LOWER BOUNDS ON HILBERT–KUNZ MULTIPlicITIES AND MAXIMAL F-SIGNATURES

JACK JEFFRIES, YUSUKE NAKAJIMA, ILYA SMIRNOV, KEI-ICHI WATANABE, AND KEN-ICHI YOSHIDA

ABSTRACT. Hilbert–Kunz multiplicity and F-signature are numerical invariants of commutative rings in positive characteristic that measure severity of singularities: for a regular ring both invariants are equal to one and the converse holds under mild assumptions. A natural question is for what singular rings these invariants are closest to one. For Hilbert–Kunz multiplicity this question was first considered by the last two authors and attracted significant attention. In this paper, we study this question, i.e., an upper bound, for F-signature and revisit lower bounds on Hilbert–Kunz multiplicity.

1. INTRODUCTION

1.1. Background. A ring of positive characteristic has a wealth of objects arising from the Frobenius endomorphism. The focus of this paper are two numerical invariants: Hilbert–Kunz multiplicity and F-signature. For simplicity, let us assume that $A$ is a local domain such that $A^{1/p}$ is a finitely generated $A$-module. The Hilbert–Kunz multiplicity of $A$ ([23, 25]) is defined as

$$e_{HK}(A) := \lim_{e \to \infty} \frac{\mu_A(A^{1/p^e})}{\text{rank}(A^{1/p^e})},$$

where $\mu_A$ denotes the minimal number of generators, and the F-signature of $A$ ([18, 36]) is

$$s(A) := \lim_{e \to \infty} \frac{\max\{n \mid A^{1/p^e} \cong A^{\oplus n} \oplus M\}}{\text{rank}(A^{1/p^e})},$$

where $M$ is a finitely generated $A$-module without free direct summands.

A fundamental result of Kunz ([22]) asserts that $A^{1/p^e}$ is free if and only if $A$ is regular. It follows that $e_{HK}(A) \geq 1$ and $1 \geq s(A) \geq 0$, and under a mild condition the value is 1 if and only if $A$ is regular ([22, 40, 18]). Furthermore, positivity of F-signature characterizes the class of strongly F-regular rings [3], a fundamental class of mild singularities that first appeared in the tight closure theory [17]. A related result of Blickle–Enescu [4] shows that small Hilbert–Kunz multiplicity also forces the ring to be strongly F-regular.

A natural question is how close can the Hilbert–Kunz multiplicity of a singularity be to 1? And a natural guess is that the simplest double point singularity $k[[x_1, \ldots, x_d]]/(x_1^2 + \cdots + x_d^2)$ should have the smallest Hilbert–Kunz multiplicity (see, Conjecture 2.4 for details). By [41, 43, 2] this is now a theorem in dimension at most 6.

In this paper, we extend this investigation by asking to find further bounds on Hilbert–Kunz multiplicity of mild singularities and considering the analogous question for F-signature. For instance, in dimension 2, most non-regular F-regular local rings are quotient singularities, in which case we have that $s(A) = 1/|G| \leq 1/2$, where $A = k[[x,y]]^G$ and $G$ is a finite subgroup of $GL_2(k)$. It seems that a similar question has no answer even in dimension 3.

Question 1.1. Let $A$ be an F-regular local domain of dimension $d \geq 3$ which is not regular. Then what is the upper bound on $s(A)$?

We give a partial answer to the question above, and pose a conjecture; see Conjecture 2.10. Let us explain the organization of the paper.
1.2. **Structure of the paper and main results.** In Section 2 we recall several definitions (Hilbert–Kunz multiplicity, F-regularity, FFRT, F-signature and so on) and pose two conjectures. In Section 3 we give a lower bound on Hilbert–Kunz multiplicities. Namely, we prove the following theorem and its refinement in the 3-dimensional case (see Theorem 3.7).

**Theorem 1.2 (= 3.2).** Let \((A, m)\) be a Cohen-Macaulay local ring of characteristic \(p > 0\). If \(d = \dim A \geq 3\), then we have

\[
e_{\ HK}(I) \geq \frac{e(I) + d}{d!}.
\]

In Section 4 we generalize an argument of De Stefani and the first author that \(s(A) \leq \frac{1}{2}\) for non-Gorenstein Cohen-Macaulay local rings \(A\) (see Proposition 4.1) and characterize the case where equality holds.

**Theorem 1.3 (= 4.6).** Let \(A\) be a Cohen-Macaulay local domain but not Gorenstein. Then \(s(A) \leq \frac{1}{2}\), and the following conditions are equivalent:

1. \(s(A) = \frac{1}{2}\).
2. \(F^eA\) is a finite direct sum of \(A\) and \(\omega_A\) for every \(e \geq 1\).

When this is the case, \(e_{\ HK}(A) = \frac{\text{type}(A) + 1}{2}\). Moreover, if, in addition, either \(A\) is \(\mathbb{Q}\)-Gorenstein or a toric singularity, then it is isomorphic to the Veronese subring \(k[[x_1, x_2, \ldots, x_d]]^{(2)}\), where \(k[[x_1, \ldots, x_d]]^{(n)} = k[[x_1, \ldots, x_d]^n]\) (see Theorem 4.17 and 5.6).

The F-signature of a Gorenstein ring may exceed \(\frac{1}{2}\). We explore an upper bound on F-signature for Gorenstein, non-regular local rings of dimension three.

**Theorem 1.4 (= 4.18).** Let \((A, m, k)\) be a 3-dimensional Gorenstein F-regular local ring with \(e(A) \geq 3\). Then \(s(A) \leq \frac{e(A)}{24}\).

We also provide a classification of (pointed, normal, affine) toric rings with F-signature greater than one half.

**Theorem 1.5 (= 5.12).** The toric rings with F-signature greater than \(\frac{1}{2}\) are, up to isomorphism, as follows:

- For a polynomial ring \(A\), we have \(s(A) = 1\).
- For the coordinate ring \(A\) of the Segre product \(\mathbb{P}^1 \# \mathbb{P}^1\), we have \(s(A) = 2/3\).
- For the coordinate ring \(A\) of the Segre product \(\mathbb{P}^2 \# \mathbb{P}^2\), we have \(s(A) = 11/20\).

### 2. Preliminaries

Let \((A, m)\) be a local ring of characteristic \(p > 0\) and let \(F^e: A \to A\) denote the \(e^{\text{th}}\) iterated Frobenius map of \(A\). For an \(A\)-module \(M\), the Frobenius push-forward of \(M\), \(F^eM = \{F^e m \mid m \in M\}\), is defined as follows: it agrees with \(M\) as an abelian group and \(A\) acts by \(a \cdot F^e m = F^e(a^{p^e} m)\) for any \(a \in A\) and \(m \in M\). If \(A\) is reduced, \(F^eA\) is identified with \(A^{1/p^e}\) which consists of \(p^e\)-th roots of \(A\). The ring \(A\) is called \(F\)-finite if \(F^eA\) is a finitely generated \(A\)-module for every (some) \(e \geq 1\).

We now recall a more general definition of Hilbert–Kunz multiplicity.

**Definition 2.1.** Let \(\ell_A(W)\) denote the length of a finitely generated \(A\)-module \(W\). For an \(m\)-primary ideal \(I \subset A\) we denote \(I^{[q]} = (a^q \mid a \in I)A\) for each \(q = p^e\). If \(M\) is a finitely generated \(A\)-module,

\[
e(I, M) := \lim_{n \to \infty} \frac{d!}{n^d} \ell_A(M/I^{[1]}M) \quad (\text{resp. } e_{\ HK}(I, M) := \lim_{q \to \infty} \frac{\ell_A(M/I^{[q]}M)}{q^d})
\]
is called the multiplicity (resp. the Hilbert–Kunz multiplicity) of $M$ with respect to $I$. For brevity, we denote $e(I) = e(I,A)$ (resp. $e_{HK}(I) = e_{HK}(I,A)$) and call it the multiplicity (resp. the Hilbert–Kunz multiplicity) of $I$. We also denote, $e(m,M) = e(M)$ and $e_{HK}(m,M) = e_{HK}(M)$.

Recall the fundamental properties of Hilbert–Kunz multiplicities; see e.g. [40].

**Proposition 2.2** ([40 (2.3),(2.4),(2.5)], [12]). Let $I \subset A$ be an $m$-primary ideal.

1. The following inequalities hold true:
   \[ \frac{e(I)}{d!} \leq e_{HK}(I) \leq e(I). \]

   If, in addition, $d \geq 3$, then $\frac{e(I)}{d!} < e_{HK}(I)$.

2. If $I$ is a parameter ideal, then $e_{HK}(I) = e(I)$.

3. Let $\text{Assh}(A)$ denote the set of all associated prime ideals $P$ with $\dim A/P = \dim A$. Then
   \[ e_{HK}(I,M) = \sum_{P \in \text{Assh}(A)} e_{HK}(I,A/P) \cdot \ell_{A_P}(M_P). \]

2.1. **Minimal value of Hilbert–Kunz multiplicity.** Now we want to discuss the conjectural lower bound on Hilbert–Kunz multiplicities of singularities. In order to state it, we recall the definition of type $(A_1)$ simple singularity.

