dh|^2 + r \int_{\partial B_r} h^2) \). (One can prove it by integration by part.) Take \( h = |\chi_0 \circ u| \), by Kato inequality and Lemma 6.9, we have

\[
    f'(r) \geq \frac{3}{r} f - c_0 r f. \tag{47}
\]

Integrate the inequality (47), then we get (46). Using this monotonicity property, we have

\[
    \int_{B_r} |\chi_0 \circ u|^2 = \int_0^r f(s) ds \leq c_0 \frac{f(r)}{r^3} \int_0^r s^3 ds \leq c_0 r f(r).
\]
Define a nonnegative function $\kappa$ by the relation $\kappa^2 = e^{-2\sigma} r^{-3} f$, where
\[
\sigma(r) = \int_0^r \frac{1}{f(s)} \left( \int_{B_s} \left( \frac{sX}{4} |\chi_0 \circ u|^2 \right) + O(s) f(s) \right) ds.
\]
Note that Corollary 6.10 implies that $|\sigma(r)| \leq c_0 r^2$ and $|\sigma'(r)| \leq c_0 r$.

The frequency function at $x$ is defined by $N_x(r) = \frac{r^3 F_x(r)}{f(r)}$. By Lemma 6.9 it is straightforward to check that we have the following differential equality
\[
\frac{d\kappa}{dr} = \frac{1}{r} N_{\kappa}.
\]

**Lemma 6.11.** The frequency function satisfies the following differential inequality:
\[
N' \geq \frac{2e^{-2\sigma}}{r^2 K^2} \int_{\partial B_r} |d_A, r|^2 - \frac{N}{r^2} \chi_0 \circ u |^2 - c_0 (|K_{FA}^{M,H}| u | + 1)^2 N - c_0 \frac{r^2 e^{-2\sigma}}{K^2}.
\]

**Proof.** By equation (48) and Lemma 6.4, we have
\[
N' = \frac{F'}{K^2} e^{-2\sigma} - 2N \sigma' - \frac{2N^2}{r}
\geq \frac{2e^{-2\sigma}}{r^2 K^2} \int_{\partial B_r} |d_A, r|^2 - c_0 (|K_{FA}^{M,H}| u | + 1)^2 N - c_0 \frac{r^2 e^{-2\sigma}}{K^2} - 2Nc_0r - \frac{2N^2}{r}.
\]

According to integration by part and Wirzenböck formula,
\[
N = \frac{e^{-2\sigma}}{r^2 K^2} \int_{\partial B_r} |d_A u|^2 = \frac{e^{-2\sigma}}{r^2 K^2} \int_{\partial B_r} < \chi_0 \circ u, d_A, r u > = \frac{e^{-2\sigma}}{r^2 K^2} \int_{\partial B_r} \frac{sX}{4} |\chi_0 \circ u|^2
\]
\[
= \frac{e^{-2\sigma}}{r^2 K^2} \int_{\partial B_r} < \chi_0 \circ u, d_A, r u > + O(r^2).
\]

The term $-2N^2/r$ in (49) equals to $-4N^2/r + 2N^2/r$. Replace $-4N^2/r$ by $-4e^{-2\sigma} \int_{\partial B_r} < \frac{N}{r} \chi_0 \circ u, d_A, r u > + O(r)N$, then we get
\[
N' \geq \frac{2e^{-2\sigma}}{r^2 K^2} \int_{\partial B_r} |d_A, r|^2 - \frac{N}{r} \chi_0 \circ u |^2 - c_0 (|K_{FA}^{M,H}| u | + 1)^2 N - c_0 \frac{r^2 e^{-2\sigma}}{K^2} - c_0 r N.
\]

\[\square\]

**Lemma 6.12.** Let $x \in X$ such that $\rho_0 \circ u(x) \neq 0$. Given $\epsilon_1 > 0$, then there exists $c_{\epsilon_1} > 0$ such that for any $r \leq \min \{ \sqrt{\epsilon_1}, c_{\epsilon_1} \rho_0 \circ u(x) \}$, then $N_x(r) \leq \epsilon_1$.

**Proof.** Let $0 < r \leq r_0$ and $\rho = \rho_0 \circ u(x)$. By the monotonicity property of $\kappa$ and (48), we have $\int_r^{r_0} 2\frac{N(t)}{t} dt = \log \frac{\kappa^2(r_0)}{\kappa^2(r)} \leq \log (c_0 \rho^{-1})$. By Lemma 6.11, we have
\[
N(t) \geq c_0^{-1} N(r) - c_0 \rho^{-1} r_0^2,
\]
for $r \leq t \leq r_0$. Therefore,
\[
N(r) \leq c_0 \frac{\log (c_0 \rho^{-1})}{\log (\frac{r_0}{r})} + c_0 r_0^2 \rho^{-1}.
\]

\[\text{(50)}\]
If \( c_0 \rho^{-1} \leq 1 \), then we can take \( r_0 = \sqrt{\epsilon_1} \). If \( c_0 \rho^{-1} > 1 \), we can take \( r_0 \) be the square root of \( \frac{1}{2c_0} \rho \). Then the right hand side of (50) less than \( \epsilon_1 \) if \( c_0 \log c_0 \rho^{-1} \leq \frac{1}{3} \epsilon_1 \). This implies that \( r \leq c_1 \rho \). \( \square \)

**Corollary 6.13.** Let \( x \in X \) such that \( \rho_0 \circ u(x) \neq 0 \), then \( r(x) \geq \min \{ \sqrt{\epsilon_1}, c_1 \rho_0 \circ u(x) \} \).

