NONLINEAR SPECTRAL RESOLUTION

WEN HSIANG WEI

Abstract. A quasi-product on the normed space is defined. In addition, the notions of the eigenvectors of a linear operator can be extended for the nonlinear operator. Based on the quasi-product and the generalized eigenvectors, the spectral theorems for certain possibly nonlinear operators which include bounded linear symmetric operators as special cases can be proved. The operational calculus of the classes of possibly nonlinear operators is developed and nonlinear spectral operators are given.

1. Introduction

Operator theory has been at the heart of research in analysis (see [1]; [8], Chapter 4). Moreover, as implied by [7], considering nonlinear case should be essential. Developing useful results for the operators holds the promise for the wide applications of nonlinear functional analysis to a variety of scientific areas.

In classical functional analysis, the space of bounded linear operators is a normed space endowed with a sensible norm. Further, by defining the composition of two bounded linear operators as the operation of multiplication, the space of the bounded linear operators is also a normed algebra. In Section 2, a normed function is defined and some set of possibly nonlinear operators from a normed space into a normed space turns out to be a normed space. Further, if the domain and the range of the possibly nonlinear operators are the same normed algebra, the normed space of the possibly nonlinear operators can be a normed algebra by defining an operation of multiplication for two operators.

Spectral theory is one of the main topics of modern functional analysis and its applications (see [5]; [10]). Spectral theory for certain classes of linear operators has been well developed (see [3]), particularly linear symmetric operators in a Hilbert space. Spectral theory for the nonlinear operators is an emerging field in functional analysis (see [2]). However, relatively little has been done for the spectral resolution of the possibly nonlinear operator of interest and the associated extensions which are the main objectives of this article. The inner product is important for the development of spectral theory in Hilbert spaces. Therefore, in order to develop the spectral

Key words and phrases. Banach algebra, Generalized eigenvectors, Nonlinear operators, Quasi-product, Spectral resolution.
decomposition of the possibly nonlinear operator on the normed space, a "product" which is referred to as the quasi-product and plays the role analogous to the inner product in the inner product space is proposed in next section. Section 3 defines a generalized real definite operator which can be considered as the generalization of the linear symmetric operator on the Hilbert space. Furthermore, the generalized eigenvalue which can be considered as the generalized version of the eigenvalue in the linear case is also defined. The spectral theorems of the bounded generalized real definite operator are given in the section. Finally, the extensions of the results in Section 3, including the operational calculus of the generalized real definite operator and the nonlinear spectral operators (see [4]), are given in Section 4. Note that the results in this article can be used to prove the spectral theorems for a more general class of possibly nonlinear operators which includes bounded linear normal operators as special cases. In addition, the spectral representations for the unbounded nonlinear operators can be also proved based on these results.

Hereafter $D(F)$ and $R(F)$ are denoted as the domain and the range of an operator $F$, respectively, and the notation $||\cdot||_Z$ is denoted as the norm of the normed space $Z$. The space of interest is the normed space implicitly. On the other hand, the Banach space or the normed algebra will be indicated explicitly. Note that the vector spaces and the normed spaces of interest in this article are not trivial, i.e., not only including the zero element. In this article, only the proofs of the main results are given. The proofs of other lemmas, theorems, and corollaries are delegated to the supplementary materials which can be found at

http://web.thu.edu.tw/wenwei/www/supplement.pdf/

2. Nonlinear functional spaces

2.1. Basics. Let $X$ and $Y$ be the normed spaces over the field $K$ with some sensible norms, where $K$ is either a real field $R$ or a complex field $C$. Let $V(X, Y)$ be the set of all operators from $X$ into $Y$, i.e., the set of arbitrary maps from $X$ into $Y$. Let the algebraic operations of $F_1, F_2 \in V(X, Y)$ be the operators with $(F_1 + F_2)(x) = F_1(x) + F_2(x)$ and $(\alpha F_1)(x) = \alpha F_1(x)$ for $x \in X$, where $\alpha \in K$ is a scalar. Also let the zero element in $V(X, Y)$ be the operator with the image equal to the zero element in $Y$.

In this subsection, the basic properties of the nonlinear functional spaces are given. The proofs of several theorems and corollaries, including Theorem 2.2, Corollary 2.3, Theorem 2.4, Corollary 2.5, and Theorem 2.7 are quite routine and are delegated to the supplementary materials.

**Theorem 2.1.** $V(X, Y)$ is a vector space over the field $K$.

The routine proof of the above theorem is not presented. Define a non-negative extended real-valued function $p$, i.e., the range of $p$ including $\infty$,
on $V(X,Y)$ by

$$p(F) = \max \left( \sup_{x \neq 0, x \in X} \frac{\|F(x)\|_Y}{\|x\|_X}, \|F(0)\|_Y \right)$$

for $F \in V(X,Y)$. The non-negative extended real-valued function $p$ is a generalization of the norm for the linear operators. Let $B(X,Y)$, the subset of $V(X,Y)$, consist of all operators with $p(F)$ being finite.

**Theorem 2.2.** $p$ is a norm on $B(X,Y)$ and $[B(X,Y), p]$ is a normed space.

Hereafter the norm $p$ is used, i.e., $\|F\|_{B(X,Y)} = p(F)$ for $F \in B(X,Y)$.

Note that the bounded linear operators fall in $B(X,Y)$. As $X = Y$, the notation $B(X) = B(X,X)$ is used.

Let the notation of the composition of two operators be $\circ$ hereafter.

**Corollary 2.3.** Let $F_1 \in B(X,Y)$ and $F_2 \in B(Y,Z)$, where $Z$ is a normed space. Then

$$\|F_1(x)\|_Y \leq \|F_1\|_{B(X,Y)} \|x\|_X, \ x \neq 0.$$  

If $F_1(0) = F_2(0) = 0$, then

$$\|F_2 \circ F_1\|_{B(X,Z)} \leq \|F_1\|_{B(X,Y)} \|F_2\|_{B(Y,Z)}.$$  

Let $BC(X,Y)$, the subspace of $B(X,Y)$, consist of the bounded continuous operators. It is well known that the space of all bounded linear operators from a normed space $X$ to a Banach space $Y$ is complete. The analogous results also hold for the spaces $B(X,Y)$ and $BC(X,Y)$.

**Theorem 2.4.** If $Y$ is a Banach space, then $B(X,Y)$ and $BC(X,Y)$ are Banach spaces.

Unlike a linear operator, a continuous nonlinear operator $F$ might not be bounded. The following corollary gives sufficient conditions for the boundedness of a continuous operator.

**Corollary 2.5.** Let $K$ be a compact subset of $X$. Let $F : X \to Y$ be continuous on $K$. $F \in B(X,Y)$ if the following conditions hold:

(a) $\|F(K^c)\|_{B(X,Y)} \leq M$, where $K^c$ is the complement of the set $K$ and $M$ is a positive number.

(b) $\lim_{x \to 0} \|F(x)\|_Y/\|x\|_X$ exists and is finite.

The linear functionals in the dual space of a normed space can distinguish the points of the normed space. Since the dual space of the normed space $X$ is a subspace of $B(X,K)$, the results holds for the nonlinear functionals in $B(X,K)$. Further, the following theorem gives the counterpart of the one for the bounded linear functional in the second dual space.

**Theorem 2.6.** Let $x \neq 0$ and $g_x : B(X,K) \to K$ be defined by $g_x(F) = F(x)$ for $F \in B(X,K)$. Then $g_x \in B[B(X,K), K]$ and

$$\|x\|_X = \sup_{F \neq 0, F \in B(X,K)} \frac{|F(x)|}{\|F\|_{B(X,K)}} = \|g_x\|_{B[B(X,K), K]}.$$
Proof. Since all bounded linear functionals fall in $B(X, K)$, then for any $x \neq 0$ there exists a bounded linear functional $F_x \in B(X, K)$ such that $\|F_x\|_{B(X, K)} = 1$ and $F_x(x) = \|x\|_X$. Thus,

$$\sup_{F \neq 0, F \in B(X, K)} \frac{|F(x)|}{\|F\|_{B(X, K)}} \leq 1 \quad \text{and} \quad F_x(x) = \|x\|_X.$$ 

On the other hand, $\|x\|_X \geq \sup_{F \neq 0, F \in B(X, K)} |F(x)| / \|F\|_{B(X, K)}$ because by Corollary 2.3 $|F(x)| \leq \|F\|_{B(X, K)} \|x\|_X$. Finally,

$$\|x\|_{B[X, K]} = \sup_{F \neq 0, F \in B(X, K)} \frac{|F(x)|}{\|F\|_{B(X, K)}} = \|x\|_X.$$

because $g_x(0) = 0$. 