**Definition 2.3.** Let $p$ be a prime number, $k$ be an algebraically closed field of characteristic $p$, and $d$ a positive integer. Then we define $A_{p,d}$ as follows:

\[ A_{p,d} := \begin{cases} 
  k[[x_0,x_1,\ldots,x_d]]/(x_0 x_1 + x_2 x_3 + \cdots + x_{d-1} x_d) & \text{ (when } d = 2m - 1, \ m \geq 1) ; \\
  k[[x_0,x_1,\ldots,x_d]]/(x_0^2 + x_1 x_2 + x_3 x_4 + \cdots + x_{d-1} x_d) & \text{ (when } d = 2m, \ m \geq 1). 
\end{cases} \]

For $p > 2$ the equation takes a more familiar form $A_{p,d} \cong k[[x_0,x_1,\ldots,x_d]]/(x_0^2 + x_1^2 + \cdots + x_d^2)$. Han and Monsky ([11]) gave an algorithm to compute $e_{HK}(A_{p,d})$ for given $p > \max\{2,d\}$. However, a closed formula for $e_{HK}(A_{p,d})$ is only known for small values of $d$. Gessel and Monsky ([10]) showed that $\lim_{p \to \infty} e_{HK}(A_{p,d}) = 1 + c_d$ where

\[ \sec x + \tan x = 1 + \sum_{i=1}^{\infty} c_d x^d \left( |x| < \frac{\pi}{2} \right). \]

The first several values of $c_d$ are recorded in Table 1 below.

**Conjecture 2.4** (cf. [43 Conjecture 4.2]). Let $(A,m,k)$ be an $F$-finite, formally unmixed, non-regular local ring of dimension $d \geq 1$. Then

1. $e_{HK}(A) \geq e_{HK}(A_{p,d}) \geq 1 + c_d$, where $c_d$ is defined above.

2. Suppose that $k = \bar{k}$. If $e_{HK}(A) = e_{HK}(A_{p,d})$, then $A \cong A_{p,d}$.

Let us summarize the cases where Conjecture 2.4 is known.

**Theorem 2.5.** Let $A$ be a formally unmixed, non-regular local ring and $p$ is an odd prime number.

1. If $d \leq 3$ then Conjecture 2.4 holds and $e_{HK}(A_{p,d}) = 1 + c_d$ ([41 Theorem 3.1], [43 Theorem 3.1]). In fact, these results also show that $e_{HK}(A) \geq e_{HK}(A_{p,d}) = 1 + c_d$ for $p = 2$.

2. If $d = 4$, then Conjecture 2.4 holds ([43 Theorem 4.3]) but $e_{HK}(A_{p,d}) = \frac{29p^2+15}{24p+12} > \frac{29}{24}$ now depends on $p$ ([10]).

3. If $d = 5,6$ then $e_{HK}(A) \geq e_{HK}(A_{p,d}) \geq 1 + c_d$ ([2 Theorem 5.2]).

4. If $A$ is a complete intersection local ring, then $e_{HK}(A) \geq e_{HK}(A_{p,d})$ (see [8 Theorem 4.6]).
(5) Yoshida ([46]) conjectures that $e_{HK}(A_{p,d})$ is a decreasing function in $p$ for a fixed $d$, thus the second part of the conjecture would imply the first.

Observation 2.6. If $p = 2$ and $d = 2m$ $(m = 1, 2, \ldots)$, then the following statement can be proved by using an argument in [11] (see [46] for details)

$$
\ell \left( A_{2,d}/m^{[2^e]} \right) = \frac{2^m + 1}{2m^2} 2^{de}.
$$

In particular, $e_{HK}(A_{2,d}) = \frac{2^m + 1}{2m}$.

Similarly, [46] conjectures that if $d = 2m - 1$ $(m = 1, 2, \ldots)$, then

$$
\ell(A_{2,d}/m^{[2^e]}) = \frac{2^m}{2^m - 1} 2^{de} - \frac{(2^m - 1)^e}{2^m - 1}
$$

for every $e \geq 1$. In particular, if would follow that $e_{HK}(A_{2,d}) = \frac{2^m}{2m - 1}$.

Based upon these observations, we pose an improved conjecture as follows:

**Conjecture 2.7.** Let $(A, m, k)$ be a formally unmixed non-regular local ring of dimension $d \geq 1$ and with algebraically closed residue field. Let $m \geq 1$ be an integer.

1. If $d = 2m - 1$, then either $\hat{A} \cong A_{p,d}$ or $e_{HK}(A) > \frac{2^m}{2m - 1}$.
2. If $d = 2m$, then either $\hat{A} \cong A_{p,d}$ or $e_{HK}(A) > \frac{2^m + 1}{2m}$.

By results of Watanabe and Yoshida, Conjecture 2.7 has an affirmative answer when $p \geq 3$ and $d \leq 4$.

The following table depicts the difference between two conjectures.

<table>
<thead>

**Table 1.** Comparison between the two conjectured bounds.

2.2. **Strong F-regularity and F-signature.** Hilbert–Kunz multiplicity is inherently connected with tight closure, a powerful theory developed by Hochster and Huneke in a series of papers starting at [16].

**Definition 2.8** (cf. [16]). Let $I \subseteq A$ be an ideal, and let $x$ be an element of $A$. Put $A^o = A \setminus \cup_{P \in \text{Min}(A)} P$. For $x \in A$, we say that $x$ is in the *tight closure* of $I$ (denoted by $I^*$) if there exists an element $c \in A^o$ such that $cx^q \in I^{[q]}$ for sufficiently large $q = p^e$.

A local ring $A$ is said to be weakly F-regular (resp. F-rational) if any ideal $I$ (resp. any parameter ideal $I$) is tightly closed, that is, $I^* = I$.

A result of Hochster and Huneke [16] Theorem 8.17] asserts that $e_{HK}(I^*) = e_{HK}(I)$ and, moreover, $I^*$ is the largest ideal containing $I$ with same Hilbert–Kunz multiplicity.

On the other hand, F-signature coincides with the *minimal relative Hilbert–Kunz multiplicity* [42] [45] [27] and is connected to the following class of singularities.

**Definition 2.9** (cf. [17]). A local ring $A$ is called *strongly F-regular* if for any $c \in A^o$, there exists $q = p^e$, $e \geq 1$ such that the map $A \leftrightarrow A^{1/q}$ defined by $x \mapsto c^{1/q}x$ splits as an $A$-linear map. Any Noetherian ring $A$ is called *strongly F-regular* if any localization of $A$ is also a (strongly) F-regular local ring.
Strongly F-regular singularities enjoy many nice properties and are always normal and Cohen-Macaulay. For example, quotient singularities and toric singularities are strongly F-regular rings. As it was already mentioned, \( s(A) > 0 \) if and only if \( A \) is strongly F-regular by a result of Aberbach and Leuschke [3, Theorem 0.2].

The simple singularity \( A_{p,d} \) discussed above is a hypersurface with \( e(A_{p,d}) = 2 \), thus by [2, Example 2.3] \( e_{HK}(A) = 2 - s(A) \) and \( s(A) \) attains the maximal value if and only if \( e_{HK}(A) \) is minimal. The following conjecture is then natural.

**Conjecture 2.10.** Let \((A, m)\) be a non-regular local ring of dimension \( d \geq 1 \). Then

\[
\text{if } r \geq \mu(A), \text{ then } s(A) \leq 2 - e_{HK}(A_{p,d}) = s(A_{p,d}).
\]

The theory of F-signature originates in the following particular case of rings of finite F-representation type, which was introduced by Smith and Van den Bergh [41] (see also [44]).

**Definition 2.11.** We say that \( A \) has finite F-representation type (FFRT) if there is a finite set \( \mathcal{S} = \{M_0, M_1, \ldots, M_n\} \) of isomorphism classes of indecomposable finitely generated \( A \)-modules such that for any positive integer \( e \), \( F_e^*A \) is isomorphic to a finite direct sum of these modules, that is,

\[
F_e^*A \cong M_0^{\oplus c_{0,e}} \oplus M_1^{\oplus c_{1,e}} \oplus \cdots \oplus M_n^{\oplus c_{n,e}}
\]

for some \( c_{i,e} \in \mathbb{Z}_{\geq 0} \). Moreover, we say that a finite set \( \mathcal{S} = \{M_0, M_1, \ldots, M_n\} \) as above is the (FFRT) system of \( A \) if every \( A \)-module \( M_i \) appears non-trivially in \( F_e^*A \) as a direct summand for some \( e \in \mathbb{N} \).

3. Lower bound on Hilbert–Kunz multiplicities

The last two authors gave a lower bound on Hilbert–Kunz multiplicities of two-dimensional unmixed (Cohen-Macaulay) local rings \( A \) in terms of usual multiplicities:

\[
e_{HK}(I) \geq \frac{e(I) + 1}{2}
\]

for any \( m \)-primary ideal \( I \) of \( A \) [44]. In this section, we consider a higher dimensional analogue of this inequality; see Theorem 3.2.

We recall [2, Theorem 3.2] which improves the volume estimation technique developed in [44]. For any real number \( s \) we define \( v_{s,d} \) to be the volume of \( \{(x_1, \ldots, x_d) \in [0,1]^d \mid \sum_{i=1}^d x_i \leq s\} \) which can be computed as

\[
v_{s,d} = \sum_{n=0}^{\lfloor s \rfloor} (-1)^n \frac{(s-n)^d}{(d-n)! n!},
\]

where \( \lfloor \ \rfloor \) stands for round down.

For an element \( x \in A \) we denote

\[
\nabla_I(x) := \lim_{n \to \infty} \sup \left\{ k \mid x^n \in I^k \right\}.
\]

It is known that this limit exists and \( \nabla_I(x) \geq k \) if and only if \( x^k \in I^k \); see Rees [29].

**Theorem 3.1** (Aberbach–Enescu[2]). Let \((A, m)\) be a formally unmixed reduced local ring of characteristic \( p > 0 \) and dimension \( d \). Let \( J \) be a minimal reduction of an \( m \)-primary ideal \( I \) and let \( r \) be an integer such that \( r \geq \mu_A(I/J^*) \). For every real number \( s \geq 0 \), we have

\[
e_{HK}(I) \geq e(I) \left( v_{s,d} - \sum_{i=1}^r v_{s-t_i,d} \right),
\]

where \( t_i = \nabla_I(z_i) \) for \( z_1, \ldots, z_r \) generators of \( I \) modulo \( J^* \).
In particular,
\[ e_{HK}(I) \geq e(I) \left( v_{s,d} - r \cdot v_{s-1,d} \right). \]

Using the above theorem and the technique developed in [1], we can improve Proposition 2.2.