**Proof.** By the uniform bound in Lemma 6.2, we have \( F_x(r) = N_x(r) \frac{r}{\sqrt{1 - r}} \leq c_0 N_x(r) \). Take \( \epsilon_1 = \frac{c_0}{c_0} \). Then Lemma 6.12 implies that \( r(x) \geq \min \{ \sqrt{\epsilon_1}, c_1 \rho_0 \circ u(x) \} \). \( \square \)

**Lemma 6.14.** There exists a constant \( c_0 > 0 \) such that \( |\rho_0 \circ u|_{C^0, \frac{1}{2}} \leq c_0 \).

**Proof.** Denote \( \rho_0 \circ u(x) \) by \( \rho(x) \) and \( r(x) \) by \( r \). For any \( x, y \in X \), it suffices to estimate \( \frac{|\rho(x) - \rho(y)|}{d(x, y)^{\frac{1}{2}}} \) for the case that \( \rho(x) \neq 0 \) and \( \rho(x) > \rho(y) \). Also, we assume that \( c_1 \rho(x) \leq \sqrt{\epsilon_1} \). The remaining case can be proved by the same argument.

Firstly, we consider the case that \( d(x, y)^{\frac{1}{2}} \leq \frac{1}{2\sqrt{c_0}} r \). Note that \( d(x, y) \leq r^2 \leq \frac{r}{4} \).

By mean value theorem, Kato inequality and the uniform bound in Lemma 6.2,

\[
0 < \rho(x) - \rho(y) \leq c_0 \sup_{B_{\frac{1}{2}}(x)} |d_A u| d(x, y)^{\frac{1}{2}}.
\]

Then the Heinz trick implies that \( \frac{\rho(x) - \rho(y)}{d(x, y)^{\frac{1}{2}}} \leq c_0 (r^{-1} \epsilon_0^{\frac{1}{2}} + 1) d(x, y)^{\frac{1}{2}} \leq c_0 \).

If \( d(x, y)^{\frac{1}{2}} \geq \frac{1}{2\sqrt{c_0}} r \), then \( \rho(x) \leq c_1^{-1} r(x) \leq c_0 d(x, y)^{\frac{1}{2}} \). Therefore,

\[
0 < \frac{\rho(x) - \rho(y)}{d(x, y)^{\frac{1}{2}}} \leq \frac{\rho(x)}{d(x, y)^{\frac{1}{2}}} \leq c_0.
\]

\( \square \)

**Proof of the Theorem [2]** Let \( \{u_n\}_{n=1}^\infty \) be the sequence of harmonic spinors. By Lemma 6.14, there is a uniform bound on \( |\rho_0 \circ u_n|_{C^0, \frac{1}{2}} \). Then there exists a subsequence of \( \{\rho_0 \circ u_n\}_{n=1}^\infty \) such that it converges to a function \( \rho \) in \( C^{0,\gamma} \), where \( 0 < \gamma < \frac{1}{2} \).

Let \( Z = \rho^{-1}(0) \). For any compact set \( K \subset X - Z \), we can find a constant \( c_K \geq 1 \) such that \( \rho_0 \circ u_n \geq c_K^{-1} \) over \( K \). Lemma 6.12 implies that \( r_n(x) \geq c_K^{-1} \) over \( K \) as well, where \( r_n(x) \) is \( u_n \)-version of the critical radius. Then the Heinz trick deduces a uniform bound \( |d_A u_n|(x) \leq C_K \) for any \( x \in K \).

Follows the standard elliptic regularity and Arzela-Ascoli theorem, we can find a subsequence of \( \{u_n\}_{n=1}^\infty \) such that it is convergence in \( C^\infty \) sense over \( K \).

As the blow-up locus \( S \) in Theorem [2] is minimal, we have \( S \subset \rho^{-1}(0) \). \( \square \)

**Remark 8.** When \( M = U(N) \) is a Swann bundle and \( N \) is compact. The assumption that the images of \( \{u_n\}_{n=1}^\infty \) are contained in a compact set of \( M \) can be removed. The reasons are as follows. By Remark 3.5.2 of [10], the Swann bundle can be written as
\[ \mathcal{U}(N) = (0, \infty) \times \mathcal{C}(N), \text{ where } \mathcal{C}(N) \text{ is a } \text{Sp}(1) \text{ principal bundle over } N. \text{ Over the compact set } K \subset X \text{ in the proof above, } c_K^{-1} \leq \rho_0 \circ u_n \leq c_0 \text{ implies that the image of } \{u_n|_K\}_{n=1}^{\infty} \text{ lie inside a compact subset of } \mathcal{M}. \text{ Then we can still apply the Arzela-Ascoli theorem.} \]