The Banach space of all bounded linear operators on a Banach space $X$ is a Banach algebra with the multiplication being the composition of the operators. The Banach space $B(X)$ is not a Banach algebra with the multiplication being the composition of the operators and $X$ being a Banach space. However, $B(X)$ can be a normed algebra or a Banach algebra depending on $X$ being a normed algebra or a Banach algebra (see Theorem 2.4) as the multiplication of the operators is defined properly.

**Theorem 2.7.** Let $X$ be a normed (Banach) algebra. Define the multiplication of $F_1$ and $F_2$ in $V(X, X)$ by

$$(F_1 \ast F_2)(x) = \frac{F_1(x)F_2(x)}{\|x\|_X}, \quad x \neq 0, x \in X,$$

and

$$(F_1 \ast F_2)(0) = F_1(0)F_2(0).$$

Then $B(X)$ is a normed (Banach) algebra. As $X$ has a unit, $B(X)$ is a normed (Banach) algebra with a unit $e$.

2.2. Quasi-product.

**Definition 2.8.** Let $X$ be a normed space and $S$ be a subset of $X$. A quasi-product $[,]_S$ on $S$ is a mapping (or a map) of $S \times S$ into the scalar field $K$ with the following properties:

(a) $[x, x]_S \geq 0$

for $x \in S$.

(b) $| [x, y]_S | \leq \overline{c} \|x\|_X \|y\|_X$
for \( x, y \in S \), where \( \overline{c} \) is a positive number.

\[
\left[ \sum_{i=1}^{n} \alpha_i x_i, y \right]_S = c(y) \sum_{i=1}^{n} \alpha_i \left[ x_i, y \right]_S
\]

for any \( n \geq 1 \), \( x_1, \ldots, x_n, y, \sum_{i=1}^{n} \alpha_i x_i \in S \) and \( \alpha_1, \ldots, \alpha_n \in K \), where \( c : S \to \mathbb{R} \) is a positive bounded function and is bounded away from 0.

A quasi-product is quasi-symmetric if and only if \( [x, y]_S = q(x, y)[y, x]_S \), where \( \overline{z} \) is the conjugate of the complex number \( z \) and \( q : S \times S \to \mathbb{R} \) is a positive bounded function and is bounded away from 0. A quasi-symmetric quasi-product is symmetric if and only if \( [x, y]_S \) is equal to the conjugate of \( [x, y]_S \), i.e., \( [x, y]_S = \overline{[y, x]_S} \).

Remark 2.9. As \( S = X \), \( c(y) = \overline{c} = 1 \), \( [x, x]_X = 0 \) implies \( x = 0 \), and the quasi-product is symmetric, \( X \) is an inner product space with the inner product being the quasi-product. On the other hand, an inner product \( < \cdot, \cdot >_X \) on the inner product space \( X \) can be a symmetric quasi-product by setting \( < x, y >_X = [x, y]_X \).

The following are examples of the quasi-products on the normed spaces or the subset of some normed space.

Example 2.10. Let \( X \) be an inner product space with an inner product \( < \cdot, \cdot >_X \) and the norm induced by the inner product. Then

\[
[x, y]_X = c(y) < x, y >_X
\]

for \( x, y \in X \), where \( c \) is a positive bounded function on \( X \) and is bounded away from 0, for example,

\[
c(y) = \frac{\|y\|_X}{\|y\|_X + 1} + k
\]

and \( k > 0 \).

Example 2.11. Let \( X \) be the real normed space of real-valued Lebesgue integrable functions on the measurable set \( \Omega \subset \mathbb{R} \) with the norm \( \|x\|_X = \int_{\Omega} |x| d\mu \) for \( x \in X \), where \( \mu \) is the Lebesgue measure. Let the symmetric quasi-product defined by

\[
[x, y]_X = \int_{\Omega} x d\mu \int_{\Omega} y d\mu
\]

for \( x, y \in X \).

Example 2.12. Let \( X \) be the real normed space of real-valued bounded functions on the compact domain \( \Omega \subset \mathbb{R} \) with the supremum norm and the subset \( S \) of \( X \) consist of the bounded Lebesgue integrable functions with positive integrals. Define the non-symmetric quasi-product on \( S \) by

\[
[x, y]_S = \int_{\Omega} x d\mu \sup_{t \in \Omega} y(t),
\]
where $\mu$ is the Lebesgue measure.

Note that the quasi-product function $[x, y]_X = f_y(x)$, considered as a function of $x$, is continuous on $X$. In addition, if the quasi-product is symmetric, it is jointly continuous.

The bilinear form on a Hilbert space has a representation associated with the continuous linear operator (see [5], Theorem 3.8-4; [9], Chapter VI, Theorem 1.2). The following theorem can be considered as the nonlinear counterpart of the linear case.

**Theorem 2.13.** Let $F \in B(X, Y)$ with $F(0) = 0$ and there exists a positive function $d$ defined on $Y$ and being bounded away from 0 such that $[y, y]_Y = d(y)||y||_Y^2$ for $y \in Y$. Then $h : X \times Y \rightarrow K$ has a unique representation

$h(x, y) = [F(x), y]_Y$

if and only if the function $h$ has the following properties:

(a) $|h(x, y)| \leq \tau ||x||_X ||y||_Y$

for $x \in X$ and $y \in Y$, where $\tau$ is a positive number.

(b) For $y \in Y$, there exists a $z \in Y$ such that

$h(x, y) = [z, y]_Y$

for any $x \in X$.

**Proof.** The "only if" part is obvious. To prove "if" part, define $F(x) = z$ with $F(0) = 0$. $F$ is well-defined since for $x_1 = x_2$,

$h(x_1, y) = [z, y]_Y = h(x_2, y)$

and thus $F(x_1) = F(x_2) = z$. Further, for $F \neq 0$, $F \in B(X, Y)$ because there exists $c_1 > 0$ such that

$$||F||_{B(X, Y)} = \sup_{x \neq 0, x \in X, F(x) \neq 0} \frac{||F(x)||_Y^2}{||x||_X ||F(x)||_Y}$$

$$\leq c_1 \sup_{x \neq 0, x \in X, F(x) \neq 0} \frac{||F(x), F(x)||_Y}{||x||_X ||F(x)||_Y}$$

$$\leq c_1 \sup_{x \neq 0, x \in X, y \neq 0, y \in Y} \frac{||F(x), y||_Y}{||x||_X ||y||_Y}$$

$$\leq c_1 \tau.$$

To prove the uniqueness of $F$, let $h(x, y) = [F(x), y]_Y = [G(x), y]_Y$ for $x \in X$ and $y \in Y$. Then by the properties of the quasi-product,

$$||F(x), y||_Y - [G(x), y]_Y \geq c_2 ||F(x) - G(x), y||_Y$$

implies $[F(x) - G(x), y]_Y = 0$ for any $y \in Y$ and thus

$$c_3 ||F(x) - G(x)||_Y^2 \leq [F(x) - G(x), F(x) - G(x)]_Y = 0,$$
where $c_2$ depending on $y$ and $c_3$ depending on $x$ are both positive numbers. Therefore, $F(x) = G(x)$. \hfill \Box

3. Generalized real definite operators

The goal of this section is to formulate the spectral resolutions of some class of possibly nonlinear operators. In this section and the following subsection, i.e., Section 3 and Section 4.1, suppose that the operator $F : X \to X$ of interest satisfies $F(0) = 0$ and the quasi-products on $X$ exist. For $\hat{F} : X \to X$ with $\hat{F}(0) \neq 0$, the corresponding spectral resolution can be obtained by the shift $\hat{F}(x) = F(x) + s(x), x \in X$, where $s : X \to X$ satisfies $s(0) = \hat{F}(0)$, for example, $s(x) = \hat{F}(0)$ (also see Remark 4.10 in Section 4.1).

The spectral resolution of the bounded linear symmetric operators, due to Hilbert, is a limit of Riemann-Stieltjes sums in the sense of operator convergence (also see [9], Chapter 31), i.e., having the form of Riemann-Stieltjes integral. The spectral resolutions of the generalized real definite operators defined in this section also have the form of Riemann-Stieltjes integral in terms of the quasi-product or in the sense of operator convergence as certain classes of quasi-products are employed. For the bounded linear symmetric operators, the spectral resolution involves both linear projection operators and linear positive operators. The nonlinear counterparts of the linear positive operators and the linear projection operators are defined and their basic properties are given in the first two subsections. Then, the spectral resolutions are given in the last subsection.

3.1. G-positive operators. Linear spectral theory for the symmetric operators involves the positive operators. Similarly, for the nonlinear operators with real spectrums, the spectral theorems also involve the positive operators. The main theorem in this subsection, Theorem 3.7 indicates that the multiplication of two positive operators remains positive given some sufficient conditions imposed on the quasi-product. Based on the theorem, two corollaries give the existence and the uniqueness of the square root of the positive operator. Furthermore, the spectral theorem in Section 3.3 can be proved by using the theorem. Note that the proofs of Theorem 3.7, Corollary 3.8, and Corollary 3.9 in this subsection are delegated to the supplementary materials.