**Theorem 3.2.** Let \((A, m)\) be a Cohen-Macaulay local ring of characteristic \(p > 0\). If \(d = \dim A \geq 3\), then we have
\[ e_{HK}(I) > \frac{e(I) + d}{d!}. \]

In what follows, we may assume that \(A\) is complete and the residue field \(k = A/m\) is infinite. Let \(I\) denote an \(m\)-primary ideal and \(J\) its minimal reduction.

**Lemma 3.3.** Suppose that \(A\) is Cohen-Macaulay and \(I = I^*\), that is, \(I\) is tightly closed. If \(mI \nsubseteq J\), then \(\mu_A(I/J^*) \leq e(I) - 2\).

**Proof.** By definition, \(\mu_A(I/J^*) = \ell_A(I/J^* + mI) \leq \ell_A(I/J + mI)\). Thus by assumption, we have
\[ \mu_A(I/J^*) \leq \ell_A(I/J + mI) \leq \ell_A(I/J) - 1 = \ell_A(A/J) - \ell_A(A/I) - 1 \leq e(I) - 2, \]
where we can use \(e(I) = \ell_A(A/J)\) since \(A\) is Cohen-Macaulay.

The following proposition gives a refinement of Aberbach and Enescu [1, Corollary 3.4].

**Proposition 3.4.** Let \((A, m)\) be a Cohen-Macaulay local ring of dimension \(d \geq 1\). Let \(I\) be an \(m\)-primary ideal and suppose that there exists a minimal reduction \(J\) of \(I\) such that \(I^2 \subset J\) (e.g. \(I\) is stable). Then
\[ e_{HK}(I) \geq \frac{e(I)}{2}. \]

**Proof.** Let \(\omega_A\) denote the canonical module of \(A\). Since \(I^{[q]} \omega_A \subseteq J^{[q]} \omega_A : I^{[q]}\) for any \(q = p^s\) by assumption, we get
\[ \ell_A(\omega_A / J^{[q]} \omega_A) = \ell_A(\omega_A / J^{[q]} \omega_A : I^{[q]} + J^{[q]} \omega_A) \]
\[ \leq \ell_A(\omega_A / I^{[q]} \omega_A) + \ell_A(J^{[q]} \omega_A : I^{[q]} / J^{[q]} \omega_A). \]

Then
\[ \lim_{q \to \infty} \frac{\ell_A(\omega_A / J^{[q]} \omega_A)}{q^d} = e_{HK}(J; \omega_A) = e_{HK}(I; \omega_A) = e_I, \quad \lim_{q \to \infty} \frac{\ell_A(\omega_A / I^{[q]} \omega_A)}{q^d} = e_{HK}(J; \omega_A) = e_{HK}(I). \]

On the other hand, since
\[ (J^{[q]} \omega_A : I^{[q]} / J^{[q]} \omega_A) \cong \text{Hom}_{A/J^{[q]}}(A/I^{[q]}, \omega_A/J^{[q]} \omega_A) \cong \text{Hom}_{A/J^{[q]}}(A/I^{[q]}, \omega_A/J^{[q]} \omega_A) \cong \omega_A/J^{[q]}, \]
we get
\[ \ell_A((J^{[q]} \omega_A : I^{[q]} / J^{[q]} \omega_A)) = \ell_A(\omega_A / J^{[q]} \omega_A) = \ell_A(A/J^{[q]}). \]

by Matlis duality. Hence
\[ \lim_{q \to \infty} \frac{\ell_A((J^{[q]} \omega_A : I^{[q]} / J^{[q]} \omega_A))}{q^d} = e_{HK}(I) \]
and thus \(e(I) \leq 2 \cdot e_{HK}(I)\), as required.

**Definition 3.5.** A Cohen-Macaulay local ring \((A, m)\) is said to have **minimal multiplicity** if \(\mu_A(m) = e(A) + \dim A - 1\). This condition is equivalent that \(m\) is stable, that is, \(m^2 = Jm\) for some minimal reduction \(J\) of \(m\).

**Corollary 3.6 ([1]).** Let \(A\) be a Cohen-Macaulay local ring with minimal multiplicity, that is, \(\mu_A(m) = e(A) + \dim A - 1\). Then \(e_{HK}(A) \geq \frac{e(A)}{2}\).
Theorem 3.7. Let $\text{HK}$ gives the optimal bound on the Hilbert-Kunz multiplicity $e$. Moreover, we may assume $e(I) \geq 2$.

Case 1. The case of $I^2 \subset J$.

We can apply Proposition 3.4 to obtain $e_{\text{HK}}(I) \geq \frac{e(I)}{2} > \frac{e(I) + d}{d!}$ if $d \geq 3$ and $e(I) \geq 2$.

Case 2. The case of $I^2 \not\subset J$.

By Lemma 3.3 we have $\mu_A(I/J^e) \leq e(I) - 2$. So we can apply Theorem 3.1 as $e = e(I) \geq 2$, $r = e - 2$ and $s = 1 + \frac{1}{e}$. Then $|s| = 1$ and

$$d! \cdot e^d(v_s - r \cdot v_{s-1}) = e^d \cdot d! \cdot \left( \frac{(1 + 1/e)^d}{d!} - \frac{(1/e)^d}{(d-1)!} - (e - 2) \frac{(1/e)^d}{d!} \right)$$

$$= (e + 1)^d - d - e + 2$$

$$= e^d + de^{d-1} + \sum_{k=2}^{d-2} \binom{d}{k} e^k + de + 1 - d - e + 2$$

$$\geq e^d + de^{d-1} + (d - 1)(e - 1) + 2 > e^{d-1}(e + d).$$

Hence $e_{\text{HK}}(I) \geq e(v_s - r \cdot v_{s-1}) > \frac{e + d}{d!}$, as required. $\square$

If we fix $d$, then this is not the best possible. In this paper, we prove the following theorem, which gives the optimal bound on the Hilbert-Kunz multiplicity $e_{\text{HK}}(A)$ in dimension 3.

Theorem 3.7. Let $(A, m, k)$ be an unmixed local ring of dimension 3 and characteristic $p > 0$. Then

$$e_{\text{HK}}(A) \geq \frac{e(A)}{6} + 1.$$ 

If equality holds, then $A$ is a strongly $F$-regular local ring with $e(A) = 2$. Moreover, if, in addition, the residue field $k$ is algebraically closed and $p \geq 3$, then $A \cong k[[x, y, z, w]]/(xz - yw)$ and $e_{\text{HK}}(A) = \frac{4}{3}$.

In order to prove the theorem, we prove a stronger result as follows.

Lemma 3.8. Under the assumptions of Theorem 3.7 we suppose that $e = e(A) \geq 3$. Then

1. $e_{\text{HK}}(A) \geq \frac{e}{6} \left( \frac{e + 2 + \sqrt{e + 2}}{e + 1} \right)^2$.

2. If $A$ is neither $F$-rational nor Cohen-Macaulay with minimal multiplicity, then

$$e_{\text{HK}}(A) \geq \frac{1}{6} \left( e + 3 \frac{2}{e} + \left( 2 + \frac{2}{e} \right) \sqrt{e + 1} \right).$$

Proof. (1) For $1 \leq s \leq 2$, we will optimize the volume estimate

$$e_{\text{HK}}(A) \geq e \cdot (v_s - (e - 1)v_{s-1})$$

$$= e \cdot \left( \frac{s^3}{6} - (s - 1)^3 - (e - 1) \frac{(s - 1)^3}{6} \right)$$

$$= e \left( \frac{s^3 - (e + 2)(s - 1)^3}{6} \right).$$
We consider a function \( f(s) = s^3 - (e+2)(s-1)^3 \). The derivative is given by \( f'(s) = 3s^2 - 3(e+2)(s-1)^2 \) and the equation \( f'(s) = 0 \) has roots \( s_{\pm} = \frac{e+2 + \sqrt{e^2 + 2}}{e+1} \). Since \( s_- < 1 < s_+ < 2 \), the maximum on \( 1 \leq s \leq 2 \) is at \( s_+ \) which gives the inequality:

\[
e_{HK}(A) \geq \frac{e}{6} \cdot f(s_+) = \frac{e}{6} \cdot s_+^2 = \frac{e}{6} \left( \frac{e+2 + \sqrt{e^2 + 2}}{e+1} \right)^2
\]

(2) Under the assumption, we have \( e_{HK}(A) \geq e \cdot (v_s - (e-2)v_{s-1}) \) and \( e \geq 3 \). So if we consider

\[
g(s) = s^3 - (e+1)(s-1)^3,\]

then \( 1 \leq \frac{e+1 + \sqrt{e+1}}{e} \leq 2 \) and a similar argument as above implies

\[
e_{HK}(A) \geq \frac{e}{6} \cdot g \left( \frac{e+1 + \sqrt{e+1}}{e} \right) = \frac{1}{6} \left( e + 3 + \frac{2}{e} + 2 + \frac{2}{e} \cdot \sqrt{e+1} \right),
\]

as required.

