

# On a family of hypergeometric Sobolev orthogonal polynomials on the unit circle.

S.M. Zagorodnyuk

## 1 Introduction.

The theories of orthogonal polynomials on the real line and on the unit circle have many similarities as well as considerable differences [11], [5], [8], [9]. For a long time they have been developed side by side by efforts of numerous mathematicians. The theory of Sobolev orthogonal polynomials is a much more *terra incognita* [6], [10]. In this theory one can also see that some ideas come from the real line to the unit circle. Examples of such ideas are adding of Dirac deltas to the classical inner products and considering of coherent pairs of measures (see, e.g., [3], [4] and references therein). In the present paper we shall follow the same line: we shall develop the ideas from [12] to get some new hypergeometric polynomials and study their properties.

Let  $\mu$  be a (non-negative) measure on  $\mathfrak{B}(\mathbb{T})$  with an infinite support,  $\mu(\mathbb{T}) = 1$ . Denote by  $p_n$  orthogonal polynomials on  $\mathbb{T}$  with respect to  $\mu$  ( $\deg p_n = n$ , but the positivity of leading coefficients is not assumed):

$$\int_{\mathbb{T}} p_n(z) \overline{p_m(z)} d\mu = A_n \delta_{n,m}, \quad A_n > 0, \quad n, m \in \mathbb{Z}_+. \quad (1)$$

Fix an arbitrary positive integer  $\rho$ . Consider the following differential equation:

$$(e^{-x} y(x))^{(\rho)} = e^{-x} p_n(x), \quad n \in \mathbb{Z}_+. \quad (2)$$

Expanding the derivative by the Leibniz formula and canceling  $e^{-x}$  we get

$$\sum_{k=0}^{\rho} (-1)^{\rho-k} \binom{\rho}{k} y^{(k)}(x) = p_n(x), \quad n \in \mathbb{Z}_+. \quad (3)$$

**Condition A.** Suppose that for each  $n \in \mathbb{Z}_+$ , there exists a  $n$ -th degree polynomial solution  $y = y_n(x)$  of (3).

If Condition A is satisfied, then  $y_n$  are Sobolev orthogonal polynomials on  $\mathbb{T}$ :

$$\int_{\mathbb{T}} \left( y_n(z), y'_n(z), \dots, y_n^{(\rho)}(z) \right) M \begin{pmatrix} y_m(z) \\ y'_m(z) \\ \vdots \\ y_m^{(\rho)}(z) \end{pmatrix} d\mu = A_n \delta_{n,m}, \quad n, m \in \mathbb{Z}_+, \quad (4)$$

where

$$M = \left( (-1)^{l+j} \binom{\rho}{l} \binom{\rho}{j} \right)_{l,j=0}^{\rho}. \quad (5)$$

In this paper we shall only consider the following case:  $p_n(x) = x^n$ , and  $\mu$  being the normalized arc length measure on  $\mathbb{T}$ . Let us briefly describe the content of the paper. Equating coefficients of the same powers on the both sides of equation (3) one obtains a linear system of equations for the coefficients of an unknown polynomial  $y(x)$  (the same idea was used in [2]). However, for large values of  $\rho$  it is not easy to get a convenient expression for solutions, without huge determinants or recurrences. In this case equation (2) turned out to be useful. It gives a possibility to express  $y_n(x)$  for  $\rho = 1$  in terms of the incomplete gamma function. A step-by-step analysis for  $\rho = 1, 2, \dots$ , allows to obtain an explicit representation of  $y_n(x)$ . Explicit representations, differential equations and orthogonality relations for  $y_n$  will be given by Theorem 1. Using Fasenmeier's method ([7]) for the reversed polynomials  $y_n^*(x) = x^n y_n(\frac{1}{x})$ , we shall derive recurrence relations for  $y_n(x)$  (Theorem 2) as well.