The nonlinear positive operator is defined as follows.

**Definition 3.1.** Let $X$ be a normed space. An operator $F : X \to X$ is generalized real definite if and only if there exist a quasi-product $\langle \cdot, \cdot \rangle_X$ and an operator $g : X \to X$ satisfying $g(x) \neq 0$ for $x \neq 0$ and

$$\langle F(x), g(x) \rangle_X \in R$$

for $x \in X$. Furthermore, $F$ is $g$-positive, denoted by $F \geq 0$, if and only if

$$\langle F(x), g(x) \rangle_X \geq 0$$
for \( x \in X \). For the operators \( F_1 : X \to X \) and \( F_2 : X \to X \),
\[
F_1 \geq F_2
\]
if and only if
\[
F_1 - F_2 \geq 0.
\]
As \( X \) is a normed algebra, a \( g \)-positive operator \( F \) has a square root if and only if there exists an operator \( G : X \to X \) such that \([G(x)]^2 = G(x)G(x) = F(x)\) for \( x \in X \). \( G \) is then called a square root of \( F \).

As \( F = 0 \), \( F \) is \( g \)-positive. \( G = 0 \) is the square root of \( F = 0 \) defined on the normed algebra \( X \).

**Remark 3.2.** The generalized real definiteness of the operator \( F \) relies on both the operator \( g \) and the quasi-product. As \( F \) is a linear symmetric operator on a Hilbert space, the operator \( g \) is the identity map, and the quasi-product is the inner product, \( F \) is generalized real definite and \( F \) being positive implies \( F \) being \( g \)-positive. Therefore, the \( g \)-positivity extends the notion of the positivity.

As \( F : D(F) \to Y \) and \( g : D(F) \to Y \) satisfies \( g(x) \neq 0 \) for \( x \neq 0 \) and \( x \in D(F) \), the above definition can be modified and the associated expressions are \([F(x),g(x)]_Y \in R\) and \([F(x),g(x)]_Y \geq 0 \) for \( x \in D(F) \), where \( D(F) \) is a subset of \( X \).

Some basic properties of the positive operators are given by the following lemma. The routine proofs are not presented.

**Lemma 3.3.** Let \( X \) be a normed space and \( F_1, F_2, G_1, G_2 \) be the operators from \( X \) into \( X \).
(a) \( F_1 \geq F_2 \) if and only if \([F_1(x),g(x)]_X \geq [F_2(x),g(x)]_X \) for \( x \in X \).
(b) If \( \alpha \in R \), \( \alpha \geq 0 \), and \( F_1 \geq 0 \), then \( \alpha F_1 \geq 0 \).
(c) If \( F_1 \geq 0 \) and \( F_2 \geq 0 \), then \( F_1 + F_2 \geq 0 \).
(d) If \( F_1 \leq G_1 \) and \( F_2 \leq G_2 \), then \( F_1 + F_2 \leq G_1 + G_2 \).

For a linear symmetric operator \( F \) on a Hilbert space \( X \), the normed value of \( F(x) \) and the associated inner product satisfy the equation \(< (F \circ F)(x), x >_X = ||F(x)||_X^2 \). It turns out that the analogous equation (inequality) defined below plays the key role in the development of the spectral resolutions of the possibly nonlinear operators.

**Definition 3.4.** Let \( X \) be a normed space and \( g : X \to X \) satisfying \( g(x) \neq 0 \) for \( x \neq 0 \). For \( x, y \in X \), a quasi-product has a left integral domain if and only if for \( g(x) \neq 0 \), \([y, g(x)]_X = 0 \) implies \( y = 0 \). Further, as \( X \) is a normed algebra with a unit 1, for \( x, y_1, y_2 \in X \), a quasi-product preserves the positivity if and only if \([y_1, y_2, g(x)]_X \geq 0 \) as \([y_1, g(x)]_X \geq 0 \) and \([y_2, g(x)]_X \geq 0 \). In addition, a quasi-product is square bounded below if and only if for \( x, y \in X \), there exists a positive number \( k \) such that \([y^2, g(x)]_X \geq k||y||_X^2 ||g(x)||_X \) as \( y = 1 \) or \([y, g(x)]_X \in R \).
The properties of the quasi-product in Definition 3.4 rely on the operator \( g \) and \( g \) is assumed to be the same as the one corresponding to the generalized real definite operators of interest (see Definition 3.1) hereafter. Note that the quasi-product has these properties on the set \( X \times R(g) \) by the above definition and thus another way is to define these properties on the subsets of \( X \times X \). However, only the set \( X \times R(g) \) is of interest in this article and hence Definition 3.4 serves the purpose.

In the following, the operators involved in the spectral theorems of the generalized real definite operators, the positive and negative parts of the operator, are defined.

**Definition 3.5.** Let \( X \) be a normed space and \( F \) be a generalized real definite operator. The operator \( |F| \) is defined by

\[
|F|(x) = \begin{cases} 
F(x) & \text{if } [F(x), g(x)]_X \geq 0 \\
-F(x) & \text{if } [F(x), g(x)]_X < 0
\end{cases}
\]

for \( x \in X \). The positive part of \( F \) is

\[
F^+ = \frac{|F| + F}{2}
\]

and the negative part of \( F \) is

\[
F^- = \frac{|F| - F}{2}.
\]

A direct check gives the following lemma.

**Lemma 3.6.** Let \( F \) be generalized real definite.

(a) Let \( X \) be a normed space. Then \( |F| \geq 0 \).

(b) Let \( X \) be a unital normed algebra. Then \( |F|^2 = F^2 \), where for \( x \in X \), \( |F|^2 \) is defined by \( |F|^2(x) = |F|(x)|F|(x) \) and \( F^2 \) is defined by \( F^2(x) = F(x)F(x) \). Furthermore, if the quasi-product is square bounded below or preserves the positivity, then \( |F| \) is a square root of \( F^2 \).

The above lemma implies that the quasi-product being square bounded below or preserving the positivity is a sensible condition. Since otherwise, the square of a generalized real definite operator or even a g-positive operator might not be g-positive.

It is natural to ask when the g-positive operator has a square root. It turns out that the quasi-product having a left integral domain or preserving the positivity is a key sufficient condition. The following theorem indicates that the pointwise multiplication of two g-positive operators is g-positive given some sufficient condition.

**Theorem 3.7.** Let \( X \) be a unital Banach algebra, \( F \geq 0 \) and \( H \geq 0 \). If there exists a quasi-product (not necessarily square bounded below) preserving the positivity with \( X \) being not necessarily commutative or a square bounded
below quasi-product having a left integral domain with \( X \) being commutative, then \( FH \geq 0 \), where \( (FH)(x) = F(x)H(x) \) for \( x \in X \).

For a positive linear symmetric operator, the positive square root of the operator is uniquely determined. In the following, the sufficient conditions for the existence and the uniqueness of the positive square root of the \( g \)-positive operator are given.

**Corollary 3.8.** Let \( X \) be a unital Banach algebra.
(a) If \( G \), the square root of the \( g \)-positive operator \( F \), exists and \( G \geq 0 \), the commutative unital Banach algebra \( X \) is an integral domain, and the quasi-product has a left integral domain, then \( G \) is unique and is denoted by \( G = F^{1/2} \).
(b) If there exists a square bounded below quasi-product preserving the positivity on \( X \) (not necessarily commutative) or a square bounded below quasi-product having a left integral domain with \( X \) being commutative, \( 0 \leq F \leq 1_X \), then \( F \) has a square root \( G \geq 0 \) and \( G \) commutes with any operator \( W \in V(X, X) \) which commutes with \( F \), where \( 1_X(x) = 1 \) for \( x \in X \).

**Corollary 3.9.** Let \( X \) be a unital Banach algebra and \( B(X) \) be the Banach algebra with the multiplication operation given in Theorem 2.7.
(a) If \( G \in B(X) \) satisfying \( G^2 = G * G = F \) exists and \( F, G \geq 0 \), the commutative unital Banach algebra \( X \) is an integral domain, and the quasi-product has a left integral domain, then \( G \) is unique.
(b) Suppose that there exists a square bounded below quasi-product preserving the positivity on \( X \) (not necessarily commutative) or a square bounded below quasi-product having a left integral domain with \( X \) being commutative. For a \( g \)-positive operator \( F \in B(X) \), there exists a \( g \)-positive operator \( G \in B(X) \) such that \( G^2 = G * G = F \) and \( G \) commutes with any operator \( W \in V(X, X) \) which commutes with \( F \).