Proof of Theorem 3.7 First suppose that \( A \) is neither F-rational nor Cohen-Macaulay with minimal multiplicity. If \( e = 2 \), then \( e_{HK}(A) = 2 > \frac{4}{3} = \frac{6}{3} + 1 \). Hence we may assume \( e = e(A) \geq 3 \). Then Lemma 3.8 yields that

\[
e_{HK}(A) \geq \frac{1}{6} \left( e + 3 + \frac{2}{e} + 2 + \frac{2}{e} \cdot \sqrt{e+1} \right) > \frac{e}{6} + 1.
\]

Next suppose that \( A \) is F-rational and Cohen-Macaulay with minimal multiplicity. If \( e \geq 4 \), then \( e_{HK}(A) \geq \frac{6}{3} > \frac{6}{6} + 1 \). If \( e = 3 \), then [43 Lemma 3.3(3)] implies \( e_{HK}(A) \geq \frac{13}{8} > \frac{3}{2} = \frac{6}{6} + 1 \).

Suppose that \( e = 2 \). Then the main theorem in [43] yields \( e_{HK}(A) \geq \frac{4}{3} = \frac{6}{3} + 1 \) and equality holds if and only if \( \tilde{A} \cong k[[x,y,z,w]]/(xz - yw) \). Therefore we complete the proof.

\[
4. \text{Upper bounds on F-signature}
\]

The main aim of this section is to give an upper bound on F-signature for non-Gorenstein Cohen-Macaulay local rings. We start with a few preliminaries.

Let \( M \) be an MCM \( A \)-module. Then \( \mu_A(M) \leq e(M) \), because multiplicity can be computed from a regular sequence. We say that \( M \) is an Ulrich \( A \)-module if \( \mu_A(M) = e(M) \). Ulrich modules first appeared in [3] under the name maximally generated maximal Cohen-Macaulay module.

If \( A \) is a local ring of positive characteristic \( p > 0 \) and \( M \) is a finitely generated \( A \)-module then the rank of the largest free summand of \( M \) is independent of a decomposition, because we may pass to the completion, see [26, Remark 3.4]. Moreover, if \( A \) is a Cohen-Macaulay local ring with the canonical module \( \omega_A \) and \( M \) is maximal Cohen-Macaulay, then the number of direct summand of \( M \) isomorphic to \( \omega_A \) is also independent of a direct decomposition, since these correspond to a free summand of \( \text{Hom}_A(M, \omega_A) \).

Last, we note that an F-finite Cohen-Macaulay ring has a canonical module by a result of Gabber [9, Remark 13.6].

The second assertion of the next proposition was initially observed by De Stefani and Jeffries in relation with Sannai’s dual F-signature ([31]).

Proposition 4.1 (cf. [24]). Let \( A \) be an F-finite Cohen-Macaulay local domain which is not Gorenstein. Then

\[
e_{HK}(A) \leq s(A)(\text{type}(A) + 1) + 2 \cdot e(A) \left( \frac{1}{2} - s(A) \right).
\]

In particular, \( s(A) \leq \frac{1}{2} \).
Proof. For every $e \geq 1$, we can write

$$F^e_* A = A^{\oplus a_e} \oplus \omega A^{\oplus b_e} \oplus M_e,$$

where $a_e$, $b_e$ are non-negative integers and $M_e$ is a maximal Cohen-Macaulay $A$-module that does not contain $A$ and $\omega_A$ as direct summands. Then

$$F^e_* \omega_A \cong \text{Hom}_A(F^e_* A, \omega_A) \cong A^{\oplus b_e} \oplus \omega A^{\oplus a_e} \oplus \text{Hom}_A(M_e, \omega_A).$$

By the argument in the proof of Sannai [31 Proposition 3.10], we have

$$\lim_{e \to \infty} \frac{a_e}{\text{rank} F^e_* A} = \lim_{e \to \infty} \frac{b_e}{\text{rank} F^e_* A} = s(A).$$

Note that $\mu_A(F^e_* A) = p^e \alpha(A) \cdot \ell_A(A/m^{[p^e]})$ and $\text{rank} A F^e_* A = p^e (\alpha(A) + d)$.

Since $M_e$ is a maximal Cohen-Macaulay $A$-module, we have

$$\mu_A(F^e_* A) = a_e + b_e \cdot \text{type}(A) + \mu_A(M_e) \leq a_e + b_e \cdot \text{type}(A) + e_A(M_e) = a_e + b_e \cdot \text{type}(A) + e(A) \text{rank}_A(M_e) = a_e + b_e \cdot \text{type}(A) + e(A)(\text{rank} F^e_* A - a_e - b_e).$$

Hence

$$\frac{\ell_A(A/m^{[p^e]})}{p^{ed}} = \frac{\mu_A(F^e_* A)}{\text{rank} F^e_* A} \leq \frac{a_e}{\text{rank} F^e_* A} + \text{type}(A) \cdot \frac{b_e}{\text{rank} F^e_* A} + e(A) \left(1 - \frac{a_e}{\text{rank} F^e_* A} - \frac{b_e}{\text{rank} F^e_* A}\right),$$

and the first assertion follows after taking limits as $e$ tends to $\infty$.

In particular, since

$$0 \leq \frac{\text{rank}_A(M_e)}{\text{rank} F^e_* A} = 1 - \frac{a_e}{\text{rank} F^e_* A} - \frac{b_e}{\text{rank} F^e_* A},$$

we get $0 \leq 1 - 2 \cdot s(A)$, that is, $s(A) \leq \frac{1}{2}$. \qed

Remark 4.2. We note that there are classes of Gorenstein rings having F-signature less than or equal to $\frac{1}{2}$. For example, if $A$ is a 2-dimensional Gorenstein strongly F-regular local ring, then $A$ is a hypersurface and has minimal multiplicity, thus $e(A) = 2$. Therefore, we have $s(A) = 2 - e_{\text{HK}}(A) \leq 2 - \frac{3}{2} = \frac{1}{2}$ by [43 Corollary 2.6] (see also [41 Example 4.1] and [18 Example 18]).

The following theorem characterizes the equality in Proposition 4.1 in terms of the FFRT property.

Theorem 4.3. Let $A$ be a strongly F-regular local domain of type at least two (i.e., not Gorenstein). The following conditions are equivalent:

1. $e_{\text{HK}}(A) = s(A) \cdot \text{type}(A) + 1 + 2 \cdot e(A) \left(\frac{1}{2} - s(A)\right)$.

2. $F^e_* A$ is a finite direct sum of $A$, $\omega_A$ and an Ulrich $A$-module for every $e \geq 1$.

Proof. For every $e \geq 1$, we can write $F^e_* A = A^{\oplus a_e} \oplus \omega A^{\oplus b_e} \oplus M_e$, where $a_e$ and $b_e$ are non-negative integers and $M_e$ is a maximal Cohen-Macaulay $A$-module that does not contain $A$ and $\omega_A$ as direct summands.

(2) $\implies$ (1): By the assumption, $M_e$ is an Ulrich $A$-module, that is, $\mu_A(M_e) = e(M_e)$. Hence the assertion follows from the proof of Proposition 4.1.

(1) $\implies$ (2): Suppose that there exists $e'$ such that $F^e'_* A = A^{\oplus a'_e} \oplus \omega A^{\oplus b'_e} \oplus M_{e'}$, where $M_{e'}$ is an MCM $A$-module but not an Ulrich $A$-module, namely, $\mu_A(M_{e'}) < e(M_{e'})$. By [26 Lemma 3.3] we may now build a similar decomposition for $e \geq e'$:

$$F^e_* A = A^{\oplus a_e} \oplus \omega^{\oplus b_e} \oplus M_{e'}^{\oplus c_e} \oplus N_e$$
such that \( \liminf_{e \to \infty} c_e / \text{rank} F_e^* A > 0 \). Following the proof of Proposition 4.1, we obtain that

\[
\mu_A(F_e^* A) \leq a_e + b_e \cdot \text{type}(A) + c_e(\text{e}(M_e) - \mu_A(M_e)) + \text{e}(A)(\text{rank} F_e^* A - a_e - b_e),
\]

which shows after dividing by rank \( F_e^* A \) and passing to the limit that

\[
e_{\text{HK}}(A) < \text{s}(A)(\text{type}(A) + 1) + \text{e}(A)(1 - 2 \cdot \text{s}(A)).
\]

One can prove the following proposition by a similar method as in the proof of Proposition 4.1 and Theorem 4.3.

**Proposition 4.4.** Suppose that \( A \) is a Gorenstein local ring of dimension \( d \geq 2 \). Then

\[
e_{\text{HK}}(A) \leq \text{s}(A) + (1 - \text{s}(A)) \cdot \text{e}(A)
\]

and the equality holds if and only if \( F_e^* A \) can be written as a direct sum of \( A \) and Ulrich \( A \)-modules for every \( e \geq 1 \).

We note that if \( \text{e}(A) = 2 \) we have \( e_{\text{HK}}(A) = 2 - \text{s}(A) \), and hence \( A \) satisfies the equality of Proposition 4.4.

**Question 4.5.** If \( A \) satisfies \( e_{\text{HK}}(A) = \text{s}(A) + (1 - \text{s}(A)) \cdot \text{e}(A) \), then is \( \text{e}(A) \leq 2 \)?

We proceed to study non-Gorenstein rings whose F-signature is \( \frac{1}{2} \).

**Theorem 4.6.** Let \( A \) be a Cohen-Macaulay local domain but not Gorenstein. Then the following conditions are equivalent:

1. \( \text{s}(A) = \frac{1}{2} \);
2. \( A \) is FFRT with the FFRT system \( \{A, \omega_A\} \).

When this is the case, \( e_{\text{HK}}(A) = \frac{\text{type}(A) + 1}{2} \).

**Proof.** (2) \( \implies \) (1) essentially follows from the proof of Proposition 4.1 because in this case there is no \( M_e \) and we have equality throughout.