**Notations.** As usual, we denote by  $\mathbb{R}, \mathbb{C}, \mathbb{N}, \mathbb{Z}, \mathbb{Z}_+$ , the sets of real numbers, complex numbers, positive integers, integers and non-negative integers, respectively. Set  $\mathbb{T} := \{z \in \mathbb{C} : |z| = 1\}$ . By  $\mathfrak{B}(\mathbb{T})$  we mean the set of all Borel subsets of  $\mathbb{T}$ . By  $\mathbb{P}$  we denote the set of all polynomials with complex coefficients. For a complex number  $c$  we denote  $(c)_0 = 1$ ,  $(c)_1 = c$ ,  $(c)_k = c(c+1)\dots(c+k-1)$ ,  $k \in \mathbb{N}$  (*the shifted factorial or Pochhammer symbol*). The generalized hypergeometric function is denoted by

$${}_mF_n(a_1, \dots, a_m; b_1, \dots, b_n; x) = \sum_{k=0}^{\infty} \frac{(a_1)_k \dots (a_m)_k}{(b_1)_k \dots (b_n)_k} \frac{x^k}{k!},$$

where  $m, n \in \mathbb{N}$ ,  $a_j, b_l \in \mathbb{C}$ .

## 2 Some Sobolev orthogonal polynomials on $\mathbb{T}$ .

As it was stated in the Introduction, in what follows we shall consider the following case:  $p_n(x) = x^n$ , and  $\mu = \mu_0$  being the (probability) normalized arc length measure on  $\mathbb{T}$ . Rewrite equations (2),(3) for this case:

$$(e^{-x} y_n(x))^{(\rho)} = e^{-x} x^n, \quad n \in \mathbb{Z}_+; \quad (6)$$

$$\sum_{k=0}^{\rho} (-1)^{\rho-k} \binom{\rho}{k} y_n^{(k)}(x) = x^n, \quad n \in \mathbb{Z}_+. \quad (7)$$

We start with the case  $\rho = 1$ . In this case equation (7) has the following form:

$$y'_n(x) - y_n(x) = x^n, \quad n \in \mathbb{Z}_+. \quad (8)$$

Fix an arbitrary  $n \in \mathbb{Z}_+$ . We shall seek for a solution of the required form:

$$y_n(x) = \sum_{k=0}^n \mu_{n,k} x^k, \quad \mu_{n,k} \in \mathbb{C}. \quad (9)$$

Substitute for  $y_n$  into (8) to get

$$\sum_{k=0}^{n-1} \{(k+1)\mu_{n,k+1} - \mu_{n,k}\} x^k - \mu_{n,n} x^n = x^n.$$

Comparing the coefficients of the same powers on the both sides we obtain that

$$\mu_{n,n} = -1, \quad \mu_{n,k} = (k+1)\mu_{n,k+1}, \quad k = n-1, n-2, \dots, 0. \quad (10)$$

It can be verified by the induction argument that

$$\mu_{n,j} = -(n)_{n-j} = -\frac{n!}{j!}, \quad j = 0, 1, \dots, n.$$

Thus,

$$y_n(x) = -n! \sum_{k=0}^n \frac{x^k}{k!}, \quad (11)$$

is a solution of (8). In the case  $\rho > 1$ , it is not easy to solve the corresponding recurrence relation for the coefficients and we shall proceed in another way.

Observe that

$$y_n(x) = -e^x \Gamma(n+1, x), \quad (12)$$

where

$$\Gamma(\alpha, x) = \int_x^\infty e^{-t} t^{\alpha-1} dt, \quad \alpha > 0,$$

is the complementary incomplete gamma function ([1]). In fact, integrating (6) (with  $\rho = 1$ ) from  $a$  to  $b$  ( $a, b \in \mathbb{R}$ ) we get

$$e^{-b} y_n(b) - e^{-a} y_n(a) = \int_a^b e^{-x} x^n dx.$$

Passing to the limit as  $b \rightarrow +\infty$  we get

$$y_n(a) = -e^a \int_a^\infty e^{-x} x^n dx, \quad (13)$$

and relation (12) follows.

Suppose that we have constructed a polynomial solution (of the required form)  $y_n(\rho; x) = y_n(x)$  of equation (6) for some positive integer  $\rho$ . Let us show how to get a polynomial solution  $y_n(\rho+1; x)$  of equation (6) with  $\rho+1$ . Notice that we do not state the uniqueness of such solutions for  $\rho > 2$ . We shall need the following auxiliary equation:

$$(e^{-x} y_n(\rho+1; x))' = e^{-x} y_n(\rho; x), \quad n \in \mathbb{Z}_+, \quad (14)$$

with an unknown  $y_n(\rho+1; x)$ . Equation (14) has a unique  $n$ -th degree polynomial solution. This can be verified comparing the coefficients of polynomials, in the same manner as for equation (8). It is not easy to solve the corresponding recurrence relation in this case, but the existence and the uniqueness of a  $n$ -th degree polynomial solution is obvious.