**Remark 3.10.** Let \( \tilde{F} \geq 0 \) and \( \tilde{H} \geq 0 \) with \( \tilde{F}(0) \neq 0 \) or \( \tilde{H}(0) \neq 0 \), and \( g(0) \neq 0 \). Then given the sufficient conditions in Theorem 3.7 and Corollary 3.8, the results also hold for \( \tilde{F} \) and \( \tilde{H} \). Furthermore, given the sufficient conditions in Corollary 3.9 and \( \tilde{F} \in B(X) \), the \( g \)-positive operator \( G \in B(X) \) defined by \( G(x) = (||\tilde{F}||_{B(X)}/k)^{1/2}||x||_X \tilde{G}(x) \) for \( x \neq 0 \) and \( G(0) = k^{-1/2} \tilde{G}(0) \) satisfies \( G * G = \tilde{F} \), where \( \tilde{G}^2 = \tilde{F} \) and \( \tilde{F}(x) = k\tilde{F}(x)/(||\tilde{F}||_{B(X)}||x||_X) \) for \( x \neq 0 \), \( \tilde{F}(0) = k\tilde{F}(0) \), and where \( k \) is some number.

### 3.2. Projection operators.

The spectral resolution of a bounded linear symmetric operator involves both the projection operator and the spectrum of the operator. The counterparts of these quantities for a generalized real definite operator are defined and some basic facts about these quantities are given in this subsection. The first two lemmas, Lemma 3.12 and Lemma 3.13, can be used to prove Lemma 3.18, the main result of this subsection. Lemma 3.18 can be applied to prove the spectral theorem in next...
subsection. Note that the proofs of Lemma 3.12, Lemma 3.13, Lemma 3.16, and Lemma 3.17 in this subsection are delegated to the supplementary materials.

The nonlinear projection operator involved in the spectral resolution of the generalized real definite operator is defined first.

**Definition 3.11.** For a subset $S$ containing 0 of a normed space $X$, the corresponding projection operator $E_S : X \to X$ is defined by $E_S(x) = x$ if $x \in S$ and $E_S(x) = 0$ otherwise. As $X$ is a unital normed algebra, the projection indicator $1_S : X \to X$ is defined by $1_S(x) = 1$ if $x \in S$ and $1_S(x) = 0$ otherwise.

Denote $N(F)$ as the null space (set) of an operator $F$, i.e., $N(F) = \{x : F(x) = 0, x \in X\}$. The following two lemmas give the basic properties of the projection operator (indicator) and the positive and negative parts of $F$. Let $S_2 \setminus S_1$ denote the intersection of the set $S_2$ and the complement of the set $S_1$.

**Lemma 3.12.** Let $S_1$ and $S_2$ both containing 0 be the subsets of the normed space $X$.
(a) $\|E_{S_1}\|_{B(X)} \leq 1$.
(b) The following are equivalent.
(i) $E_{S_1} \circ E_{S_2} = E_{S_2} \circ E_{S_1} = E_{S_1}$.
(ii) $S_1 \subset S_2$.
(iii) $N(E_{S_2}) \subset N(E_{S_1})$.
(iv) $\|E_{S_1}(x)\|_X \leq \|E_{S_2}(x)\|_X$ for $x \in X$.
As $X$ is a unital normed algebra, the following are equivalent.
(i)$^*$
$1_{S_1}1_{S_2} = 1_{S_2}1_{S_1} = 1_{S_1}$.
(ii)$^*$ $S_1 \subset S_2$.
(iii)$^*$ $N(1_{S_2}) \subset N(1_{S_1})$.
(iv)$^*$ $\|1_{S_1}(x)\|_X \leq \|1_{S_2}(x)\|_X$ for $x \in X$.
(c) Let $S_1 \subset S_2$. Then $E_{S_2-S_1} = E_{S_2} - E_{S_1}$ is idempotent, i.e., $E_{S_2-S_1} \circ E_{S_2-S_1} = E_{S_2-S_1}$, and the range of $E_{S_2-S_1}$ is $S_2 - S_1 = (S_2 \setminus S_1) \cup \{0\}$. As $X$ is a unital normed algebra, $1_{S_2-S_1} = 1_{S_2} - 1_{S_1}$ satisfies $1_{S_2-S_1}1_{S_2-S_1} = 1_{S_2-S_1}$.

**Lemma 3.13.** Let $X$ be a unital normed algebra, $F$ be generalized real definite, and $S = N(F^+)$.
(a) $|F|$, $F^+$, and $F^-$ commute with every operator $W \in V(X, X)$ which commutes with $F$.
(b) $F^+F^- = F^-F^+ = 0$.
(c) $F^+1_S = 1_SF^+ = 0$ and $F^-1_S = 1_SF^- = F^-$.
(d) $F1_S = 1_SF = -F^-$ and $F(1_X - 1_S) = (1_X - 1_S)F = F^+$.
(e) $F^+ \geq 0$ and $F^- \geq 0$. 

---

**NONLINEAR SPECTRAL RESOLUTION**

11
The spectrum corresponding to the quasi-product and the g-positivity is defined as follows.

**Definition 3.14.** Let $F : D(F) \to X$, where $D(F) \subset X$ and $X$ is a normed space. Let $\gamma : D(F) \to X$ be a g-positive operator (see Remark 3.2) satisfying $[\gamma(x), g(x)]_X = k_1(x)||x||_X||g(x)||_X$ and $||\gamma(x)||_X = k_2(x)||x||_X$ for $x \in D(F)$, where both $k_1$ and $k_2$ are positive bounded functions and are bounded away from 0. The g-resolvent set of $F$ with $\tilde{F}$ is referred to as the g-spectrum of $\rho A_1$.2, is bounded, and $D$ is positive operator $\gamma$ for the operators $F$ referred to as the g-eigenvector of $\lambda$ for the values of the quasi-product of the bounded operators and the g-indicator and the projection operator corresponding to $\sigma(F) = C \setminus \rho(F)$ is referred to as the g-spectrum of $F$. As $F(x) = \lambda \gamma(x)$ for some $x \neq 0$, $x$ is referred to as the g-eigenvector of $F$ corresponding to the g-eigenvalue $\lambda$.

In this article, the generalized real definite operators of interest and the g-positive operator $\gamma$ are in relation to the same quasi-product and the same operator $g$.

**Remark 3.15.** The above definition can be also used for the operator $\tilde{F}$ with $\tilde{F}(0) \neq 0$. Moreover, as $X$ and $Y$ are Banach spaces and $G, J$ are in the space of continuous operators from $X$ into $Y$, the classical eigenvalue $\lambda$ of the pair $(G, J)$ corresponding to the eigenvector $x \neq 0$ satisfies the equation $G(x) = \lambda J(x)$ (see [2], Chapter 9.5, Chapter 10). As $X$ and $Y$ are normed spaces, the g-eigenvalue $\lambda$ and g-eigenvector $x \neq 0$ can be defined similarly for the operators $F : D(F) \to Y$ and $\gamma : D(F) \to Y$ (also see Remark 3.2), i.e., $F(x) = \lambda \gamma(x)$, where $D(F)$ is a subset of $X$.

The following two lemma, Lemma 3.16 and Lemma 3.17, give the results for the values of the quasi-product of the bounded operators and the g-eigenvalues of the bounded generalized real definite operators, respectively.

**Lemma 3.16.** Let $F \in B(X)$, where $X$ is a normed space. There exists a positive number $\overline{k}$ such that

$$||[F(x), g(x)]_X| \leq \overline{k}||x||_X ||g(x)||_X$$

for $x \in X$.

**Lemma 3.17.** Let $F$ be generalized real definite defined on $X$, where $X$ is a normed space. Then all g-eigenvalues of $F$, if exist, are real. Further, as $F \in B(X)$, all g-eigenvalues, if exist, fall in some bounded interval of $R$.

Note that the results in Lemma 3.17 also hold for the generalized real definite operator $\tilde{F}$ with $\tilde{F}(0) \neq 0$, i.e., all g-eigenvalues of $\tilde{F}$, if exist, are real and fall in some bounded interval of $R$ if $F \in B(X)$.

Hereafter denote $F_\lambda = F - \lambda \gamma$ and let $1_\lambda$ and $E_\lambda$ be the projection indicator and the projection operator corresponding to $N(F_\lambda^+)$, respectively, where $\lambda \in R$. In addition, let $\Delta = \mu - \lambda$, $E_\Delta = E_\mu - E_\lambda$, and $1_\Delta = 1_\mu - 1_\lambda$, where $\lambda < \mu$.