(1) \( \implies \) (2): Assume that for some \( e' \geq 1 \), we write \( F_{e'}^* A \) as

\[
F_{e'}^* A = A^{a_{e'}} \oplus \omega^{b_{e'}} \oplus M_{e'},
\]

where \( 0 \neq M_{e'} \) is a maximal Cohen-Macaulay \( A \)-module that does not have \( A \) and \( \omega_A \) as direct summands. Since \( R \) is strongly F-regular by the assumption, as explained in [26, Lemma 3.3] we may now build similar decompositions for \( e \geq e' \):

\[
F_e^* A = A^{\frac{a_e}{\text{rank} F_e^* A}} \oplus \omega^{\frac{b_e}{\text{rank} F_e^* A}} \oplus M_{e'}^{\frac{c_e}{\text{rank} F_e^* A}} \oplus N_e
\]

with \( \liminf_{e \to \infty} c_e / \text{rank} F_e^* A > 0 \). After taking ranks we then have that

\[
1 \geq \frac{a_e}{\text{rank} F_e^* A} + \frac{b_e}{\text{rank} F_e^* A} + \frac{\text{rank} A M_{e'}}{\text{rank} F_e^* A} \frac{c_e}{\text{rank} F_e^* A}
\]

which after taking limits then gives that \( 1 > \text{s}(A) + \text{s}(A) \) which is a contradiction. \( \square \)

Let us give an example of local rings having \( s(A) = \frac{1}{2} \).

**Example 4.7.** Let \( d \geq 2 \) be an integer. Let \( A = k[[x_1, \ldots, x_d]]^{(2)} \) be the second Veronese subring of the formal power series ring over \( k \). Then \( s(A) = \frac{1}{2} \). Moreover, \( A \) is not Gorenstein if and only if \( d \) is odd.

Let \( A \) be a Cohen-Macaulay local domain with minimal multiplicity. Then \( A \) is not Gorenstein if and only if \( \text{e}(A) \geq 3 \). Moreover, then \( \text{type}(A) = \text{e}(A) - 1 \). So we can obtain the following corollary by combining 3.6, 4.1, 4.6 and 4.3.

**Corollary 4.8.** Suppose that \( A \) is a Cohen-Macaulay local domain with minimal multiplicity \( \text{e}(A) \geq 3 \). Then
(1) \( s(A) \leq \frac{1}{2} \).

(2) \( \frac{e(A)}{2} \leq e_{HK}(A) \leq (1 - s(A))e(A) \).

(3) The following conditions are equivalent:
   (a) \( s(A) = \frac{1}{2} \).
   (b) \( A \) has FFRT with the FFRT system \( \{ A, \omega_A \} \).

When this is the case, \( e_{HK}(A) = \frac{e(A)}{2} \).

(4) Suppose \( s(A) > 0 \). Then the following conditions are equivalent:
   (a) \( e_{HK}(A) = (1 - s(A))e(A) \).
   (b) \( F^e_A \) can be written as a direct sum of \( A \), \( \omega_A \) and Ulrich \( A \)-modules for every \( e \geq 1 \).

Example 4.9. Let \( A = k[[x, y, z]]^{(2)} \). Then \( A \) has minimal multiplicity and its multiplicity is \( 4 \). Moreover, \( e_{HK}(A) = \frac{e(A)}{2} = 2 \) and \( s(A) = \frac{1}{2} \).

Example 4.10. Let \( A = k[[x^3, xy^2, xy^2, y^3]] = k[[x, y]]^{(3)} \). Then, \( F^e_A \) can be written as direct sum of \( A \), \( \omega_A = Ax + Ay \) and \( M = Ax^3 + Ax^2 + Ay^2 \). In this case, \( s(A) = \frac{1}{2} \) by [42], and \( e(A) = 3 \), type(\( A \)) = 2. Since \( \mu_A(M) = 3 = e_A(M) = e(A) \text{rank}_A(M) \), we see that \( M \) is an Ulrich \( A \)-module, and we have

\[
e_{HK}(A) = 2 = s(A) \text{type}(\ A \) + 1) + 2 \cdot e(A) \left( \frac{1}{2} - s(A) \right).
\]

We pose the following question.

Question 4.11. Let \( A \) be a \( d \)-dimensional Cohen-Macaulay local domain with isolated singularity and that \( s(A) = \frac{1}{2} \). Then is \( A \) isomorphic to the ring defined in Example 4.7?

4.1. \( \mathbb{Q} \)-Gorenstein local rings. We are able to give an affirmative answer to Question 4.11 in a particular case.

Let \( A \) be a Cohen-Macaulay reduced local ring. For an ideal \( I \subset A \) of height 1, the \( n^{th} \) symbolic power \( I^{(n)} \) denotes the intersection of height one primary components of \( I^n \).

Definition 4.12. Let \( A \) be a normal local domain having a canonical module \( \omega_A \).

(1) The ring \( A \) is said to be \( \mathbb{Q} \)-Gorenstein if there exists an ideal \( J \) of height 1 which is isomorphic to \( \omega_A \) as an \( A \)-module such that \( J^{(n)} \) is principal. Furthermore,

\[ \text{index}(A) := \min \{ n \in \mathbb{N} \mid J^{(n)} \text{ is principal} \} \]

is called the index of \( A \).

(2) Suppose that \( A \) is a \( \mathbb{Q} \)-Gorenstein normal local domain of \( r = \text{index}(A) \geq 2 \), and let \( J \) be an ideal such that \( J \cong \omega_A \). Put

\[ B := \bigoplus_{i=0}^{r-1} J^{(i)}. \]

Then \( B \) is called the canonical cover of \( A \).

Note that \( A \) is Gorenstein if and only if it is \( \mathbb{Q} \)-Gorenstein of index 1.

Definition 4.13. Let \( \varphi : A \to B \) be ring homomorphism. A ring homomorphism \( \varphi \) is called étale if \( B \) is a finitely generated \( A \)-algebra and \( A \to B \) is flat and unramified. Put

\[ U = \{ P \in \text{Spec}(A) \mid A_P \to B \otimes_A A_P \text{ is étale} \}. \]

A ring homomorphism \( \varphi \) is called étale in codimension 1 if \( \text{Spec}(A) \setminus U \) is a closed subset of codimension at least two.

We will need the following result from [39].
Theorem 4.14. Let $A$ be a $\mathbb{Q}$-Gorenstein strongly $F$-regular local ring with $r = \text{index}(A) \geq 2$, and $B$ its canonical cover. Suppose that $(r, p) = 1$. Then

1. $A \to B$ is module-finite and étale in codimension 1.
2. The free rank of $B$ as an $A$-module is one.
3. $A \to B$ is split.
4. $B$ is a strongly $F$-regular $\mathbb{Q}$-Gorenstein local domain.

Note that if $A \hookrightarrow B$ is a module-finite extension of local domains, then $e_{HK}(A) = \frac{1}{[Q(B) : Q(A)]} e_{HK}(B)$. But such a formula is not satisfied in general for $F$-signatures. So the following theorem is very useful.

Theorem 4.15 ([37, Theorem 2.6.5], see also [30]). Let $(A, m, k) \to (B, m, k)$ be a module-finite extension of normal local domains, where the residue field $k$ has positive characteristic. Suppose that $A \to B$ is split and étale in codimension one and the free rank of $B$ as an $A$-module is equal to one. Then we have

$$s(A) = \frac{1}{[Q(B) : Q(A)]} s(B).$$

Corollary 4.16. Let $A$ be a strongly $F$-regular $\mathbb{Q}$-Gorenstein local domain but not Gorenstein. Let $r \geq 2$ be the index of $A$ such that $(r, p) = 1$. Let $B$ be a canonical cover of $A$. Then we have $s(A) = \frac{1}{r} s(B)$.

Using this, we can prove the following theorem.

Theorem 4.17. Let $A$ be an $F$-finite $\mathbb{Q}$-Gorenstein normal local domain of characteristic $p > 0$. Assume the index $r$ of $A$ satisfies $(r, p) = 1$. Then the following conditions are equivalent:

1. $s(A) = \frac{1}{r}$.
2. $r = 2$ and $A$ admits a canonical cover $B$ which is regular.

Proof. Suppose (1). Let $B$ a canonical cover of $A$. Then $s(A) = \frac{s(B)}{r}$. If $r \geq 3$, then $s(B) = r \cdot s(A) > 1$. This is a contradiction. Hence $r = 2$ and $s(B) = 1$. Hence $B$ is regular. The converse is easy. □

4.2. The $F$-signatures of 3-dimensional Gorenstein rings. We want to present a few upper bounds on $F$-signature in view of Question [11]. We first estimate $F$-signature using the multiplicity.

Theorem 4.18. Let $(A, m, k)$ be a 3-dimensional Gorenstein $F$-regular local ring with multiplicity $e(A) \geq 3$. Then $s(A) \leq \frac{e(A)}{2^2}$.

Proof. Let $J$ be a minimal reduction of $m$. Then we can write $J : m = (J, u)$ for some $u \in m \setminus J$ because $A$ is Gorenstein. Moreover, we have

$$s(A) \leq e_{HK}(J) - e_{HK}(J : m) = e(J) - e_{HK}(J : m) = e - e_{HK}(J : m).$$

Since $A$ is F-regular, the Briançon–Skoda theorem implies that $m^3 \subset J$, and thus $m^2 \subset J : m$. Since $A$ is not double point, $m^2 \not\subset J$. Hence there exists an element $v \in m^2$ such that $v \in J : m \setminus J$. Write $v = a + ru$ for some $a \in J$ and $r \in A$. Suppose $r \in m$. Then $ru \in J$ and thus $v = a + ru \in J$, which is a contradiction. Hence $r \in A \setminus m$ and $(J, u) = (J, v)$. So we may assume that $u \in m^2$. Then $u^q \in m^{2q}$ and we get

$$\ell_A \left( \frac{u^q A + J^q}{J^q} \right) \leq \ell_A \left( \frac{u^q A + m^{2q} + J^q}{m^2 + J^q} \right),$$

$$= \ell_A \left( \frac{u^q A + m^{2q} + J^q}{m^{2q} + J^q} \right) + \ell_A \left( \frac{m^{2q} + J^q}{J^q} \right).$$

Note that $\overline{A} = A/J^q$ is an Artinian Gorenstein local ring. Thus the Matlis duality yields that

$$\ell_A \left( \frac{u^q A + m^{2q} + J^q}{m^{2q} + J^q} \right) \leq \ell_A (A/m^{1q}) \quad \text{and} \quad \ell_A \left( \frac{m^{2q} + J^q}{J^q} \right) \leq \ell_A (A/m^{1q}).$$
Therefore
\[ s(A) = \lim_{e \to \infty} \ell_A \left( \frac{u^g A + J^q}{J^q} \right) / \ell \leq 2 \cdot \lim_{e \to \infty} \frac{\ell_A(A/m \overline{A})}{\ell} = 2 \times \frac{1}{3!} \left( \frac{1}{2} \right)^3 e(A) = \frac{1}{24} e(A), \]
as required.