Integrating relation (14) from  $t$  to  $b$  we get

$$e^{-b} y_n(\rho+1; b) - e^{-t} y_n(\rho+1; t) = \int_t^b e^{-x} y_n(\rho; x) dx.$$

Passing to the limit as  $b \rightarrow +\infty$  we get

$$y_n(\rho+1; t) = -e^t \int_t^\infty e^{-x} y_n(\rho; x) dx. \quad (15)$$

By (6), (14) we may write:

$$e^{-x} x^n = (e^{-x} y_n(\rho; x))^{(\rho)} = (e^{-x} y_n(\rho+1; x))^{(\rho+1)}.$$

Therefore  $y_n(\rho+1; \cdot)$  given by (15) is a required polynomial solution of (6) for  $\rho+1$ .

Equation (15) shows how to construct polynomial solutions step by step for  $\rho = 1, 2, \dots$ . However, we are interested to get an explicit representation for every  $y_n(\rho; x)$ . Let

$$y_n(\rho; x) = \sum_{j=0}^n d_j(\rho) \frac{x^j}{j!}, \quad n \in \mathbb{Z}_+, \quad \rho \in \mathbb{N}, \quad (16)$$

with some unknown complex numbers  $d_j(\rho)$ . By (15),(13),(11) we may write

$$\begin{aligned} y_n(\rho + 1; t) &= -e^t \sum_{j=0}^n d_j(\rho) \frac{1}{j!} \int_t^\infty e^{-x} x^j dx = \sum_{j=0}^n d_j(\rho) \frac{1}{j!} y^j(1; t) = \\ &= - \sum_{j=0}^n \sum_{k=0}^j d_j(\rho) \frac{x^k}{k!}, \quad n \in \mathbb{Z}_+, \rho \in \mathbb{N}. \end{aligned} \quad (17)$$

Changing the order of summation in (17) we write:

$$y_n(\rho + 1; t) = - \sum_{k=0}^n \sum_{j=k}^n d_j(\rho) \frac{x^k}{k!}.$$

Therefore

$$d_k(\rho + 1) = - \sum_{j=k}^n d_j(\rho), \quad j = 0, 1, \dots, n; \rho \in \mathbb{N}. \quad (18)$$

Relation (18) can be written in a matrix form for the vectors of coefficients  $\vec{d}(\rho) := (d_0(\rho), \dots, d_n(\rho))^T$ , and a  $(n+1) \times (n+1)$  upper-diagonal Toeplitz matrix  $T$ , having all nonzero elements equal to 1:

$$\vec{d}(\rho + 1) = -T\vec{d}(\rho), \quad \rho \in \mathbb{N}. \quad (19)$$

Therefore

$$\vec{d}(\rho) = (-1)^\rho T^\rho (0, \dots, 0, 1)^T, \quad \rho \in \mathbb{N}. \quad (20)$$

Applying the Riesz calculus for evaluating  $T^\rho$ , one obtains the following solution:

$$d_k(\rho) = (-1)^\rho \binom{n-k+\rho-1}{n-k}, \quad k = 0, 1, \dots, n; \ n \in \mathbb{Z}_+, \rho \in \mathbb{N}. \quad (21)$$

We shall omit the details of calculating the resolvent  $(T - \lambda E)^{-1}$ . We only notice that it was convenient to subtract the subsequent rows when solving the linear system of equations  $(T - \lambda E)f = (0, \dots, 0, 1)^T$ . It can be directly verified that the resulting expression (21) obeys (18), by using the Pascal identity and the induction argument.