**Lemma 3.18.** Let $X$ be a unital normed algebra. Suppose that $F \in B(X)$ is generalized real definite, $\mu, \lambda \in R$, and $\lambda < \mu$. 
Similarly, there exist positive numbers \( k \) respectively. Let \( \lambda \) be a unital Banach algebra in the subsection. The spectral resolution of interest can be defined based on the lemma below. In this subsection, the spectral resolutions of the generalized real definite operators in terms of the quasi-product and with \( \lambda \) where \( m = 1 \) and the convergence is independent of the choice of \( \lambda \) as \( n \to \infty \), where \( 1_\lambda(x) = 0 \) for \( x \neq 0 \) as \( \lambda = m \), \( 1_\lambda = 1_X \) as \( \lambda = M \), and \( 0 < \epsilon_n \to 0 \).

**Proof.** (a): If \( x \neq 0 \) and \( 1_\lambda(x) = 1 \), i.e., \( x \in N(F_\lambda^+) \), \( [F_\lambda(x), g(x)]_X \leq 0 \) then and thus \( [F(x), g(x)]_X \leq [\lambda_\gamma(x), g(x)]_X \). Since \( [\lambda_\gamma(x), g(x)]_X = [\mu_\gamma(x), g(x)]_X \), \( [F(x), g(x)]_X < [\mu_\gamma(x), g(x)]_X \) and \( [F_\mu(x), g(x)]_X = [F(x) - \mu_\gamma(x), g(x)]_X < 0 \) thus. The last inequality implies \( F_\mu(x) = 0 \) and \( 1_\mu(x) = 1 \) then. Therefore, \( 1_\lambda(x) ||x|| \leq 1_\mu(x) ||x|| \) for \( x \in X \).

(b): By Lemma 3.16 there exist positive numbers \( k \), \( k_1 \), and \( k_2 \) such that

\[
[F_\lambda(x), g(x)]_X \\
\geq k_1 \left\{ [F(x), g(x)]_X - [\lambda_\gamma(x), g(x)]_X \right\} \\
\geq k_1 (k - k_2 \lambda) ||x||_X ||g(x)||_X \\
> 0
\]

for \( \lambda < -k/k_2 \) and \( x \neq 0 \). This gives that \( 1_\lambda(x) = 0 \) for \( \lambda < -k/k_2 \). Similarly, there exist positive numbers \( k_1^* \) and \( k_2^* \) such that

\[
[F_\lambda(x), g(x)]_X \\
\leq k_1^* \left\{ [F(x), g(x)]_X - [\lambda_\gamma(x), g(x)]_X \right\} \\
\leq k_1^* (k - k_2^* \lambda) ||x||_X ||g(x)||_X \\
< 0
\]

for \( \lambda > k/k_2 \) and \( x \neq 0 \). This gives that \( 1_\lambda = 1_X \) for \( \lambda > k/k_2 \). The results for \( E_\lambda \) follow because \( E_\lambda(x) = 1_\lambda(x)x \) for \( x \in X \).

(c): Since \( F_\mu 1_\Delta = F_1 \lambda - \mu_\gamma \circ E_\Delta \) and \( -F_\mu 1_\Delta = -F_\mu 1_\mu(1_\mu - 1_\lambda) = E_\mu^-(1_\mu - 1_\lambda) \geq 0 \) by Lemma 3.12 (b), Lemma 3.13 (d), and Lemma 3.13 (e), hence \( F_1 \lambda \Delta \leq E_\mu \circ E_\Delta \). Similarly, because \( F_\lambda 1_\Delta \Delta = F_1 \lambda - \lambda_\gamma \circ E_\Delta \) and \( F_\lambda 1_\Delta \Delta = F_\lambda(1_\lambda - 1)(1_\mu - 1_\lambda) = F_\mu^+(1_\mu - 1_\lambda) \geq 0 \) by Lemma 3.12 (b), Lemma 3.13 (d), and Lemma 3.13 (e), hence \( F_1 \Delta \Delta \geq \lambda_\gamma \circ E_\Delta \) holds.

**3.3. Spectral theorems.** In this subsection, the spectral resolutions of the generalized real definite operators in terms of the quasi-product and with respect to some topology are stated in Theorem 3.21 and Theorem 3.23 respectively. Let \( X \) be a unital Banach algebra in the subsection.

The spectral resolution of interest can be defined based on the lemma below.

**Lemma 3.19.** Let \( F \in B(X) \) be generalized real definite. There exists a bounded interval \([m, M]\) with any partition \( \{s_j\} \) satisfying \( m = s_0 < s_1 < \cdots < s_n = M \) and \( \Delta_j = s_j - s_{j-1} < \epsilon_n \) such that \( F_n = \sum_{j=1}^{n} \lambda_j (\gamma \circ E_{\Delta_j}) \) converges to an operator in \( B(X) \) with respect to the norm topology \(||\cdot||_{B(X)}\) and the convergence is independent of the choice of \( \lambda_j \) as \( n \to \infty \), where \( 1_\lambda(x) = 0 \) for \( x \neq 0 \) as \( \lambda = m \), \( 1_\lambda = 1_X \) as \( \lambda = M \), and \( 0 < \epsilon_n \to 0 \).
Proof. By Lemma 3.12 (b) and Lemma 3.18 (b), there exist $m$ and $M$ such that $1_\lambda(x) = 0$ for $x \neq 0$ as $\lambda \leq m$ and $1_\lambda = 1_X$ as $\lambda \geq M$. Since for fixed $x \neq 0$, $1_m(x) = 0$, $1_M(x) = 1$, and $1_\lambda(x)$, considered as a function of $\lambda$, is right-continuous, there exists $\lambda_x \in [m, M]$ such that $1_{\lambda_x}(x) = 1$ and $1_\lambda(x) = 0$ for $\lambda < \lambda_x$. Define the operator $\tilde{F}(x) = \lambda_x \gamma(x)$ as $x \neq 0$ and $\tilde{F}(0) = 0$. Then $\tilde{F} \in B(X)$. Since $\lambda_x \in (s_{j-1}, s_j]$ for some $j$ and $\Delta_j < \epsilon_n$, hence

$$\|F_n(x) - \tilde{F}(x)\|_X = \|(\lambda_j - \lambda_x)\gamma(x)\|_X \leq k\epsilon_n \|x\|_X$$

for $x \in X$, where $k$ is some positive number. □

The following definition gives the spectral resolution in terms of operator convergence.

Definition 3.20. Let $X$ be a unital Banach algebra, $F \in B(X)$ be generalized real definite, and $\{s_j\}$ be any partition of a bounded interval $[m, M]$ with $m = s_0 < s_1 < \cdots < s_n = M$ and $\Delta_j = s_j - s_{j-1} < \epsilon_n$, where $0 < \epsilon_n \to 0$. If $\sum_{j=1}^n \lambda_j (\gamma \circ E_{\Delta_j})$ converges to an operator in the sense of operator convergence, i.e., with respect to the norm topology $\| \cdot \|_{B(X)}$, and the convergence is independent of the choice of $\lambda_j$ for $\lambda_j \in (s_{j-1}, s_j]$ as $n \to \infty$, the limit operator is denoted as $\int_m^M \lambda d(\gamma \circ E_{\lambda})$. Furthermore, if $f(\lambda_1)1_{s_1} + \sum_{j=2}^n f(\lambda_j)1_{\Delta_j}$ converges to an operator in the sense of operator convergence and the convergence is independent of the choice of $\lambda_j$ as $n \to \infty$, the limit operator is denoted as $\int_m^M f(\lambda)d1_{\lambda}$, where $f: R \to V(X, X)$ is a mapping from $R$ into $V(X, X)$.

The following two theorems give the spectral representations of the generalized real definite operators in terms of the quasi-product and with respect to the norm topologies $\| \cdot \|_{B(X)}$, respectively. Moreover, $[F(x), g(x)]_X, x \in X$, can be expressed as an ordinary Riemann-Stieltjes integral in terms of a certain equivalence relation. The involved equivalence relation $\equiv$ for two functionals $G_1$ and $G_2$ from $X$ into $K$ is denoted as $G_1 \equiv G_2$ (or $G_1(x) \equiv G_2(x)$ for convenience) if and only if there exist positive numbers $\underline{k}$ and $\overline{k}$ such that

$$\underline{k}|G_2(x)| \leq |G_1(x)| \leq \overline{k}|G_2(x)|$$

for all $x \in X$.

Theorem 3.21. Let $F \in B(X)$ be generalized real definite. Then

$$[F(x), g(x)]_X = \left[\int_m^M \lambda d(\gamma \circ E_{\lambda})(x), g(x)\right]_X$$
and

\[ (F(x), g(x))_X \equiv \int_m^M \lambda dw_x(\lambda) \]

for \( x \in X \), where \([m, M]\) is some bounded interval depending on \( F \), \( w_x(\lambda) = [(\gamma \circ E_\lambda)(x), g(x)]_X \), and the second integral is the ordinary Riemann-Stieltjes integral.