The next example shows Theorem 4.18 gives the best possible bound.

**Example 4.19.** Let \( R^{(2)} \) be the 2nd Veronese subring of \( R = k[x, y, z, w]/(xw - yz) \). Set
\[ A = k[[x, y, z, w]]/(xw - yz), \]
which is the completion with respect to the irrelevant maximal ideal \( m \) of \( R^{(2)} \). Then \( A \) is a 3-dimensional Gorenstein F-regular local domain. Hence [19, Theorem 5.1(1)] implies \( e(A) \leq \text{emb}(A) - 1 = 8 \). On the other hand, since \( A \) is not hypersurface (of multiplicity 2), \( e(A) \geq \text{emb}(A) - \dim A + 2 = 9 - 3 + 2 = 8 \) and thus \( e(A) = 8 \). Moreover, we have
\[ s(A) = \frac{s(R)}{2} = \frac{2/3}{2} = \frac{1}{3} = \frac{e(A)}{24}. \]

On the other hand, by [41, Corollary 1.10], we have
\[ e_{HK}(m^2_R) = e(m) \left( \frac{2 + 3 - 2}{3} \right) + e_{HK}(m) \left( \frac{2 + 3 - 2}{3 - 1} \right) = e(R) + 3 \cdot e_{HK}(R) = 2 + 3 \cdot \frac{4}{3} = 6. \]

Hence
\[ e_{HK}(A) = \frac{e_{HK}(m_A R)}{2} = \frac{e_{HK}(m^2_R)}{2} = \frac{6}{2} = 3 > \frac{7}{3} = \frac{8}{6} + 1 = \frac{e(A)}{6} + 1. \]

**Remark 4.20.** The argument given in the proof of Theorem 4.18 is also valid for some classes of higher dimensional Gorenstein rings. For example, let \( A := k[[x_0, x_1, \ldots, x_d]]/(x_0^d + x_1^d + \cdots + x_d^d) \). For the maximal ideal \( m \) and its minimal reduction \( J \), we have that \( m^d \subset J \) and \( m^{d-1} \not\subset J \). Thus, by the same argument as the proof of Theorem 4.18, we see that \( s(A) \leq \frac{e(A)}{2^2 1! d!} = \frac{1}{2^2 1! (d-1)!} \), see also [42, Proposition 2.4 and Question 2.6].

As the first open case, we will investigate Question 1.1, Conjecture 2.10 for 3-dimensional Gorenstein rings. In particular, we ask the following question.

**Question 4.21.** Let \( (A, m) \) be a 3-dimensional non-regular Cohen-Macaulay local ring. Is \( s(A) \leq \frac{2}{5} \)?

If this is correct, then this bound is best possible because if \( A = k[x, y, z, w]/(xw - yz) \), then \( s(A) = \frac{2}{5} \). We will give a positive answer to this question for the case of toric rings in the next section (see Theorem 5.12). For a general situation, we only have the inequality given in Proposition 4.22.

**Proposition 4.22.** Let \( A \) be a 3-dimensional F-regular local domain which is not regular. Then \( s(A) < \frac{5}{6} \).

**Proof.** We may assume that \( A \) is Gorenstein (see Proposition 4.1). By Proposition 4.4(1), we have
\[ e_{HK}(A) \leq s(A) + e(A)(1 - s(A)). \]

On the other hand, Theorem 5.7 implies that
\[ \frac{e(A)}{6} + 1 \leq e_{HK}(A) \leq s(A) + e(A)(1 - s(A)). \]

Hence
\[ e(A) \left( s(A) - \frac{5}{6} \right) \leq s(A) - 1 < 0. \]

and thus \( s(A) < \frac{5}{6} \).
5. Observations on toric rings

In this section, we further study an upper bound on F-signature of a toric ring. In particular, in Theorem 5.12 we give a positive answer to Question 4.21.

5.1. Preliminaries. Let \( \mathbb{Z}^d \) be a lattice of rank \( d \). Let \( M = \text{Hom}_\mathbb{Z}(\mathbb{Z}^d, \mathbb{Z}) \) be the dual lattice of \( \mathbb{Z}^d \). We set \( N_R = \mathbb{Z} \otimes \mathbb{Z} R \) and \( M_R = M \otimes \mathbb{Z} R \). We denote the inner product by \( \langle \cdot, \cdot \rangle : M_R \times N_R \to \mathbb{R} \). Let \( \sigma := \mathbb{R}_{\geq 0} v_1 + \cdots + \mathbb{R}_{\geq 0} v_n \subset N_R \) be a strongly convex rational polyhedral cone of dimension \( d \) generated by \( v_1, \ldots, v_n \in \mathbb{Z}^d \) where \( d \leq n \). We assume that \( v_1, \ldots, v_n \) are minimal generators of \( \sigma \). Namely, \( \sigma \) is generated by any proper subset of \( \{v_1, \ldots, v_n\} \) is a proper subset of \( \sigma \), and each \( v_i \) is the lattice point of smallest magnitude on the ray it generates. For each generator, we define the linear form \( \lambda_i(-) := (-, v_i) \). We consider the dual cone \( \sigma^\vee := \{ x \in M_R | \lambda_i(x) \geq 0 \text{ for all } i = 1, 2, \ldots, n \} \).

In this case, \( \sigma^\vee \cap M \) is a positive normal affine monoid. Given an algebraically closed field \( k \) of characteristic \( p > 0 \), we define the toric ring
\[
A := k[\sigma^\vee \cap M] = k[t_1^{m_1} \cdots t_d^{m_d} | (m_1, \ldots, m_d) \in \sigma^\vee \cap M].
\]
Thus, in this paper, a toric ring is a pointed normal affine monomial ring. We denote the irrelevant ideal of \( A \) as \( m \).

For each \( a = (a_1, \ldots, a_n) \in \mathbb{Z}^n \), we set
\[
V(a) := \{ x \in M | (\lambda_1(x), \ldots, \lambda_n(x)) \geq (a_1, \ldots, a_n) \}.
\]
Then we define the divisorial ideal (rank one reflexive module) \( D(a) \) generated by all monomials whose exponent vectors are in \( V(a) \). For example, we have that \( R = D(0) \) and \( \omega_A = D(1, 1, \ldots, 1) \). Let \( p_i := D(\delta_1, \ldots, \delta_i, \ldots) \), where \( \delta_i \) is the Kronecker delta. The height one prime ideals \( p_1, \ldots, p_n \) generate the class group \( \text{Cl}(A) \). When we consider a divisorial ideal \( D(a) \) as the element of \( \text{Cl}(A) \), we denote it by \( [D(a)] \).

In what follows, we will pay attention to a certain class of divisorial ideals called conic.

**Definition 5.1** (see e.g. [7] [6]). We say that a divisorial ideal \( D(a) \) is conic if there exist \( x \in M_R \) such that \( a = (\lceil \lambda_1(x) \rceil, \ldots, \lceil \lambda_n(x) \rceil) \), where \( \lceil \cdot \rceil \) stands for the round up.

Any conic divisorial ideal is a rank one MCM module (see [7] Corollary 3.3]). We denote the set of isomorphism classes of conic divisorial ideals of a toric ring \( A \) by \( \mathcal{C}(A) \). This is a finite set because the number of isomorphism classes of rank one MCM \( A \)-modules is finite (see [7] Corollary 5.2]). The following proposition guarantees that any conic divisorial ideal appears in \( F^*_r A \) as a direct summand.

**Theorem 5.2** ([7] Proposition 3.6], [33 Subsection 3.2]). Let \( A \) be a toric ring as above. Then, \( A \) has FFRT by the FFRT system \( \mathcal{C}(A) \).

We recall that our arguments can be reduced to the \( m \)-adic completion of \( A \), as we mentioned in the beginning of Section 4. Thus, we may assume that \( A \) is complete local, in which case the Krull–Schmidt condition holds for \( A \).

**Remark 5.3.** In some parts of this section, we assume that if the class group \( \text{Cl}(A) \) contains a torsion element, then the order of that element is coprime to \( p \). In this case, the toric ring \( A \) is a ring of invariants.

Namely, let \( k^\times \) be the multiplicative group of \( k \) and \( G := \text{Hom}((\text{Cl}(A), k^\times) \) be the character group of \( \text{Cl}(A) \). The group \( G \) acts on \( B := k[x_1, \ldots, x_n] \) by \( g(x_i) = g([p_i]) x_i \) for each \( g \in G \) and any \( i \). Then, by [7] Theorem 2.1(b)), \( A \) can be described as \( A \cong B^G \). Moreover, to avoid the triviality, we assume that \( g([p_i]) \neq 1 \) for any \( i \), that is, \([p_i] \neq 0 \) in \( \text{Cl}(A) \).