Thus, we have obtained the following representation for  $y_n$ :

$$y_n(\rho; x) = (-1)^\rho \sum_{j=0}^n \binom{n-k+\rho-1}{n-k} \frac{x^j}{j!}, \quad n \in \mathbb{Z}_+, \rho \in \mathbb{N}. \quad (22)$$

**Theorem 1** Let  $y_n(\rho; x)$  be polynomials given by relation (22) ( $\rho \in \mathbb{N}$ ,  $n \in \mathbb{Z}_+$ ). They have the following properties:

(a) Polynomials  $y_n(\rho; x)$  admit the following representation:

$$y_n(\rho; x) = \frac{(-1)^\rho}{n!} x^n {}_2F_0 \left( -n, \rho; -; -\frac{1}{x} \right), \quad n \in \mathbb{Z}_+, \rho \in \mathbb{N}; x \in \mathbb{C} \setminus \{0\}. \quad (23)$$

(b) Polynomials  $y(x) = y_n(\rho; x)$  satisfy the following differential equation:

$$x \sum_{k=0}^{\rho} (-1)^{\rho-k} \binom{\rho}{k} y^{(k+1)}(x) - n \sum_{k=0}^{\rho} (-1)^{\rho-k} \binom{\rho}{k} y^{(k)}(x) = 0. \quad (24)$$

(c) Polynomials  $y(x) = y_n(\rho; x)$  obey the following differential equation:

$$xy''(x) - (x + \rho - 1)y'(x) - n[y'(x) - y(x)] = 0. \quad (25)$$

(d) Polynomials  $y_n(x) = y_n(\rho; x)$  are Sobolev orthogonal polynomials on  $\mathbb{T}$ :

$$\int_{\mathbb{T}} \left( y_n(z), y'_n(z), \dots, y_n^{(\rho)}(z) \right) M \overline{\begin{pmatrix} y_m(z) \\ y'_m(z) \\ \vdots \\ y_m^{(\rho)}(z) \end{pmatrix}} d\mu_0 = \delta_{n,m}, \quad n, m \in \mathbb{Z}_+, \quad (26)$$

where  $M$  is given by (5).

**Proof.** (a): It is readily checked that the reversed polynomial for  $y_n$  is given by

$$y_n^*(\rho; x) = \frac{(-1)^\rho}{n!} x^n {}_2F_0(-n, \rho; -; -x), \quad n \in \mathbb{Z}_+, \rho \in \mathbb{N},$$

and relation (23) follows.

(b): Substitute for  $x^n$  from (7) into the following identity:

$$x(x^n)' = nx^n.$$

(c): Hypergeometric polynomials

$$u = u_n(z) := F_0(-n, \rho; -; z), \quad n \in \mathbb{Z}_+, \rho \in \mathbb{N}, \quad (27)$$

satisfy the following differential equation:

$$z(-n + \theta)(\rho + \theta)u - \theta u = 0, \quad (28)$$

where  $\theta = z \frac{d}{dz}$ . The differential equation for the generalized hypergeometric function  ${}_pF_q$  is usually written when  $p, q \geq 1$ . However, the arguments in [7, p. 75] can be applied in the case  $q = 0$  as well. Then for  $z \neq 0$  we may write

$$z^2 u''(z) + (\rho + 1)zu'(z) - n(zu'(z) + \rho u(z)) - u'(z) = 0. \quad (29)$$

Observe that

$$u_n(z) = \frac{n!}{(-1)^{n+\rho}} z^n y_n(\rho; -\frac{1}{z}). \quad (30)$$

Calculating the derivatives  $u'_n, u''_n$  and inserting them into relation (29), after some algebraic simplifications, we get relation (25).

(d): This follows from our motivation and relation (4) in the Introduction.  
□

In order to obtain a recurrence relation for polynomials  $y_n(\rho; x)$  we shall apply Fasenmeier's method ([7]) to hypergeometric polynomials  $u_n(z)$  from (27). In the following considerations, we shall admit for  $\rho$  not only positive integer values but  $\rho > 0$  as well. We shall express  $u_n, u_{n-1}, u_{n-2}, zu_n(z), zu_{n-1}(z)$ , using  $u_{n+1}(z)$ . Choose and fix an arbitrary integer  $n$  greater or equal to 2. We may write

$$u_{n+1}(z) = \sum_{k=0}^{\infty} (-n-1)_k (\rho)_k \frac{z^k}{k!} = \sum_{k=0}^{\infty} \varepsilon_{n+1}(k),$$