**Proof.** \( \int_m^M \lambda d(\gamma \circ E_\lambda) \) exists by Lemma 3.19 where \( 1_m(x) = 0 \) for \( x \neq 0 \) and \( 1_M = 1_X \). Note that \( \sum_{j=1}^n \Delta_j = M - m \) and \( \sum_{j=1}^n 1_{\Delta_j}(x) = 1 \) for \( x \neq 0 \). Then \( F = F \sum_{j=1}^n 1_{\Delta_j} = \sum_{j=1}^n F \Delta_j \). By Lemma 3.18 (c) and Lemma 3.3 (b), (c), and (d),

\[
\sum_{j=0}^{n-1} s_j(\gamma \circ E_{\Delta_{j+1}}) \leq F \leq \sum_{j=1}^n s_j(\gamma \circ E_{\Delta_j})
\]

and hence

\[
0 \leq \sum_{j=1}^n s_j(\gamma \circ E_{\Delta_j}) - F \leq \sum_{j=1}^n \Delta_j(\gamma \circ E_{\Delta_j}) \leq \epsilon_n \sum_{j=1}^n \gamma \circ E_{\Delta_j}.
\]

Then by Lemma 3.3 (a),

\[
\left[ \sum_{j=1}^n s_j(\gamma \circ E_{\Delta_j})(x) - F(x), g(x) \right]_X \\
\leq \epsilon_n \sum_{j=1}^n (\gamma \circ E_{\Delta_j})(x), g(x) \right]_X \\
= [\epsilon_n \gamma(x), g(x)]_X \\
\leq \|\epsilon_n\|_X \|x\|_X \|g(x)\|_X
\]

for \( x \in X \), where \( \epsilon \) is some positive number. \([\int_m^M \lambda d(\gamma \circ E_\lambda) - F(x), g(x)]_X = 0 \) by the continuity of the quasi-product and \([\int_m^M \lambda d(\gamma \circ E_\lambda)(x), g(x)]_X = [F(x), g(x)]_X \) thus. Since by property (c) of the quasi-product,

\[
\left[ \sum_{j=1}^n \lambda_j(\gamma \circ E_{\Delta_j})(x), g(x) \right]_X \equiv \sum_{j=1}^n \lambda_j [\gamma \circ E_{\Delta_j})](x), g(x)]_X
\]
for \( x \in X \),

\[
\int_m^M \lambda dw_x(\lambda) \\
\equiv \lim_{n \to \infty} \sum_{j=1}^n \lambda_j \left[ (\gamma \circ E_{\Delta_j})(x), g(x) \right]_X
\equiv \lim_{n \to \infty} \left[ \sum_{j=1}^n \lambda_j (\gamma \circ E_{\Delta_j})(x), g(x) \right]
= \left[ F(x), g(x) \right]_X
\]

thus.

In the following, the spectral resolution of the generalized real definite operator in terms of operator convergence is given. The key sufficient condition for the operator convergence in this subsection and in Section 4.1 is defined below.

**Definition 3.22.** The uniform spectral representation condition on a unital Banach algebra \( X \) is as follows: There exists a quasi-product (a) which is square bounded below and preserves the positivity or (b) has the left integral domain.

**Theorem 3.23.** Let \( F \in B(X) \) be generalized real definite. If the uniform spectral representation condition on \( X \) holds, then \( F \) has the spectral representation

\[
F = \int_m^M \lambda d(\gamma \circ E_{\lambda}),
\]

where \([m, M]\) is some bounded interval depending on \( F \).

**Proof.** \( \int_m^M \lambda d(\gamma \circ E_{\lambda}) \) exists by Lemma 3.19. As the quasi-product has the left integral domain, i.e., the uniform spectral representation condition (b) satisfied, the equation \( [(\int_m^M \lambda d(\gamma \circ E_{\lambda}) - F)(x), g(x)]_X = 0 \) implies that \( F(x) = [\int_m^M \lambda d(\gamma \circ E_{\lambda})](x) \) for every \( x \in X \). Then by Lemma 3.19 \( F = \int_m^M \lambda d(\gamma \circ E_{\lambda}) \).

Next, assume that the uniform spectral representation condition (a) holds. Let \( F_n = \sum_{j=1}^n s_j(\gamma \circ E_{\Delta_j}) \). Then

\[
0 \leq F_n - F \leq \epsilon_n \sum_{j=1}^n \gamma \circ E_{\Delta_j}
\]

and thus

\[
0 \leq (F_n - F)^2 \leq \epsilon_n^2 \left( \sum_{j=1}^n \gamma \circ E_{\Delta_j} \right)^2
\]
by Theorem 3.7. Since the quasi-product is square bounded below, then there exist positive numbers \( k_1 \) and \( k_2 \) such that for \( x \in X \),
\[
\begin{align*}
k_1 \| F_n(x) - F(x) \|^2_X \| g(x) \|_X & \leq \left[ (F_n - F) \right]^2 (x), g(x) \right]_X \\
& \leq \left[ 2\varepsilon_n^2 \left( \sum_{j=1}^n \gamma \circ E_{\Delta_j} \right)^2 (x), g(x) \right]_X \\
& \leq k_2 \varepsilon_n^2 \| x \|^2_X \| g(x) \|_X.
\end{align*}
\]

Hence \( \| F_n - F \|_{B(X)} \xrightarrow{n \to \infty} 0 \) holds. \( \square \)

**Remark 3.24.** Theorem 3.21 and Theorem 3.23 under only the uniform spectral representation condition (b) also hold as \( X \) is a Banach space, i.e., the condition for \( X \) being relaxed. The key is to use \( F \circ E_S \) in place of \( F_1S \) in the associated results, where \( S \) containing 0 is a subset of \( X \).

## 4. Extensions

In this section, the operational calculus of the generalized real definite operators is given in the first subsection. Furthermore, the bounded generalized real definite operators with the spectral representation in the sense of operator convergence turns out to be associated with a class of operators defined in the second subsection.

### 4.1. Operational calculus

In this subsection, the extensions of the spectral theorem in the previous subsection to polynomial functions and continuous functions are stated in two theorems, Theorem 4.3 and Theorem 4.9 respectively. Let \( X \) be a unital Banach algebra as in Section 3.3. The polynomial of the generalized real definite operator is defined below. Note that the proofs of the lemmas in this subsection are delegated to the supplementary materials.

**Definition 4.1.** Let \( B(X) \) be a unital Banach algebra with the multiplication operation \( * \) given in Theorem 2.7. Let \( p(\lambda) = \sum_{i=0}^n a_i \lambda^i \) be a polynomial in \( \lambda \) with real coefficients \( a_i \), i.e., \( p \) being over the real field. Then \( p(F) = \sum_{i=0}^n a_i F^* \), where \( F \in B(X) \) and \( F^{*0} = e \).

**Lemma 4.2.** Let \( F_{1n}, F_1, F_{2n}, F_2 \in B(X) \). If \( F_{1n} \xrightarrow{n \to \infty} F_1 \) and \( F_{2n} \xrightarrow{n \to \infty} F_2 \) in the sense of operator convergence, then \( F_{1n} * F_{2n} \xrightarrow{n \to \infty} F_1 * F_2 \) in the sense of operator convergence.

**Theorem 4.3.** Let \( F \in B(X) \) be generalized real definite. Then \( p(F) \) has the spectral representation
\[
p(F) = \int_M p(\lambda \gamma) d\lambda
\]
if the uniform spectral representation condition on \( X \) holds.
Proof. Since for $k > j$,

$$1_{\Delta_j}1_{\Delta_k} = \left(1_{s_j} - 1_{s_{j-1}}\right)\left(1_{s_k} - 1_{s_{k-1}}\right) = 1_{s_j} - 1_{s_{j-1}} + 1_{s_{j-1}} = 0$$

by Lemma 3.12 (b) and thus $(\gamma \circ E_{\Delta_j})(\gamma \circ E_{\Delta_k}) = \gamma^2 1_{\Delta_j}1_{\Delta_k} = 0$. Therefore,

$$\left[\sum_{j=1}^{n} \lambda_j (\gamma \circ E_{\Delta_j})\right]^k = \sum_{j=1}^{n} \lambda_j^k (\gamma \circ E_{\Delta_j}) = \sum_{j=1}^{n} (\lambda_j \gamma)^{sk} 1_{\Delta_j},$$

where $k$ is a nonnegative integer. By the condition imposed on the quasi-product and then using Theorem 4.2, $\sum_{j=1}^{n} \lambda_j (\gamma \circ E_{\Delta_j}) \rightarrow F$ in the sense of operator convergence. By Lemma 4.2

$$\sum_{j=1}^{n} (\lambda_j \gamma)^{sk} 1_{\Delta_j} = \left[\sum_{j=1}^{n} \lambda_j (\gamma \circ E_{\Delta_j})\right]^k \rightarrow F^{sk}$$

and hence

$$p(\lambda_1 \gamma)1_{s_1} + \sum_{j=2}^{n} p(\lambda_j \gamma)1_{\Delta_j} = p\left[\sum_{j=1}^{n} \lambda_j (\gamma \circ E_{\Delta_j})\right] \rightarrow p(F),$$

i.e., $p(F) = \int_{[m, M]} p(\lambda) d1_\lambda$ in the sense of operator convergence.