Last, we will use that the F-signature of a toric ring can be computed combinatorially and, in particular, does not depend on the characteristic.
Theorem 5.4 ([42, Theorem 5.1], see also [6, 32, 37]). Let \( A \) be a toric ring. Then, we may compute
\[
s(A) = \text{vol}\{ x \in M_\mathbb{R} \mid 0 \leq \lambda_i(x) \leq 1 \text{ for all } i \}.
\]

5.2. Cohen-Macaulay toric rings. We recall that the F-signature of non-Gorenstein ring is less than or equal to \( \frac{1}{2} \) (see Proposition 4.1). We now determine the non-Gorenstein toric rings whose F-signature is \( \frac{1}{2} \).

Proposition 5.5. Let \( A \) be a toric ring as in Remark 5.3. Then, the following conditions are equivalent.

1. The FFRT system of \( A \) is \( \{A, M\} \) with \( M \neq A \).
2. \( A \) is isomorphic to the Veronese subring \( k[x_1, \ldots, x_d]^{(2)} \) of degree 2.

When this is the case, the F-signature is \( s(A) = \frac{1}{2} \).

Proof. We first assume that the FFRT system of \( A \) is \( \{A, M\} \). We note that \( M \cong \omega_A \) if \( A \) is not Gorenstein. In fact, \( \omega_A \) certainly appears in \( F^e_A \) as a direct summand for sufficiently large \( e \), if \( A \) is strongly F-regular (cf. [31, Proof of Proposition 3.10], [15, Proposition 2.1]). By [17, Remark 3.4], the divisorial ideals \( \rho_i \) (resp. \( n_i \rho_i \)) are conic. Since \( \mathcal{C}(A) = \{A, M\} \), we have that \( [p_1] = \cdots = [p_n] = [M] \) in \( \text{Cl}(A) \). On the other hand, since \( [\omega_A] = [p_1] + \cdots + [p_n] \), we see that \( n_i [p_i] = 0 \) (resp. \( n_i = 0 \)) in \( \text{Cl}(A) \) for any \( i \) if \( A \) is Gorenstein (resp. not Gorenstein). Thus, we conclude that \( \text{Cl}(A) \) is a finite cyclic group generated by \( [p_i] \), that is, \( \text{Cl}(A) \cong \langle [p_i] \rangle \). This implies that the cone \( \sigma \) defining \( A \) is simplicial (i.e., \( n = d \)), thus we have that \( A \cong B^G \) where \( B = k[x_1, \ldots, x_d] \) and \( G = \text{Hom}(\text{Cl}(A), k^\times) \) is a finite cyclic group. We may assume that \( G \) is small (see e.g. [20, Proof of Theorem 5.7]). By [33, Proposition 3.2], each indecomposable direct summand of \( F^e_A \) is a module of covariants which takes the form \( (B \otimes_k V_i)^G \), where \( V_i \) is an irreducible representation of \( G \). Since the FFRT system is \( \{A, M\} \) and \( G \) is small, we have only two non-isomorphic irreducible representations of \( G \). Then we have that \( |G| = 2 \), and the elements of \( G \) are the characters of \( \rho_0, \rho_1 \in \text{Hom}(\text{Cl}(A), k^\times) \) defined by \( \rho([p_i]) = 1 \) and \( \rho([p_i]) = -1 \) respectively. Consequently, we have that \( A \cong k[x_1, \ldots, x_d]^{(2)} \). By [42, Theorem 4.2], the F-signature of \( A \cong B^G \) is \( \frac{1}{|G|} = \frac{1}{2} \).

On the other hand, we assume that \( A \cong k[x_1, \ldots, x_d]^{(2)} \). Then, \( A \) is the invariant subring of \( k[x_1, \ldots, x_d] \) under the action of the cyclic group \( \langle g = \text{diag}(-1, \ldots, -1) \rangle \) defined by \( g \cdot x_i = -x_i \) for any \( i \). Thus, the condition (1) follows from [33, Proposition 3.2.1].

This is the main result in this subsection.

Theorem 5.6. Let \( A \) be a toric ring as Remark 5.3. Assume that \( A \) is not Gorenstein, then the following conditions are equivalent.

1. \( \text{F}(A) = \frac{1}{2} \).
2. The FFRT system of \( A \) is \( \{A, \omega_A\} \).
3. \( A \) is isomorphic to the Veronese subring \( k[x_1, \ldots, x_d]^{(2)} \) of degree 2, where \( d \) is an odd number.

Proof. (3) \( \implies \) (1) follows from [42, Theorem 4.2]. (1) \( \iff \) (2) follows from Theorem 4.6. Then we show (2) \( \iff \) (3). By Proposition 5.5, we see that \( A \cong k[x_1, \ldots, x_d]^{(2)} = k[x_1, \ldots, x_d]^G \), where \( G \cong \langle \text{diag}(-1, \ldots, -1) \rangle \). Since \( A \) is not Gorenstein, \( G \) is not a subgroup of \( \text{SL}(d,k) \), thus \( d \) is an odd number (see [38]).

Example 5.7. If \( A \) is a Gorenstein toric ring, then \( s(A) = \frac{1}{2} \) does not imply the conditions (2) and (3) in Theorem 5.6. Namely, consider the Segre product \( P_n := k[x_1, y_1] \# \cdots \# k[x_n, y_n] \) of \( n \) polynomial rings with two variables, which is a Gorenstein toric ring in dimension \( n + 1 \). Then, by [15, Proposition 6.1], one can compute \( s(P_n) = \frac{2}{n+1} \). For example, \( s(P_3) = \frac{1}{2} \) but the FFRT system of \( P_3 \) consists of 7 conic divisorial ideals (see [14, Example 2.6]).

This example shows that it is difficult to bound F-signature of a Gorenstein ring \( A \) using the number of modules in the FFRT system. For this reason, we give an observation regarding Gorenstein toric rings whose FFRT system consists of three modules.
Proposition 5.8. Let \( A \) be a toric ring as in Remark 5.3. We assume that \( A \) is Gorenstein. Then, the following conditions are equivalent.

1. The FFRT system of \( A \) is \( \{A, M_1, M_2\} \).
2. \( A \) is isomorphic to one of the following rings:
   a. \( k[x_1, \ldots, x_d] \) where \( G = \langle \text{diag}(\xi, \ldots, \xi, \xi^2, \ldots, \xi^2) \rangle \) with \( d = 2m \) and \( \xi \) is a primitive cubic root of unity, in which case \( s(A) = \frac{1}{3} \).
   b. The Segre product \( k[x_1, y_1]#k[x_2, y_2] = k[x_1x_2, x_1y_2, y_1x_2, y_1y_2] \) of two polynomial rings, in which case \( s(A) = \frac{2}{3} \).

Proof. We first show (1) \( \implies \) (2). By [15] Proposition 2.1, we have that \( M_1 \cong M_2^* \). Since \( p_i \) is conic, each \( p_i \) is isomorphic to either \( M_1 \) or \( M_2^* \). Moreover, since \([\omega_A] = [p_1] + \cdots + [p_n] = 0\), we see that \( n \) is an even number and we may assume that

\[
[p_1] = \cdots = [p_m] = -(p_{m+1}) = \cdots = -(p_n)
\]

where \( n = 2m \). Then, we see that \( \text{Cl}(A) \) is generated by \([p_1]\), and we have two cases depending on whether it is torsion.

- If \( \text{Cl}(A) \cong \mathbb{Z}/r\mathbb{Z} \), then, by an argument similar to the proof of Proposition 5.5, \( G \cong \mathbb{Z}/3\mathbb{Z} \). For a generator \( g \) of \( G \), we can set \( g([p_1]) = \zeta \) where \( \zeta \) is a primitive cubic root of unity. In this case, the action of \( G \) in \( S \) can be described as

\[
\begin{cases}
g \cdot x_i = \xi x_i & (i = 1, \ldots, m), \\
g \cdot x_i = \xi^{-1} x_i = \xi^2 x_i & (i = m + 1, \ldots, n),
\end{cases}
\]

and we have the case (a). The F-signature of \( A \) can be obtained from [42] Theorem 4.2.

- If \( \text{Cl}(A) \cong \mathbb{Z} \), then we see that \( G \cong k^\times \) and if \( g([p_1]) = \zeta \in k^\times \) for a generator \( g \) of \( G \), then \( g(-[p_1]) = \zeta^{-1} \). Thus, the action of \( G \) on \( B \) can be described as

\[
\begin{cases}
g \cdot x_i = \xi x_i & (i = 1, \ldots, m), \\
g \cdot x_i = \xi^{-1} x_i & (i = m + 1, \ldots, n).
\end{cases}
\]

In this case, we have that

\[
A \cong k[x_1, \ldots, x_m]#k[x_{m+1}, \ldots, x_n] = k[x_i x_j \mid i = 1, \ldots, m, j = m + 1, \ldots, n].
\]

This Segre product of two polynomial rings can be considered as a Hibi ring [13], and the conic classes in Hibi rings are characterized in [14]. By [14] Theorem 2.4 and Example 2.6, we see that the Segre products of two polynomial rings that satisfy the condition (1) are only the one with \( m = 2 \). Thus, we have that \( s(A) = \frac{2}{3} \) by Example 5.7 (the case of \( n = 2 \)), or we easily see that \( A \cong k[x, y, z, w]/(xz - yz) \), in which case \( s(A) = e(A) - e_{HK}(A) = 2 - \frac{4}{3} = \frac{2}{3} \).

(2) \( \implies \) (1) is well known, see e.g. [33] Proposition 3.2 for the case (a) and [35] the proof of Theorem 6.1 for (b). \( \square \)

5.3. Maximal toric F-signatures. In this subsection, we completely classify the toric rings \( A \) for which \( s(A) > \frac{1}{2} \). To this purpose, it will be helpful to introduce the following notation.