where  $\varepsilon_{n+1}(k) = \varepsilon_{n+1}(z; \rho; k) := (-n-1)_k (\rho)_k \frac{z^k}{k!}$ . Using

$$(-n)_k = (-n-1)_k \frac{(n+1-k)}{(n+1)}, \quad k \in \mathbb{Z}_+,$$

$$(-n+1)_k = (-n-1)_k \frac{(n+1-k)(n-k)}{(n+1)n}, \quad k \in \mathbb{Z}_+,$$

and similar relations we obtain that

$$u_n(z) = \sum_{k=0}^{\infty} \varepsilon_{n+1}(k) \frac{(n+1-k)}{(n+1)}, \quad (31)$$

$$u_{n-1}(z) = \sum_{k=0}^{\infty} \varepsilon_{n+1}(k) \frac{(n+1-k)(n-k)}{(n+1)n}, \quad (32)$$

$$u_{n-2}(z) = \sum_{k=0}^{\infty} \varepsilon_{n+1}(k) \frac{(n+1-k)(n-k)(n-1-k)}{(n+1)n(n-1)}, \quad (33)$$

$$zu_n(z) = \sum_{k=0}^{\infty} \varepsilon_{n+1}(k) \frac{(-k)}{(n+1)(\rho+k-1)}, \quad \rho \neq 1, \quad (34)$$

$$zu_{n-1}(z) = \sum_{k=0}^{\infty} \varepsilon_{n+1}(k) \frac{(-k)(n+1-k)}{n(n+1)(\rho+k-1)}, \quad \rho \neq 1. \quad (35)$$

We now assume that  $\rho \neq 1$ . Consider the following expression  $R_n(z)$ :

$$\begin{aligned} R_n(z) := & \varphi_1 u_{n-1}(z) + \varphi_2 u_n(z) + \varphi_3 u_{n+1}(z) + \varphi_4 z u_n(z) + \\ & + \varphi_5 z u_{n-1}(z) + \varphi_6 u_{n-2}(z), \quad \varphi_k \in \mathbb{C}. \end{aligned} \quad (36)$$

We intend to choose parameters  $\varphi_k$  (depending on the chosen  $n$ ) in such a way that  $R_n(z) = 0, \forall z \in \mathbb{C}$ . Substitute above expressions for  $u_{n-2}, u_{n-1}, u_n, zu_n, zu_{n-1}$  into (36) to get

$$R_n(z) = \sum_{k=0}^{\infty} \varepsilon_{n+1}(k) \frac{1}{(n-1)n(n+1)(\rho+k-1)} I_{n,k},$$

where

$$\begin{aligned} I_{n,k} = & \varphi_1(n-k)(n+1-k)(n-1)(\rho+k-1) + \varphi_2(n+1-k)(n-1)n(\rho+k-1) + \\ & + \varphi_3(n-1)n(n+1)(\rho+k-1) + \varphi_4(-1)k(n-1)n + \varphi_5(n+1-k)(-1)k(n-1) + \\ & + \varphi_6(n+1-k)(n-k)(n-1-k)(\rho+k-1). \end{aligned} \quad (37)$$

Observe that  $I_{n,k}$  is a polynomial of degree  $\leq 4$ . Therefore we may check that  $I_{n,k} = 0$  for some distinct five values of  $k$  to get  $R_n(z) \equiv 0$ . This is a crucial point in Fassenmeier's method.

We choose  $k = -\rho+1; n+1; n; n-1; 0$ . After some obvious simplifications we get the following five equations:

$$\varphi_5 = -\frac{\varphi_4}{n+\rho}, \quad (38)$$

$$\varphi_3 = \frac{\varphi_4}{n+\rho}, \quad (39)$$

$$\varphi_2(\rho+n-1) + \varphi_3(n+1)(\rho+n-1) + \varphi_4(-1)n - \varphi_5 = 0, \quad (40)$$

$$\varphi_1 2(\rho+n-2) + \varphi_2 2n(\rho+n-2) + \varphi_3 n(n+1)(\rho+n-2) -$$