For a bounded linear self-adjoint operator $T$, the normed values of $p(T)$ is not greater than the normed value of $p(\lambda)$, where $p(\lambda)$ is considered as an element in the space of all continuous functions defined on some compact interval. The following lemma can be considered as the counterpart of the one for the bounded linear self-adjoint operator. Let $C([m, M])$ be the Banach space of all real-valued continuous functions defined on $[m, M]$ with the supremum norm.

Lemma 4.4. Let $F \in B(X)$ be generalized real definite. If the uniform spectral representation condition on $X$ holds, then there exist a positive number $k$ and a bounded interval $[m, M]$ depending on $F$ such that for any polynomial function $p$ with real coefficients,

$$||p(F)||_{B(X)} \leq k \max_{\lambda \in [m, M]} |p(\lambda)| = \overline{k} ||p||_{C([m, M])}.$$ 

For any $f \in C([m, M])$, the operator $f(F)$ and its spectral theorem can be defined and established based on Lemma 4.4. The following theorem gives the existence of the limit operator of a sequence of polynomials of the generalized real definite operator.

Theorem 4.5. Let $F \in B(X)$ be generalized real definite. If the uniform spectral representation condition on $X$ holds, then there exists a bounded interval $[m, M]$ depending on $F$ such that $\{p_n(F)\}$ converges to an operator in $B(X)$ in the norm $|| \cdot ||_{B(X)}$, where $\{p_n\}$ is any convergent sequence of polynomial functions with real coefficients in the space $C([m, M])$. 
Proof. By Lemma 4.4, for any $\epsilon > 0$, there exist a positive number $N$ such that for $n, l > N$,
\[
||p_n(F) - p_l(F)||_{B(X)} \leq \overline{k} ||p_n - p_l||_{C([m, M])} < \epsilon
\]
and thus $\{p_n(F)\}$ is a Cauchy sequence in the Banach space $B(X)$, where $\overline{k}$ is some positive number. \hfill \Box

According to the above theorem, the operator corresponding to any $f \in C([m, M])$ and the generalized real definite operator $F \in B(X)$ can be defined as follows.

**Definition 4.6.** Let $B(X)$ be a unital Banach algebra. If there exists a sequence of polynomial functions $\{p_n\}$ defined on $[m, M]$ over the real field converging uniformly to $f$ in $C([m, M])$, i.e., the convergence being in the norm $|| \cdot ||_{C([m, M])}$, and the limit of the sequence of operators $\{p_n(F)\}$ in the norm $|| \cdot ||_{B(X)}$ corresponding to the generalized real definite operator $F \in B(X)$ exists, then the limit in $B(X)$ is denoted by $f(F)$.

As the uniform spectral representation condition on $X$ holds, $f(F)$ exists and is unique, i.e., $f(F)$ being the limit corresponding to any sequence of polynomial functions converging to $f$ in $C([m, M])$, as indicated by the corollary below.

**Corollary 4.7.** Let $F \in B(X)$ be generalized real definite. If the uniform spectral representation condition on $X$ holds, then $f(F)$ exists for any $f \in C([m, M])$ and is independent of the choice of the sequence of polynomial functions in $C([m, M])$, i.e., $f(F)$ being the limit of any sequence of operators $\{p_n(F)\}$ satisfying that $\{p_n\}$ defined on $[m, M]$ over the real field converges uniformly to $f$ in $C([m, M])$, where $[m, M]$ is some bounded interval depending on $F$.

Proof. Because there exists a sequence of polynomial functions converging uniformly to $f$ in $C([m, M])$ by Weierstrass theorem, $f(F)$ exists by Theorem 4.5 and Definition 4.6. Next, let $\{p_n\}$ and $\{p_n^*\}$ be the sequences of polynomial functions both converging uniformly to $f$ in $C([m, M])$. Then $p_n(F) \xrightarrow{n \to \infty} f(F)$ and $p_n^*(F) \xrightarrow{n \to \infty} f^*(F)$ by Theorem 4.5. Furthermore, because
\[
||f(F) - f^*(F)||_{B(X)} \leq ||f(F) - p_n(F)||_{B(X)} + ||p_n(F) - p_n^*(F)||_{B(X)} + ||p_n^*(F) - f^*(F)||_{B(X)}
\]
and
\[
||p_n(F) - p_n^*(F)||_{B(X)} \leq \overline{k} ||p_n - p_n^*||_{C([m, M])}
\]
then letting $n \to \infty$ gives $f(F) = f^*(F)$ \hfill \Box

The following lemma is an extension of Lemma 4.4 to the continuous functions and can be used to prove the spectral theorem corresponding to the continuous functions.
Lemma 4.8. Let $F \in B(X)$ be generalized real definite. If the uniform spectral representation condition on $X$ holds, then there exist a positive number $\tilde{k}$ and a bounded interval $[m, M]$ depending on $F$ such that for any $f \in C([m, M])$,
\[
\|f(F)\|_{B(X)} \leq \tilde{k} \max_{\lambda \in [m, M]} |f(\lambda)| = \tilde{k} \|f\|_{C([m, M])}.
\]

Theorem 4.9. If the uniform spectral representation condition on $X$ holds, then for a generalized real definite operator $F \in B(X)$ and any $f \in C([m, M])$, $f(F)$ has the spectral representation
\[
f(F) = \int_{m}^{M} f(\lambda \gamma) d1_{\lambda},
\]
where $[m, M]$ is some bounded interval depending on $F$.

Proof. There exists a bounded interval $[m, M]$ and a positive number $\tilde{k}$ such that $\|f(\lambda \gamma)\|_{B(X)} \leq \tilde{k} \|f\|_{C([m, M])}$ for any $f \in C([m, M])$ and $\lambda \in [m^*, M^*]$ by Lemma 4.8 with $1_{m^*}(x) = 0$ for $x \neq 0$, $1_{M^*} = 1$, and $[m^*, M^*] \subset [m, M]$. Let $\{p_l\}$ be a sequence of polynomial functions defined on $[m, M]$ over the real field converging uniformly to $f$ in $C([m, M])$. By Definition 4.6, Theorem 4.3, Corollary 2.3, and Lemma 4.8, for every $\epsilon > 0$, there exist positive numbers $N$ and $N_1$ such that for $n > N_1$ and $l > N$, $\|p_l(F) - f(F)\|_{B(X)} \leq \epsilon/3$, $\|p_l(\lambda \gamma)_{s_1} + \sum_{j=2}^{n} p_l(\lambda_{j} \gamma)_{1_{\Delta_j}} - p_l(\lambda_{j} \gamma)_{1_{\Delta_j}}\|_{B(X)} \leq \epsilon/3$, and
\[
\begin{align*}
&\left\|f(\lambda_{j} \gamma)_{1_{s_1}} + \sum_{j=2}^{n} f(\lambda_{j} \gamma)_{1_{\Delta_j}} - p_l(\lambda_{j} \gamma)_{1_{s_1}} - \sum_{j=2}^{n} p_l(\lambda_{j} \gamma)_{1_{\Delta_j}}\right\|_{B(X)} \\
&\leq \max_{m^* \leq \lambda \leq M^*} \|f(\lambda \gamma) - p_l(\lambda \gamma)\|_{B(X)} \\
&\leq \tilde{k} \|f - p_l\|_{C([m, M])} \\
&\leq \epsilon/3.
\end{align*}
\]
Therefore,
\[
\begin{align*}
&\left\|f(\lambda \gamma)_{1_{s_1}} + \sum_{j=2}^{n} f(\lambda_{j} \gamma)_{1_{\Delta_j}} - f(F)\right\|_{B(X)} \\
&\leq \left\|f(\lambda_{j} \gamma)_{1_{s_1}} + \sum_{j=2}^{n} f(\lambda_{j} \gamma)_{1_{\Delta_j}} - p_l(\lambda_{j} \gamma)_{1_{s_1}} - \sum_{j=2}^{n} p_l(\lambda_{j} \gamma)_{1_{\Delta_j}}\right\|_{B(X)} \\
&+ \left\|p_l(\lambda_{j} \gamma)_{1_{s_1}} + \sum_{j=2}^{n} p_l(\lambda_{j} \gamma)_{1_{\Delta_j}} - p_l(F)\right\|_{B(X)} + ||p_l(F) - f(F)||_{B(X)} \\
&\leq \epsilon
\end{align*}
\]
and the result holds. \qed
Theorem 4.9 is