Definition 5.9. For \( w_1, \ldots, w_m \in \mathbb{N} \), a finite set of vectors in the lattice \( \mathbb{N} \), define the dual zonotope as

\[
\mathcal{P} \supseteq \{w_1, \ldots, w_m\} = \{x \in M_\mathbb{R} \mid \langle x, w_i \rangle \in [0, 1]\}.
\]
In this notation, Theorem 5.4 says that $s(k[\sigma^\vee \cap M]) = \mathcal{P}^\vee(\{v_1, \ldots, v_n\})$, where $v_1, \ldots, v_n$ are the minimal generators of $\sigma$.

Our techniques will be based on volumes of slices of the unit cube, as in Section 3. First, we interpret certain volumes as Eulerian numbers.

Lemma 5.10. The volume of the portion of the unit $d$-cube where the sum of the coordinates lies between $k$ and $k+1$ is $\frac{A(d,k)}{d!}$, where $A(d,k)$ denotes the Eulerian number with parameters $d$ and $k$.

Proof. The following argument is due to Stanley [34]. The hyperplanes $x_i = x_j$ cut the interior of the unit cube into $d!$ simplices of equal volume. Each can be characterized as the set of points $\Delta \sigma$ where $0 < x_{\sigma(1)} < x_{\sigma(2)} < \cdots < x_{\sigma(d)} < 1$ for some $\sigma \in \mathcal{S}_d$, giving a natural bijection between the simplices and $\mathcal{S}_d$. Define a map

$$\phi(x_1, \ldots, x_d) = \begin{cases} x_{i+1} - x_i & \text{if } x_i < x_{i+1} \text{ and } i \neq d \\ 1 + x_{i+1} - x_i & \text{if } x_i > x_{i+1} \text{ and } i \neq d \\ 1 - x_n & \text{if } i = d. \end{cases}$$

Note that $\phi$ maps into the unit cube, and that $\phi|_{\Delta \sigma}$ is affine with determinant $\pm 1$. Further, if $(x_1, \ldots, x_d) \in \Delta \sigma$, then

$$k \leq \phi(x_1, \ldots, x_d)_1 + \cdots + \phi(x_1, \ldots, x_d)_d \leq k + 1,$$

where $k$ is the number of descents of $\sigma$. Additionally, the map

$$\psi(x_1, \ldots, x_d)_i = \left[x_i + \cdots + x_n\right] - (x_i + \cdots + x_n)$$

provides an inverse for $\phi$ on its image. \qed

Lemma 5.11. For the Eulerian numbers $A(d,k)$, $\frac{A(d,k)}{d!} > \frac{1}{2}$ if and only if $(d,k) = (1,0),(3,1),\text{or}(5,2)$.

Proof. By symmetry, it is clear that $\frac{A(d,k)}{d!} < \frac{1}{2}$ for an even integer $d$. Let $k \geq 3$; we will show that $\frac{A(2k+1,k+j)}{(2k+1)!} < \frac{1}{2}$ by induction. The values can explicitly checked for $k = 3$. By twice applying the relation

$$A(n,m) = (n-m)A(n-1,m-1) + (m+1)A(n-1,m)$$

one obtains the equality

$$A(2k+1,k+j) = (k-j+1)!A(2k-1,k-j-2) + (k+j+1)!A(2k-1,k-j)$$

$$+ 2(k^2 + k - j^2)A(2k-1,k-j-1).$$

By induction, this is less than $(2k-1)!\left(k^2 + \frac{3}{2}k + \frac{1}{2}\right)$, which, for $k \geq 3$, is less than $\frac{1}{2}(2k+1)!$ as required. \qed

Theorem 5.12. The toric rings with $F$-signature greater than $1/2$ are, up to isomorphism, as follows:

- For a polynomial ring $A$, we have $s(A) = 1$.
- For the coordinate ring $A$ of the Segre product $\mathbb{P}^1 \# \mathbb{P}^1$, we have $s(A) = \frac{2}{3}$.
- For the coordinate ring $A$ of the Segre product $\mathbb{P}^2 \# \mathbb{P}^2$, we have $s(A) = \frac{11}{20}$.

Proof. We use the notation of Subsection 5.1. We can write

$$\mathcal{P}^\vee(\{v_1, \ldots, v_n\}) = \bigcap_{J \subset \{1, \ldots, n\}} \mathcal{P}^\vee(\{v_{j_1}, \ldots, v_{j_d}\}). \quad (5.1)$$
By the Jacobian formula,

\[
\text{vol}(\mathcal{P}^\vee(\{v_j, \ldots, v_{d}\})) = \frac{1}{\det[v_j, \ldots, v_{d}]}. \]

Thus, if \( s(R) > \frac{1}{2} \), \( \det[v_j, \ldots, v_{d}] = 1 \) for any \( J \subset \{1, \ldots, n\} \) with \( |J| = d \). Assume for now that this is the case. If \( n = d \), then \( \{v_1, \ldots, v_n\} \) is a basis for \( M \), so \( A \) is isomorphic to a polynomial ring.

Consider the case where \( n = d + 1 \). The vectors \( \{v_1, \ldots, v_d\} \) form a basis for \( N \). Let \( x_1, \ldots, x_d \) be coordinates of \( M \) forming a dual basis to \( v_1, \ldots, v_d \). We may thus compute the volume of \( \mathcal{P}^\vee(\{v_1, \ldots, v_n\}) \) in these coordinates. Since \( \det[v_1, \ldots, v_d, v_{d+1}] = 1 \), the \( i^{th} \) coordinate of \( v_{d+1} \) is \( \pm 1 \). That is, in these coordinates,

\[
[v_1, \ldots, v_{d+1}] = \begin{bmatrix}
1 & 0 & \cdots & 0 & \pm 1 \\
0 & 1 & \cdots & 0 & \pm 1 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & 1 & \pm 1 \\
\end{bmatrix}.
\]

Note that if \( d \leq 2 \), then our generating set for \( \sigma \) is not minimal, so we may assume that \( d \geq 3 \). Renumber the coordinates so that in the matrix above, \( \langle x_i, v_{d+1} \rangle = +1 \) for \( i \leq k \) and \( \langle x_i, v_{d+1} \rangle = -1 \) for \( i > k \). Then \( \mathcal{P}^\vee(\{v_1, \ldots, v_{d+1}\}) \) is the subset of the unit \( d \)-cube where

\[
0 \leq x_1 + \cdots + x_k - x_{k+1} - \cdots - x_d \leq 1.
\]

Using \( x_j \mapsto 1 - x_j \) symmetry of the cube, we have

\[
\text{vol}(\mathcal{P}^\vee(\{v_1, \ldots, v_{d+1}\})) = \text{vol}(\{(x_1, \ldots, x_d) \in [0, 1]^d \mid k \leq \sum_{i=1}^{d} x_i \leq k + 1 \}).
\]

By Lemma 5.11, we see that the volume \( s(A) \) is greater than \( \frac{1}{2} \) only if \( d = 3 \) and \( k = 1 \) or \( d = 5 \) and \( k = 2 \). These correspond to the coordinate rings of \( \mathbb{P}^1 \# \mathbb{P}^1 \) and \( \mathbb{P}^2 \# \mathbb{P}^2 \).

We now consider what happens if \( n \geq d + 2 \). If \( \text{vol}(\mathcal{P}^\vee(\{v_1, \ldots, v_n\})) > 1/2 \), with \( d = 3 \), then

\[
[v_1, \ldots, v_4] = \begin{bmatrix}
1 & 0 & 0 & 1 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & -1
\end{bmatrix}
\]

in the dual basis to \( v_1, v_2, v_3 \). If \( n \geq 5 \), the same arguments show that if \( \text{vol}(\mathcal{P}^\vee(\{v_1, \ldots, v_n\})) > \frac{1}{2} \), in a particular basis we have

\[
[v_1, \ldots, v_5] = \begin{bmatrix}
1 & 0 & 0 & 1 & 1 \\
0 & 1 & 0 & 1 & -1 \\
0 & 0 & 1 & -1 & 1
\end{bmatrix}
\]

where one computes \( \text{vol}(\mathcal{P}^\vee(\{v_1, \ldots, v_5\})) = 1/3 \). Thus, the F-signature cannot be greater than or equal to \( 1/2 \) in this case. Now consider when \( d = 5 \). If \( \text{vol}(\mathcal{P}^\vee(\{v_1, \ldots, v_n\})) > \frac{1}{2} \),

\[
[v_1, \ldots, v_6] = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & -1 \\
0 & 0 & 0 & 0 & 1 & -1
\end{bmatrix}
\]

in the dual basis to \( v_1, v_2, v_3, v_4, v_5 \). If \( n \geq 7 \), a case-by-case analysis similar to above shows that the volume \( \text{vol}(\mathcal{P}^\vee(\{v_1, \ldots, v_n\})) < \frac{1}{2} \).

\( \square \)

If \( A \) is not a toric ring, we have a family of 3-dimensional Gorenstein rings whose F-signature are greater than \( \frac{1}{2} \).
Example 5.13. Let $c > 2$ be an integer. Put $A := k[[x,y,z,w]]/(x^2 + y^2 + z^2 + w^c)$, where $k$ is an algebraically closed field of characteristic $p > c$. Then, $A$ is a normal hypersurface of dim $A = 3$, and

$$\frac{1}{2} < s(A) < \frac{2}{3}.$$

In fact, since $e(A) = 2$ we have that $s(A) = 2 - e_{HK}(A)$, thus this follows from [43, Corollary 3.11].

Acknowledgements. This work started during the third author’s stay at the Nihon University and he thanks them for hospitality. The second author would like to thank Kazuhiko Kurano, Akihiro Higashitani, and Kohsuke Shibata for valuable discussions.