$$-\varphi_4(n-1)n - \varphi_5 2(n-1) = 0, \quad (41)$$

$$\varphi_1 + \varphi_2 + \varphi_3 + \varphi_6 = 0. \quad (42)$$

Set  $\varphi_4 = n + \rho$ . Then

$$\varphi_5 = -1, \quad \varphi_3 = 1.$$

By (40) we get

$$\varphi_2 = \frac{n - \rho}{n + \rho - 1}.$$

By (41) we obtain that

$$\varphi_1 = -\frac{n(n+1)}{2} - \frac{(n-\rho)n}{n+\rho-1} - \frac{n-1}{n+\rho-2} + \frac{(n+\rho)(n-1)n}{2(n+\rho-2)}.$$

Finally, by (42) we conclude that

$$\varphi_6 = \frac{n(n+1)}{2} + \frac{(n-\rho)(n-1)}{n+\rho-1} + \frac{n-1}{n+\rho-2} - \frac{(n+\rho)(n-1)n}{2(n+\rho-2)} - 1.$$

Consequently, polynomials  $u_n(z)$  satisfy the following relation:

$$\begin{aligned} & \left( -\frac{n(n+1)}{2} - \frac{(n-\rho)n}{n+\rho-1} - \frac{n-1}{n+\rho-2} + \frac{(n+\rho)(n-1)n}{2(n+\rho-2)} \right) u_{n-1}(z) + \\ & + \frac{n-\rho}{n+\rho-1} u_n(z) + u_{n+1}(z) + (n+\rho)z u_n(z) - z u_{n-1}(z) + \\ & + \left( \frac{n(n+1)}{2} + \frac{(n-\rho)(n-1)}{n+\rho-1} + \frac{n-1}{n+\rho-2} - \frac{(n+\rho)(n-1)n}{2(n+\rho-2)} - 1 \right) * \\ & * u_{n-2}(z), \quad n = 2, 3, \dots; \rho > 0, \rho \neq 1. \end{aligned} \quad (43)$$

**Theorem 2** Let  $y_n(x) = y_n(\rho; x)$  be polynomials from relation (22) with  $\rho \in \mathbb{N} \setminus \{1\}$ . They satisfy the following recurrence relation:

$$\begin{aligned} & \left( -\frac{n(n+1)}{2} - \frac{(n-\rho)n}{n+\rho-1} - \frac{n-1}{n+\rho-2} + \frac{(n+\rho)(n-1)n}{2(n+\rho-2)} \right) x^2 * \\ & * (n-1)y_{n-1}(x) + \frac{n-\rho}{n+\rho-1} x(n-1)ny_n(x) + (n-1)n(n+1)y_{n+1}(x) + \\ & + \left( \frac{n(n+1)}{2} + \frac{(n-\rho)(n-1)}{n+\rho-1} + \frac{n-1}{n+\rho-2} - \frac{(n+\rho)(n-1)n}{2(n+\rho-2)} - 1 \right) x^3 * \\ & * y_{n-2}(x) - (n+\rho)(n-1)ny_n(x) + x(n-1)y_{n-1}(x) = 0, \\ & n = 2, 3, \dots \end{aligned} \quad (44)$$

**Proof.** Use relations (30) and (43).  $\square$

Observe that  $y_1(\rho; x) = (-1)^\rho(x + \rho)$ . Thus  $y_1(1; x)$  has its root on the unit circle, while the roots of  $y_1(\rho; x)$ , for  $\rho > 1$ , are outside  $\mathbb{T}$ . Consequently, polynomials  $y_n(\rho; x)$  are not orthogonal on the unit circle with respect to a scalar measure.

**On a family of hypergeometric Sobolev orthogonal  
polynomials on the unit circle.**

**S.M. Zagorodnyuk**

In this paper we study the following family of hypergeometric polynomials:  $y_n(x) = \frac{(-1)^\rho}{n!} x^n {}_2F_0(-n, \rho; -; -\frac{1}{x})$ , depending on a parameter  $\rho \in \mathbb{N}$ . Differential equations of orders  $\rho + 1$  and 2 for these polynomials are given. A recurrence relation for  $y_n$  is derived as well. Polynomials  $y_n$  are Sobolev orthogonal polynomials on the unit circle with an explicit matrix measure.