Remark 4.10. For the generalized real definite operator \( \tilde{F} \in B(X) \) with \( \tilde{F}(0) \neq 0 \), i.e., \( \tilde{F} = F + \tilde{F}(0)e \) and the projection indicator \( 1_\lambda \) corresponding to the null space of \( F_\lambda^+ \), the spectral resolution of the polynomial \( p(\tilde{F}) \) given the condition in Theorem 4.8 is

\[
p(\tilde{F}) = \int_M^M p(\lambda + \tilde{F}(0)e) \, d1_\lambda.
\]

Similarly, the spectral integral of the operator \( f(\tilde{F}) \) given the condition in Theorem 4.9 is

\[
f(\tilde{F}) = \int_M^M f(\lambda + \tilde{F}(0)e) \, d1_\lambda.
\]

4.2. Nonlinear spectral operators. In [4], the theory of the linear spectral operators has been discussed thoroughly. In this subsection, the nonlinear spectral operators based on the projection operator given in Definition 3.11 are defined and a basic result, Theorem 4.14, is given.

Definition 4.11. Let \( X \) be a normed space. A spectral projection \( E \) on \((m, M)\) is an operator-value function from the subsets \( \bigcup_{i=1}^n (a_i, b_i) \) of \((m, M)\) into \( B(X) \), \( m, M \in R, (a_i, b_i) \subseteq (m, M) \), with the following properties.

(a) \( E\{(a_i, b_i]\} \) is a projection operator, i.e., \( E\{(a_i, b_i]\}(x) = x \) if \( x \in S \) and \( E\{(a_i, b_i]\}(x) = 0 \) otherwise, where \( S \) containing 0 is some subset of \( X \).

(b) \( E(\phi) = 0 \) and \( E\{(m, M)\} = I \).

(c) \( E\{(a_1, b_1] \cap (a_2, b_2] = E\{(a_1, b_1] \cap E\{(a_2, b_2]\ = E\{(a_1, b_2]\ \cap E\{(a_1, b_1]\}\). \)

In addition, if \( (a_1, b_1] \cap (a_2, b_2]\ = \phi \), then
\[
E\{(a_1, b_1] \cup (a_2, b_2]\} = E\{(a_1, b_1]\} + E\{(a_2, b_2]\}.
\]

The existence of the spectral operators of interest is due to the following lemma. The proof of this lemma is analogous to Lemma 3.19 and is not presented.

Lemma 4.12. Let \( X \) be a Banach space and \( \{s_j\} \) be a partition of a bounded interval \([m, M]\) with \( m = s_0 < s_1 < \cdots < s_n = M, s_j - s_{j-1} < \epsilon_n \) and \( \epsilon_n \to 0 \). Then, \( \sum_{j=1}^n f(\lambda_j)E\{(s_{j-1}, s_j]\} \) converges to an operator in \( B(X) \) with respect to the norm topology \( \|\cdot\|_{B(X)} \) and the convergence is independent of the choice of the points \( \lambda_j \in (s_{j-1}, s_j] \) as \( n \to \infty \), where \( f \in C([m, M]) \).

Based on the above lemma, the resulting limit operator can be defined.

Definition 4.13. Let \( X \) be a Banach space and \( \{s_j\} \) be a partition of a bounded interval \([m, M]\) with \( m = s_0 < s_1 < \cdots < s_n = M, s_j - s_{j-1} < \epsilon_n \) and \( \epsilon_n \to 0 \). Then, the limit operator \( F \) of \( \sum_{j=1}^n f(\lambda_j)E\{(s_{j-1}, s_j]\} \) as \( n \to \infty \) with respect to the norm topology \( \|\cdot\|_{B(X)} \) is denoted as
\[
F = \int_M^M f(\lambda) E\,d1,
\]
where \( \lambda_j \in (s_{j-1}, s_j] \) and \( f \in C([m, M]) \). The operator \( F \) is referred to as the nonlinear spectral operator with respect to the spectral projection \( E \) on \( (m, M] \) and the function \( f \). The class of nonlinear spectral operators with respect to the spectral projection \( E \) on \( (m, M] \) and any function \( f \in C([m, M]) \) is denoted as \( S_{E,C([m,M])}(X) \).

**Theorem 4.14.** \( S_{E,C([m,M])}(X) \) is a subspace of \( B(X) \), where \( X \) is a Banach space. Further, if \( E\{(m, \bar{\lambda})\} - E\{(m, \bar{\lambda})\} \neq 0 \) for any \( \bar{\lambda} \in (m, M] \) and \( \bar{\lambda} < \lambda \), then \( S_{E,C([m,M])}(X) \) is a Banach space.

**Proof.** \( S_{E,C([m,M])}(X) \) is a subspace of \( B(X) \) because for the operators \( F_1, F_2 \in S_{E,C([m,M])}(X) \) corresponding to the functions \( f_1 \) and \( f_2 \), respectively, and \( \alpha \in K \),

\[
\begin{align*}
(\alpha F_1 + F_2) &= \lim_{n \to \infty} \sum_{j=1}^{n} \alpha f_1(\lambda_j) E \{(s_{j-1}, s_j]\} \\
&+ \lim_{n \to \infty} \sum_{j=1}^{n} f_2(\lambda_j) E \{(s_{j-1}, s_j]\} \\
&= \lim_{n \to \infty} \sum_{j=1}^{n} [\alpha f_1(\lambda_j) + f_2(\lambda_j)] E \{(s_{j-1}, s_j]\} \\
&= \int_{m}^{M} [\alpha f_1(\lambda) + f_1(\lambda)] dE,
\end{align*}
\]

and \( \alpha f_1 + f_2 \in C([m, M]) \).

To prove the completeness of \( S_{E,C([m,M])}(X) \), let \( F_n \xrightarrow{n \to \infty} F \), where \( F_n \in S_{E,C([m,M])}(X) \) and \( F \in B(X) \). Then \( \{F_n\} \) is Cauchy. Further, if the required condition holds, there exists a \( x_\lambda \) depending on \( \lambda \) such that for any \( \lambda \in (m, M] \),

\[
\left\| \left\{ \sum_{j=1}^{n} [f_1(\lambda_j) - f_m(\lambda_j)] E \{(s_{j-1}, s_j]\} \right\} (x_\lambda) \right\|_X
= \left\| [f_1(\lambda) - f_m(\lambda)] x_\lambda \right\|_X
= [f_1(\lambda) - f_m(\lambda)] \| x_\lambda \|_X,
\]

where \( f_1 \) and \( f_m \) are the functions in \( C([m, M]) \) corresponding to the spectral operators \( F_1 \) and \( F_m \), respectively. Then by letting \( n \to \infty \) in the above equation, for any \( \epsilon > 0 \), there exists a positive integer \( N \) such that for \( l, m > N \),

\[
\| f_l - f_m \|_{C([m, M])} \leq \epsilon.
\]

Hence \( \{f_n\} \) is Cauchy and there exists a function \( f \in C([m, M]) \) such that \( f_n \xrightarrow{n \to \infty} f \) with respect to \( \| \cdot \|_{C([m, M])} \) owing to the completeness of
C([m, M]). Then, $F_n \xrightarrow{n \to \infty} \int_m^M f dE$ because for $x \neq 0$,

$$
\left\| \left[ F_n - \int_m^M f(\lambda) dE \right](x) \right\|_X = \left\| \left\{ \int_m^M f_n(\lambda) - f(\lambda) \right\} dE \right\|(x) \right\|_X 
\leq \| f_n - f \|_{C([m, M])} \| x \|_X.
$$

Therefore, $F = \int_m^M f dE$ and $F \in S_{E,C([m, M])}(X)$, i.e., $S_{E,C([m, M])}(X)$ being closed.

**Remark 4.15.** As $\gamma = I$, the bounded generalized real definite operators with the spectral representation fall in $S_{E,C([m, M])}(X)$. Note that a more general class of nonlinear spectral operators can be defined as the limiting operators of the operators

$$
\sum_{j=1}^n f(\lambda_j)(r \circ E\{(s_{j-1}, s_j)\}) \text{ as } n \to \infty \text{ with respect to the norm topology } \| \cdot \|_{B(X)} \text{ and can be denoted as}
$$

$$
F = \int_m^M f(\lambda) d(r \circ E).
$$

Moreover, Lemma 4.12 and Theorem 4.14 can be generalized for the class of the nonlinear spectral operators.
